

Kentico CMS 7.0 Developer's Guide

Table of Contents

Introduction	34
Introduction.....	34
About this guide.....	36
Where do I get further help?.....	37
Version history.....	37
Kentico CMS overview	39
What are the benefits of Kentico CMS?.....	39
How does it really work?.....	40
Where is the content stored?.....	42
How do I edit content?.....	44
How do I develop a website?.....	46
Installation and deployment	49
Overview	49
System requirements	50
Installation procedure	52
Setup (KenticoCMS.exe)	52
Web installer	54
Overview	54
Local IIS server.....	57
Built-in web server in Visual Studio.....	60
Remote (production or testing) server.....	64
Existing Kentico CMS installation.....	67
Database setup	70
New site wizard	77
Overview	77
New site	79
Website template.....	84
Deployment	89
Deployment to the live server	89
Deployment to Windows Azure	90
Additional configuration tasks	90
Overview	90
Creating a virtual directory	91
Configuring Application Pools	97
Configuration for Medium Trust environment	102
Configuring Windows Communication Foundation	104
SMTP server configuration	106
Installation on shared hosting server	109
Installation in medium-trust environment	110
AppPool permissions on Windows 7 or Windows Server 2008 R2	111

Configuring custom error pages	115
Securing the CMSHelp folder	117
Installing and configuring WebClient service	119
Database replication	120
Overview	120
Creating a publication.....	121
Creating a subscription.....	127
Modifying structure of a replicated DB.....	134
Configuration of full-text search in files	139
Overview	139
Manually configuring full-text search on MSSQL Server.....	140
Enabling full-text search on MSSQL Server (Script).....	143
Searching PDF files.....	144
Searching Microsoft Office documents.....	146
Custom URL extensions and extensionless URLs	147
Overview	147
IIS 7 and higher.....	147
IIS 6	153
Configuration of custom URL extensions (.html or other).....	155
Lock violation on IIS7.....	157
Visual Studio integration.....	159
Opening the project	159
Adding Kentico CMS Controls to the Toolbox	162
Debugging	164
Precompilation (Publish function)	165
Visual Source Safe and Team Development	168
Opening a VS2005 project in VS2008	169
Troubleshooting installation issues.....	170
Overview	170
SQL Server connection problems	171
ASP.NET not working on Windows Server 2003	175
Disk permissions problems	175
Disk permissions problems.....	175
Solution on Windows 7.....	176
Solution on Windows Vista or Server 2008.....	179
System backup and recovery.....	182
Silent Install.....	183
Overview	183
XML configuration	184
Uninstallation.....	190
Content management	193
Overview.....	193
Organizing pages, files and documents.....	195
Storing data effectively.....	198
Editing content (CMS Desk).....	199
Basic content tree actions	199
Creating a new page	201
Creating a new structured document	204
Creating a linked document	206

Drag-and-drop operations with documents	208
Previewing documents	210
Document status icons	213
On-site editing	216
On-site editing overview	216
Editing content	217
Adding new pages	221
Document management	226
Security	229
WYSIWYG editor	231
Overview	231
Insert image or media	232
Overview	232
File sources	234
View modes	238
Inserting images	241
Inserting flash	245
Inserting audio/video	247
Inserting images or media from the Web	249
Quickly insert image or media	250
Insert link	253
Overview	253
Link properties	254
Links to content within the CMS	255
Links to the Web	258
Links to anchors	259
Mailto links	260
Insert YouTube video	261
Editing inserted items	265
Copy & Paste from Microsoft Word	266
Defining custom toolbars	268
Defining styles	271
Dialog configuration	273
Dialog security	276
HTML5 media tags	278
Document properties	278
Overview	278
General	279
URLs	282
Template	284
Metadata	285
Categories	287
Navigation	287
Workflow	289
Versions	290
Related docs	290
Linked docs	291
Security	291
Attachments	292
Languages	293
File management	293
File management overview	293
Document attachments	294

Overview	294
Example: Unsorted attachments.....	295
Example: Grouped attachments.....	298
Available web parts.....	304
Available inline widget.....	305
Handling attachments in transformations.....	307
Using the File field.....	311
Temporary attachments handling.....	313
Attachment names.....	313
Where the files are stored	314
File-related settings	315
Using the Media selection control	317
Image editor	321
Overview	321
Image editing.....	322
Saving changes.....	326
Metadata editor	328
Resizing images on upload	329
Uploading multiple files at once	330
File administration UI	332
Multilingual content.....	336
Overview	336
Configuring multilingual content	336
Using language-specific page templates	340
Selecting default languages for visitors	343
Languages and URLs	344
Managing multilingual websites	349
Language status overview.....	350
Language version comparison.....	352
Culture-dependent workflow scopes.....	354
Language-bound editors.....	355
Translation services	356
Overview	356
Translating documents.....	357
Configuring content for translation.....	361
Customizing XLIFF export.....	363
Machine translation services.....	365
Translating localization strings.....	365
Default machine services.....	367
Microsoft Translator.....	367
Google Translate.....	368
Standard translation services.....	368
Managing translation submissions.....	369
Importing completed translations.....	370
Default standard services.....	371
Translations.com.....	371
Manual translation.....	373
E-mail translation.....	374
Adding custom translation services.....	376
Creating machine services.....	377
Creating human translation services.....	380
Loading service classes from App_Code.....	389
Translation service properties.....	391
Translating via the REST service.....	392

Security	394
Workflow and versioning.....	395
Overview	395
Defining a workflow	397
Creating a workflow.....	397
Applying workflow on documents.....	398
Defining workflow steps.....	401
Creating and managing basic workflow steps.....	401
Designing advanced workflow.....	402
Introduction to workflow designer.....	402
Adding and configuring steps.....	404
Connecting steps.....	406
Defining if/else conditions.....	407
Defining user decisions.....	408
Defining automatic decisions.....	409
Setting timeouts for automatic approving.....	410
Adding action steps.....	411
Creating custom action steps.....	417
Defining macro rules	418
Configuring workflow operators	418
Configuring e-mail notifications	420
Using workflows	423
Versioning	428
Content locking.....	429
Versioning without workflow.....	430
Workflows internals and API	432
Overview	432
Database tables.....	432
API classes	433
API examples.....	433
Overview	433
Managing workflow s.....	434
Managing workflow steps.....	436
Managing workflow scopes.....	439
Validators.....	441
Overview	441
HTML validator	441
CSS validator	443
Link checker	444
Accessibility validator	446
Document listing.....	448
Content search.....	450
Content scheduling.....	451
Using the built-in spell-checker.....	452
Permissions and security.....	453
FAQ.....	453
Content management internals and API.....	454
Overview	454
Database tables	454
API classes	457
API examples	458

Basics	458
Overview	458
Creating documents.....	458
Managing documents.....	461
Deleting documents.....	463
Advanced	466
Overview	466
Sample document structure.....	466
Organizing documents.....	468
Recycle bin.....	469
Document attachments.....	471
Overview	471
Sample document structure.....	471
Managing attachments.....	472
Document relationships.....	477
Overview	477
Managing relationship names.....	477
Managing relationships.....	480
Workflow basics.....	481
Overview	481
Sample documents and objects.....	482
Creating documents.....	485
Managing documents.....	488
Workflow advanced.....	490
Overview	490
Sample documents and objects.....	491
Managing documents.....	494
Workflow process.....	499
Versioning.....	503

Managing sites	508
Site Management Overview	508
Managing sites	509
Starting and stopping sites	513
Creating a new site	513
Export and import	513
Overview	513
Folder structure and import/export	514
Excluding files and folders from export	516
Export	517
Exporting a site.....	517
Exporting objects.....	522
Exporting single objects.....	527
Import	529
Importing a site or objects.....	529
Importing from web site to web application projects	539
Export and import internals and API	540
Overview	540
API classes	540
API examples.....	540
Overview	540
Import	541

Export	542
Deleting sites.....	544
Creating web templates.....	545
License management.....	547
Managing site settings.....	547
Configuring multiple web sites.....	548
Multiple web sites on a single domain (in subfolders).....	558
Configuring nested web sites.....	560
Site objects.....	564
Sites internals and API.....	567
Overview	567
Database tables	567
API classes	568
API examples	568
Overview	568
Managing sites.....	569
Managing site cultures.....	571
Managing domain aliases.....	571
Starting and stopping sites.....	572
Web templates internals and API.....	573
Overview	573
Database tables	573
API classes	574
API examples	574
Overview	574
Managing web templates.....	575
Website settings	579
Overview.....	579
Adding custom settings.....	579
Managing custom settings.....	582
Configuring settings.....	586
Website settings internals and API.....	590
Overview	590
Database tables	590
API classes	591
API examples	592
Overview	592
Development	594
Overview.....	594
Web development overview.....	594
The role of a web developer	594
What is a page template	594
Development model overview	595
Portal engine development model	597
Portal engine overview.....	597

Creating a new page template.....	600
Re-using an ad-hoc page template.....	603
Cloning and modifying a page template.....	605
Managing the page template catalog.....	608
Page template scopes.....	611
Page layouts	612
The master page concept.....	619
Editing the master page.....	620
Visual inheritance.....	621
Content tree and page templates.....	628
Using and configuring web parts.....	629
Common web part properties.....	634
Adding custom code to a portal page template.....	641
Displaying data from an external database or Web Service.....	644
Page template internals and API.....	646
Overview	646
Database tables.....	646
API classes.....	647
API examples.....	647
Overview.....	647
Managing page template categories.....	648
Managing page templates.....	650
Page templates and sites.....	652
Managing page template scopes.....	653
Page layout internals and API.....	654
Overview	654
Database tables.....	654
API classes.....	655
API examples.....	656
Overview.....	656
Managing page layouts.....	656
ASPX page template development model	658
Overview	658
Creating a new ASPX page template.....	660
Creating ASPX master pages.....	666
Adding portal engine functionality to ASPX templates.....	669
Adding custom code to an ASPX template.....	672
Combining ASPX templates and portal engine templates.....	674
Integration with your existing ASP.NET application.....	675
Displaying data from an external database.....	676
MVC development model	677
MVC development overview.....	677
Caching and performance	684
Overview	684
Caching options	684
Code minification and compression	693
File management and performance	696
Troubleshooting performance issues	696
Caching in custom code	698
Cookies.....	698
Overview	698
Cookie levels	699
Available web parts	700

Reference: Kentico CMS cookies	701
CSS stylesheets and design.....	703
Overview	703
CSS for page components	709
App themes	712
Printer friendly CSS styles	714
Print page	715
Combining stylesheets	721
CSS stylesheet internals and API	723
Overview	723
Database tables.....	723
API classes	724
API examples.....	724
Overview	724
Managing CSS stylesheets.....	725
CSS stylesheets and sites.....	726
Debugging and system information.....	727
Overview	727
System information UI	730
Particular debug tabs	733
System objects.....	733
Cache items	734
Worker threads.....	735
Cache access.....	737
SQL queries	740
IO	743
Page ViewState.....	745
Output	747
Security	749
Macros	751
Analytics	753
Requests	755
Web farm	758
All	761
Log files	761
E-mails	762
General settings and keys for all debugs	763
System error notifications	765
Document types and transformations.....	766
Overview	766
Defining a new document type	767
Document type properties	773
Uploading document type icons	783
Transformations	785
Overview	785
Transformations.....	786
Writing transformations.....	790
Hierarchical transformations.....	797
Context menus in transformations.....	801
Adding custom functions to transformations.....	803
Transformations in macro expressions.....	806
Editing code in the UI.....	810
Code editor overview	810

Design preview	812
E-mail templates.....	815
E-mail templates	815
Form controls.....	816
Overview	816
Managing form controls	817
Assigning form controls to fields	820
Form control parameters	824
Developing form controls	826
Inline controls.....	837
Overview	837
How to develop inline controls	838
Macro expressions.....	842
Overview	842
Types of macros	842
K# syntax	848
Available macro methods	853
Macro parameters	866
Entering macro expressions	869
Macro conditions	875
Macro security	884
Registering custom macro methods	887
Resolving macros using the API	892
Macro result caching	896
Membership, permissions and security.....	897
Security model overview	897
User management	898
Role management	904
Username customization	908
Permissions	908
Permissions overview.....	908
Document permissions.....	911
Document permissions.....	911
Permissions for all content.....	912
Document type permissions.....	913
Document-level permissions.....	914
Hiding documents in the content tree based on permissions	919
Document permissions internals and API.....	920
Overview	920
Database tables.....	920
API classes.....	921
API examples.....	922
Overview	922
Preparing document structure.....	922
Setting document level permissions	923
Managing permission inheritance.....	926
Checking permissions.....	927
Design permissions.....	930
Module permissions management.....	932
UI personalization	935
Overview	935
Quick example.....	936

How it works	937
Personalizable parts of CMS Desk.....	941
Overview	941
CMS Desk main tabs.....	941
CMS Desk -> Content tab.....	942
CMS Desk -> Content -> Edit -> Properties tab.....	944
CMS Desk -> Content -> New	952
CMS Desk -> My desk tab.....	954
CMS Desk -> Tools tab.....	955
CMS Desk -> Administration tab.....	957
CMS Desk -> E-commerce tab.....	958
WYSIWYG editor.....	958
Media dialog.....	960
Enabling UI personalization.....	960
UI profile configuration.....	961
UI element management.....	967
UI element management.....	967
Example: Adding a new main tab to CMS Desk.....	971
Memberships	975
Membership overview.....	975
Managing memberships.....	976
Security	980
Secured website areas.....	980
SSL (HTTPS) support.....	983
Cross site scripting (XSS).....	987
Clickjacking protection.....	988
Configuration of allowed request parameters.....	989
Screen locking.....	990
User registration	991
Available registration web parts.....	991
Registration form web part.....	991
Creating a custom registration form.....	991
Registration approval and double opt-in.....	996
User registration e-mails.....	999
Shared user accounts.....	1000
Badges	1001
Badges	1001
Defining badges.....	1002
Assigning badges to users.....	1003
Activity points.....	1003
Available form controls.....	1004
Badges internals and API.....	1004
Overview	1004
Database tables.....	1004
API classes.....	1005
API examples.....	1005
Overview	1005
Managing badges	1006
Managing user badges.....	1007
Custom field visibility	1009
How it works.....	1009
Enabling visibility controls.....	1011
Use in custom form layouts.....	1015
Configuring the web parts.....	1016

Authentication	1017
Authentication overview.....	1017
Session management.....	1018
Automatic user name completion.....	1019
Windows authentication (Active Directory).....	1019
Configuring Windows authentication (Active Directory).....	1019
Windows authentication on Windows 7/2008 R2/Vista (IIS7 or higher).....	1021
Securing a web site section using Windows authentication.....	1023
Configuring mixed mode authentication.....	1025
Integrating authentication with external systems.....	1027
Single sign-on.....	1028
Displaying personalized content.....	1030
Password management	1034
Overview	1034
Password format.....	1034
Password recovery.....	1035
Password strength policy.....	1038
Password expiration.....	1040
Invalid logon attempts.....	1042
Unlocking an account.....	1042
Third-party authentication services	1043
Overview	1043
Windows Live ID.....	1044
Overview	1044
Registering your application.....	1046
Settings.....	1047
Available web parts.....	1048
OpenID	1050
Overview	1050
Settings.....	1052
Available web parts.....	1052
Facebook Connect.....	1054
Overview	1054
Registering your application.....	1057
Settings.....	1059
Available web parts.....	1060
LinkedIn	1062
Overview	1062
Registering your application.....	1064
Settings.....	1066
Available web parts.....	1067
Managing imported users.....	1069
Membership internals and API	1070
Overview	1070
Database tables.....	1070
API classes	1072
API examples.....	1073
Overview	1073
Managing users	1074
Users and sites.....	1076
Managing roles.....	1077
Roles and users.....	1078
Mobile development.....	1079
Enabling mobile development features	1080

Creating device profiles	1081
Resizing images for devices	1082
Creating page layouts for devices	1083
Mapping shared layouts	1085
Creating mobile pages	1087
Creating a separate mobile section	1094
Device macro reference	1098
Microsoft Silverlight integration.....	1099
Overview	1099
Adding a Silverlight application to your site	1100
IIS configuration	1102
Object cloning.....	1104
Overview	1104
Cloning objects through the API	1106
Object versioning.....	1107
Overview	1107
Supported object types	1108
Configuring object versioning	1109
Using object versioning	1111
Objects recycle bin	1115
Object versioning internals and API	1117
Overview	1117
Database tables.....	1117
API classes	1117
API examples.....	1118
Overview	1118
Object versioning.....	1118
Object recycle bin.....	1121
Page processing and URLs.....	1123
Overview	1123
URL rewriting	1124
Multiple document aliases	1127
URL format and configuration	1130
Wildcard URLs	1133
Linking pages and files	1135
GetFile.aspx parameters	1137
Custom handling of URL path values	1138
Output filters	1141
Search engine optimization	1145
SEO overview.....	1145
Google Sitemaps.....	1150
Managing robots.txt.....	1155
Document aliases internals and API	1158
Overview	1158
Database tables.....	1158
API classes	1159
API examples.....	1159
Overview	1159
Managing document aliases.....	1159
Query string parameters in UI.....	1162
Rebranding.....	1164
Changing the logo in the header	1164

Removing the log-on bar	1167
Changing the CMS Desk and Site Manager logo	1169
Renaming resource strings	1169
REST service	1170
Overview	1170
Prerequisites	1171
Configuration for REST	1173
Authenticating REST requests	1176
Data retrieval methods	1177
Data manipulation methods	1181
URL parameters	1187
Retrieved data examples	1190
ODATA service documents	1193
Scheduler	1194
Overview	1194
Configuring task execution	1194
Installing the Scheduler Windows service	1196
Scheduled tasks administration	1198
Scheduling custom code	1199
Scheduler internals and API	1206
Overview	1206
Database tables	1206
API classes	1207
API examples	1208
Overview	1208
Managing scheduled tasks	1208
Social networking	1211
Overview	1211
Autoposting	1213
System tables and custom fields	1215
Overview	1215
Custom document data	1216
Team development	1217
Overview	1217
Supported object types	1217
Object locking	1218
Deployment and source control	1221
UI cultures and localization	1223
Overview	1223
Configuring multilingual and RTL UI	1224
RTL languages	1230
Localization expressions	1231
Web parts	1233
Overview	1233
Web part management	1234
Developing web parts	1239
Modifying web parts	1246
Modifying web parts	1246
Setting web part properties dynamically in your code	1246
Customizing web part layout	1248
Modifying the code of standard web parts	1251
Web part inheritance	1253

Adding custom code to web parts (obsolete).....	1254
Web part binding (obsolete).....	1256
AJAX support	1263
Data source web parts	1264
Using Data source web parts.....	1264
Problems with XML data sources.....	1268
Developing Data source web parts.....	1269
Developing custom filters.....	1275
Layout web parts	1282
Overview	1282
Developing layout web parts.....	1284
Web part containers	1290
Containers overview.....	1290
Creating web part containers.....	1294
Web parts internals and API	1296
Overview	1296
Database tables.....	1296
API classes	1297
API examples.....	1298
Overview	1298
Managing web part categories.....	1298
Managing web parts.....	1300
Managing web part layouts.....	1302
Managing web part containers.....	1304
Web part containers and sites.....	1306
Widgets.....	1307
Overview	1307
Developing widgets	1307
Using widgets	1314
Inline widgets	1319
Security	1322
Widgets internals and API	1323
Overview	1323
Database tables.....	1324
API classes	1325
API examples.....	1326
Overview	1326
Managing widget categories.....	1326
Managing widgets.....	1328
Managing widget security.....	1330
Wireframing.....	1331
Overview	1331
Managing wireframes	1332
Setting up wireframe templates	1338
Configuring content inheritance	1341
Developing wireframe components	1345
Security	1351
Modules	1354
Overview.....	1354
Accessing modules.....	1354
Developing custom modules.....	1357

A/B testing	1362
Overview	1362
Abuse report	1362
Overview	1362
Available web parts	1363
Using the In-line abuse report web part in transformations	1365
Abuse reports management	1367
Integration with other modules	1369
Security	1370
Abuse report internals and API	1370
Overview	1370
Database tables	1371
API classes	1371
API examples	1371
Overview	1371
Managing abuse reports	1372
Alternative forms	1374
Overview	1374
Creating an alternative form	1375
Joining two classes into one form	1379
Automatically used alternative forms	1380
Creating filter forms	1381
Avatars	1385
Overview	1385
Changing user avatars	1386
Changing group avatars	1388
Managing avatars	1389
Gravatars	1393
General avatar settings	1396
Displaying avatars in transformations	1397
Avatars internals and API	1399
Overview	1399
Database tables	1400
API classes	1400
API examples	1400
Overview	1400
Managing avatars	1401
Managing user avatars	1403
Bad words	1404
Overview	1404
Enabling the module	1404
Defining a bad word	1405
Possible actions	1407
Multilingual support	1408
Security	1409
Bad words internals and API	1410
Overview	1410
Database tables	1410
API classes	1410
API examples	1411
Overview	1411
Managing bad w ords	1411

Performing bad word checks	1413
Banned IPs	1416
Overview	1416
Enabling IP banning	1416
Banning an IP address	1417
Finding an IP address	1419
Security	1420

Part

Introduction

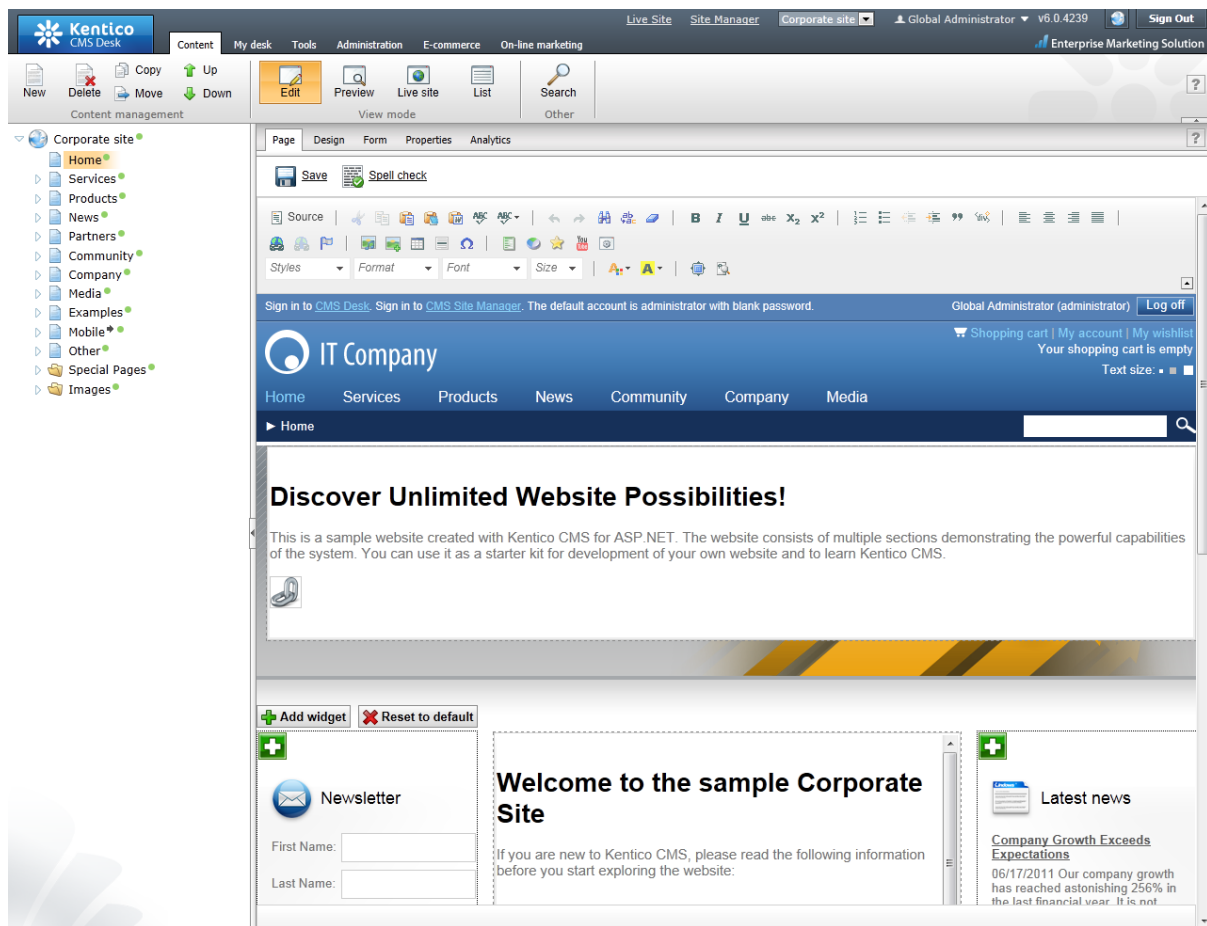

1 Introduction

1.1 Introduction

Thank you for using Kentico CMS, the content management system for ASP.NET developers. Kentico CMS 7.0 empowers developers in creation of dynamic websites. It provides rich functionality out of the box:

- Flexible content repository for storing structured content with versioning and workflow.
- Powerful portal engine for assembling web pages from web parts.
- A wide range of built-in web parts and web controls.
- Export and import for easy deployment.
- Granular security model.
- Support for multiple-site configuration.
- Support for multiple-languages on a single website.
- Many built-in modules:
 - E-commerce
 - Forms
 - Forums
 - Image gallery
 - Media libraries
 - Staging
 - Content rating
 - Blogs
 - Polls
 - Reporting
 - Web Analytics
 - Time zones
 - Events
 - User contributions (Wiki)
 - and others

Kentico CMS enables a **high level of flexibility, customization and integration** – you can create:

- custom page templates
- custom web parts
- custom document types
- custom workflow schemas
- custom modules

Kentico CMS object model and **open, well-documented application programming interface (API)** allow you to enhance the system and script any system feature by your .NET code. You can also write custom handlers to add your own actions when a system event (such as creation of a new document) occurs.

More product information

You can download Kentico CMS, find additional information, make the purchase and get support at <http://www.kentico.com>

1.2 About this guide

Who is this guide for?

Kentico CMS Developer's Guide contains reference information for Kentico CMS developers and system administrators.

It is expected that you are familiar with the basics of Kentico CMS explained in [Kentico CMS Tutorial](#) (or [Kentico CMS Tutorial ASPX](#) if you are developing in the ASPX page templates mode). It is also expected that you have a certain degree of experience in ASP.NET web development and C# programming to be able to fully understand all articles in this guide.

What information can I find in the guide?

This guide should provide comprehensive reference for website development and administration in Kentico CMS. It provides description of the system's functionality and step-by-step examples of typical development and administration tasks.

How is the guide structured?

The guide is divided into several logical chapters:

- [Kentico CMS overview](#) - basic information about the system intended for a first-time user.
- [Installation and deployment](#) - covers the installation process, additional configuration tasks that might be needed after installation and a troubleshooting section with solutions to usual installation issues.
- [Content management](#) - information on how to manage the content of your website. It explains how pages can be edited, how the WYSIWYG editor can be used, how files can be managed, etc.
- [Managing sites](#) - management of sites, i.e. creation of a new site, running and stopping sites, import and export of sites and objects, license management, etc.
- [Website settings](#) - overview chapter with links to other sections of the guide where various website settings are explained in different contexts.
- [Development](#) - provides information on various topics related to website development and system administration.
- [Modules](#) - a reference for the out-of-the-box modules and other types of functionality in Kentico CMS.
- [API programming and Kentico CMS internals](#) - examples of the usage of Kentico CMS API and an explanation of the internals of the system.

Valuable references can also be found in the appendices:

- [Appendix A - Path expressions](#) - explains how path expressions can be entered in various parts of the system
- [Appendix B - Web.config parameters](#) - list of keys which can be added to the *web.config* file of your site to perform additional low-level settings

Are there different versions of the guide?

This guide is available in three different formats. You can always find the most up to date version of the guides in the locations listed below:

- An **HTML** version of the guide can be [found here](#).
- A **PDF** version of the guide can be [found here](#).

- A CHM version of the guide can be [downloaded here](#).

1.3 Where do I get further help?

This guide is not the only reference available. All documentation can be found in various formats at devnet.kentico.com/documentation.aspx.

If you can't find the information that you are looking for, please visit devnet.kentico.com. This is the official portal for Kentico CMS developers where you can find:

- [Blogs](#)
- [Discussion forums](#)
- [Knowledge base](#)
- [FAQs](#)

Another useful source of information is the [Deliver Now! Methodology](#). It outlines all important aspects of the website development and delivery process with Kentico CMS. Apart from the base methodology text, it also contains a set of checklists, and templates usable for creation of project specification documents and website structure sheets.

Paid license owners can also contact our highly-responsive support team, please visit www.kentico.com/support.aspx to learn more details.

You are also welcome to send us feedback on particular topics in this guide. You can do it by clicking the **Mail us feedback on this topic!** button at the top right corner of the HTML and CHM versions.

1.4 Version history

Listing of all new features, minor improvements and bug fixes in each released version of Kentico CMS can be found at http://www.kentico.com/Support/Support-files/Version_History.

Part

Kentico CMS overview

2 Kentico CMS overview

2.1 What are the benefits of Kentico CMS?

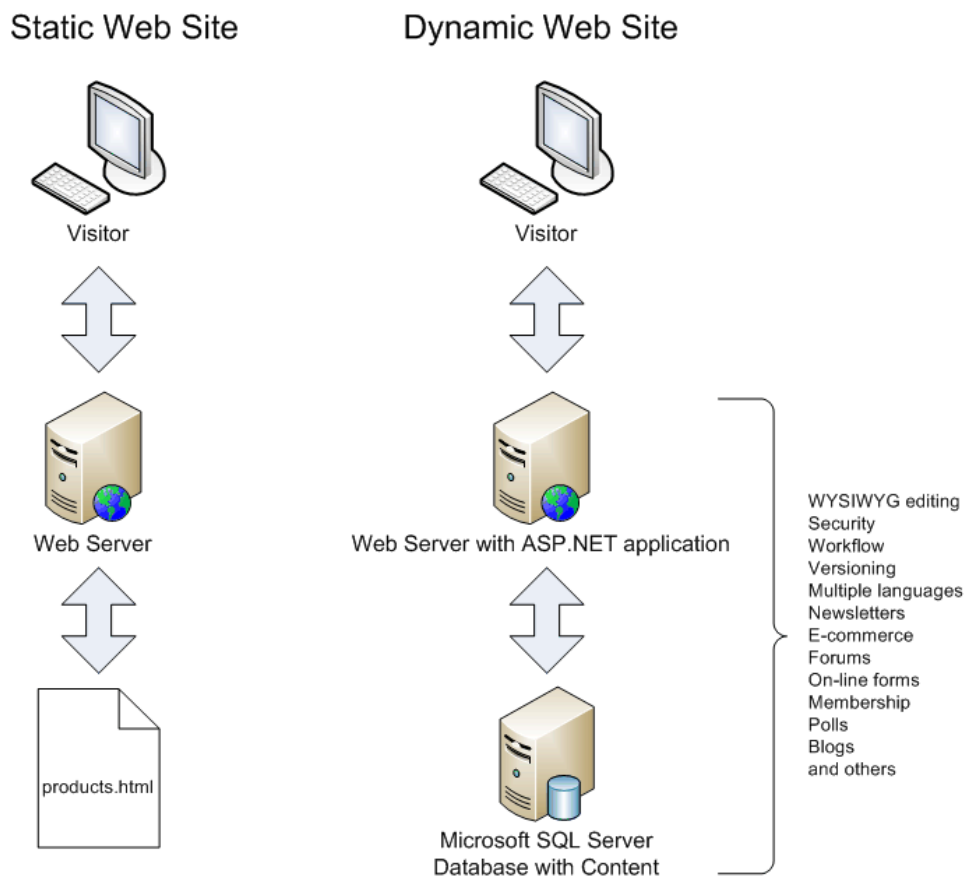

Before you dive into the details, it may be useful to understand the big picture. This chapter explains how the system works, describes its architecture and answers the most common questions you may have.

Is Kentico CMS a standard ASP.NET application?

Yes, Kentico CMS is a standard ASP.NET 3.5 SP1 application written in C#. It uses only standard functionality of .NET managed code which means you can use it on basically any ASP.NET 3.5 SP1-enabled web server without complicated configuration.

How does the CMS work?

The CMS allows you to manage content of dynamic websites. Unlike static websites that use static HTML files stored on a disk, a dynamic website displays content from the database. Kentico CMS provides both content storage and all surrounding infrastructure to manage the content and display it on the website. Kentico CMS doesn't pre-render static HTML pages; instead, it renders the content in real time, when it's requested by the visitor.

The main advantages of a dynamic website with a content management system include:

- **Easy content editing** through a WYSIWYG, browser-based interface for non-technical users
- **Content re-use** - you can display the same structured content in various ways while managing the data in one place
- **Multi-user environment** - website management is not limited to a single web developer
- **Additional functionality and applications**, such as Newsletters, E-commerce, Forums, etc.

Why should I use Kentico CMS and what benefits does it bring to me?

Kentico CMS simplifies the development of dynamic websites. Instead of developing the whole infrastructure for editing, you can utilize the flexible content management framework of Kentico CMS and focus on the site-specific functionality and design. If you consider how much time you would spend only by developing the security system, there's no doubt you should use an existing framework.

With Kentico CMS, you:

- save time and money by developing the dynamic website faster
- focus on the client's business needs instead of core infrastructure
- provide your client with additional functionality, such as Newsletters, Forums, and others that would be difficult and expensive to develop

Is it flexible enough for my needs?

Well, now you may think "If I develop the website from scratch I can create the system and enhance it at any time as my client requests." Yes, you're right, but you can do the same with Kentico CMS. Kentico CMS has been used for thousands of websites worldwide and it was designed to fit various needs of web developers and their clients. Besides, if you need to add extra functionality, you can:

- create your own modules
- add your own code to the pages
- modify default system behavior using custom handlers and providers
- customize the core engine of the system (if you purchase the source code version)

Kentico CMS was designed for the needs of web developers and their clients. You can be confident that you can **implement basically any website structure, navigation, graphic design and integrate custom functionality**.

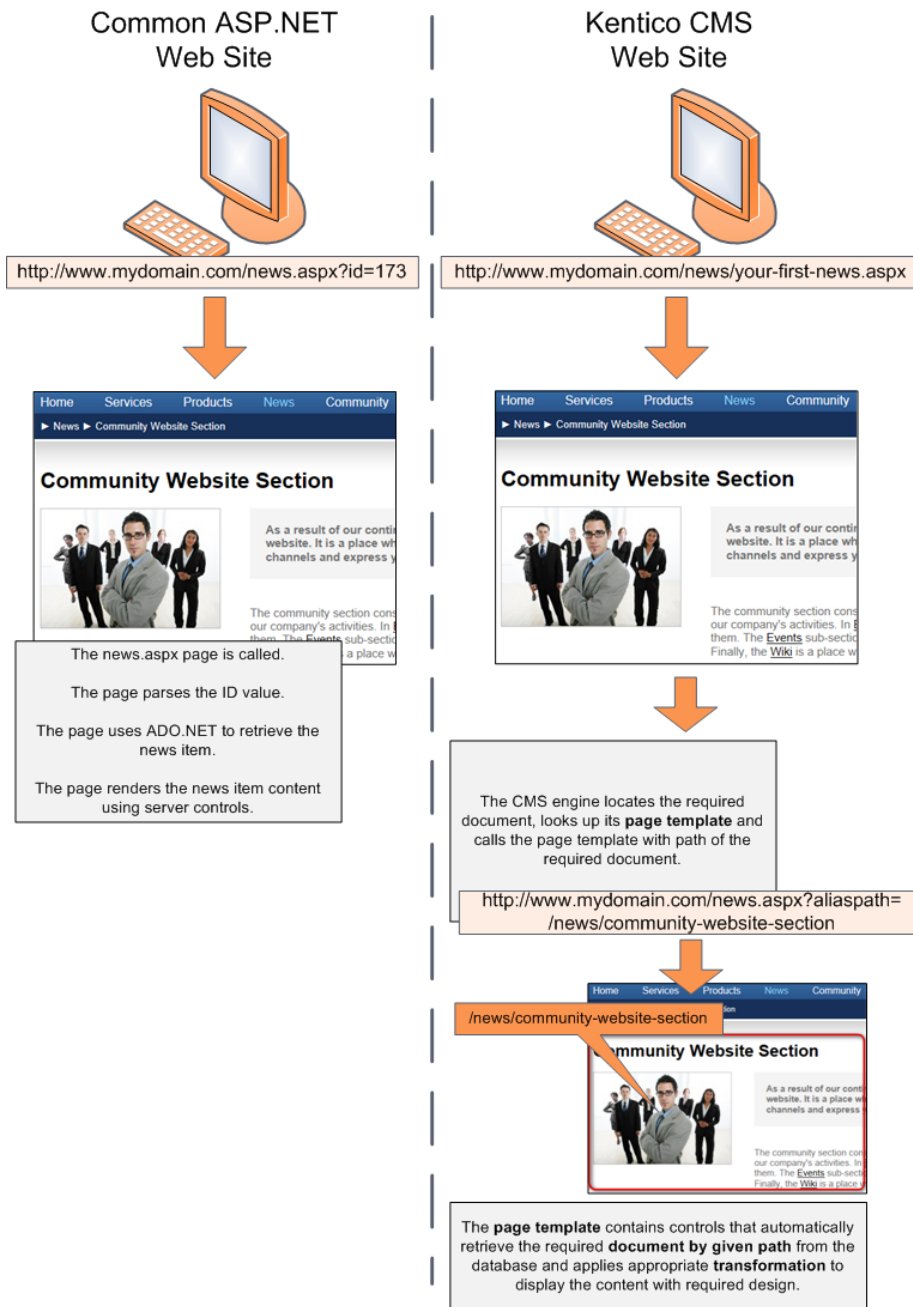

Don't take our word for it

Please visit the Kentico CMS Showcase at <http://www.kentico.com/Showcase.aspx> for reference websites, clients and testimonials.

2.2 How does it really work?

If you're familiar with dynamic websites, you may want to know what the difference between a CMS system and a common ASP.NET website is. Technically, Kentico CMS is just another ASP.NET web application. Its advantage is that it provides a ready-to use framework for all common tasks.

Here's a comparison of page processing in a typical ASP.NET and Kentico CMS:

But it looks more complex!

Yes, the CMS system is more complex to make your job easier. In Kentico CMS, you do not need to develop complex pages, write ADO.NET code or SQL queries.

The CMS does much of that for you and you usually only drag-and-drop controls or web parts and set their properties. You write .NET code only if you need to add additional business logic or functionality that is not supported out-of-the-box.

What else does the CMS do for me?

Kentico CMS provides a powerful content repository for your web content. Read the next chapter to learn more.

2.3 Where is the content stored?

Kentico CMS provides a content management sub-system, also known as **content repository**, that allows you to organize website structure and content. Moreover, it provides **a layer of security, workflow, versioning, search** and other services. All types of content can be retrieved and modified through a single **Application Programming Interface (API)**.

The following figure explains the difference between common data access approach and a content repository of Kentico CMS:

As you can see, a common approach to building dynamic websites is to write code for every page and every content type. It means that you need to write similar ADO.NET commands and SQL queries over and over again. With unified content repository, you use a complete set of API methods that allow you to save and retrieve any content type using methods someone wrote for you.

It greatly simplifies the management and retrieval of content since:

- you do not need to write your own methods, **you only call API or use built-in controls**
- **the same rules and mechanisms can be applied to any content type**, without writing additional code for every new type

An important part of the content repository is **metadata**. The metadata includes:

- content organization into a tree hierarchy that also represents the site map
- information about content authors and modifications
- workflow-related details, such as the current workflow step
- content expiration
- permissions for the given document

In the example above, you can see that with the classic approach, both News and Articles tables contain the attribute Author. In the content repository, the author is stored in shared metadata for all documents, regardless of their type.

Please note

Metafiles and attachments are stored either in the database, or the server's file system under a folder specified in the **Site Manager -> Settings -> System -> Files -> Files folder** setting. If this path is not set:

- metafiles of objects not connected with a particular site (global objects) are stored under `<web root>/CMSFiles`
- metafiles of objects connected with a particular site are stored under `<web root>/<site name>/metafiles`
- attachments (always connected with a particular site) are stored under `<web root>/site name>/files`

As you can see, the **content repository represents a systematic approach to content storage, manipulation and security.**

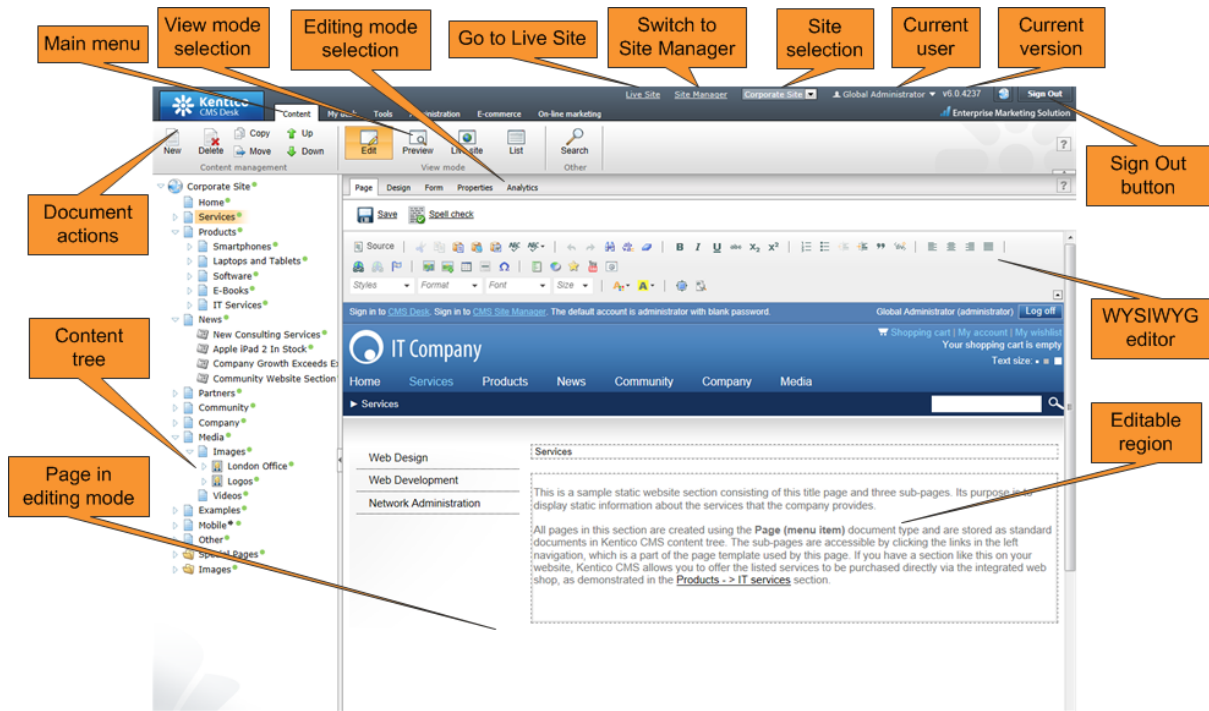

2.4 How do I edit content?

Until now, we have discussed how the system works and its architecture. But how do I edit the content? After all, it's the most important feature of a content management system.

Kentico CMS comes with a browser-based interface, which is divided into several parts:

- **CMS Desk** (<http://www.example.com/cmsdesk>) - the main user interface for the management of a specific website, intended for content editors, website designers and marketers.
- **On-site editing mode** (<http://www.example.com/cmsedit>) - a convenient editing interface that may be used to make content adjustments directly while viewing the live site.
- **CMS Site Manager** (<http://www.example.com/cmssitemanager>) - a global system administration interface, intended for top-level administrators and web developers.

The following figure shows an overview of the CMS Desk user interface.

The **content tree** on the left allows you to browse the content and choose the document you want to edit. The content tree also represents a site map of the site and it's used for rendering navigation. In the following figure, you can see how the content tree, navigation and site map fit together:

The **action menu** allows you to create, delete, copy, move and change the order of documents.

The **view mode** allows you to switch between the following views:

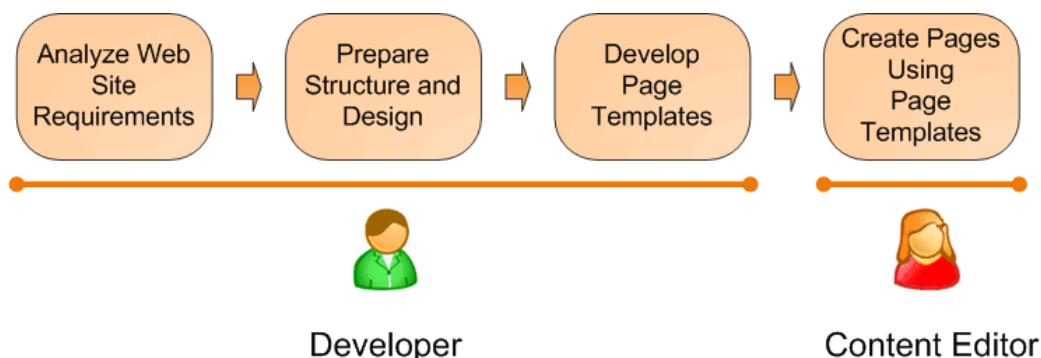

- **Edit** - editing mode.
- **Preview** - a preview mode that displays the current version of the page, even before it is published to the live site. It also shows content without using caching, which allows you to preview the content even if the live website displays the cached version.
- **Live site** - allows you to view exactly how the page appears on the live site while still remaining in CMS Desk.
- **List** - displays a list of child documents under the currently selected document. It may be used to perform mass actions for multiple documents simultaneously and can also be useful if there are too many documents in a given section and cannot be browsed comfortably in the content tree.

The **editing area** allows you to edit the content and metadata of the document selected in the content tree. You can choose from the following tabs/editing modes:

- **Page** - here you can edit the content of editable regions that are used for unstructured content. Additionally, any document can also have structured content that may be edited in the editing form on the *Form* tab.
- **Design** - used to modify the main layout of the page, as well as fixed content and functionality added through web parts (this applies to the portal engine development model that will be described later in this guide). This tab is only available for designated developers and global administrators.
- **Form** - here you can modify the structured data of the document, such as a news title, news summary, release date, etc.
- **Product** - here you can modify the product specification of documents representing products that can be added to the shopping cart (when using the e-commerce module).
- **Properties** - here you can modify various settings, permissions, metadata and design options of the document.
- **Analytics** - may be used to view statistical data measured for the document when using the built-in web analytics, and set up advanced on-line marketing functionality.

2.5 How do I develop a website?

Now that you know how to edit the content, you may want to know how to develop the website and manage the design. Although these topics will be described later in this guide, let's take a quick look at the general development process:

This figure shows how you develop the website and how the roles are split between developers and editors. The typical development process consists of the following steps:

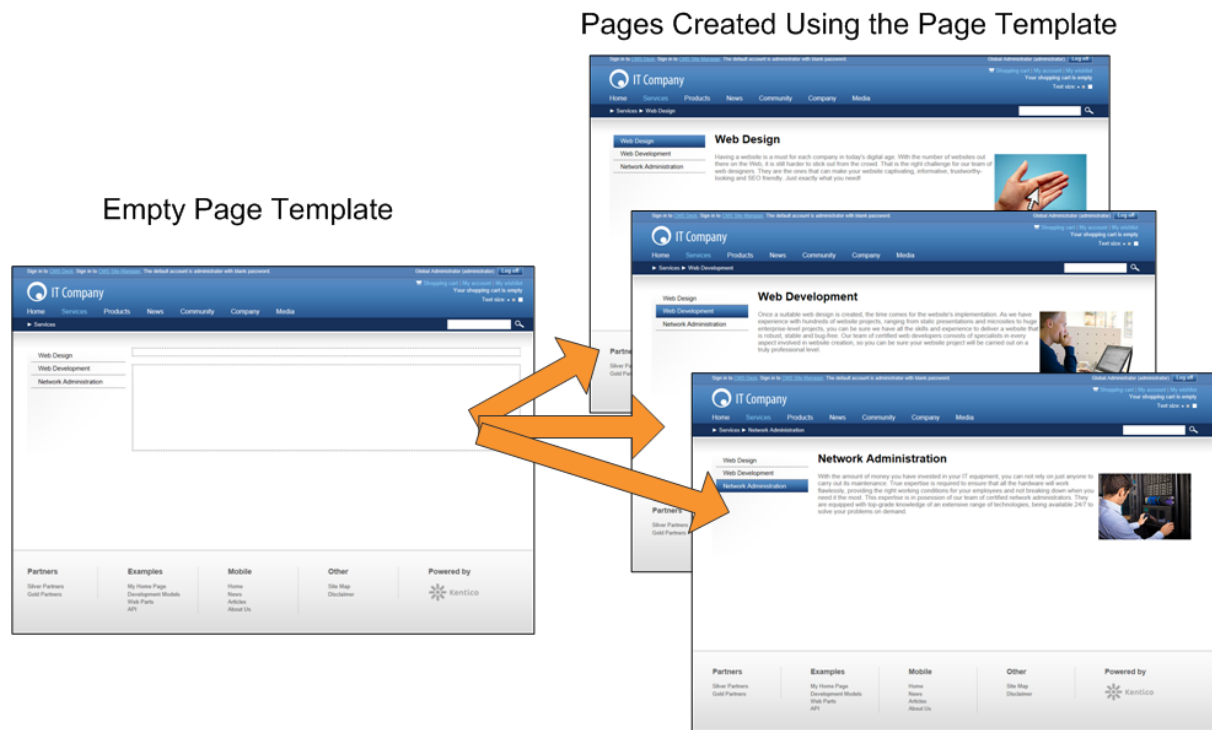

1. The developer analyzes the client requirements.
2. The developer prepares the site structure (site map) and web design.

3. The developer creates **page templates** for every type of the page (home page, solutions, products, news, etc.)
4. The content editor creates new pages - they enter text and images into the page templates defined by the developer.

What is a page template?

A page template is a predefined look for pages that allows content editors to enter the content. A single template can be re-used for multiple pages with the same structure and design, but with different content.

Templates allow content editors to focus on content editing, without taking care of the page formatting. They also help keep the web design consistent throughout the website. The following figure shows how a single page template can be used for multiple pages:

The details on page template development are described later in this guide.

Part

Installation and deployment

3 Installation and deployment

3.1 Overview

Before you begin with the installation procedure, please check whether your machine meets the [System requirements](#).

New Kentico Installer

This section describes the installation of Kentico released before 5/2013. If you are looking for the new installation type documentation, see the [Kentico CMS 7 Installer Documentation](#).

Old Kentico Installer

The old version of the installer that this documentation describes has been deprecated. However, if you need to use the old installer, [download it here](#).

Kentico CMS installation consists of several steps depending on the installation type:

Installation on the local development machine

1. [Setup \(KenticoCMS.exe\)](#) - installs only the program files. No changes to the system configuration (registry, IIS or SQL Server) are made. You do not need to run the setup on your production server - it's intended primarily for development machines.
2. [Web Installer](#) - creates a new website project and optionally configures IIS or uploads the project to the server using FTP. Again, you do not need to run the Web Installer on your production server - you can run it locally and deploy the files over FTP.
3. [Database setup](#) - runs in the web user interface. It creates a new database on your SQL Server with system tables and basic data.
4. [New site wizard](#) - runs in the web user interface after you create a new database. It allows you to create a new site managed by Kentico CMS.

Installation on a remote (production) server

On the remote (production) server, it's not necessary to run any executable or register DLL libraries. Unless you have full administrative access to the server, you will typically follow these steps:

1. Install Kentico CMS on your development machine using [Setup \(KenticoCMS.exe\)](#).
2. Run the [Web Installer](#) on your development machine. Choose to install Kentico CMS on a [Remote server](#) and choose a temporary folder on your local disk.
3. Copy the files from the temporary folder to the production server (e.g., over FTP). If the files are not copied directly to the root of the website, you will need to create a virtual directory. See [Additional configuration tasks -> Creating a virtual directory](#) for details.
4. Open a web browser and navigate to the root URL of the copied files on your web server.

The rest of the installation is the same as on the local machine ([Database setup](#) and [New site wizard](#)).

If you encounter any problems during the installation, please see the [Troubleshooting installation issues](#) chapter or contact our support at <http://www.kentico.com/Support.aspx>

Tip: There's no magic behind it!

Kentico CMS is a **standard ASP.NET application**. Since it doesn't make any modifications to the system, you can move it to another system as you would with any other ASP.NET project. You can also open the project in Visual Studio and debug it or compile it.

The database is a standard MSSQL database, so you can move it to another server using a typical backup/restore procedure. The connection string is stored in the *web.config* file, in the *ConnectionStrings/CMSConnectionString* element.

Silent Install

If you want to install Kentico CMS in the background without having to interact with the installation interface, navigate directly to the [Silent Install](#) topic.

3.2 System requirements

The following configurations are supported by Kentico CMS. Other configurations have not been tested, but may be functional.

Server-side Requirements

- Windows Vista Home Premium/Business/Enterprise/Ultimate, Windows 7 (both 32bit and 64bit) or Windows 8 (both 32bit and 64bit), or Windows Server 2008, 2008 R2, 2012.
- Microsoft .NET Framework [3.5 SP1](#) or [4.0](#) or higher.
- Microsoft Internet Information Services (see the table below) or Visual Studio/Visual Web Developer 2008/2010/2012 built-in web server.
- Microsoft SQL Server 2005, 2008, 2008 R2, 2012 (including free SQL Server Express Edition [2005/2008/2012](#)).

Internet Information Services overview

Internet Information Services version	Operating system	Details and installation instructions
IIS 5.1	Windows XP Professional	not supported
IIS 6.0	Windows Server 2003	not supported
IIS 7.0	Windows Vista	IIS 7 Installation and Deployment
	Windows Server 2008	
IIS 7.5	Windows 7	

	Windows Server 2008 R2	
IIS 8.0	Windows 8	Installing IIS on Windows Server 2012
	Windows Server 2012	

It's recommended to install IIS with all its available features.

Hosting Requirements

- ASP.NET 3.5 SP1 (or higher) and Microsoft SQL Server 2005/2008/2012 support.
- Medium-trust or full-trust permissions for the ASP.NET application.
- If the server uses medium trust, ASP.NET AJAX 1.0 must be installed on the server.
- If the application uses .NET Framework 3.5 SP1 and is hosted in a medium trust environment, it is necessary to have [Microsoft Chart Controls](#) installed on the server.
- It's recommended that your hosting plan comes with 250 MB or more memory and 100+ MB database.

You can use your favorite hosting provider or choose from our [hosting partners](#).

Windows Azure

Kentico CMS fully supports the Microsoft Windows Azure platform, including SQL Azure, Azure Storage and other services. Windows Azure SDK 1.7 is required.

Development Tools

If you want to create custom web parts or integrate custom code, you need **Visual Studio 2008/2010/2012** or free **Visual Web Developer 2008/2010/2012 Express Edition**.

External utilities

Kentico AD Import Utility, Kentico Import Toolkit, Kentico Installation Manager, Kentico Hotfix and Upgrade utility and Kentico Service Manager require **.NET Framework 3.5** to run.

Supported Client Browsers for Content Editors

- Internet Explorer 8, 9
- Firefox 4.0+
- Chrome 12
- Safari 4.0+ or Firefox 4.0+ on Mac OS

Supported Client Browsers for Site Visitors

- Internet Explorer 6.0+
- Firefox 1.0.5+
- Chrome 12+
- Mozilla 1.7.1+
- Netscape 7.1+

- Opera 7.52+
- Safari or Firefox on Mac OS
- Mobile browsers, such as Safari on iPhone, are supported as well, but some features may be limited by browser capabilities.

(the visitor browser requirements also depend on the functionality used on the website)

3.3 Installation procedure

3.3.1 Setup (KenticoCMS.exe)

New Kentico Installer

This section describes the installation of Kentico released before 5/2013. If you are looking for the new installation type documentation, see the [Kentico CMS 7 Installer Documentation](#).

Use this file to install the program files on your development machine.

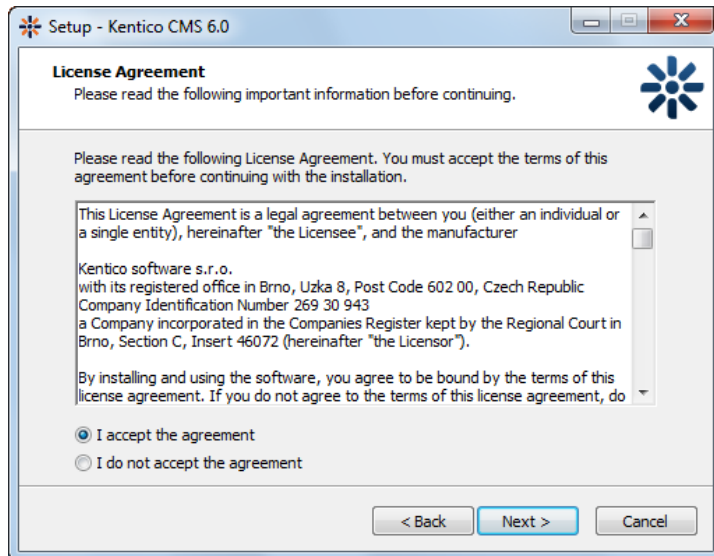

Installation on a shared hosting server

If you're going to run Kentico CMS on a shared hosting server, you do not need to run any EXE file or register any DLL file on the server (you're usually not allowed to do that anyway). Please read [Additional configuration tasks -> Installation on shared hosting server](#) to find out how to solve this.

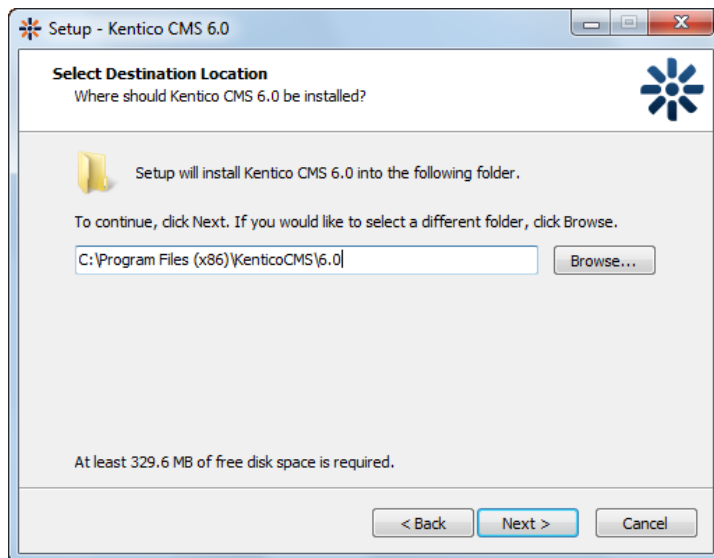

1. Run *KenticoCMS_<version>.exe*. You will see the welcome screen.

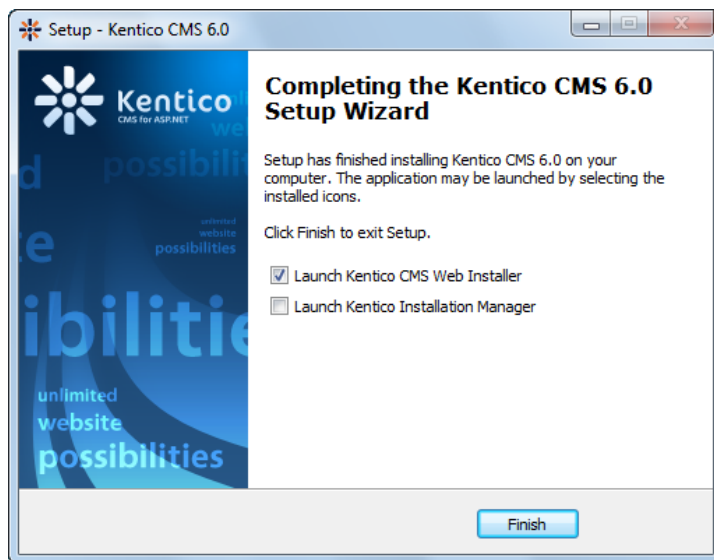

2. Click **Next**.
3. Read and accept the license agreement and click **Next**.

4. Choose the location where the Kentico Web Installer and documentation will be deployed.
5. Click **Next** and **Install**.
 - **Please note:** this is not the folder where your website will be placed, it's only a place for Kentico CMS program files and help files.

6. After the installation is finished, enable the **Launch Kentico Web Installer** option and click **Finish**.
7. Continue to the [Web Installer](#) chapter.

3.3.2 Web installer

3.3.2.1 Overview

New Kentico Installer

This section describes the installation of Kentico released before 5/2013. If you are looking for the new installation type documentation, see the [Kentico CMS 7 Installer Documentation](#).

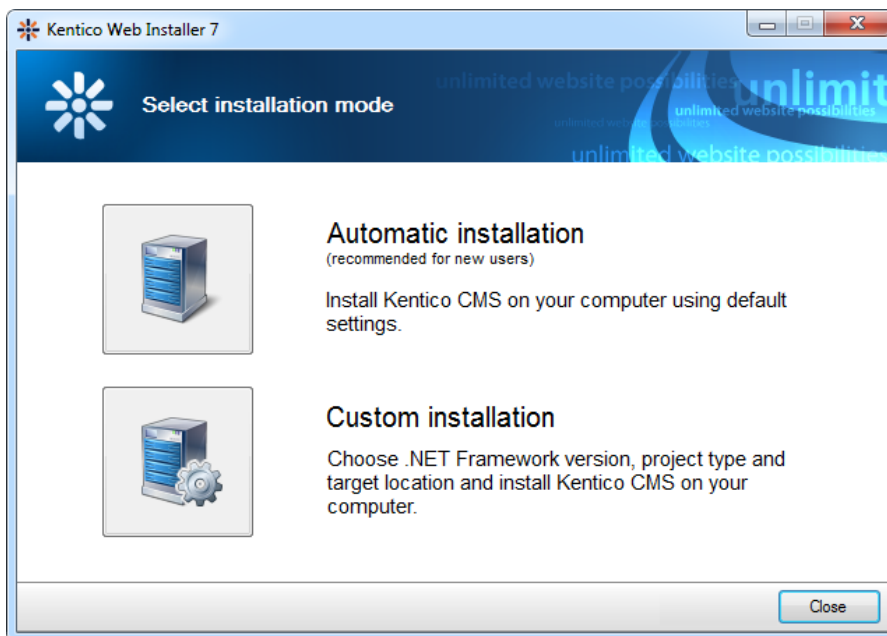

Kentico Web Installer allows you to create a new project and (optionally) configure the Microsoft IIS web server.

Selecting installation mode

You have two ways to proceed with the installation:

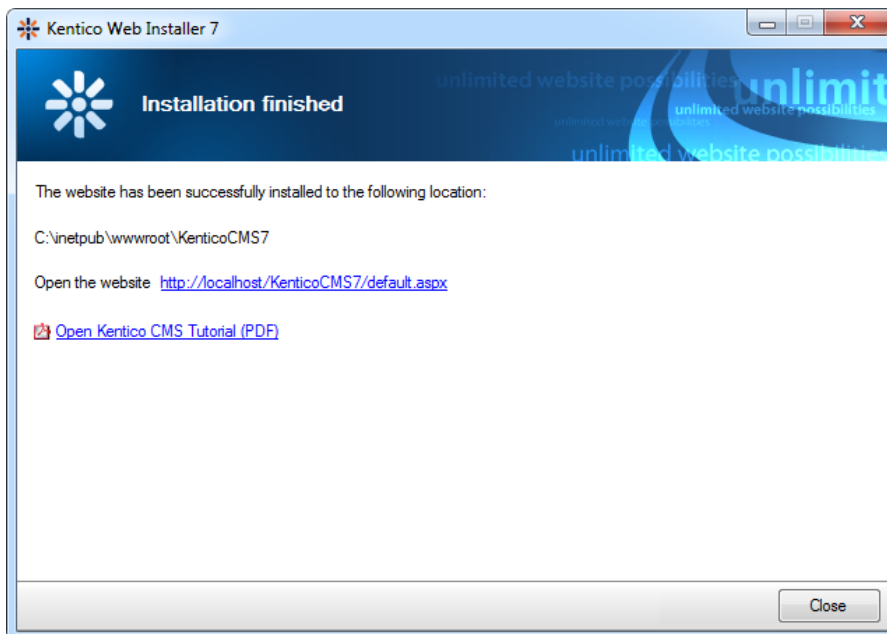

- [Automatic installation](#) - uses default settings. Recommended if you are new to Kentico and want to, e.g., evaluate the functionality.
- [Custom installation](#) - allows you to choose the .NET framework, as well as the type of the project and the installation location folder.

Note that **Automatic installation** chooses .NET framework based on the framework that is available in your system, first checking for .NET 4.0, .NET 4.5 and finally 3.5. *Web site project* and default IIS *inetpub\wwwroot* installation folder are selected.

Automatic installation

If you clicked Automatic installation, the installer copies the necessary files to the default folder and displays a link to view your website.

Continue to the [Database setup](#) topic.

Custom installation

If you clicked **Custom installation**, the wizard continues through the following steps.

Step 1 - Select .NET Framework version

First, you need to choose whether you use:

- **.NET Framework 3.5 and Visual Studio 2008**
- **.NET Framework 4.0 and Visual Studio 2010**
- **.NET Framework 4.5 and Visual Studio 2012**

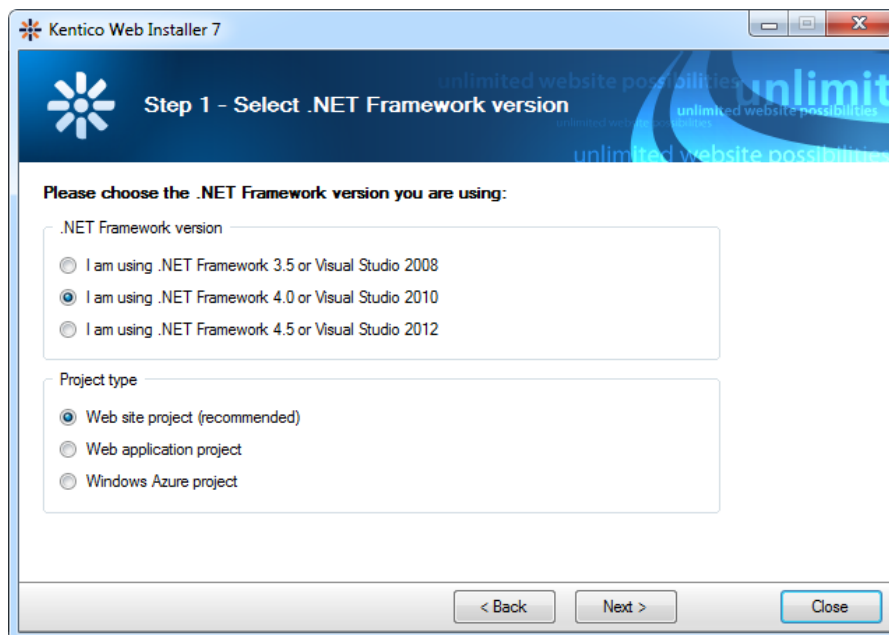

Depending on your choice, the installer will use appropriate *web.config* and *webproject.sln* files. The binaries and code are the same for both options; they are compiled for .NET 3.5 SP1 and can be used with .NET 4.0 as well.

Then, you need to select from the following options:

- **Web site project (recommended)**
- **Web application project**
- **Windows Azure project**

This determines which Visual Studio project type the web installer will create. The name of the solution file will be *WebProject.sln* for a web site project or *WebApp.sln* for a web application.

The last option creates a web application suitable for deployment to the [Windows Azure Platform](#). For more information about this type of installation, please refer to the [Windows Azure Deployment Guide](#).

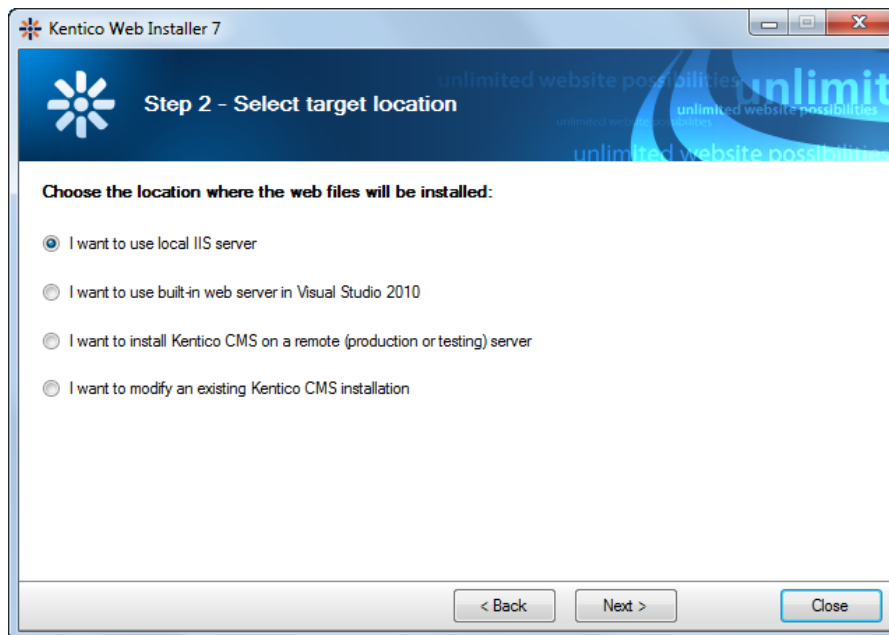

Step 2 - Select target location

Choose one of the options. Click the link to view instructions for the selected option.

- [I want to use local IIS server](#) - you must have local IIS server installed, running and configured for the version of ASP.NET which you chose in the previous step

- [I want to use built-in web server in Visual Studio](#) - you must have Visual Studio or Visual Web Developer Express Edition installed on your local machine
- [I want to install Kentico CMS on a remote \(production or testing\) server](#) - this option only copies the project files to a temporary folder on your disk and you need to copy the files to your production server manually (e.g., over FTP)
- [I want to modify existing Kentico CMS installation](#) - this option modifies (adds or removes components) an existing installation on a local machine

3.3.2.2 Local IIS server

If your machine is running the IIS server locally, choose **I want to use local IIS server** in Step 2 of the Web installer and click **Next**.

Step 3 - Local IIS

Specify the following information:

- **Choose website:** choose one of the websites configured on your IIS; please make sure that the website you choose is running
- **Type of application pool:** type of application pool which will be used for the website (*Integrated* by default, read [this article](#) for more information)
- **Choose target folder:** choose the disk folder where the web project files will be placed

If you're installing Kentico CMS into the root of your website (such as `http://www.example.com`) and do not wish to create another virtual directory (such as `http://www.example.com/cms`), check the **This is an installation to the root** check-box.

Installation to the root

**Check this option (use the website's root virtual directory for the application):**

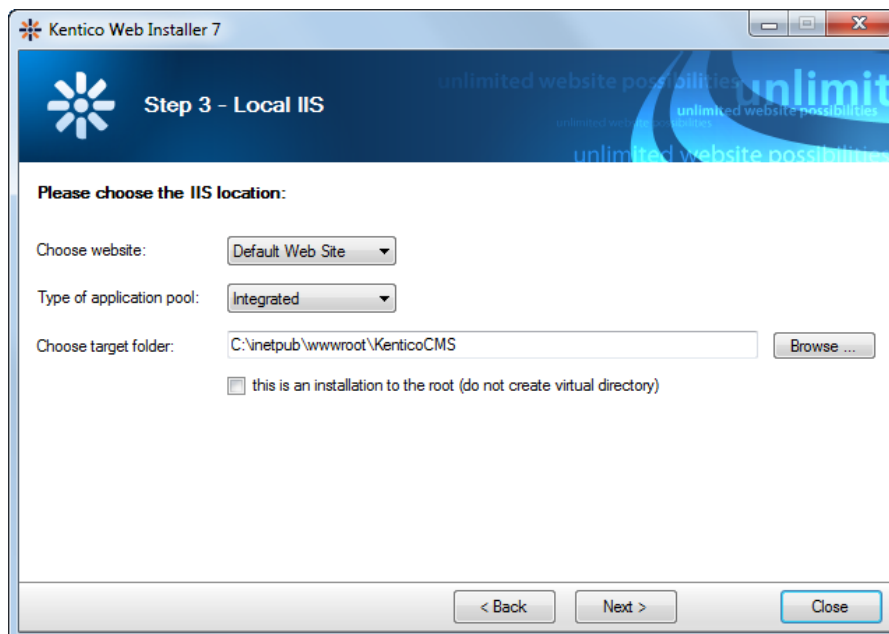

- If you want to have only one application under the website.
- If you want to set different bindings for your applications (to have your applications under different domains and IPs). You can set bindings only for websites, so you will have to use multiple websites.
- When you want to deploy your web application to a hosting server, as it might be easier to export the IIS settings this way.

Uncheck this option (create a virtual directory):

- If you want to install more applications under one website (best for developing purposes).

Concerning Kentico, there are not any differences between these two options.

You can find more information about virtual directories in this article: [Understanding Sites, Applications, and Virtual Directories on IIS 7](#).

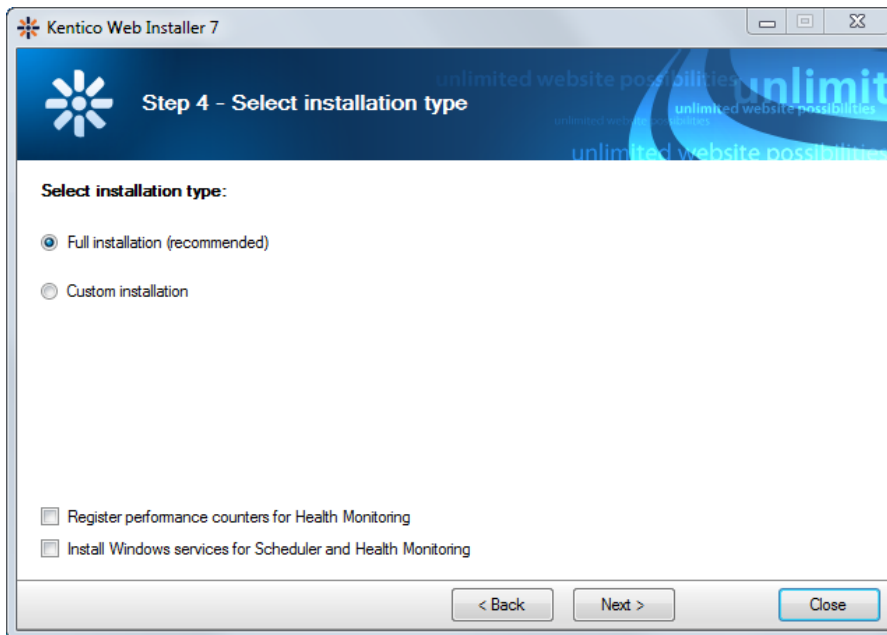

**Step 4 - Select installation type**

Decide between the following options:

- **Full installation** - performs full installation using all optional components
- **Custom installation** - lets you choose which components will be installed

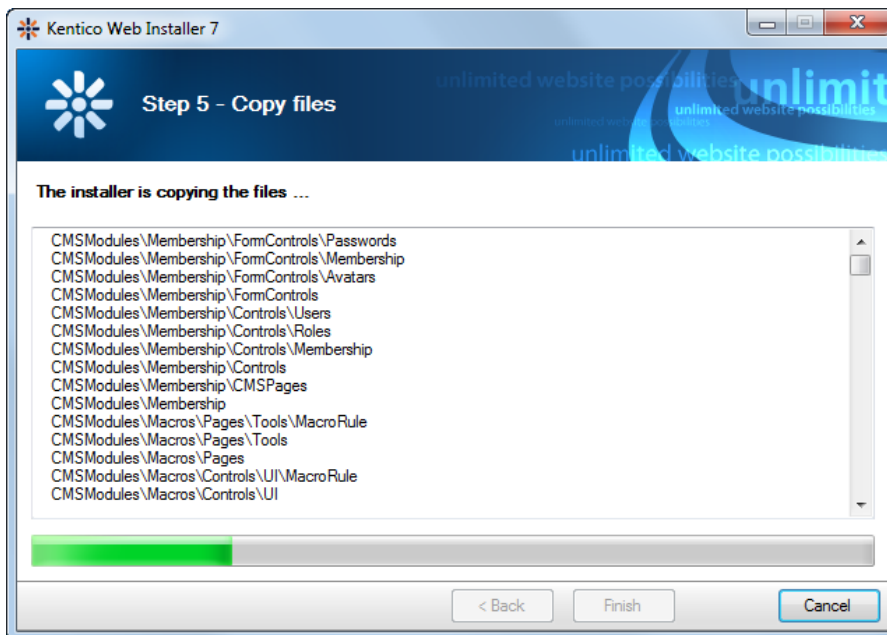

Enabling the **Register performance counters for Health Monitoring** option registers performance counters for the currently installed instance of Kentico CMS in Windows. The counters can be used for monitoring of system load and performance in an external application.

Checking the **Install Windows services for Scheduler and Health Monitoring** option installs the **Kentico CMS Scheduler** and **Kentico CMS Health Monitor** services. Please refer to [Modules -> Health monitoring](#) for more details on these features.

Step 5 - Copy files

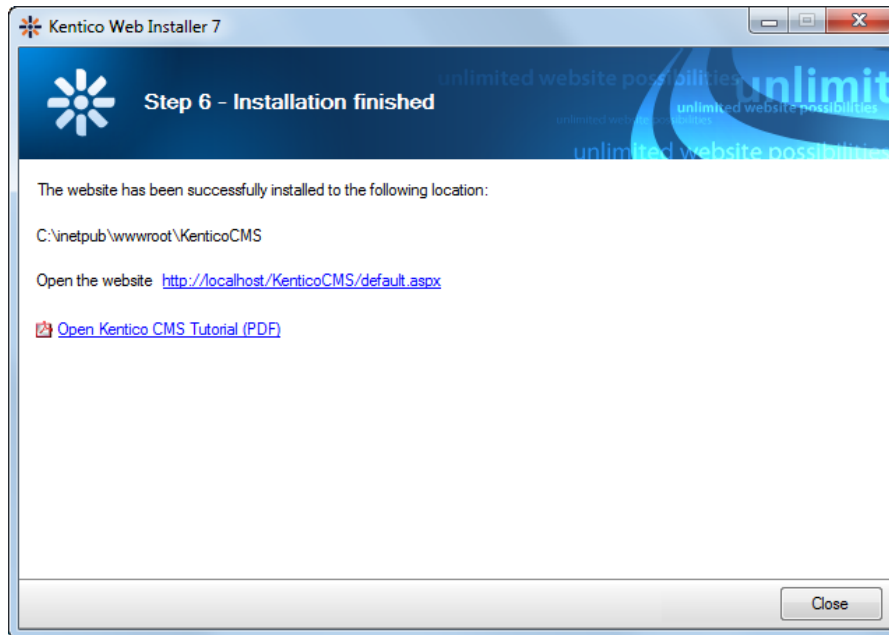

The installer copies the project files to the specified folder:

Step 6 - Installation finished

On the final page of the installer you can click on the displayed link to open the website in your default

browser.

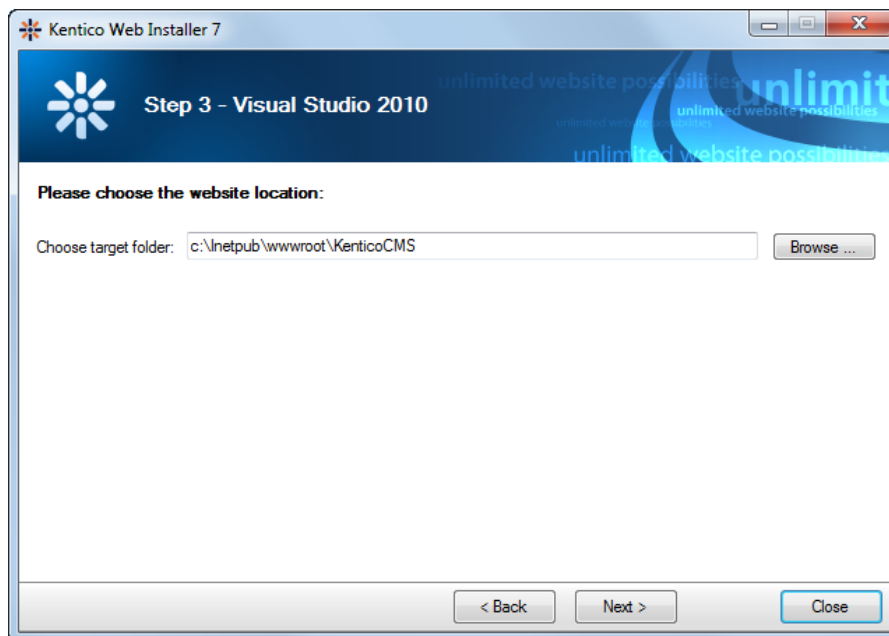

Continue to the [Database setup](#) topic.

3.3.2.3 Built-in web server in Visual Studio

If you want to use the built-in server which is included in Visual Studio, choose **I want to use built-in web server in Visual Studio** in Step 2 of the Web installer and click **Next**.

Step 3 - Visual Studio 2010

Choose the target location of the files on your disk and proceed by clicking **Next**.

Step 4 - Select installation type

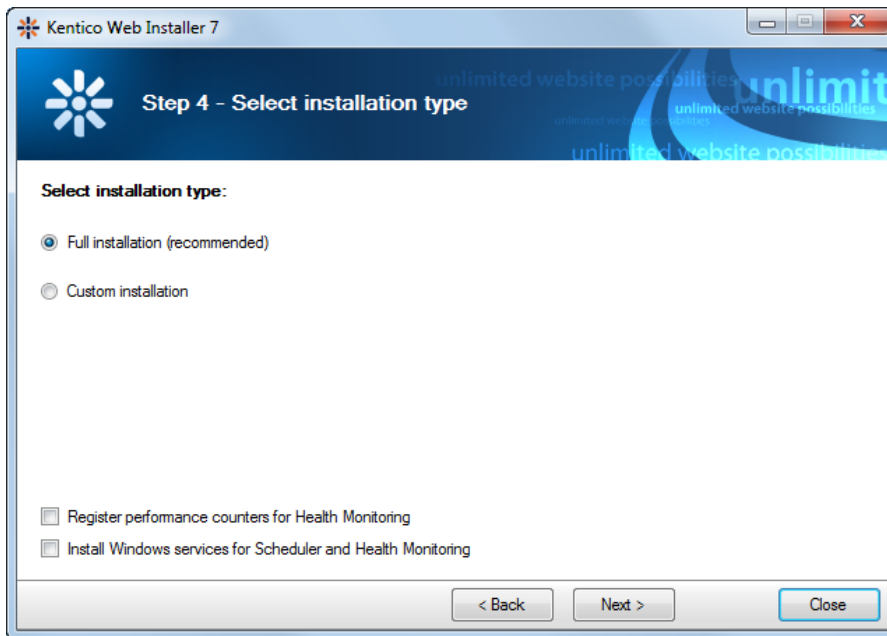

Decide between the following options:

- **Full installation** - performs full installation using all optional components
- **Custom installation** - lets you choose which components will be installed

Enabling the **Register performance counters for Health Monitoring** option registers performance counters for the currently installed instance of Kentico CMS in Windows. The counters can be used for monitoring of system load and performance in an external application.

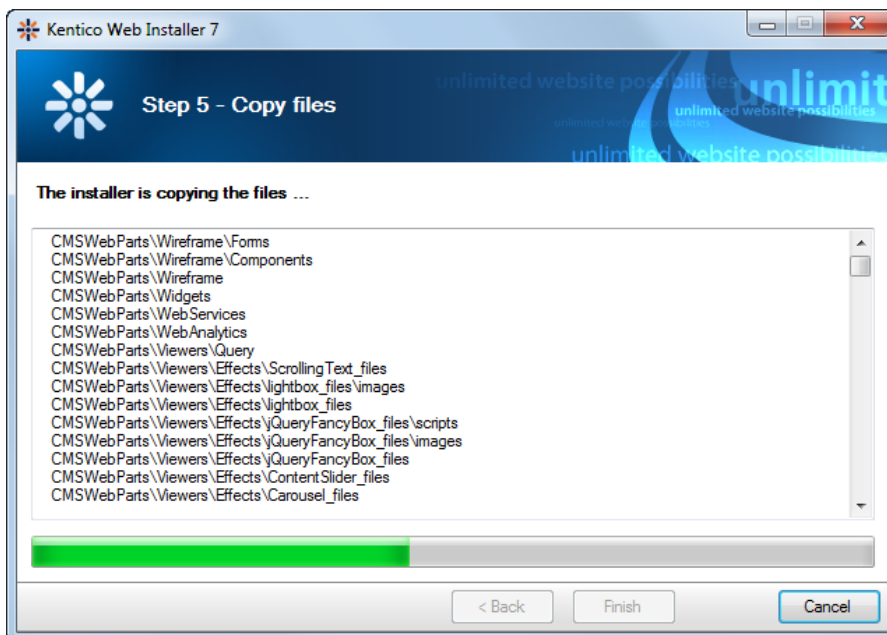

Checking the **Install Windows services for Scheduler and Health Monitoring** option installs the **Kentico CMS Scheduler** and **Kentico CMS Health Monitor** services.

Please refer to [Modules -> Health monitoring](#) for more details on these features.

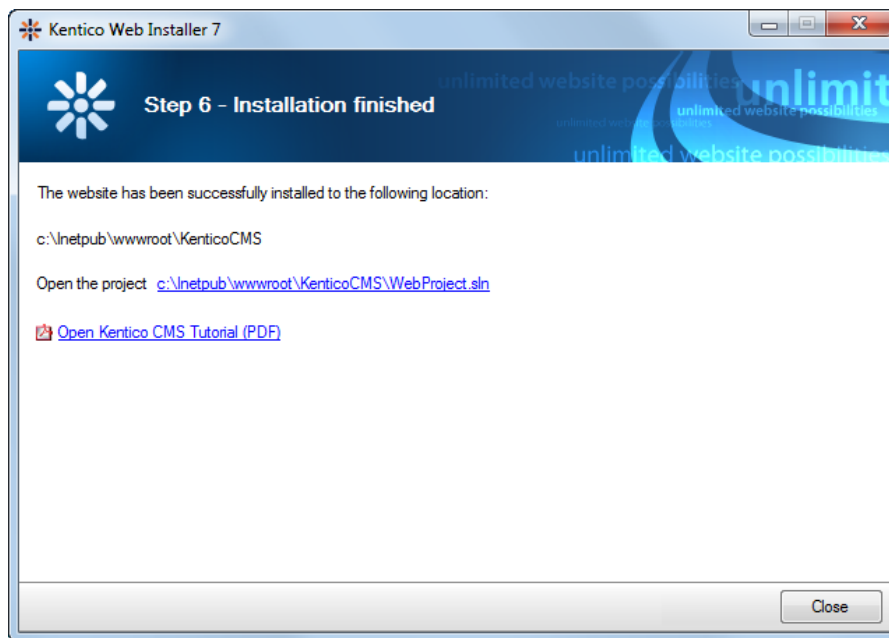

Step 5 - Copy files

The installer copies the project files to the specified folder:

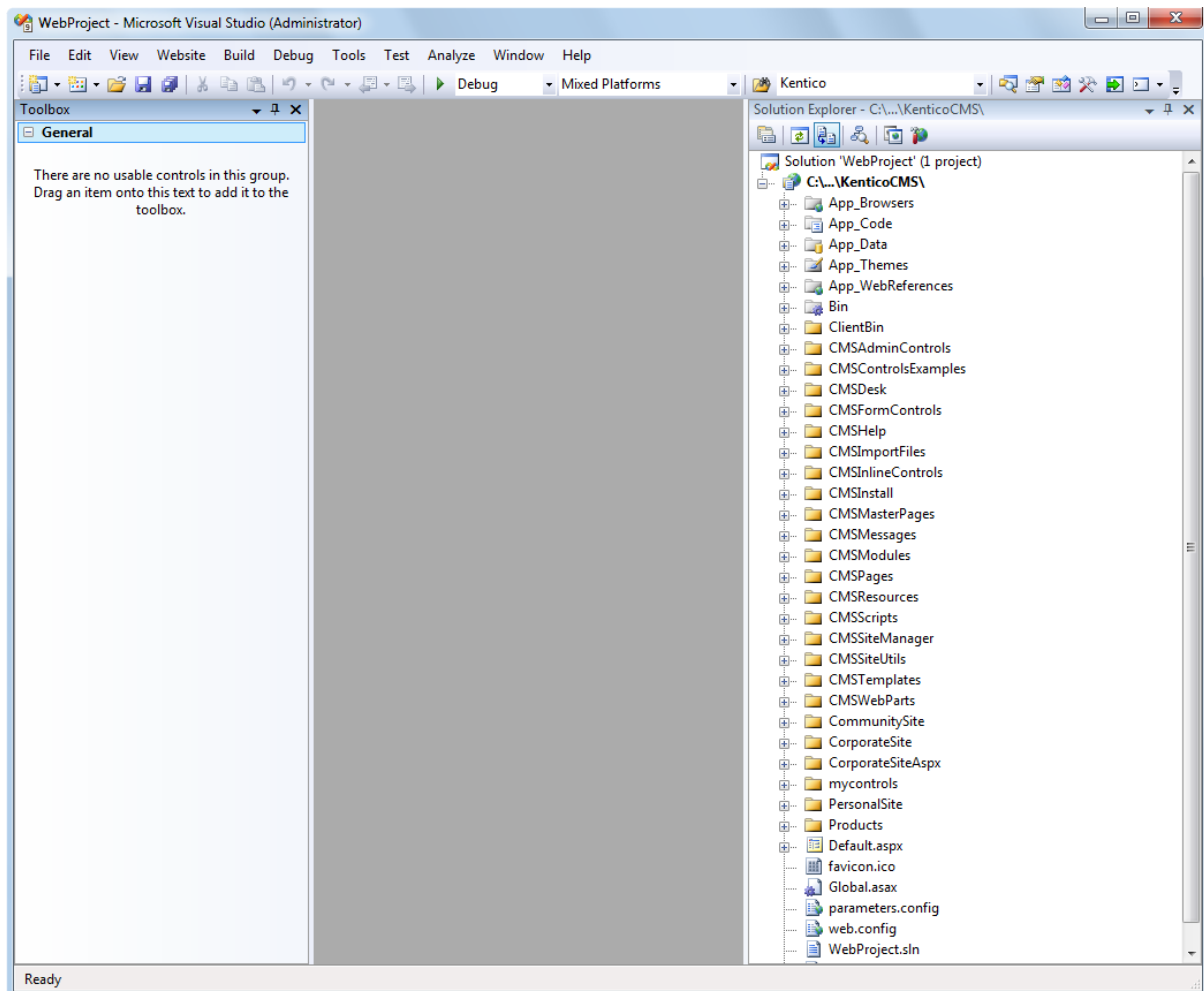

Step 6 - Installation finished

Once the files have been copied to the folder, you can open the solution in Visual Studio by clicking the link:

The project opens in Visual Studio:

Choose **Debug -> Start without debugging** from the main menu. The site is displayed in the new browser window, using the built-in VS web server.

When you cannot open the website in Visual Studio

If the link for opening the project in Visual Studio doesn't work, you may need to start Visual Studio manually. Then choose **File -> Open -> website...** from the main menu and locate the project folder on your disk manually.

Continue to the [Database setup](#) topic.

3.3.2.4 Remote (production or testing) server

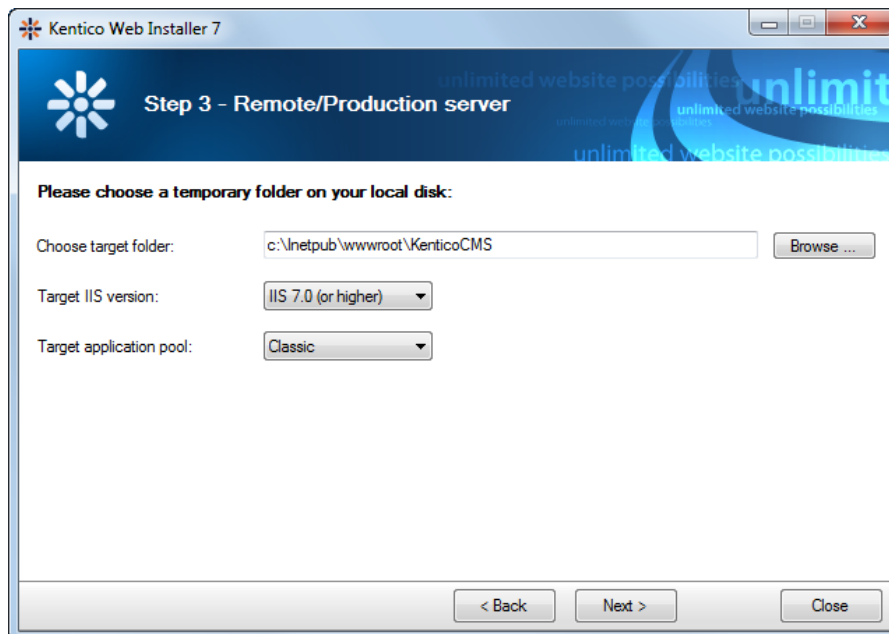

If you need to install Kentico CMS on a remote web server where you cannot run the setup directly (e.g., a shared hosting server), you need to choose the **I want to install Kentico CMS on a remote (production or testing) server** option in Step 2 of the Web installer.

Step 3 - Remote/Production server

Specify the following:

- **Choose target folder** - a temporary folder on your local disk where the web project will be created
- **Target IIS version** - version of IIS installed on the remote server where you want to deploy the CMS
- **Target application pool** - type of the target application pool on the remote server where the CMS should be running

Click **Next** to proceed through the rest of the wizard.

Step 4 - Select installation type

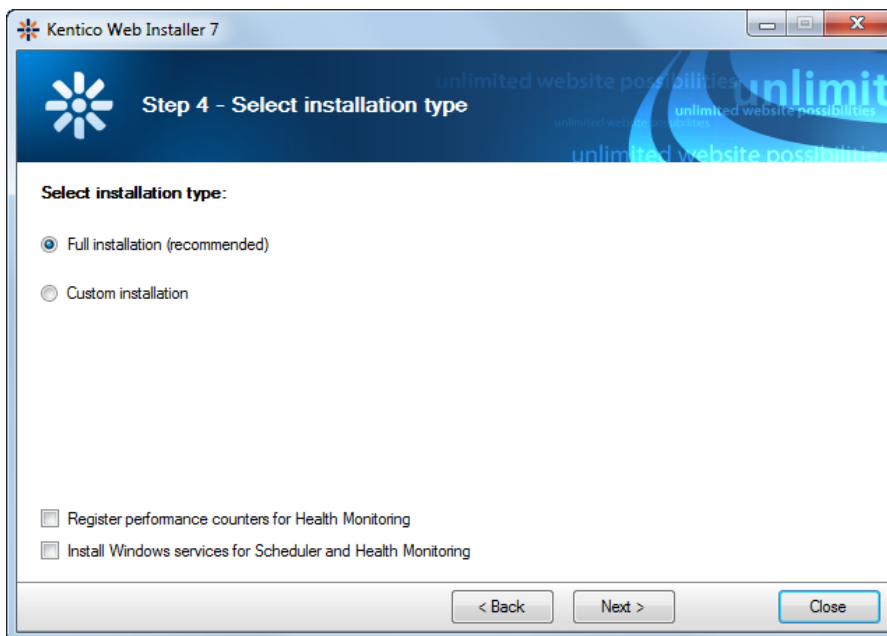

Decide between the following options:

- **Full installation** - performs full installation using all optional components
- **Custom installation** - lets you choose which components will be installed

Enabling the **Register performance counters for Health Monitoring** option registers performance counters for the currently installed instance of Kentico CMS in Windows. The counters can be used for monitoring of system load and performance in an external application. Please note that by enabling this option in installation to a remote server, the counters will be registered on the current machine, not the remote one.

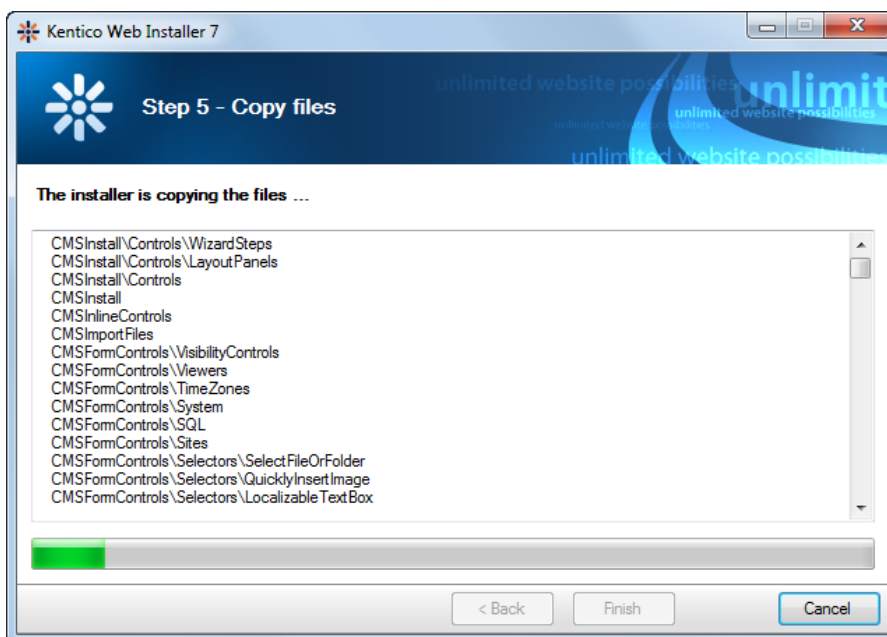

Checking the **Install Windows services for Scheduler and Health Monitoring** option installs the **Kentico CMS Scheduler** and **Kentico CMS Health Monitor** services.

More details on these features can be found in [Modules -> Health monitoring](#).

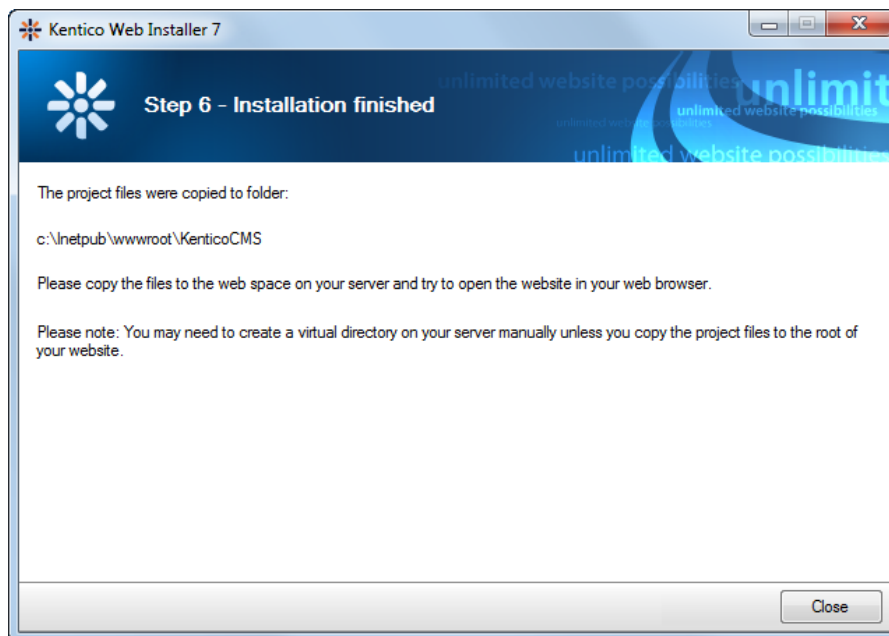

Step 5 - Copy files

The installer copies the project files to the specified folder:

Step 6 - Installation finished

The system creates the web project on your disk and displays a confirmation message:

Now you need to copy the website to your server (e.g., over FTP). If your web project isn't placed in the root of the remote website, you may need to create a virtual directory as described in [Creating a virtual directory](#).

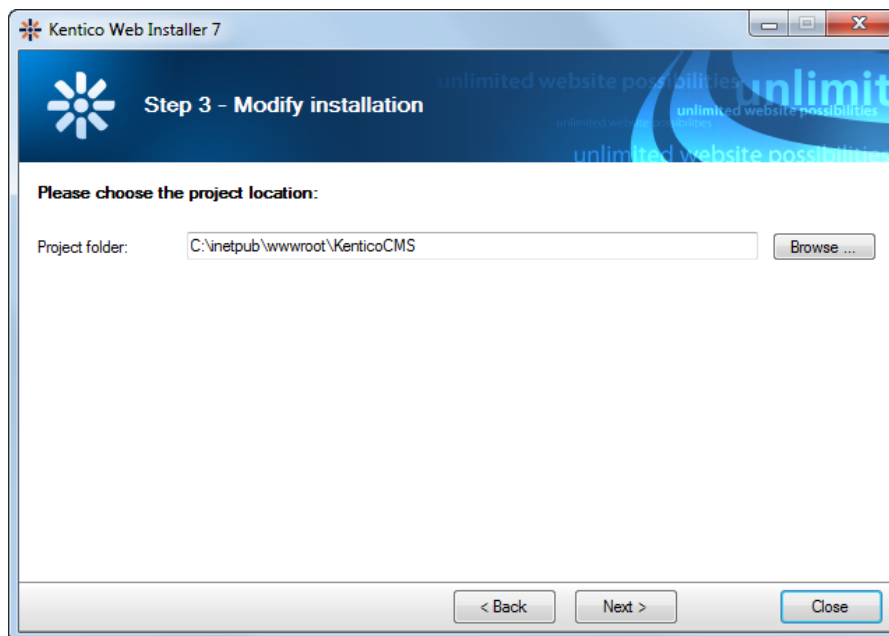

Continue to the [Database setup](#) topic.

3.3.2.5 Existing Kentico CMS installation

The **I want to modify existing Kentico CMS installation** option in Step 2 of the Web installer enables you to add or remove components in an existing Kentico CMS web project.

Step 3 - Modify installation

Specify the root folder of the project that you want to modify and click **Next**.

Step 4 - Select components

The installer displays a component tree. Gray components are a native part of the installation and cannot be removed. Black components are optional. The check-boxes indicate which components are currently installed and you can modify the installation by selecting or unselecting them.

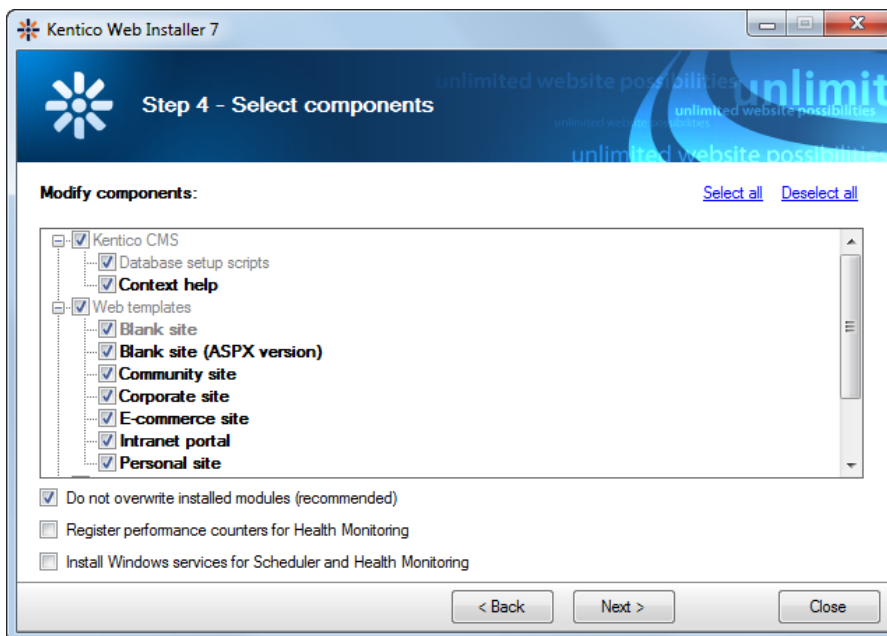

If you enable the **Do not overwrite installed modules (recommended)**, only unselected components will be removed and additionally selected components will be added. If the option is disabled, all enabled components (including *web.config*) will be overwritten by the installation, which means that your modifications to these components may get lost!

Enabling the **Register performance counters for Health Monitoring** option registers performance counters for the currently installed instance of Kentico CMS in Windows. The counters can be used for monitoring of system load and performance in an external application.

Checking the **Install Windows services for Scheduler and Health Monitoring** option installs the **Kentico CMS Scheduler** and **Kentico CMS Health Monitor** services.

Please refer to [Modules -> Health monitoring](#) for more details on these features.

Click **Next**.

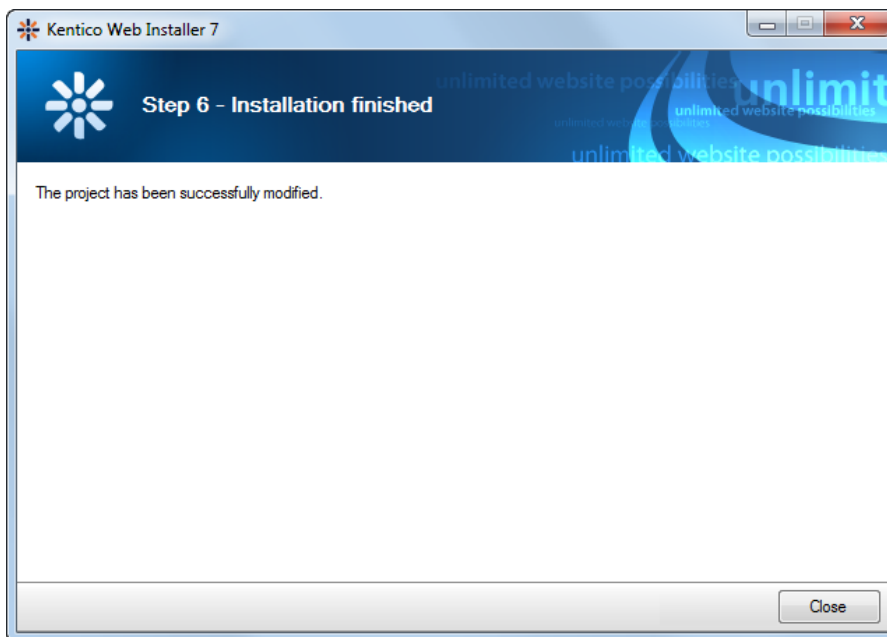

Step 5 - Copy files

The installer modifies the requested components.

Step 6 - Installation finished

When you reach the following screen, it indicates that your project has been successfully modified.

3.3.3 Database setup

After you successfully finish the Web Installer, open a web browser with the Database Setup. It will create database tables for Kentico CMS in a specified SQL Server database.

Step 1 - SQL Server and Authentication Mode

Specify the SQL Server and authentication mode used to access the server:

- **SQL Server name or IP address** - enter the name of the server. You will typically use one of these:
 - the name of the server (such as DBSERVER1) or
 - the IP address of the server (such as 192.168.1.105) or (local)
 - `<SERVERNAME>\sqlexpress` (if you're using Microsoft SQL Server 2005 Express Edition)
- **Use SQL Server account** - use this option if your server is configured for **mixed mode** authentication with SQL logins
- **Use integrated Windows authentication (ASP.NET account)** - use this option if your server is configured for Windows integrated authentication. In this case, you need to use SQL Server 2005/2008 Management Studio to create a new login for user account under which you currently run the web application (ASPNET for Windows XP and Network Service for 2003 - the actual ASP.NET account name is displayed on the screen).

Click the **Next** button.

The screenshot shows a web browser window displaying the 'Kentico CMS Database Setup' wizard. The title bar indicates the URL is `http://localhost/KenticoCMS/cmsinstall/install.aspx`. The main content area features a progress bar with four steps: 'SQL Settings' (highlighted in orange), 'Database', 'Starter Site', and 'Finish'. Below the progress bar, the 'SQL server' section contains the following fields and options:

- SQL Server name or IP address:
- Use SQL Server account
 - Login name:
 - Password:
- Use integrated Windows authentication (ASP.NET account: NT AUTHORITY\NETWORK SERVICE)

At the bottom of the form, there is a help icon (question mark) and a 'Next >' button. The footer of the wizard includes the text 'Do you need help with installation? Please contact our [support](#)' and 'Version: 7.0 Build: 7.0.4611'. The browser's address bar and status bar are also visible.

Step 2 - Database Instance

Now you can decide if you want to use an **existing database** or **create a new database**. In both cases, you need to enter the name of the database into the appropriate field.

In case you are using an existing database, you can choose if you want to **Create Kentico CMS database objects**.

- If the existing database already contains Kentico CMS objects (tables, stored procedures, views), then uncheck the box.
- If the database does not contain these objects (typically when you are installing into an empty database), leave the option enabled.

Click **Next**.

Step 2 - Database Instance

SQL Settings → **Database** → Starter Site → Finish

Database

Create a new database

New database name:

Use an existing database

Existing database name:

Create Kentico CMS database objects

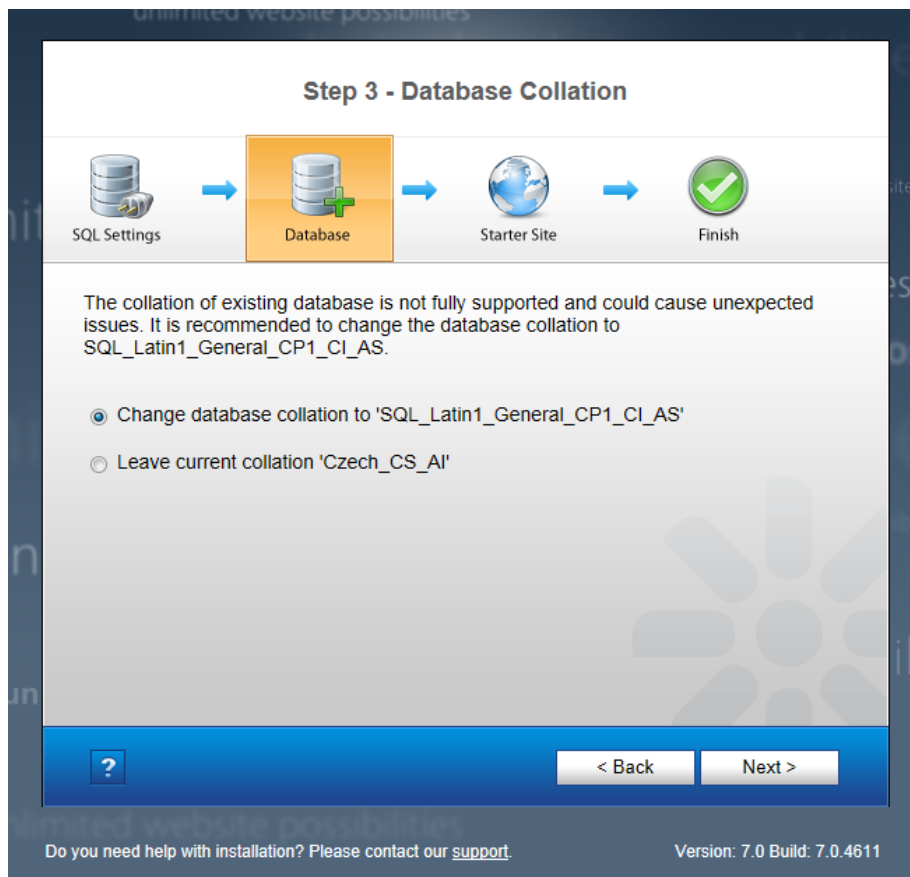

[?](#)

Do you need help with installation? Please contact our [support](#). Version: 7.0 Build: 7.0.4611

Step 3 - Database Collation

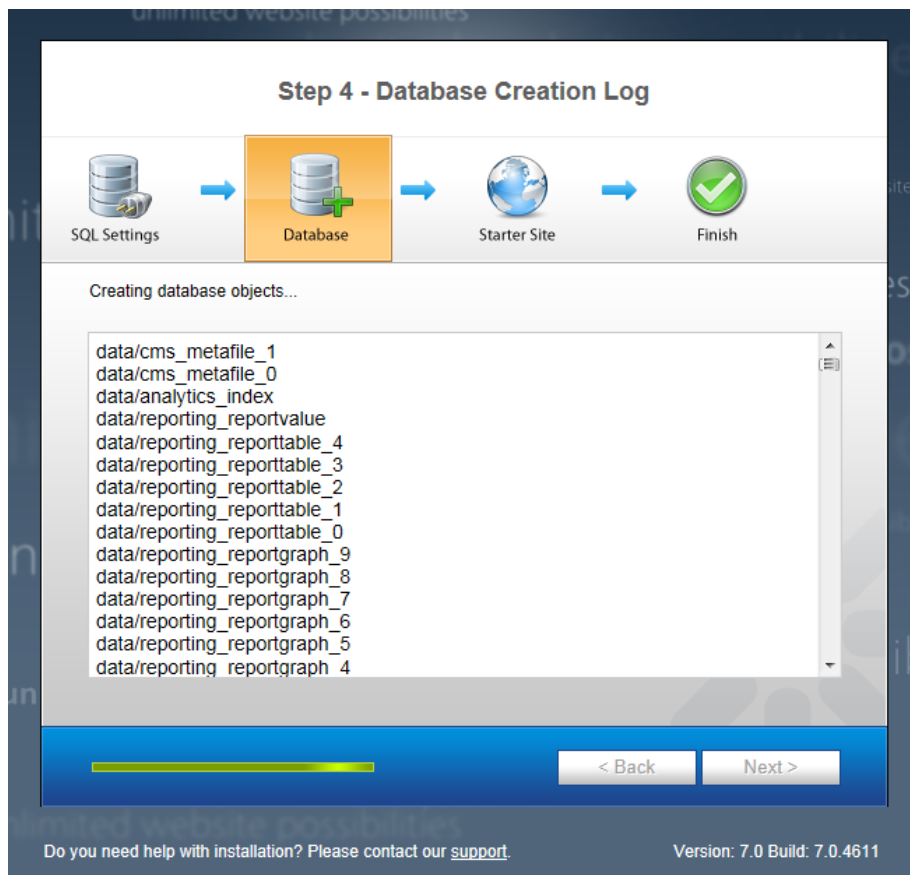

When using an existing database, you may also come across the following dialog. It is displayed if the [database collation](#) is different from `SQL_Latin1_General_CP1_CI_AS`. The dialog lets you choose if you want to change the collation or leave the original one.

For correct functionality, it is highly recommended to change it to the recommended value.

Step 4 - Database Creation Log

A log will be displayed, showing the progress of database creation. After it finishes, a message *Database has been successfully created.* appears at the top of the log and you are moved forward to the next step.

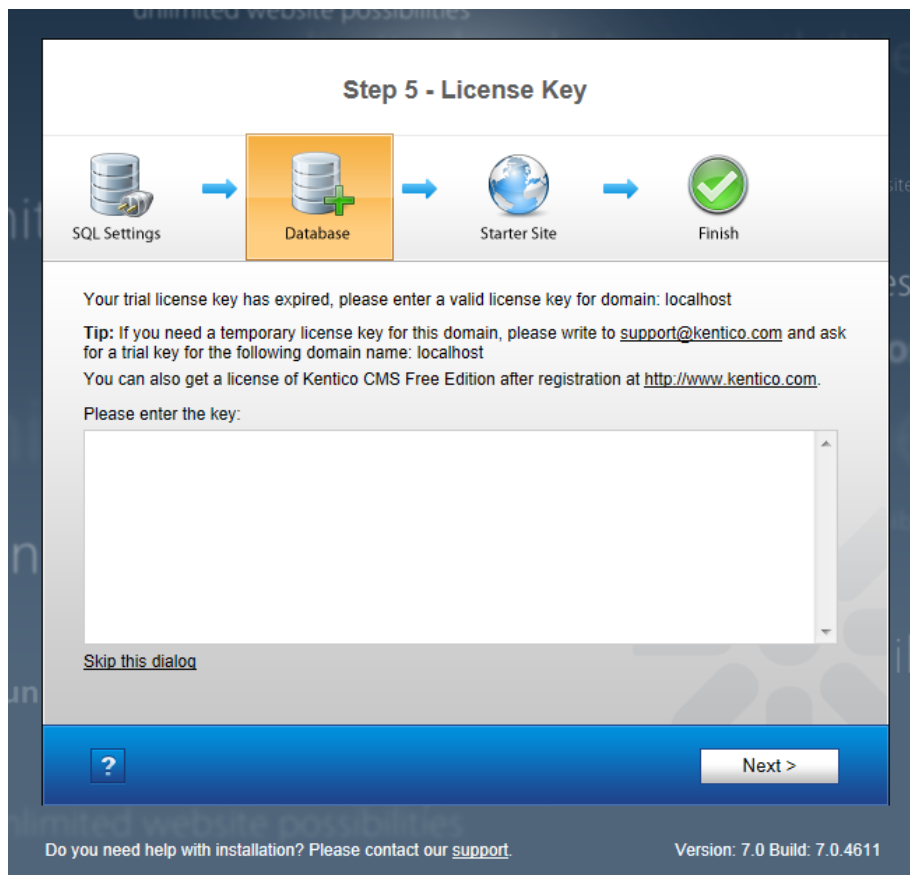

Step 5 - License Key

If you run Kentico CMS on a domain other than *localhost* or *127.0.0.x* (where *x* is between 1 and 255), you will be asked to insert a license key. Since the trial version works only with *http://localhost* and *http://127.0.0.x* (where *x* is between 1 and 255), the same dialog is displayed if your trial period has expired.

Enter a valid license key and click the **Next** button.

Alternatively, you can skip this dialog by clicking **Skip this dialog** link at the bottom left part of the dialog and continue to the [New site wizard](#). You can enter a license key later under [Site Manager -> Licenses](#).

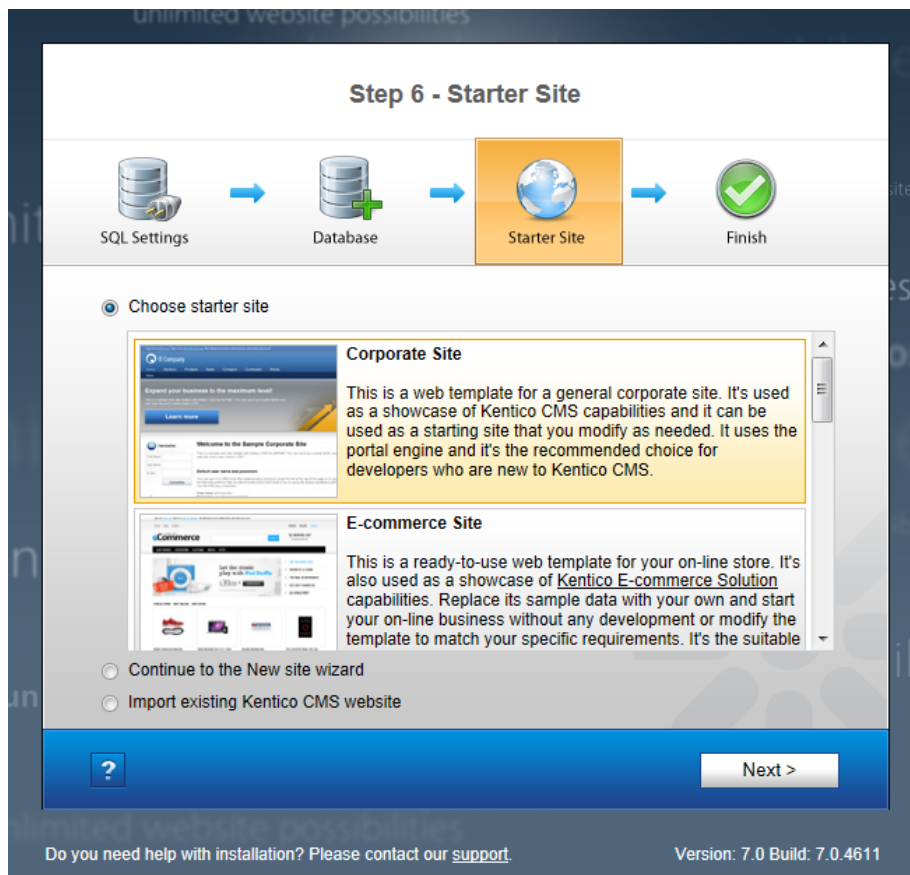

Step 6 - Starter Site

The installer offers you the following options:

- **Choose a starter site:**
 - **Corporate Site** - this option installs the sample corporate site - it is recommended for most users, especially for evaluators
 - **Blank site** - this is a blank site without any content; you will use it to create a new site from scratch
 - **Blank site ASPX** - the same as above, but for ASPX page templates
 - and others
- **Continue to the New site wizard** - this option is recommended if you're starting a new site from scratch; learn more in the [New site wizard](#) chapter
- **Import existing Kentico CMS website** - use this option if you have already created a website with Kentico CMS and you need to import it into a new installation (e.g., on the production server)

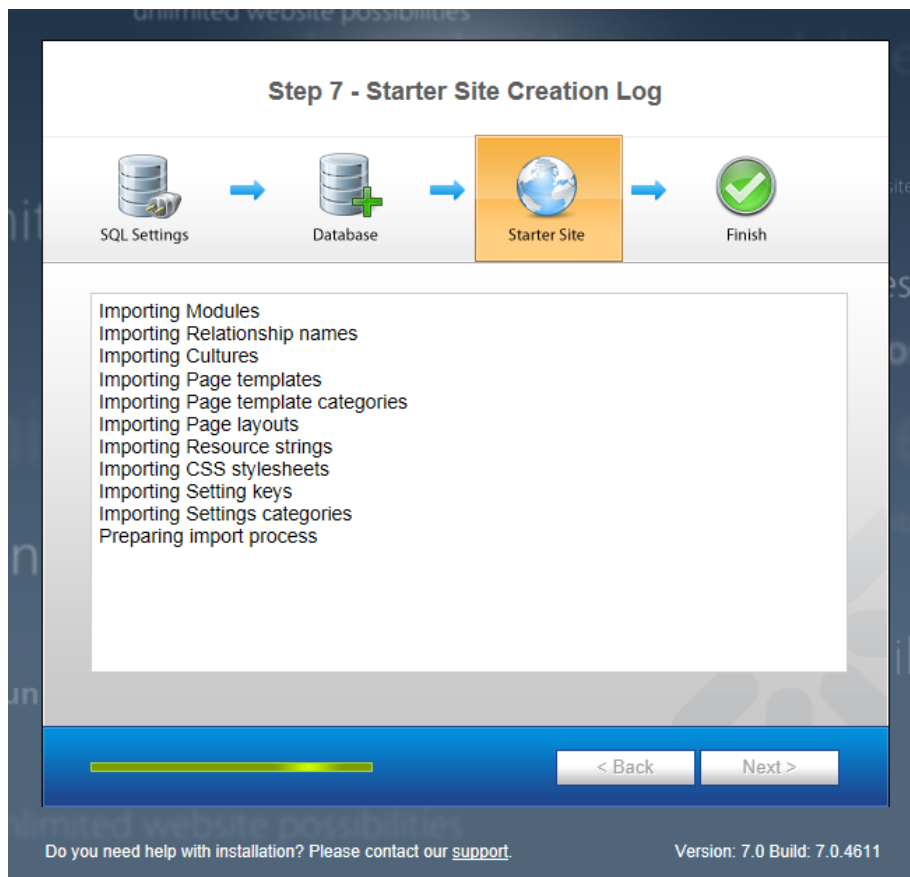

If you're new to Kentico CMS, it's highly recommended that you start with the sample Corporate Site (portal engine). If you decide to run the New site wizard, you can find more details in the following chapter.

Select an option and click the **Next** button.

Step 7 - Starter Site Creation Log

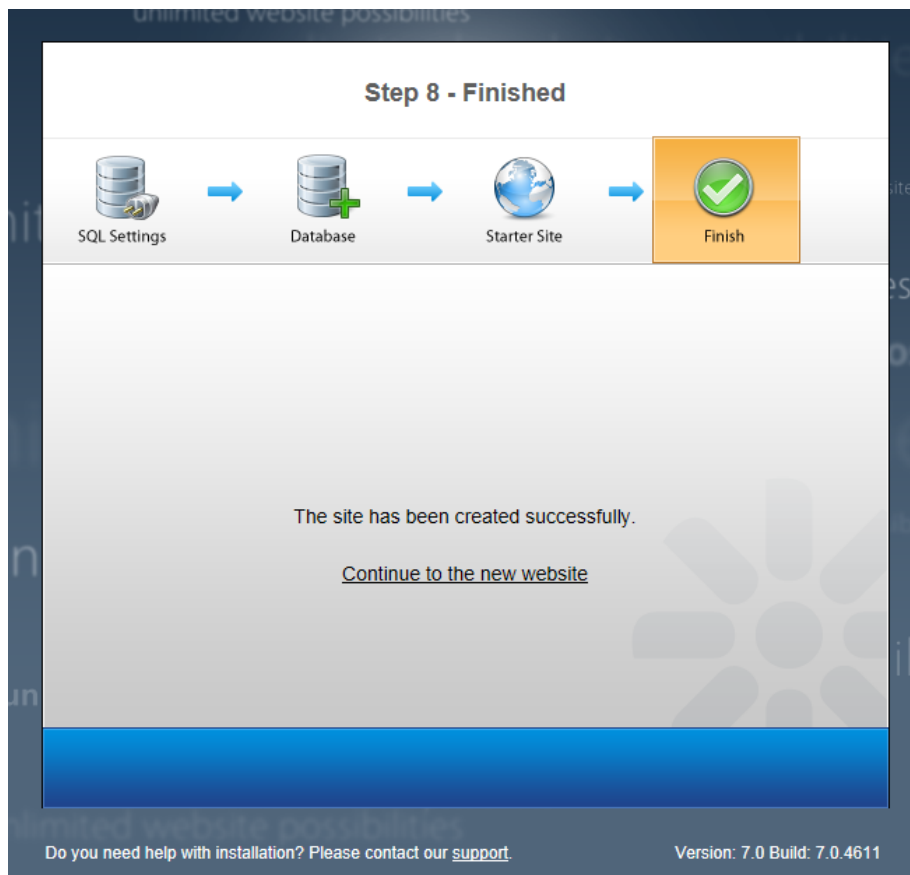

A log is displayed showing you the progress of website creation.

Step 8 - Finished

Once the website is created, the installer displays a confirmation and you can follow the link to access the new live website.

This is the final step of the necessary installation procedure. You can now begin with [managing the website content](#).

Default user name and password

The default user name is **administrator**, the default password is blank.

It's highly recommended that you change the password after you finish the installation.

The default URL of your site is `http://localhost/KenticoCMS`.

The default URL of CMS Desk is `http://localhost/KenticoCMS/CMSDesk`.

The default URL of Site Manager is `http://localhost/KenticoCMS/CMSSiteManager`.

3.3.4 New site wizard

3.3.4.1 Overview

The New site wizard guides you through the process of adding a new website to the system. It is accessible from the *Starter Site* step of the [Database setup](#). You can also launch the wizard from **Site Manager -> Sites**.

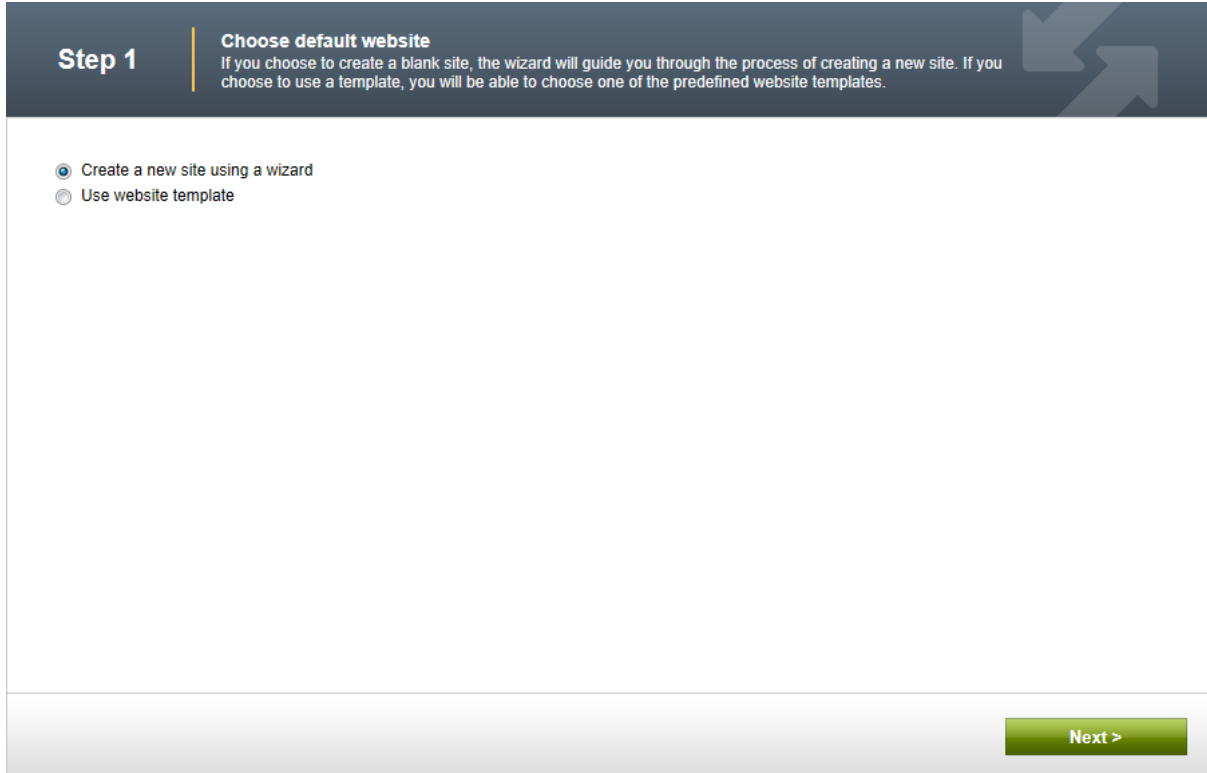

Step 1 - Choose default website

In the first step of the wizard, you can select if you want to create the new site using a wizard or use a website template.

- [Create a new site using a wizard](#) - creates a new blank site and allows you to configure the basic structure of the site.
- [Use website template](#) - creates a new site based on a template chosen in the next step.

Select one of the options and click the **Next** button. Click one of the links above to learn about the following steps of the wizard for the chosen option.

3.3.4.2 New site

This topic describes adding of a new website to the system using the **New site wizard** when the **Create a new site using a wizard** option is chosen in the [first step](#) of the wizard.

Step 2 - Enter new site settings

Enter the following basic site properties:

- **Site display name** - name of the new site displayed in the administration interface.
- **Site code name** - name of the new site used in website code.
- **Domain name** - domain name on which the new site will be running. The domain must be unique for each website running in the system. If you enter the same domain for two websites, they cannot be running at the same time.
- **Site culture** - the default culture of the site.

Click **Next** to continue.

Step 2 **Enter new site settings**
Enter the display name and code name of the website. The Domain field must contain the domain that you will use to access the website during development (you may change it when the site goes live). The default culture is the main language of the website.

Site display name:

Site code name:

Domain name:

Site culture:

< Previous Next >

Step 3 - Objects selection

In this step, you can select which objects will be imported along with your new site. You can make this selection by choosing one of the categories displayed in the tree view on the left side of the screen. By selecting a category, a set of check boxes appears in the right part of the screen, letting you select the exported objects.

If you select the root of the tree, the following options will be offered:

Global selection

- **Load default selection** - if clicked, object pre-selection will be done based on choice in Step 1.
- **Select all objects** - if clicked, all objects will be preselected.
- **Select only new objects** - if clicked, only objects not existing in the database will be preselected.
- **Deselect all objects** - if clicked, all objects will be de-selected.

Import settings

- **Assign all objects to the imported site (recommended)** - if checked, all imported site related objects will be assigned to the imported site.
- **Run the site after import** - if checked, the updated site will be run after the import is finished.
- **Delete incomplete site when import fails** - if checked, incomplete site will be deleted when import fails.
- **Import files (recommended)** - if checked, files will be imported.
- **Do not import objects where parent object is missing** - if checked, objects that are in the package but whose parent object is not present in the target instance will not be imported
- **Import tasks (recommended)** - if checked, delete tasks (incremental deployment) included in the package will be imported

You may leave the default settings and click **Next** to continue.

Step 3 | **Objects selection**
Please select objects which should be imported.

All objects

- Website
 - Documents
 - Administration
 - Settings
 - Development
- Global objects
 - Tools
 - Administration
 - Development

Import objects

Please note: The import process may overwrite your existing objects. The existing objects are marked with * and will be overwritten if checked.

Please select the object type from the tree if you wish to change the default selection. Click **Next** to start the import of selected objects.

Global selection

[Load default selection](#)
 [Select all objects](#)
 [Select only new objects](#)
 [Deselect all objects](#)

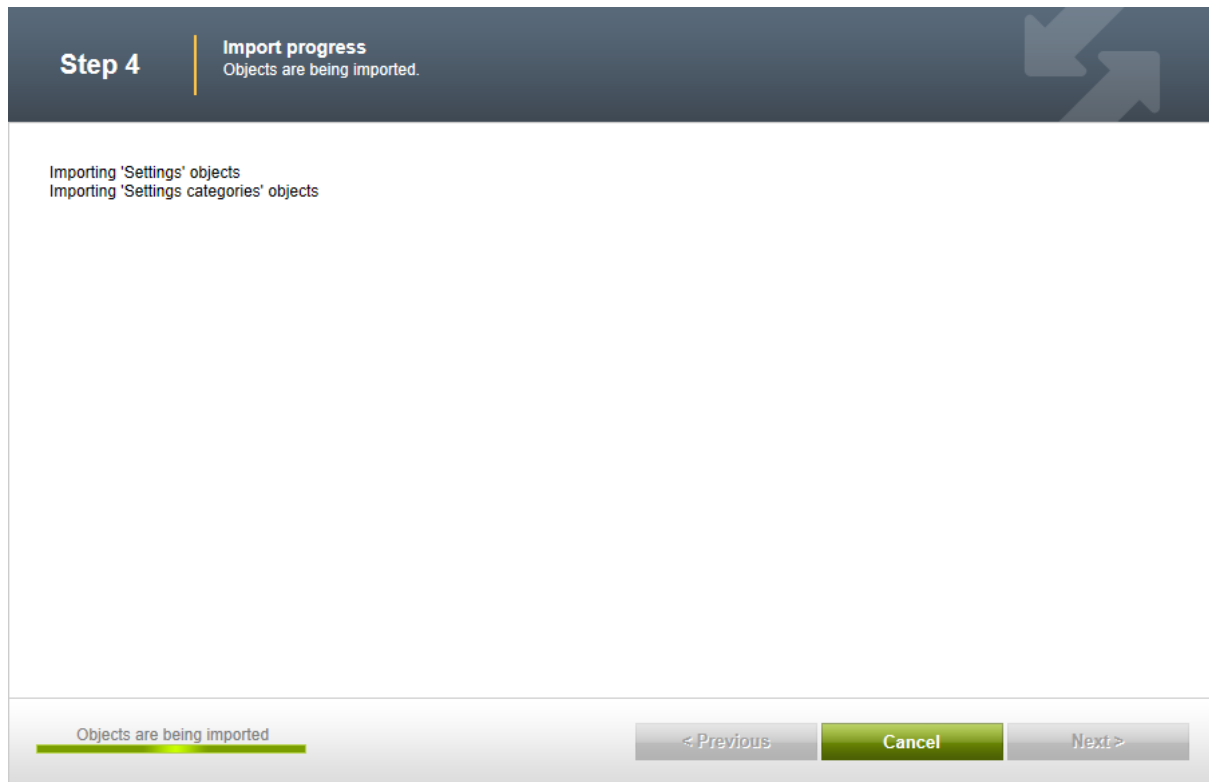

Import settings

- Assign all objects to the imported site (recommended)
- Run the site after import
- Delete incomplete site when import fails
- Do not import objects where parent object is missing
- Import tasks (recommended)
- Import files (recommended)
- Import global folders
- Import assembly files

< Previous Next >

Step 4 - Import progress

A log will be displayed, showing you the progress of the site import. When the process finishes, click the **Next** button.

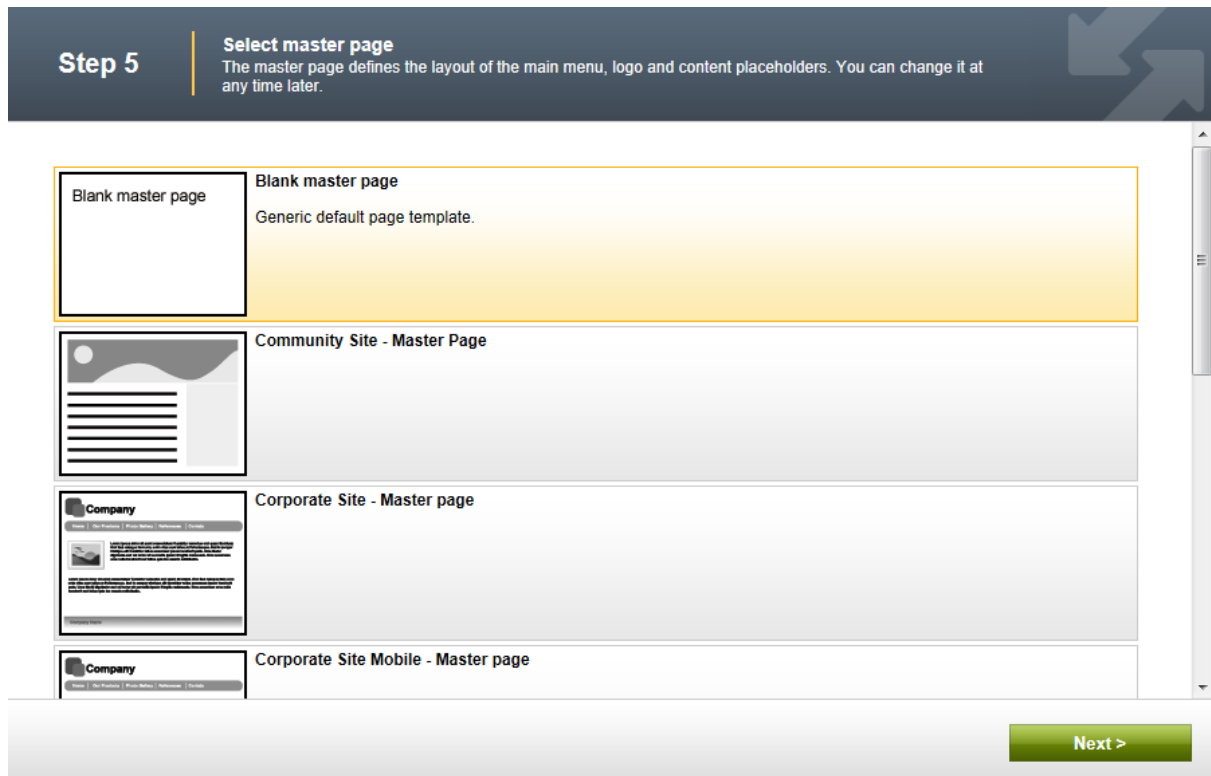

Step 5 - Select master page

Here you can select the master page layout, which defines the basic visual structure of the website. These settings can be altered any time later, no matter which layout you have selected. Select one of the layouts and click **Next**.

Step 5

Select master page

The master page defines the layout of the main menu, logo and content placeholders. You can change it at any time later.

Blank master page	Blank master page Generic default page template.
	Community Site - Master Page
	Corporate Site - Master page
	Corporate Site Mobile - Master page

Next >

Step 6 - Define basic site structure

Now you can define the site map of your new website. Select a node of the tree under which you want to place a new page and click **New**. Enter the name of the new page and select a page template which will be used on the page. Alternatively, you can inherit the page template from the parent page by clicking the **Inherit template** button. Click **OK**.

The newly created page will appear in the tree view. Repeat this procedure until you have defined the desired site structure, then click **Next**. The defined site structure can be modified later.

Step 6 | **Define basic site structure**
Define the site map of your new website. The pages you create will be displayed in the site menu. Each page must have a template specified or it can inherit page template from the parent page.

Content management

new site

[Next >](#)

Step 7 - The website has been created successfully

You have successfully created the new website. Click the **Edit your new website** link to switch to CMSDesk and start editing the site immediately. Alternatively, click the **Finish** button to get redirected to **Site manager -> Sites**.

This is the final step of the necessary installation procedure. You can now begin with [managing the website content](#).

3.3.4.3 Website template

This topic describes creation of a new website using the **New site wizard** when the **Use website template** is chosen in the [first step](#) of the wizard.

Step 2 - Choose website template

You can choose from a number of website templates:

- **Corporate site** is a typical web presentation of a company.
- **E-commerce site** is a typical e-shop showing the possibilities of the E-commerce module.
- **Community site** is a sample community website demonstrating social networking capabilities of Kentico CMS.
- **Blank site** is a blank template used for creating websites from scratch.
- and others.

Some of the templates are available in two versions, one using the [portal engine](#) and the other using [ASPX page templates](#).

Choose one of the listed website templates and click the **Next** button.

Step 2

Choose website template

Choose the predefined website template that will be used for your new website. The website template may contain site structure, design, basic content, new document types and other settings.

Corporate Site

This is a web template for a general corporate site. It's used as a showcase of Kentico CMS capabilities and it can be used as a starting site that you modify as needed. It uses the portal engine and it's the recommended choice for developers who are new to Kentico CMS.

E-commerce Site

This is a web template for a simple E-commerce site. It's used as a showcase of Kentico CMS E-commerce module capabilities and it can be used as a starting site that you modify as needed. It uses the portal engine and it's the recommended choice for developers who are new to Kentico CMS.

Personal Site

This is a web template for a sample Personal site. Several Kentico CMS features, such as blogs, forums and photo galleries, are included. It can be used as a cornerstone for the custom personal site development. The template uses the portal engine and it is the recommended choice for developers who are new to Kentico CMS.

Community Site

This is a web site template for a sample community site. Social networking features of Kentico CMS are used on the site to

< Previous Next >

Step 3 - Enter new site settings

Enter the following basic site properties:

- **Site display name** - display name of the new site.
- **Site code name** - code name of the new site.
- **Domain name** - domain name on that the new site will be running. The domain must be unique for each website running in the system. If you enter the same domain for two websites, they can't be running at the same time.

Click **Next** to continue.

Step 3

Enter new site settings

Enter the display name and code name of the website. The Domain field must contain the domain that you will use to access the website during development (you may change it when the site goes live). The default culture is the main language of the website.

Site display name:

Site code name:

Domain name:

Step 4 - Objects selection

In this step, you can select which of the objects from the site package will be imported. You can make this selection by choosing one of the categories displayed in the tree on the left side of the screen. By selecting a category, a set of check boxes appears in the right part of the screen, letting you select which objects will be imported.

If you select the root of the tree, the following options will be offered:

Global selection

- **Load default selection** - if clicked, object preselection will be done based on choice in Step 1.
- **Select all objects** - if clicked, all objects will be preselected.
- **Select only new objects** - if clicked, only objects not existing in the database will be preselected.
- **Deselect all objects** - if clicked, all objects will be deselected.

Import settings

- **Assign all objects to the imported site (recommended)** - if checked, all imported site related objects will be assigned to the imported site.
- **Run the site after import** - if checked, the updated site will be run after the import is finished.
- **Delete incomplete site when import fails** - if checked, incomplete site will be deleted when import fails.
- **Import files (recommended)** - if checked, files will be imported.
- **Do not import objects where parent object is missing** - if checked, objects that are in the package but whose parent object is not present in the target instance will not be imported
- **Import tasks (recommended)** - if checked, delete tasks (incremental deployment) included in the

package will be imported

You may leave the default settings and click **Next** to continue.

Step 4 | **Objects selection**
Please select objects which should be imported.

All objects

- Website
 - Documents
 - Tools
 - Administration
 - Settings
 - Development
 - E-commerce
- Global objects
 - Tools
 - Administration
 - Development
 - E-commerce

Import objects

Please note: The import process may overwrite your existing objects. The existing objects are marked with * and will be overwritten if checked.

Please select the object type from the tree if you wish to change the default selection. Click **Next** to start the import of selected objects.

Global selection

[Load default selection](#) [Select all objects](#) [Select only new objects](#) [Deselect all objects](#)

Import settings

Objects are being imported

< Previous **Cancel** Next >

Step 6 - The website has been created successfully

You have successfully created the new website. Click the **Edit your new website** link to switch to CMSDesk and start editing the site immediately. Alternatively, click the **Finish** button to get back to **Site manager -> Sites**.

This is the final step of the necessary installation procedure. You can now begin with [managing the website content](#).

3.4 Deployment

3.4.1 Deployment to the live server

With Kentico CMS, you can easily develop a website on your local machine. When the website is ready to go live, you need to export it into an export package. You will need to make sure that the ASP.NET account has the **Modify permission** for the disk, specifically for the `CMSSiteUtils\Export` folder. See the [Troubleshooting installation issues -> Disk permissions problems](#) chapter for more information on how to set up these permissions.

Go to **Site Manager -> Sites** and click the **Export site** icon next to the site to be exported. Enter the name of the export package and click **OK**. The site will be exported to the `<web project>\CMSSiteUtils\Export` folder.

Now you need to install Kentico CMS on the live server. If you're using a remote server without desktop access, follow these steps:

1. Run [Kentico Web Installer](#) on your **local development computer**.
2. Choose to create a new website on a **remote (production) server** and deploy the website into some local disk folder.
3. **Copy all deployed files** to the root of your web server (i.e., the web.config file must be placed in the root of the server). If you need to run the website in a sub-folder, you need to create a virtual directory manually as described in [Additional configuration tasks -> Creating a virtual directory](#).
4. Copy your exported package into the `<website root>\CMSSiteUtils\Import` folder.

5. Make sure your live server is **configured for ASP.NET 3.5 SP1**. It's also highly recommended that the ASP.NET account has Modify permission on the server disk for easy import (however, it's possible to complete the import without Modify permission as well).
6. Open the page /default.aspx of your live web server in the web browser.
7. The [Database setup](#) wizard will be displayed. Create the database for Kentico CMS.
8. You may be asked for the license key for your production domain.
9. In step 3, choose to **Import existing Kentico CMS website**.
10. Choose to import the previously exported package and overwrite all duplicates. The import wizard is described in [Managing sites -> Export and import -> Importing a site](#).

Now that you have imported the site, you may need to adjust its configuration:

1. Go to the **Sites** section. Edit website properties and make sure the website domain and domain aliases are configured correctly for the production domain(s).
2. Go to the **Site Manager -> Settings** and make sure your site settings contain correct values, especially the **SMTP server** value in the **System -> E-mails** section.
3. Go to the **Sites** section. Click the **Open live site** icon next to your new site and make sure the website is displayed correctly.

Alternative Approach

If you, for some reason, cannot deploy the website using the procedure described above, you can use a classic backup/restore approach:

1. Backup your development database and restore it on the production server.
2. Copy the web project folder into the root of your production website.
3. Update the CMSConnectionString value in the web.config file.

Shared Hosting Environment and Medium Trust Level

If you're deploying Kentico CMS on a shared hosting server that requires medium trust level, you may need to make additional configuration changes as described in [Additional configuration tasks -> Configuration for Medium Trust environment](#).

Related topics: [Visual Studio integration -> Pre-compilation \(Publish function\)](#)

3.4.2 Deployment to Windows Azure

Kentico CMS is compatible with the [Windows Azure Platform](#). To learn how to install, configure and deploy a website to this type of environment, please refer to the [Windows Azure Deployment Guide](#).

3.5 Additional configuration tasks

3.5.1 Overview

The following chapters contain descriptions of various configuration tasks that require changes to your system. You needn't perform them for [standard installation](#), they are required only in specific situations.

3.5.2 Creating a virtual directory

If you need to install Kentico CMS manually on a remote server or restore it from backup and, at the same time, you run Kentico CMS in a sub-folder (in contrast to running Kentico CMS in the root of the website), you need to create a new virtual directory for the folder where you have the web project files.

Application root

The root of the website or the virtual directory must be the same as the folder that contains the *web.config* file of Kentico CMS. This folder is called **application root**.

The creation of a virtual directory depends on the installed IIS version:

Creating a virtual directory using IIS 7.5 and 7.0

Since IIS 7, there exists a separate concept for a *virtual directory* and an *application*.

- You can map a virtual directory to a physical directory that is located on a local or a remote computer. The physical directory (under the specified name of the virtual directory) then becomes part of the application's URL.
- An application, on the other hand, is a group of files that provides services over protocols. So if you want to run your website as `http://localhost/KenticoCMSDemo`, you have to **use an application instead of a virtual directory** and specify `KenticoCMSDemo` as the application's alias.

1. Open IIS Manager

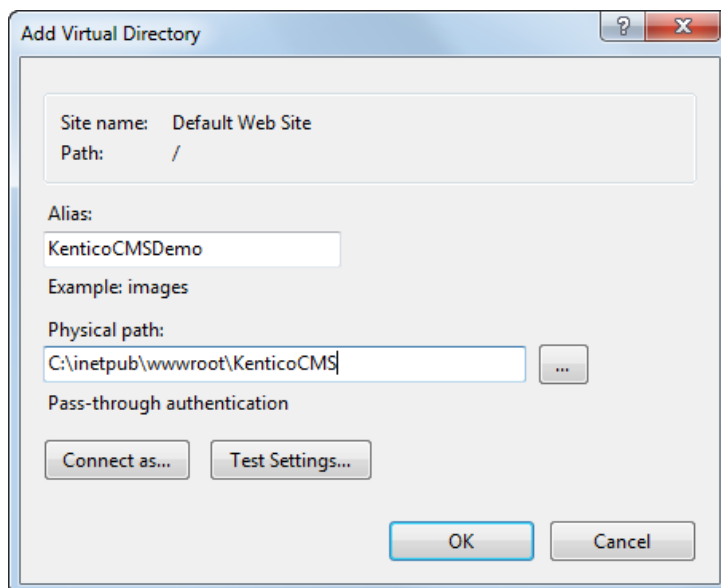

- On Windows 7: Open **Start -> Control Panel -> System and Security** category -> **Administrative Tools -> Internet Information Services (IIS) Manager**.
- On Windows Server 2008 or Windows Vista: Open **Start -> Control Panel -> System and Maintenance** category -> **Administrative Tools -> Internet Information Services (IIS) Manager**.

2. Expand **local computer -> Sites ->** right-click on **Default Web Site** (or other website if you're running multiple websites on the same computer) and choose **Add Virtual Directory...**

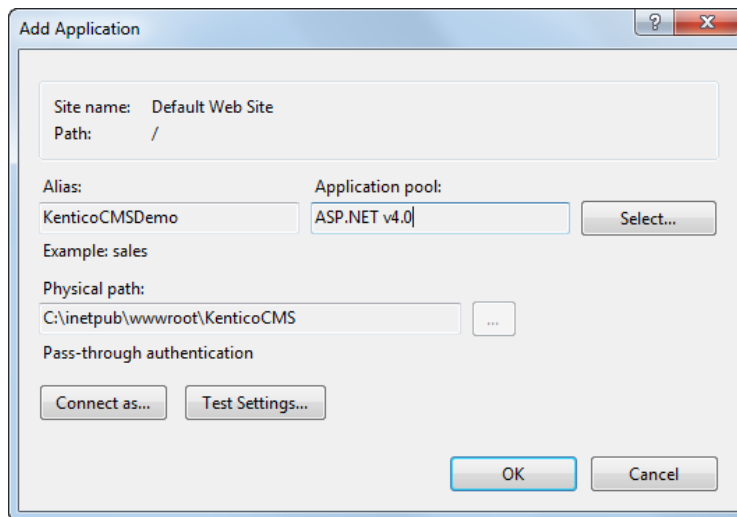

- An **Add Virtual Directory** dialog appears.

3. Enter the Virtual Directory **Alias**. If you want the website to run as `http://localhost/KenticoCMSDemo`, enter alias **KenticoCMSDemo**.
4. Type a path or browse to the physical directory that contains the chosen directory.

5. Click **OK**.
 - The system creates a new virtual directory.
6. Right-click the virtual directory and choose **Convert to Application**.
 - An **Add Application dialog** appears.
7. Click **Select...** and choose the **ASP.NET v4.0** application pool from the drop-down menu.

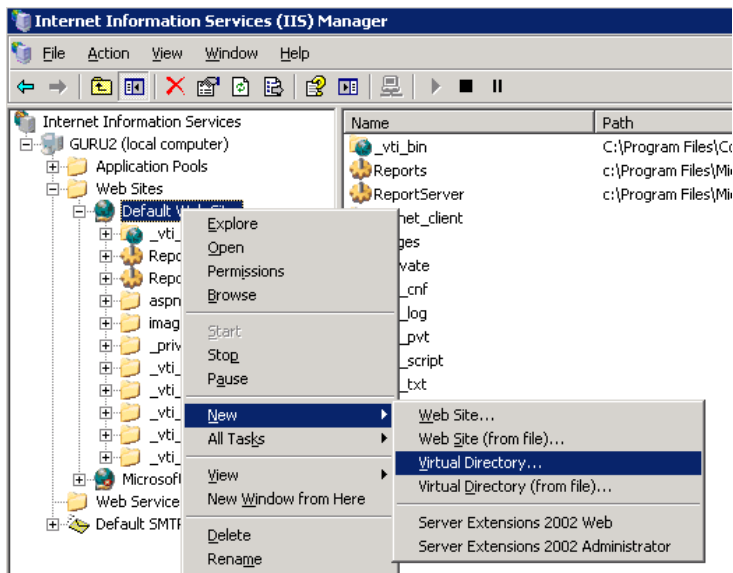

8. Click **OK**.
 - The system converts the virtual directory to an application.

Alternatively, you can create an application in one step by right-clicking a web site and choosing **Add Application...** and filling the required information in the **Add Application** dialog as mentioned above.

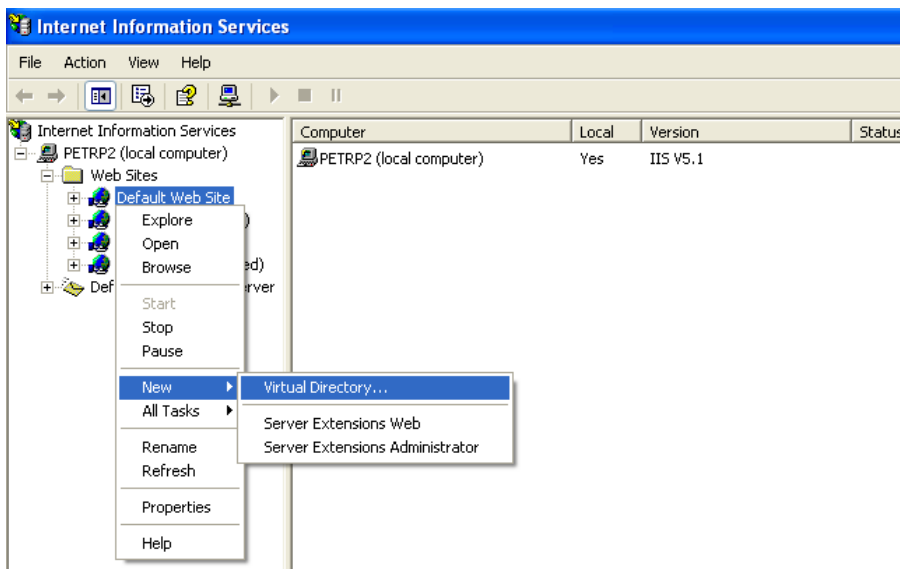

Creating a virtual directory using IIS 6.0 and 5.1

In IIS version 6.0 and earlier, the concept of a virtual directory and an application overlaps, so creating a virtual directory is all you need to do.

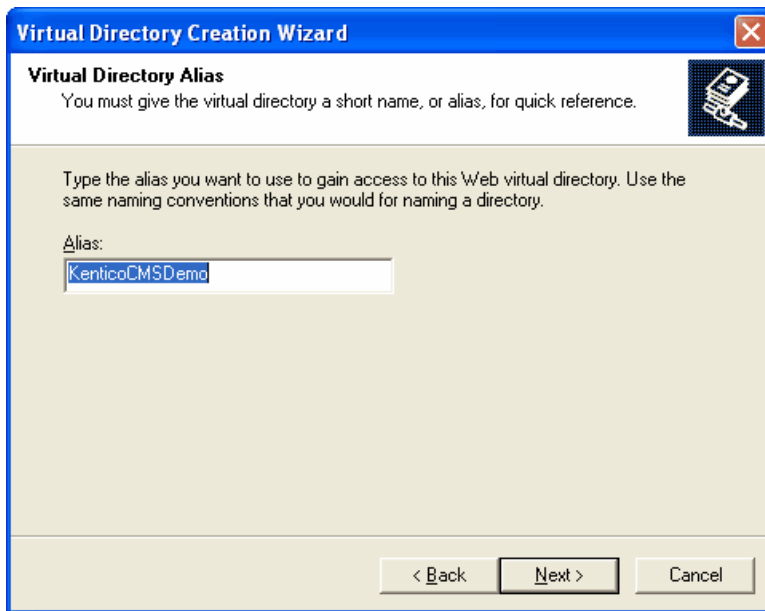

1. Open IIS Manager
 - On Windows Server 2003: Open **Start -> Administrative Tools -> Internet Information Services (IIS) Manager**.

- On Windows XP: Open **Start -> Control Panel -> Administrative Tools -> Internet Information Services**.

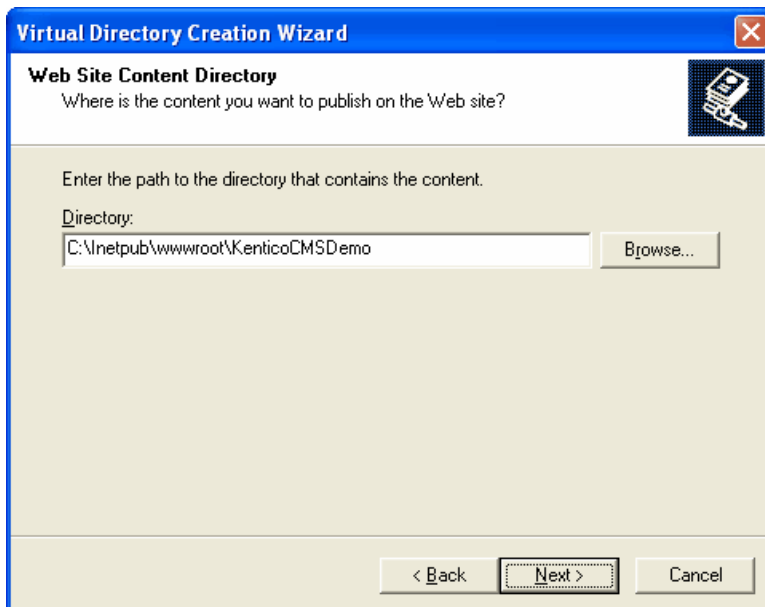

2. Expand **local computer -> Web Sites ->** right-click on **Default Web Site** (or other website if you're running multiple websites on the same computer) and choose **New -> Virtual Directory....**
 - The **Virtual Directory Creation Wizard** appears. It looks the same for both operating systems.
3. Click **Next** on the first screen.
4. Enter the Virtual Directory **Alias**. If you want the website to run as `http://localhost/KenticoCMSDemo`, enter alias **KenticoCMSDemo**.
5. Click **Next**.

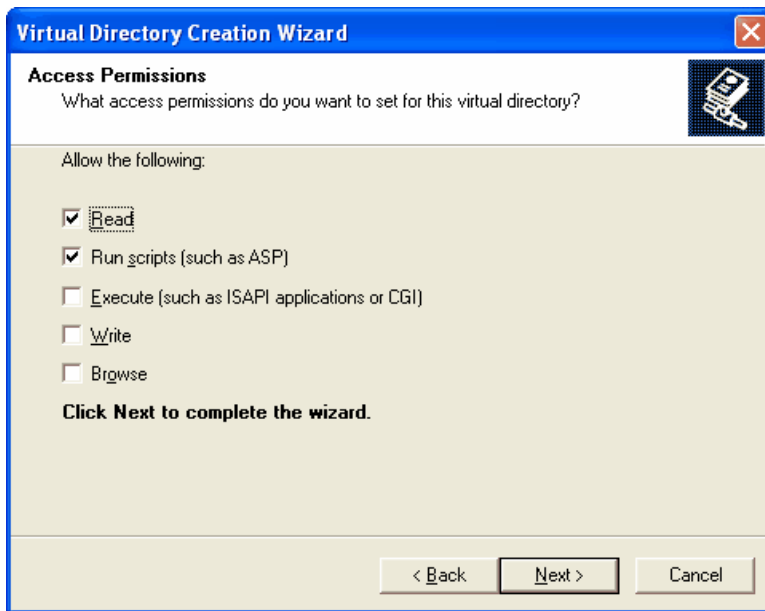

6. Type a path or browse to the physical directory where the Kentico CMS web project files are placed.
 - Please note that you cannot use a remote (shared) disk. The web project files are NOT the files in the C:\Program Files folder - you need to create the web project using the Kentico Web Installer first
 - see chapter [Web Installer](#) for details.

7. Click **Next**.

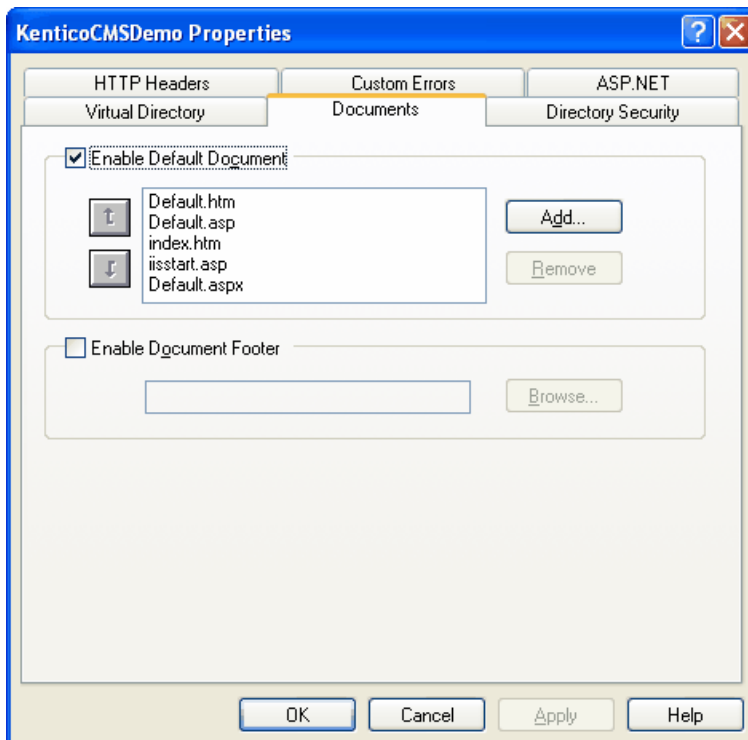

8. Specify the access permissions for the new virtual directory. Select at least **Read** and **Run scripts** check boxes, and it's recommended that you do NOT allow any other options.

9. Click **Next** and click **Finish**.

The system creates a new virtual directory. Now you need to specify its details.

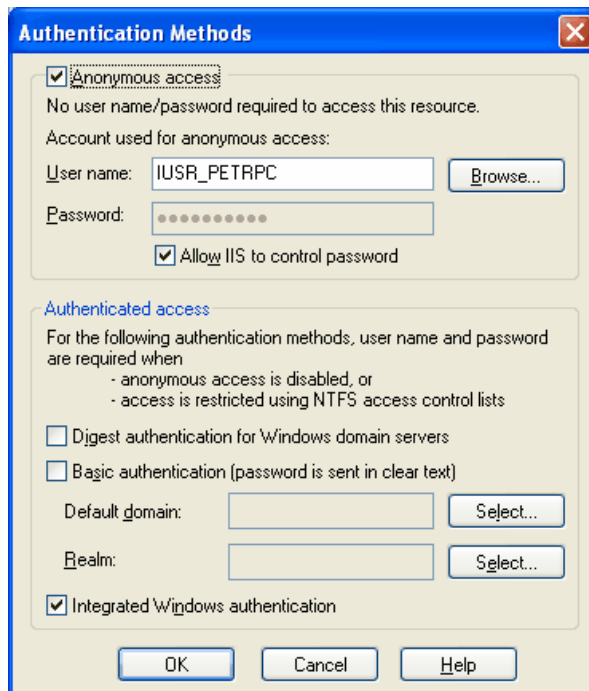

1. Right-click the virtual directory and choose **Properties**.
2. Choose the **Documents** tab and make sure the **Enable Default Document** box is checked and the list contains the **Default.aspx** file.

3. Choose the **ASP.NET** tab and make sure the **ASP.NET version is 2.0.50727** (the last number may be different) is selected. If you cannot see the **ASP.NET** tab, you may not have **ASP.NET 3.5 SP1**

installed or registered correctly. IIS 6 may display the **ASP.NET version as 2.0.50727** even if you have **ASP.NET 3.5 SP1** or higher installed and registered.

4. Choose the **Directory Security** tab, click **Edit** in the **Anonymous access and authentication control** section and make sure that both **Anonymous access** and **Integrated Windows authentication** are chosen.

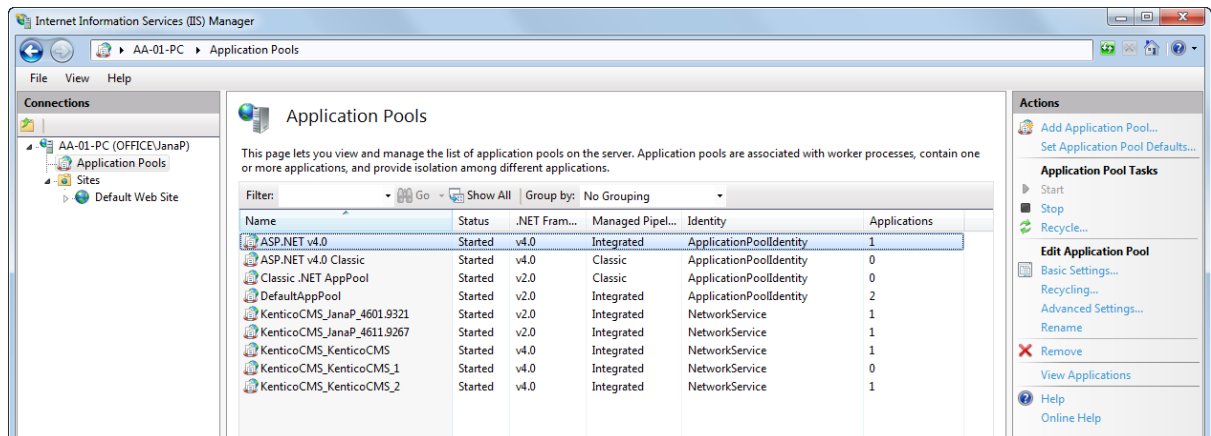

5. Click **OK** on all dialogs to save the changes.

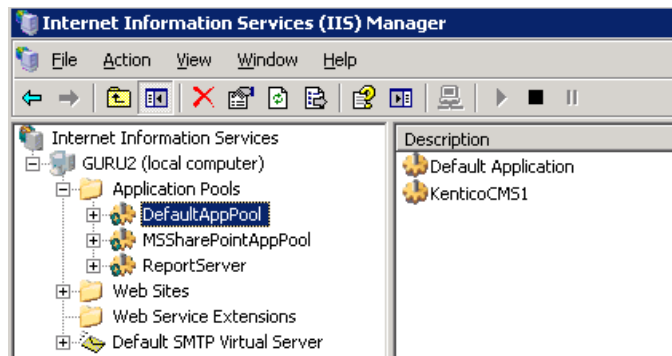

3.5.3 Configuring Application Pools

Application Pools provide you with additional level of website management. They are supported only by Windows Server 2003/2008/Vista/7. You can configure them in the **Internet Information Services (IIS) Manager** under **local computer -> Application Pools**.

IIS 7.0:

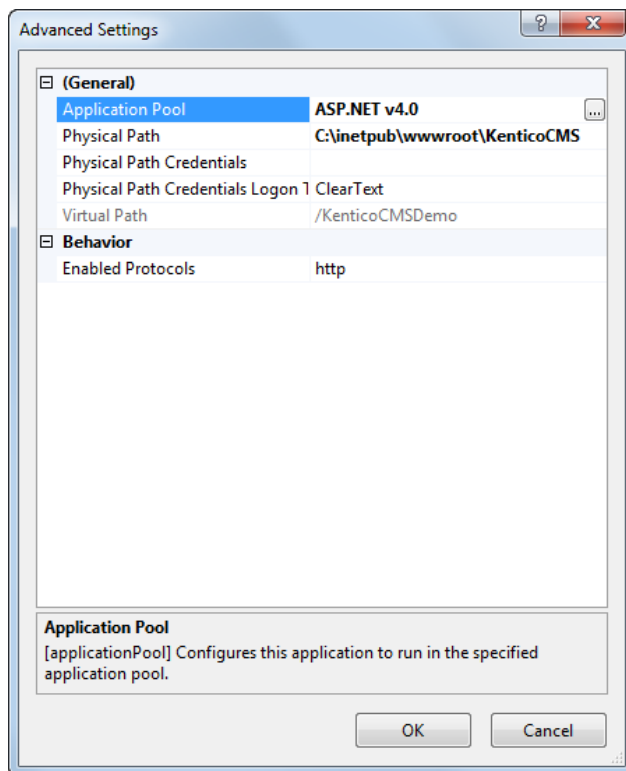

IIS 6.0:

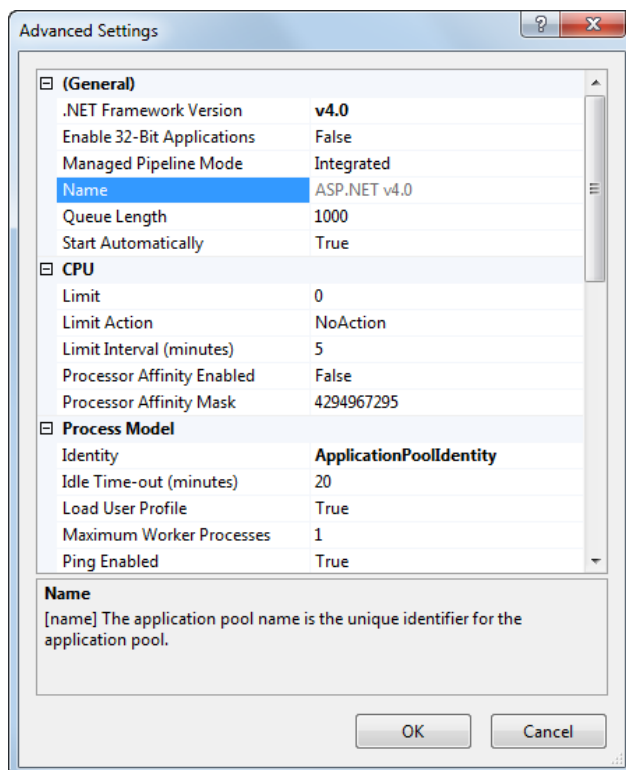

The application pools allow you to group applications (websites) into pools that share server resources using the same rules. This chapter contains recommendations on how to configure the website application pools for Kentico CMS.

Application pools in IIS 7.0 and higher

You can check and change the assigned application pool by right-clicking an application under **local computer** -> **Sites** -> **Default Web Site** (or other web site) and selecting **Manage Application** -> **Advanced Settings...**

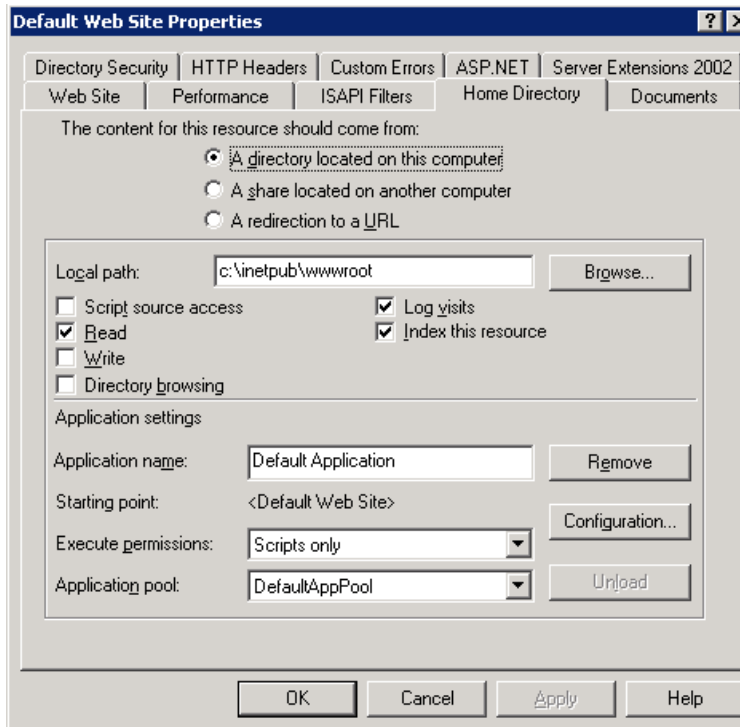

You can set the Recycling and other options by right-clicking on an application pool under **local computer** -> **Application Pools** and selecting **Advanced Settings...**

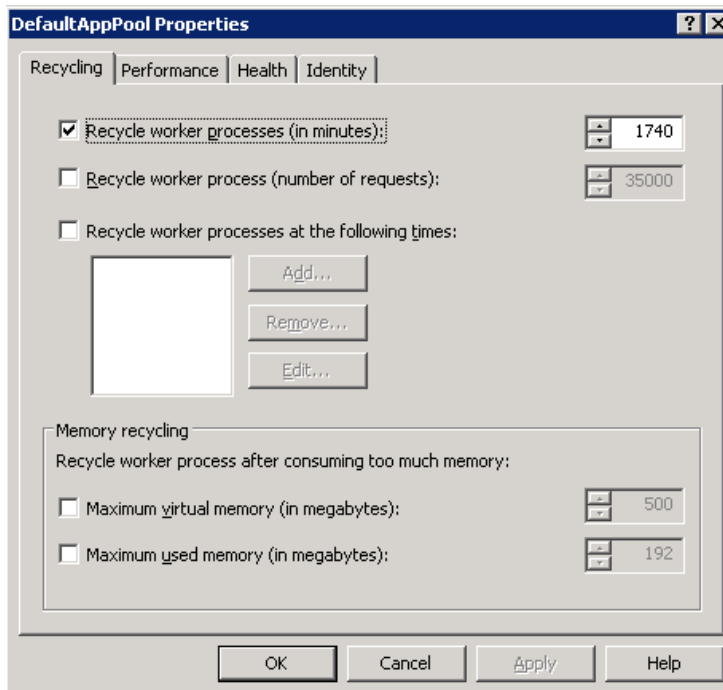

Application pools in IIS 6.0 and earlier

You can check the name of the application pool in the website Properties dialog, on the Home Directory tab. If you're running Kentico CMS in a virtual directory, you will find it in the Virtual Directory Properties dialog, on the Virtual Directory tab.

You can see the **Application Pool Properties** dialog by right-clicking the appropriate application pool and selecting Properties from the context menu. You will see dialog like this:

Recommended Application Pool Configuration

- It's highly recommended that you run Kentico CMS in a separate application pool. If you share the pool with other websites, the system may behave unpredictably.
- If you need to run multiple websites in a single pool, be sure to run only ASP.NET 3.5 applications in the same pool.
- It's recommended that you specify some value in the **Recycle worker** processes on the **Recycling** tab. This value shouldn't be too short (less than **60 minutes**) or too long (more than **1440 minutes/1 day**). Setting this value ensures that the **memory is recycled and the application is automatically recovered from failures** by regular restart. **If your website freezes** time to time, you can temporarily set the value to 30 minutes to ensure that the website is restarted automatically. **Short intervals** may lead to high server load and slow response since after each recycling, the application needs to be restarted and data reloaded to the cache.
- It's recommended that you **do not limit the maximum virtual or used memory**. If you need to use some value, use **at least 100 MB**. If your website is being **restarted too often**, it may be caused by low maximum memory limit. You can check the frequency of application restarts in Kentico CMS Event Log (Site Manager -> Administration -> Event log).
- The **Maximum number of worker processes** on the **Performance** tab must be set to 1. If you set a higher value, the worker processes will not be synchronized and Kentico CMS website will not work correctly. This may lead to **unexpected caching of content and system objects**.
- You can configure the **user account** under which the application runs on the **Identity** tab. This information is useful if you need to troubleshoot issues with **permissions**, such as disk write permissions.
- Kentico CMS **does not support Web garden**. Therefore, the **Maximum number of worker**

`processes` has to be set to 1.

3.5.4 Configuration for Medium Trust environment

This topic describes how to run a Kentico CMS website in a Medium Trust Level environment.

Medium trust level

The .NET Framework provides a batch of predefined code access security policies, categorized into several trust levels, which determine the permissions available for applications running on the given machine.

The medium trust level is often used by web hosts on shared servers to prevent applications from accessing certain resources that could be harmful to other websites running on the server. Kentico CMS can be used with the default medium trust policy. To run the system under medium trust, you need to follow certain rules. There are three main components that require higher than medium trust and must be considered in this situation:

- **VirtualPathProvider for .NET 3.5** - retrieves resources (ASCX layouts and transformations) from the database and provides them through a virtual file system.
- [Staging module](#) - ensures synchronization of content between production and live site servers.
- [Bounced e-mail monitoring](#) - this feature of the newsletters module tracks the amount of unsuccessfully delivered e-mails.

Note

It is recommended to develop websites under *Full trust*. Medium trust environments should only be used for hosting live production websites.

Virtual path provider when running on .NET 3.5

This library handles virtual objects stored in the database that need to be compiled, such as document transformations and page layouts. The system references the files through a virtual path, and the Virtual path provider provides the control code to the compiler.

The .NET 3.5 Virtual path provider cannot run under medium trust (requires `AspNetHostingPermission` with "high" trust level), so you need to [store the physical files on the file system](#) before deploying the website to the production environment.

1. Go to **Site Manager -> Administration -> System -> Virtual objects**.
2. Click **Store all virtual objects in file system**. This saves all virtual objects into files under the following folder:

- `~/CMSVirtualFiles`

The system loads the data from the files on the disk instead of the database. You can still make changes to the objects through the administration interface (they are carried over to the files immediately).

3. When you are ready to deploy the website, copy the web project over FTP to the server (including the content of the *CMSVirtualFiles* folder).

You cannot edit the content of the virtual objects directly on the production website, because the CMS application will usually not be allowed to access the file system on a medium trust server. You need to redeploy the website if you wish to modify the virtual objects.

When using .NET 4.0 or newer, the Virtual path provider runs under medium trust, so the issues described in this section do not occur (you can store virtual objects in the database even on medium trust servers).

Staging (Microsoft Web Services Extensions 3.0)

This section applies only if you're using the Staging module.

The **Microsoft.Web.Services3.dll** library from the Web Services Extensions 3 (WSE) package which is used by the Staging module requires Full trust permissions because of the low level operations related to the communication protocols. To ensure the proper functionality, the library needs to be registered in the Global Assembly Cache (GAC) of the server. The library is provided by Microsoft and most hosting providers pre-install it on their shared servers.

If you manage the server, please follow these steps:

1. Go to **Control panel -> Administrative tools -> Microsoft .NET Framework 2.0 Configuration**.
2. Select the **Assembly cache**, click on **Add an Assembly to the Assembly Cache** and select the *bin\Microsoft.Web.Services3.dll* library file from your web project.
3. Delete the *bin\Microsoft.Web.Services3.dll* file from your web project if it's present.
4. Make sure that your project *web.config* file contains the following item:

```
<system.web>
...
<compilation debug="false" numRecompilesBeforeAppRestart="100">
  <assemblies>
    ...
    <add assembly="Microsoft.Web.Services3, Version=3.0.0.0, Culture=neutral,
    PublicKeyToken=31bf3856ad364e35" />
    ...
  </assemblies>
</compilation>
...
</system.web>
```

If you are not able to install the library to the GAC or convince your web host to do so, you may still run Kentico CMS under medium trust, but you will not be able to use the Staging module. If this is the case, you will need to manually remove some of the system components by deleting the **bin/Microsoft.Web.Services3.dll** file from your web project if it is present.

After these changes, your system will work correctly in a medium trust environment but you will not be able to use content staging operations.

Bounced e-mail monitoring

This section is only relevant if you wish to use the bounced e-mails feature of the newsletters module.

To be able to check bounced e-mails, the newsletters module makes use of a component that creates outgoing network connections using POP3, a standard e-mail protocol for receiving maildrops from an e-mail server. This component requires the **SocketPermission** for its operation, otherwise it fails when attempting to connect to the server. This permission is denied for applications under medium trust.

If you cannot raise the trust level or create a custom security policy that includes this permission, the only solution is to attempt to convince the hosting administrators to grant the **SocketPermission** to your application. If you are unable to do so, the bounced e-mail monitoring feature will unfortunately not be functional in a medium trust environment.

Reporting graphs (MS Charts)

The [Reporting](#) module utilizes Microsoft Chart Controls to generate its graphs. If your application uses the 3.5 SP1 version of the .NET Framework and is hosted in a medium trust environment, it is necessary to have the MS Chart package installed on the server to ensure that the appropriate library is available in the Global Assembly Cache. The installation executable can be downloaded from the Microsoft website: <http://www.microsoft.com/download/en/details.aspx?id=14422>

The required assemblies are already included in .NET Framework 4.0, so the installation is not necessary if your application uses this version.

Running the website

Now the system should work under a medium trust level properly. Restart your IIS in order for the configuration changes to take effect and run the website.

If your website uses any third-party components that do not support a medium trust level by default, you may need to configure the system for them. In this case, please contact their author to get the information how to perform the configuration required to run in a medium trust environment.

3.5.5 Configuring Windows Communication Foundation

This topic describes the installation and configuration process of **Windows Communication Foundation (WCF)**. You have to configure WCF for [Workflow designer](#) and [Chat module](#) to become usable.

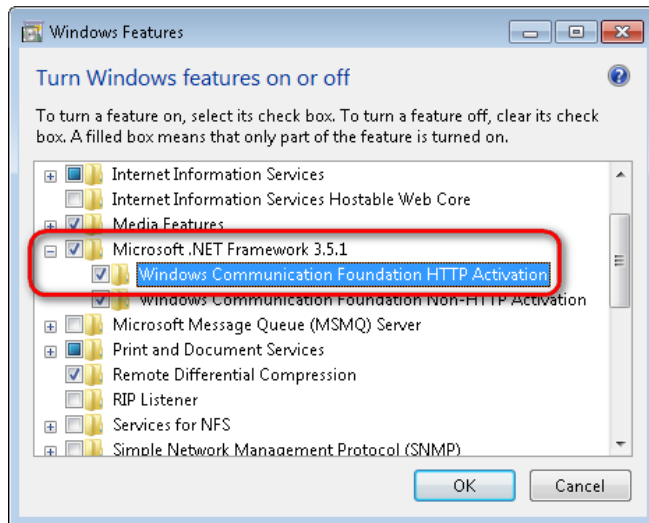

WCF overview

WCF is a component of the .NET Framework that provides a programming model for building service-oriented multi-platform applications that communicate across the web. For more information on the technology, visit <http://msdn.microsoft.com/en-us/netframework/aa663324>.

Installing WCF

WCF is automatically installed with .NET 3.0 and any higher version. However, you still need to install the WCF HTTP Activation feature yourself:

1. Open the **Start menu**.
2. Navigate to **Settings -> Control Panel -> Programs -> Programs and Features**.
3. Click on **Turn Windows features on or off**.
4. Under the **Microsoft .NET Framework 3.5** node, turn the **Windows Communication Foundation HTTP Activation** checkbox on.

5. Click **OK** to start the installation.

Activating WCF on IIS

If you installed IIS after installing WCF and are running **Windows XP** or **Windows Server 2003**, you have to register script maps in IIS. This will enable IIS to recognize WCF Services (.svc files).

If you are using **.NET framework 3.5**, run the following command from the command line to register script maps in IIS:

```
"%WINDIR%\Microsoft.Net\Framework\v3.5\WFServicesReg.exe" /c
```

Run the following command if you are using **.NET framework 4.0**:

```
"%WINDIR%\Microsoft.Net\Framework\v4.0.30319\ServiceModelReg.exe" -r
```

To find more information about troubleshooting problems related to WCF Services hosted by IIS, refer to the following MSDN document: <http://msdn.microsoft.com/en-us/library/ms752252.aspx>.

3.5.6 SMTP server configuration

Kentico CMS includes many features and modules that utilize e-mail messages as part of their functionality, including automatic notifications, various types of confirmation messages, subscriptions, [newsletters](#) and more. To allow the application to send out e-mails, you need to register and configure SMTP servers for it.

After you finish the [New site wizard](#), you can set up the SMTP servers directly through the administration interface. The website's primary server can be specified in **Site Manager -> Settings -> System -> E-mails**. This server will be used as the default option when sending e-mails. Depending on the value selected in the **Site** drop-down list, the server will either be dedicated to a single website, or designated as a global server (i.e. it will accept e-mails from all sites in the system and also handle mails that are not related to any specific website). You can enter the following values:

- **SMTP server** - must contain the domain name or IP address of the server, including the port number if it is not 25. Enter *localhost* if you wish to use the server provided by your local machine.
- **SMTP server user** - if the server requires authentication, you can enter the user name here.
- **SMTP server password** - if the server requires authentication, you can enter the password here.
- **Use SSL** - indicates if the SMTP connection to the server should be secured by SSL. The server must be configured to use SSL in order for this to work.

The screenshot shows the Kentico CMS Site Manager administration interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The 'Settings' section is expanded, and the 'E-mails' configuration page is displayed. The 'Site' dropdown is set to '(global)'. The 'E-mails' page has a 'Save' button and a 'Reset these settings to default' link. A note states: 'These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.' The 'General' section includes 'E-mail encoding' (utf-8) and 'E-mail format' (HTML). The 'E-mail processing' section includes 'Enable e-mails' (checked), 'Enable e-mail queue' (checked), 'Batch size' (50), and 'Archive e-mails (days)' (0). The 'SMTP server' section, highlighted with a red box, includes 'SMTP server' (localhost), 'SMTP server user', 'SMTP server password', and 'Use SSL' (unchecked). An 'Export these settings' link is at the bottom.

In addition to the default server, you may add any number of servers in **Site Manager -> Administration -> SMTP servers**. Having multiple SMTP servers available for a website allows it to send out a greater volume of e-mail traffic, since the extra servers will be used whenever the default one is busy.

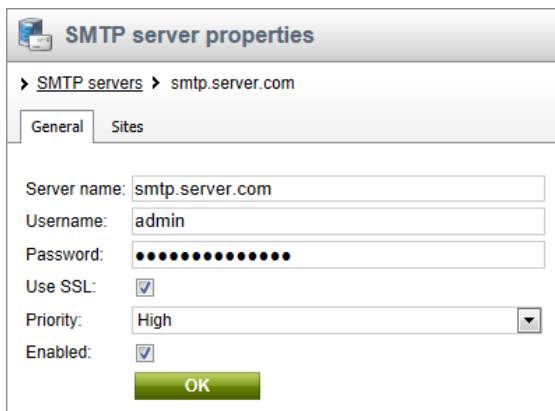

The screenshot shows the Kentico Administration interface. The left sidebar contains a navigation menu with the following items: Administration, Avatars, Bad words, Badges, Banned IPs, Categories, E-mail queue, E-mail templates, Event log, Integration bus, Membership, Permissions, Recycle bin, Roles, Scheduled tasks, Smart search, SMTP servers (highlighted), System, UI personalization, Users, and Web farm. The main content area is titled "SMTP servers" and includes a "New SMTP server" button. Below this is a table with the following data:

Actions	Server name ^	Enabled	Is global
  	localhost	Yes	No
  	mail.test.com	No	No
  	smtp.server.com	Yes	No

Servers can be defined by clicking  **New SMTP server**. Once some servers are added, you can manage them through the appropriate icons in the actions column, i.e. delete () them or edit () their configuration. Servers may also be **Disabled** () or **Enabled** () at any time (within the context of Kentico CMS).

When creating a new SMTP server or editing an existing one on the **General** tab, you can fill in the same options as described above for the default server. In addition, you may also select a **Priority**. Further information about server priority can be found in the section below.

The screenshot shows the "SMTP server properties" dialog box. It has two tabs: "General" (selected) and "Sites". The "General" tab contains the following fields and options:

- Server name: smtp.server.com
- Username: admin
- Password: [masked with dots]
- Use SSL:
- Priority: High (dropdown menu)
- Enabled:

There is an "OK" button at the bottom.

If there are multiple sites running under your application, you may wish to assign different servers to individual websites. You can do so by switching to the **Sites** tab of a server's editing interface, where the given server can either be set as global or limited to one or more specific websites.

E-mail processing

There are several other settings available in **Site Manager -> Settings -> System -> E-mails** that affect how e-mails are delivered to the SMTP servers.

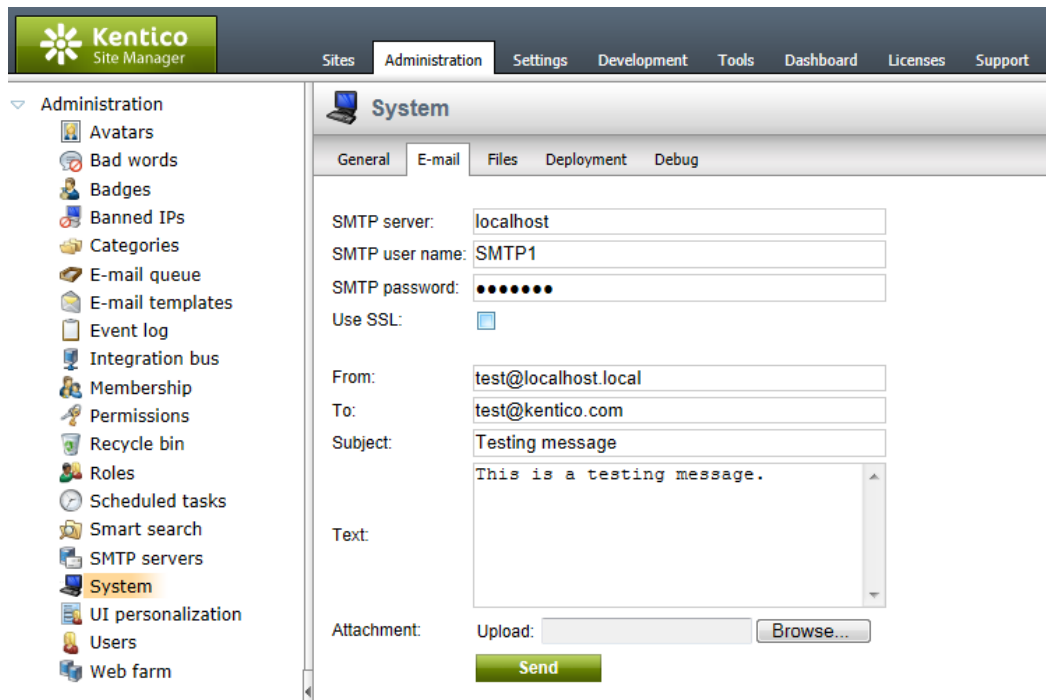

If **Enable e-mail queue** is checked, e-mails generated by the system are temporarily stored in the database instead of being sent directly to the servers. This allows advanced e-mail processing (as described below) and automatic resending of mails that are lost due to errors. Please see the [Modules -> E-mail queue](#) chapter of this guide to learn more. Using the e-mail queue is highly recommended when sending out large amounts of e-mails over a short amount of time.

This queue is processed periodically (every minute by default) and the stored e-mails are asynchronously distributed to the appropriate SMTP servers. First, a predefined amount of e-mails is loaded from the queue as a batch. The system then goes through the available SMTP servers in the order of their priority and assigns the batch to the first server that is not busy. The default SMTP server always has the highest priority and other servers are ordered according to the value of their **Priority** property (i.e. batches are first assigned to *High* priority servers, then *Normal* and finally *Low*). When a server receives a batch of e-mails, it is flagged as busy until the sending is complete. A new batch is then loaded from the queue and assigned to the next available server. This process is repeated until all e-mails in the queue are mailed out.

The maximum number of e-mails that can be transferred from the queue to an SMTP server in a single batch is determined by the value of the **Batch size** setting. This setting affects all sites in the system, so it is only available if the (*global*) option is selected from the **Site** drop-down list on the top left of the settings page. Entering an appropriate batch size can significantly affect performance. The ideal batch size depends on the amount of available SMTP servers and their capacity. If it is too large, a server may not be able to process all of the e-mails at once or its send limit may be reached. Using a smaller batch size requires more operations, but it ensures that the load is spread more evenly across multiple servers.

Testing an SMTP server

If you wish to confirm that the values entered for an SMTP server are valid and that it is available, you can send a testing e-mail using the **Site Manager -> Administration -> System -> E-mail** dialog.

3.5.7 Installation on shared hosting server

If you want to deploy Kentico CMS directly to the live server (or generally to a remote server), you need to follow these steps:

1. Install Kentico CMS on your **local machine** if you haven't done so yet.
2. Run the [Kentico Web Installer](#) (you can find it in *Start -> All Programs -> Kentico CMS*).
3. Select **I want to install Kentico CMS on a remote (production or testing) server** and enter the path `C:\tempfiles`. Finish the wizard - it only copies the files to the given folder. You do not need to have Visual Studio installed.
4. **Copy the files** from your local folder `C:\tempfiles` to the root of the website using FTP. If you want to use a sub-folder, create a new virtual directory as described in [Creating a virtual directory](#).
5. **Open a web browser** and navigate to your website. The [Database Setup](#) wizard starts up.
6. Go through the wizard and create a **new Kentico CMS database** on your live server.
7. At the end of the Database Setup Wizard, choose to either create a new website or import your existing Kentico CMS website.

Installation in Medium Trust Level

If you're installing Kentico CMS in medium-trust environment, please read chapters [Installation in medium-trust environment](#) and [Configuration for Medium Trust](#)

[environment](#).

Related topic: [Deployment to the live server](#)

3.5.8 Installation in medium-trust environment

If you want to deploy Kentico CMS directly to the live server (or generally to a remote server) that uses a **medium trust security level**, you need to follow these steps:

1. Install Kentico CMS on your **local machine** if you haven't done so yet.
2. Run the [Kentico Web Installer](#) (you can find it in *Start -> All Programs -> Kentico CMS*).
3. Select **I want to install Kentico CMS on a remote (production or testing) server** and enter the path *C:\temp\site*. Finish the wizard - it only copies the files to the given folder. You do not need to have Visual Studio installed.
4. **Copy the files** from your local folder *C:\temp\files* to the root of the website using FTP. If you want to use a sub-folder, create a new virtual directory as described in [Creating a virtual directory](#).
5. Make sure the web.config file on your server contains the following value in the **appSettings** section (it specifies that the CMS should use the managed provider):

```
<add key="CMSDirectoryProviderAssembly" value="CMS.DirectoryProviderDotNet" />
```

6. **Open a web browser** and navigate to your website. The [Database Setup](#) wizard starts up.
7. Go through the wizard and create a **new Kentico CMS database** on your live server. At the end of the process, you will be asked to update your web.config file manually - please follow the instructions on the screen.
8. Choose to either create a **new website** or **import your existing** Kentico CMS website.
9. If you are using .NET version **3.5**, you need to save all virtual objects to the disk after creating the new website:
 - a. Go to **Site Manager -> Administration -> System -> Virtual objects**.
 - b. Click **Store all virtual objects in file system**.
 - c. If the medium trust server does not allow your application to write on the disk, you first need to create the web project on a local machine using the Web installer, save all virtual objects to the disk and then copy the web project over FTP.

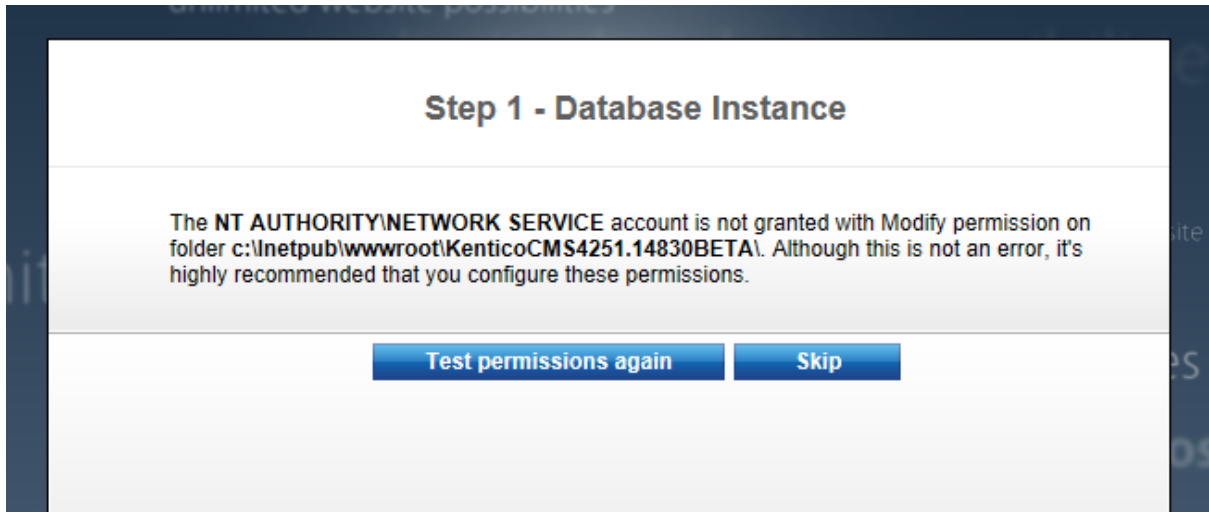

Medium trust environment specifics

For more information about running under the medium trust level, please read the [Configuration for Medium Trust environment](#) topic.

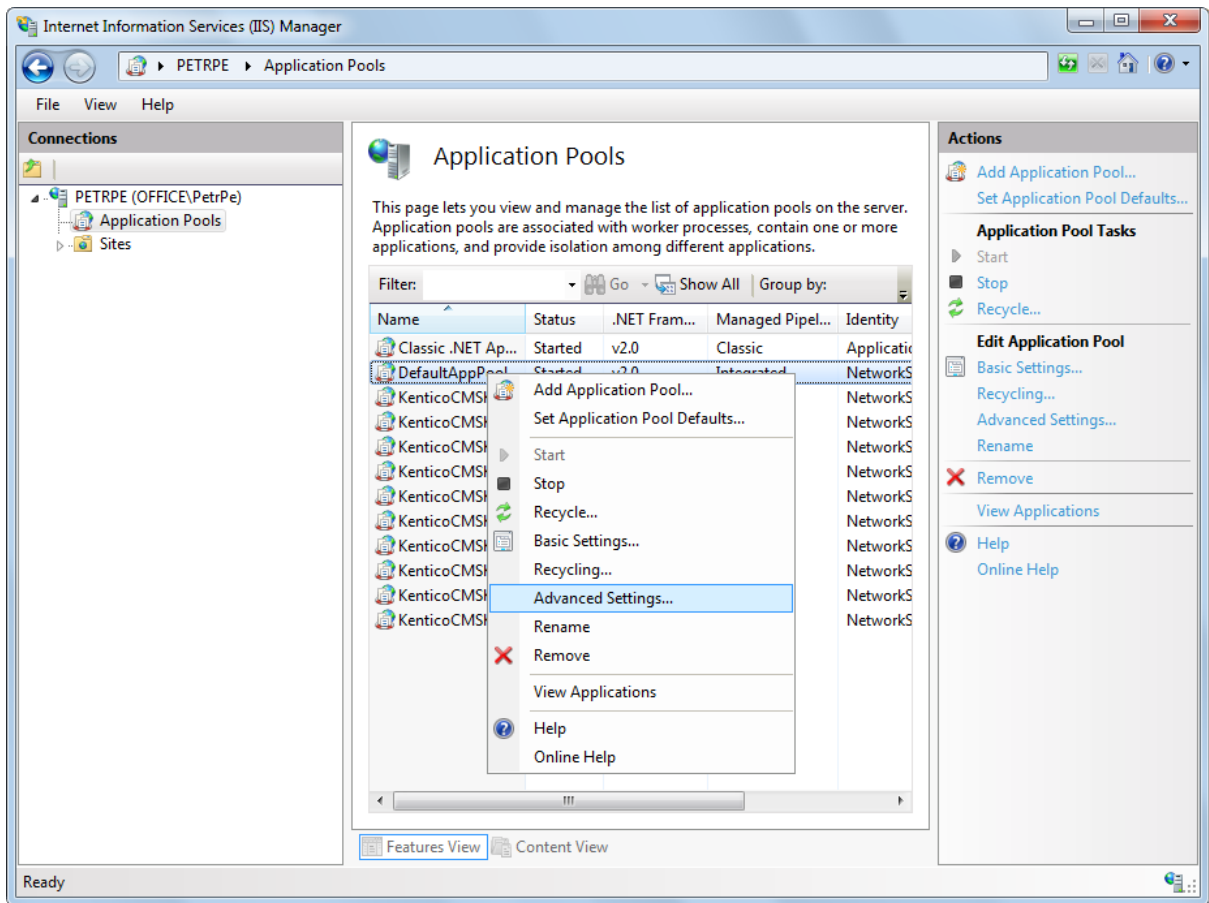

3.5.9 AppPool permissions on Windows 7 or Windows Server 2008 R2

Kentico CMS runs on both **Windows 7** and **Windows Server 2008 R2**. On both systems, you need to add the **Write** permission to the website's folder as described in [Troubleshooting installation issues -> Disk permissions problems](#).

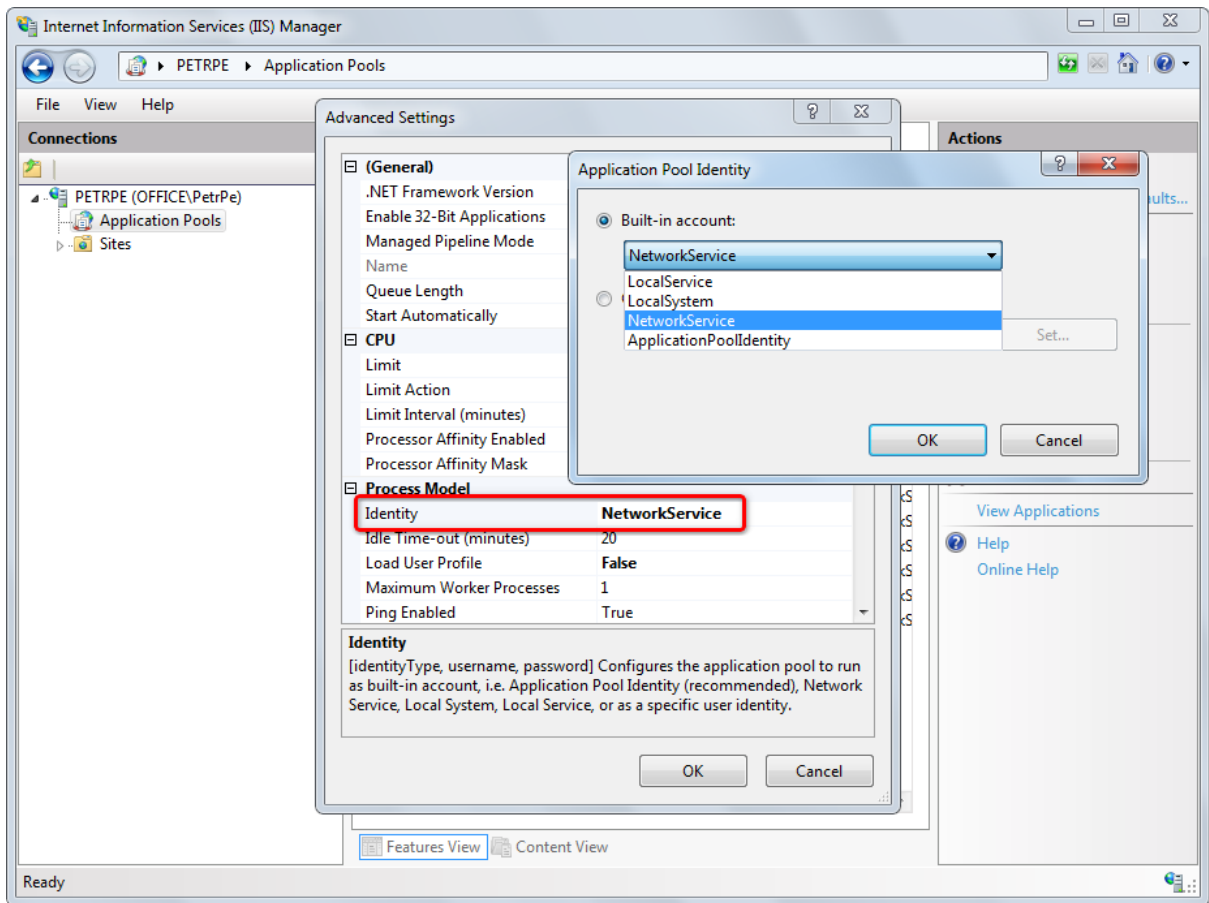

If you can still see the following screen after the end of the [Database setup](#) in either of the systems, it's necessary to make some further settings in your IIS.

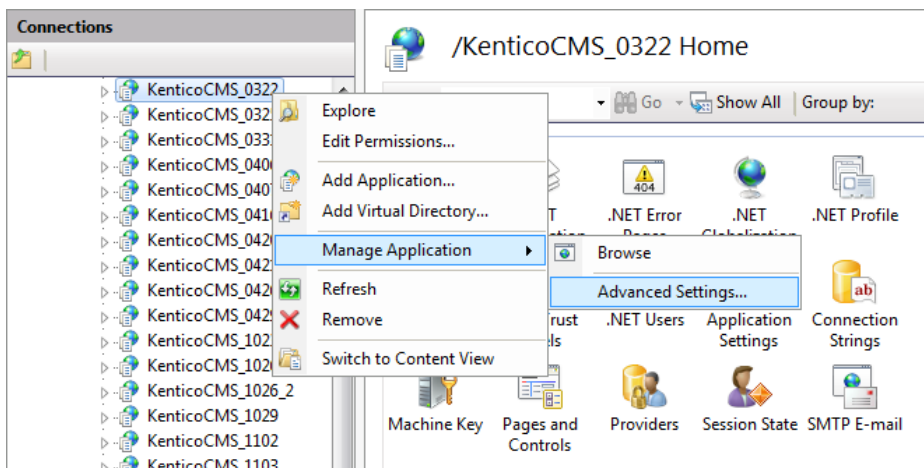

1. Select the **Application Pools** node in the **Connections** tree in the IIS console. All application pools will be listed. Right-click the **DefaultAppPool** and chose **Advanced settings** from the context menu.

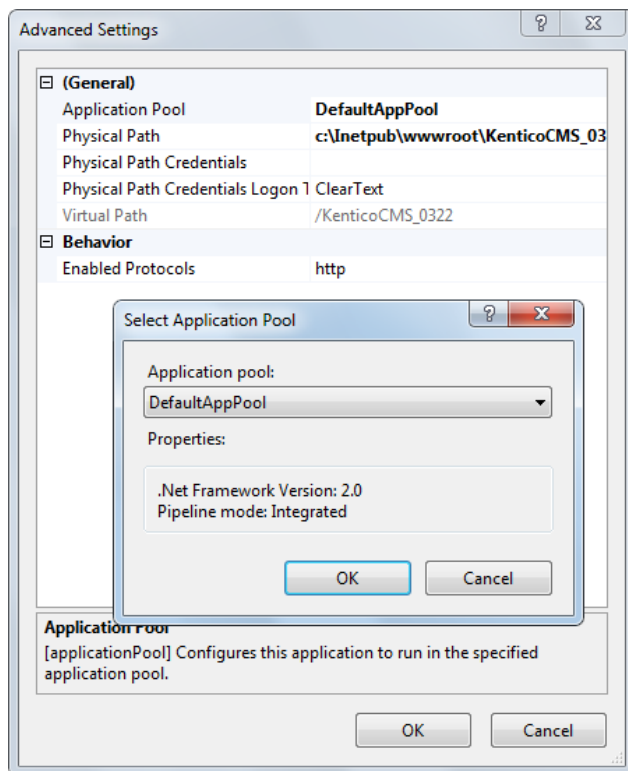

2. In the following dialog, switch the **Identity** value in the **Process Model** category to **Network Service**.

3. Now go to your website's **Advanced settings** ...

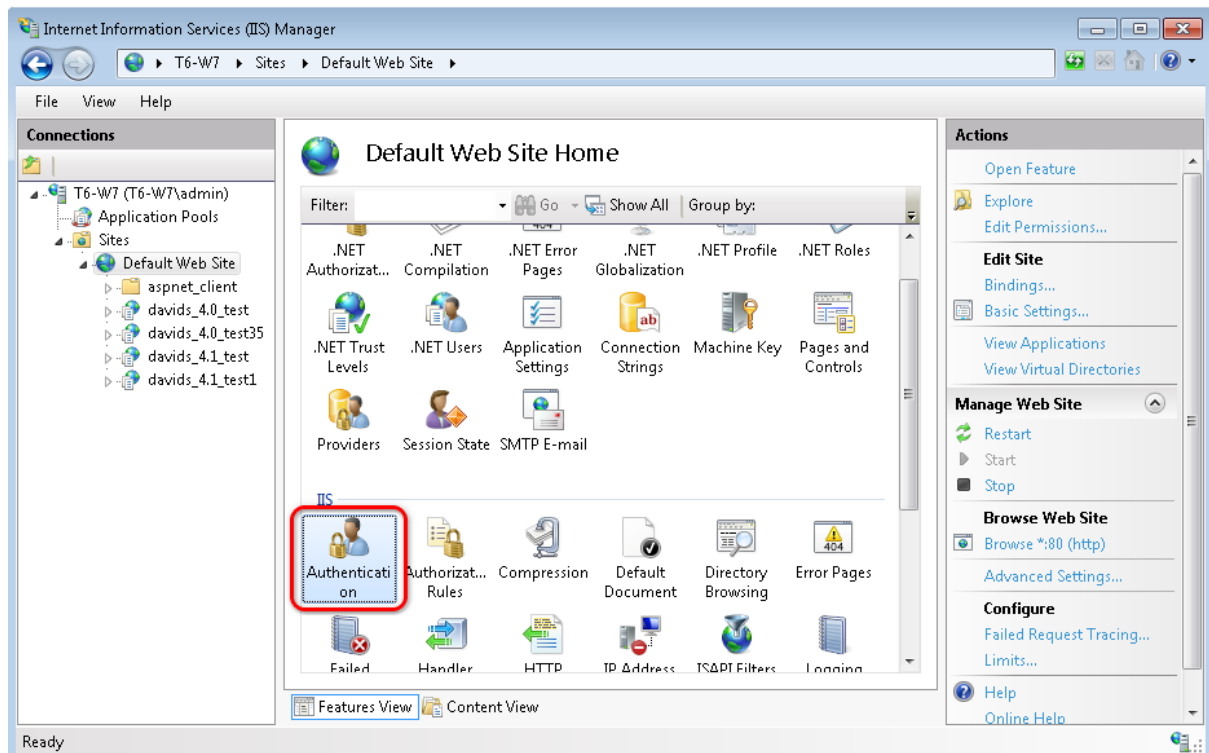

4. ... and set the **Application Pool** property to **DefaultAppPool**.

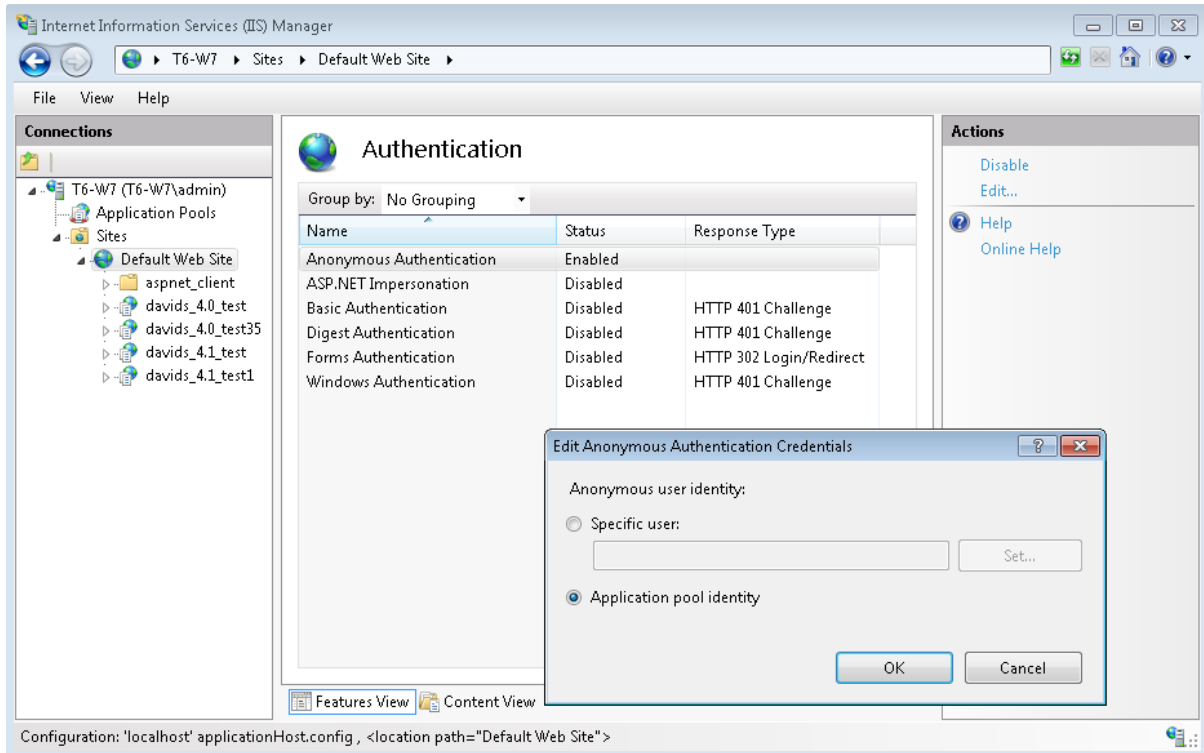

On **Windows 7**, you also need to change the Anonymous authentication settings as described below:

1. Open **IIS manager**, select your site and double-click the **IIS -> Authentication** icon.

2. Select **Anonymous authentication** from the list and click **Edit**. In the pop-up dialog, choose **Application pool identity** and click **OK**.

3.5.10 Configuring custom error pages

There are several possible reasons why you might wish to configure the system to display custom pages instead of standard error messages. This can help reduce the inconvenience caused to visitors if they run into an error while browsing your website, and also improves the security of the site by hiding potentially sensitive internal data (e.g. code in stack traces). You can create custom pages for this purpose with any kind of content, such as an apology or additional instructions, and then configure the system to ensure that they are displayed in the appropriate situations.

Custom Page not found error pages

Because the *Page not found* error (404 HTTP status code) is one of the most common problems encountered by visitors, there are several features that provide a convenient way to set up a custom page that will be displayed as a response. For this type of error, the page can either be a physical *.aspx* file placed under the web project or a dedicated document created in a specific website's content tree.

To assign your custom page to a particular website (or globally), simply go to **Site Manager-> Settings -> Content** and enter the URL of the given page as the value of the **Page not found URL** setting, for example:

```
~/SpecialPages/PageNotFound.aspx
```

Since there are two possible types of error pages, this value could be interpreted in two different ways. It

could be used to specify the URL of a physical page named *PageNotFound.aspx* located in a folder called *SpecialPages*. If such a file does not exist, the system would try to select a document under the current website with an alias path equal to */SpecialPages/PageNotFound*.

It is recommended to use documents for this purpose. With this approach, you can define the error page's content using the portal engine and leverage all of its features just like you would with any other page. For instance, you can translate the page not found document on a [multilingual website](#) and the CMS will automatically display the culture version that matches the currently selected language.

The screenshot shows the Kentico CMS 7.0 Administration interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The 'Settings' section is expanded, and the 'Content' settings are visible. The 'Page not found' section contains the following settings:

- Page not found for non-published documents:
- Page not found URL: (highlighted with a red box)
- Log page not found exception:

The 'Multilingual' section contains the following settings:

- Default content culture: English - United States
- Combine with default culture:
- Combine files with default culture:

There is no need to manually handle the HTTP response code of the page specified by the setting. It will automatically return a 404 code when accessed (applies to both documents and physical pages). This way, applications, services and web crawlers can identify it as the appropriate type of error page.

Handling 404 errors for general content

To ensure that the system returns your custom *Page not found* error page for invalid requests that target all types of site content, not just the pages processed by the Kentico CMS engine, you need to fulfill several additional requirements.

- The site must be hosted on IIS version 7 or newer.
- The *Managed pipeline mode* of the application pool needs to be set to *Integrated*.

If your environment meets the conditions above, edit your application's **web.config** file, find the **system.webServer** section directly under the root (i.e. not under a specific `<location>` element) and add the following attribute to the **<modules>** element:

```
<modules runAllManagedModulesForAllRequests="true">
```

General error pages

Since Kentico CMS is a standard ASP.NET application, it is possible to configure the handling of all types of errors and exceptions by adding the **<httpErrors>** element into the **<system.webServer>** section of your web.config file as shown below:

```
<system.webServer>
...
<httpErrors existingResponse="Auto" errorMode="Custom">
  <clear />
  <error statusCode="500" path="/<Virtual_Directory>/CMSMessages/
CustomError.aspx" responseMode="ExecuteURL" />
</httpErrors>
...
</system.webServer>
```

The **errorMode** attribute sets the basic error page behavior. You may use one of the following possible options:

- **Detailed** - in this mode, the default error pages display details of the encountered error to all users.
- **DetailedLocalOnly** - with this option, detailed error information is only shown to the local host. Simplified error pages are displayed to everyone else, i.e. users who access the site remotely.
- **Custom** - this mode should be used if you wish to replace the default error pages with a custom alternative.

When specifying completely custom error pages, set the **errorMode** to *Custom* and add any number of child **<error>** elements representing individual types of HTTP errors that you wish to handle. It is necessary to enter the HTTP response code of the given error into the **statusCode** attribute and the URL of the appropriate error page as the **path** value. If your Kentico CMS application is running in a virtual directory, replace the *<Virtual_Directory>* string in the sample path value above with the directory's name.

It is recommended to add general error pages directly into your web project as .aspx files, e.g. under the **CMSMessages** folder. In this case, the **responseMode** attribute of the corresponding **<error>** elements should be set to *ExecuteURL*. The actual content may be defined to match your specific requirements, but keep in mind that an error page should always return the appropriate *HTTPResponse* status code.

The approach described above works for applications running on IIS 7 or newer with an application pool using *Integrated* Managed pipeline mode. On older versions, you can instead edit the **<customErrors>** element under the **<system.web>** section of the web.config to achieve similar results.

3.5.11 Securing the CMSHelp folder

Kentico CMS comes with an on-line help reference that is available in the database installer and most parts of the administration interface. Users can view it to access context-specific information about the current section of the application's interface. By default, any users (including public) can open the HTML content of the on-line help by entering the appropriate URL, which may not be desirable in certain scenarios, e.g. in the case of high-security websites or if you are creating a rebranded solution.

There are several ways to solve this issue. The simplest is to delete the **~/CMSHelp** folder from the

project of your production website. This removes the possibility of public users opening the help files, but the on-line help in the Kentico CMS administration interface will no longer be available.

If you wish to keep the on-line help on your live website, you can limit access to the content of the help folder so that only users with the appropriate authorization are allowed to view it. Follow the steps below to perform the required configuration:

1. Edit your application's **web.config** file.
2. Find the `<system.webServer>` section directly under the `web.config` root (i.e. not under a specific `<location>` element).
3. Configure the application to handle the requests for the HTML help files:
 - a. One option is to add the **runAllManagedModulesForAllRequests** attribute to the `<modules>` element:

```
<system.webServer>
...
<modules runAllManagedModulesForAllRequests="true">
...
</modules>
...
</system.webServer>
```

Setting this attribute to `true` ensures that the CMS application processes all types of requests and requires authentication if needed.

- b. If you do not want the application to process all additional request types, only `.html` and `.htm`, add the following two handlers into the `<handlers>` element:

```
<handlers>
...

<add name="HTMLRequestHandler" path="*.html" verb="*" modules="IsapiModule"
scriptProcessor="C:\Windows\Microsoft.NET\Framework64\v4.0.30319
\aspnet_isapi.dll" resourceType="Unspecified" preCondition="" />
<add name="HTMRequestHandler" path="*.htm" verb="*" modules="IsapiModule"
scriptProcessor="C:\Windows\Microsoft.NET\Framework64\v4.0.30319
\aspnet_isapi.dll" resourceType="Unspecified" preCondition="" />
...

</handlers>
```

Adjust the path in the **scriptProcessor** attribute as necessary according to your specific .NET environment.

4. Define the authorization rules applied to the content of the **CMSHelp** folder by adding the following section into your **web.config** file:

```
<location path="CMSHelp">
  <system.web>
    <authorization>
      <deny users="?" />
    </authorization>
  </system.web>
</location>
```

The example above only allows authenticated users to access the on-line help files. Public users cannot reach the files through a direct URL without being prompted to log in. To further increase the security, you can restrict access only for a specific set of roles by editing the `<authorization>` section as shown below:

```
<authorization>
  <allow roles="GlobalAdmin, CMSDeskAdmin" />
  <deny users="*" />
</authorization>
```

This ensures that only users who belong to the given roles (specified by their code names) have access.

3.5.12 Installing and configuring WebClient service

The WebClient service is a client prerequisite for connecting to a [WebDav](#) server. The service comes pre-installed if you are using desktop versions of Microsoft Windows. However, you need to install it as part of the Desktop Experience feature when using Windows Server 2008 and 2012.

Installing WebClient service on Windows Server 2008 and 2012

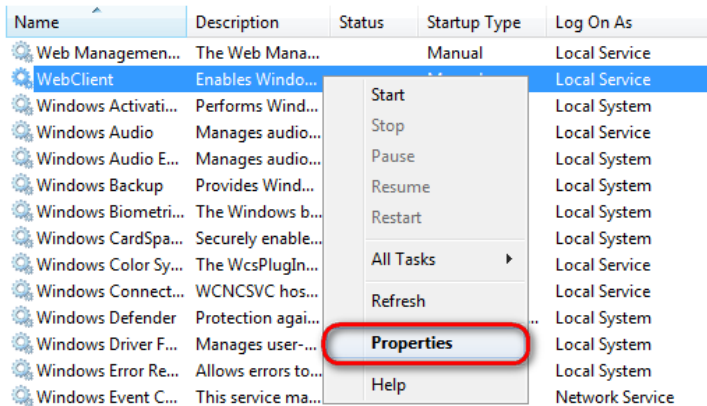

1. Start the **Windows Server Manager**.
2. In the tree view, click on the **Features** node.
3. In the details pane, click **Add Features**.
4. In the **Add Features Wizard**, check the **Desktop Experience** box, and then click **Next**.
5. Click **Install**.
6. When the **Add Features Wizard** has finished, click **Close**.
7. Click **Yes** when promoted to restart the computer.

Running WebClient service

1. Press WinKey + R or type into the search dialog:

services.msc

2. Press Enter. The Services window opens.
3. Right-click the **WebClient** service.
4. Click on **Properties**. The WebClient properties window opens.

5. If the service is stopped, click on **Start**.
6. Change the **Startup type** to **Automatic**.

7. Click **OK** to confirm the changes.

3.5.13 Database replication

3.5.13.1 Overview

Replication is a set of technologies for copying and distributing data and database objects from one database to another and then synchronizing between databases to maintain consistency. The databases can be running either on separate servers or even on the same server. You will typically use it for back-up purposes (you have two databases with the same content) or in case that you need to spread the load among more databases.

Kentico CMS database can be replicated using the **merge replication**. It can be configured in MS SQL Server Management Studio. The configuration process consists of creating a publication and one or more subscriptions:

- [Publication](#) - the database which has the data to offer to the other server
- [Subscription](#) - the database which receives updates from the publisher when the data is modified

Detailed information about replication in MS SQL can be found at: <http://msdn.microsoft.com/en-us/library/ms151198.aspx>.

Limitations caused by DB replication!

Using database replication with Kentico CMS results in the following limitations:

- importing is not functional
- upgrade from previous versions of Kentico CMS to a higher one is not possible
- newly created document types, forms and custom tables can't be synchronized to the subscribers
- field changes in document types and system tables can't be synchronized to the subscribers
- any other additional changes to the database structure are not guaranteed to be synchronized to the subscribers

It is therefore recommended to go through the following procedure when your website is complete, i.e. when you won't need to use any of the limited features.

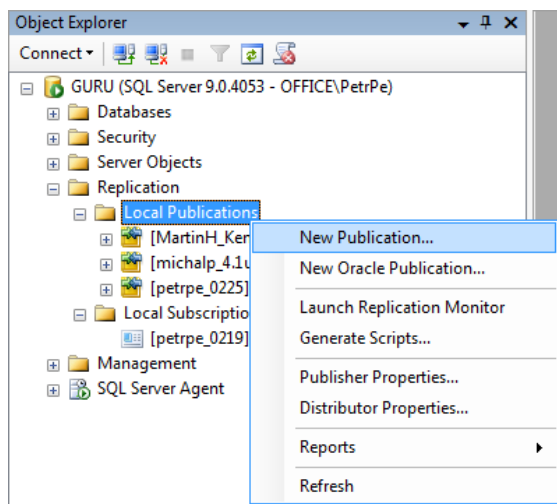

In case that you needed to use any of the limited features listed above, you would need to disestablish your existing replication, make the required changes and set up new database replication from scratch.

If you want to achieve this manually without disestablishing the existing replication, you can follow the instructions on [this page](#).

3.5.13.2 Creating a publication

The first logical step in setting up database replication is to create the publication.

1. Open MS SQL Server Management Studio. Expand the **Replication** node, right-click the **Local Publications** folder and select **New Publication** from the context menu.

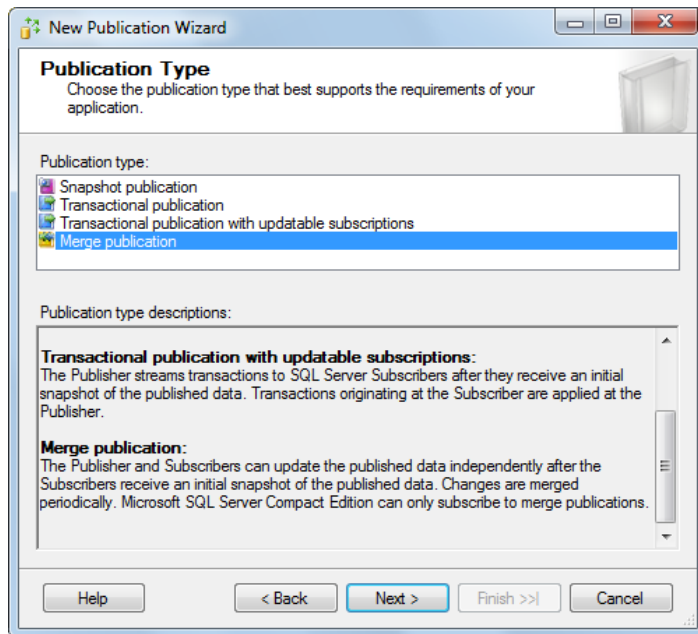

2. The **New Publication Wizard** starts. Click **Next** in the first step.

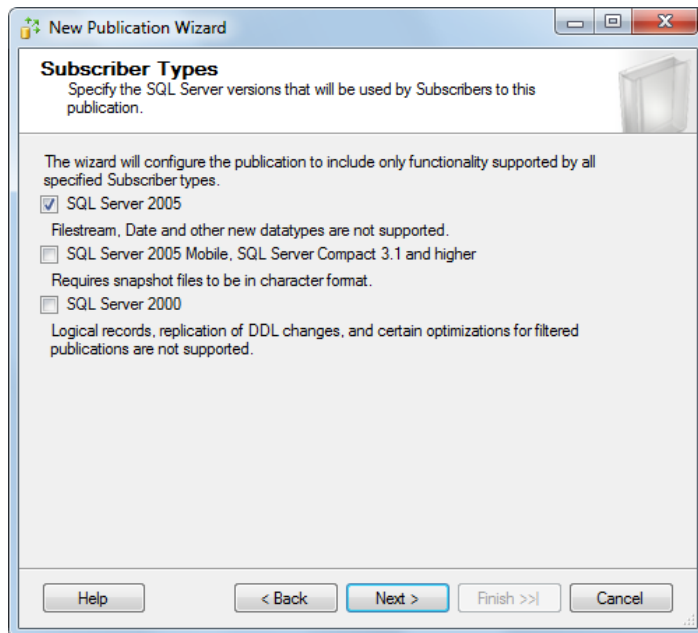

3. Now you need to select the publication database. All databases on the server will be listed, so choose the one which you want to be the publisher and click **Next**.

4. The **Publication Type** step lets you choose the type of replication which you are going to use. Kentico CMS supports merge replication only, so choose **Merge publication** and click **Next**.

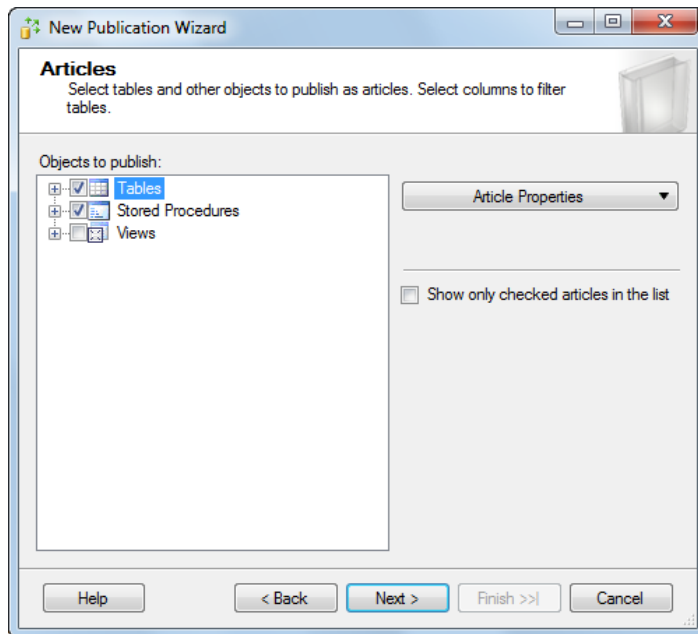

5. This step lets you specify which versions of SQL Server are supported for the subscribers. Choose the versions that your subscribers are running on and click **Next**.

6. This step lets you configure which **Tables** and **Stored Procedures** will be synchronized between the servers. You should not select any **Views** as because changes in metadata which cause changes in any of the Views can't be synchronized automatically (see the note in [Overview](#) for more details).

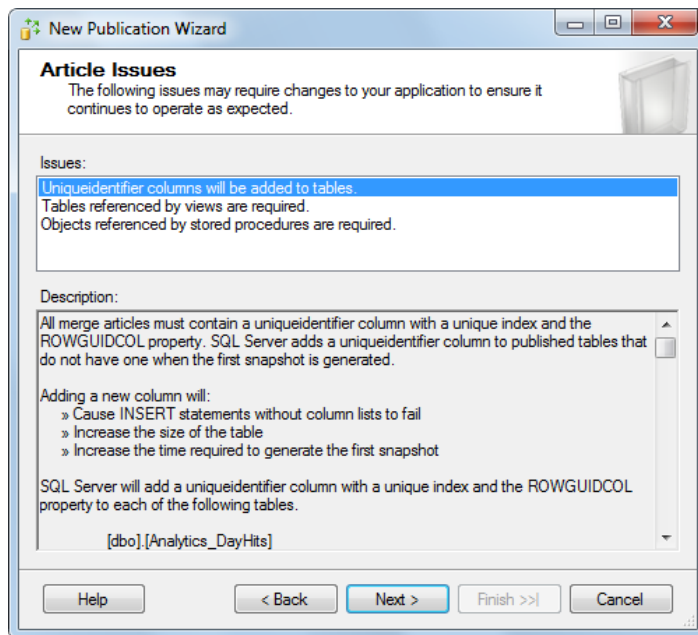

Select the tables and stored procedures that you wish to synchronize (unless you have some specific needs, it makes the most sense to select all) and click **Next**.

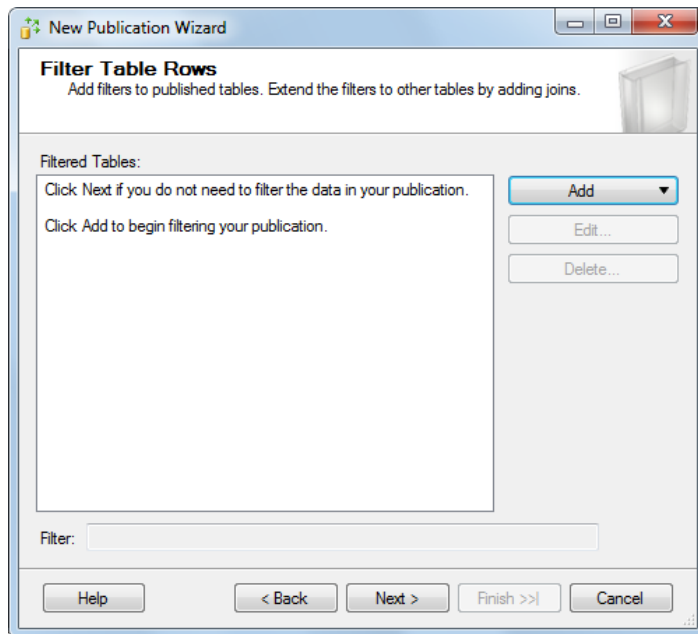

7. The **Article Issues** step is only informational - it notifies you about modifications to your database which are required for the application to work as expected with the replication.

The most important modification is that a column named **rowguid** (uniqueidentifier column with a unique index) and the **ROWGUIDCOL** property are added to each table.

Read through the info and click **Next**.

8. In the **Filter Table Rows** step, you can add filters the published tables. This depends on your specific needs, so add filters as needed (or do not add any) and click **Next**.

9. Now you need to configure the **Snapshot Agent** to take a snapshot of the publisher database. The snapshot will be used for the initial content of the subscriber database, which can't be created without it. You have the following two options:

- **Create a snapshot immediately** - if enabled, the Snapshot Agent will take the snapshot immediately after this wizard is completed
- **Schedule the Snapshot Agent to run at the following times** - if enabled, the Snapshot Agent will take the snapshot on a regular basis, which can be specified if you click the *Change* button

Make the selection and click **Next**.

10. In this step, you need to configure the Snapshot Agent's security settings, i.e. how the Snapshot Agent will get authenticated when accessing the database to create the snapshot. The default **SQL Server Agent account** works fine in most cases, but you may need to specify different account in specific cases.

Make a configuration suitable for your environment and click **Next**.

11. The **Wizard Actions** step lets you decide what happens when you finish the wizard. You have the following two options:

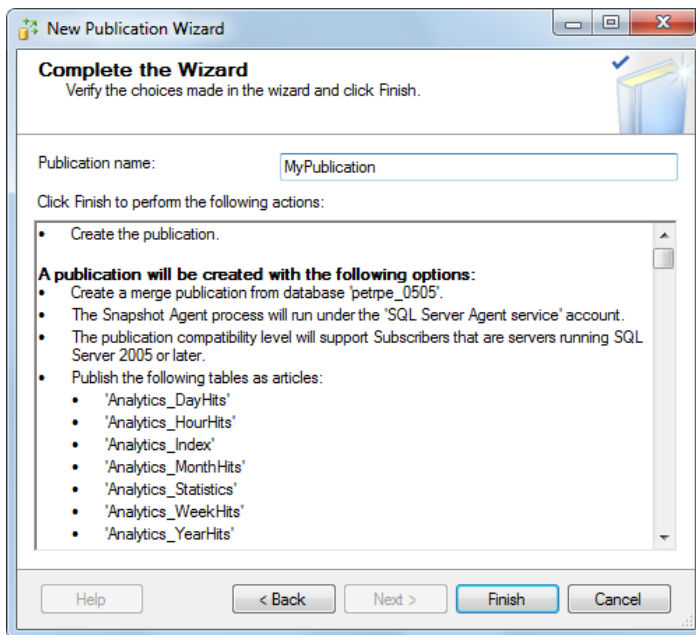

- **Create the publication** - if enabled, the publication will be created as defined throughout the wizard
- **Generate a script file with steps to create the publication** - if enabled, the wizard generates a script which, when executed, creates the publication as defined throughout the wizard

Click **Next**.

12. In the final step, you need to enter the name of your new publication into the **Publication name** field. The section below gives an overview of options which you defined throughout the wizard.

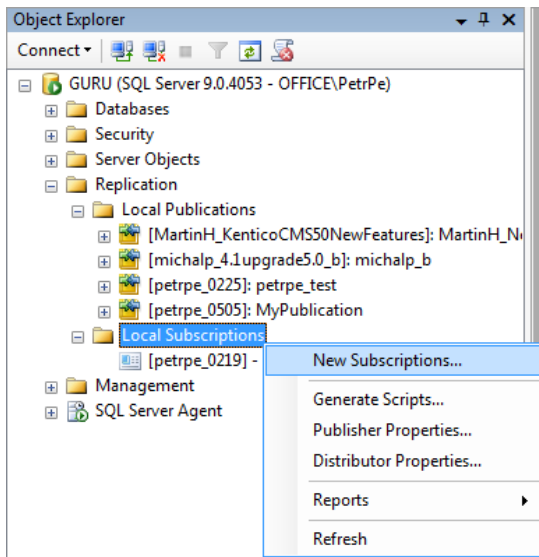

Click **Finish** to create the publication based on the listed options.

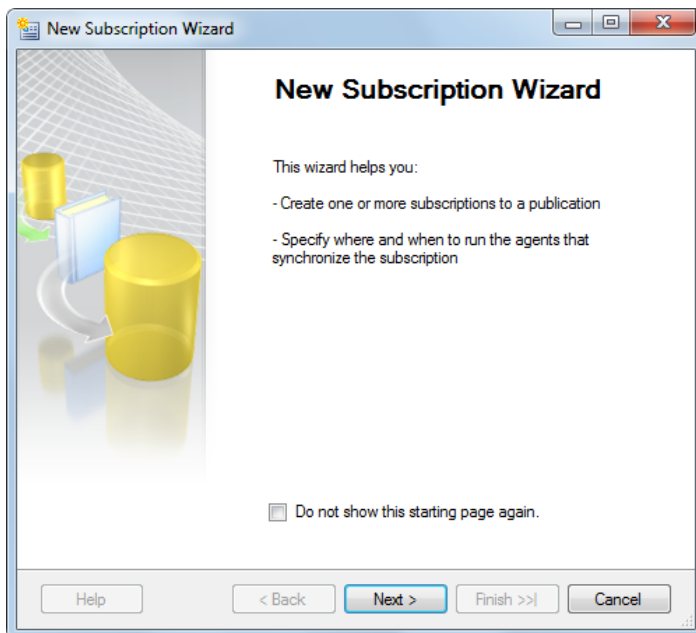

3.5.13.3 Creating a subscription

When you have a publication configured, you can proceed to creating the subscriptions. There can be one or more subscriptions, while you will need a dedicated database for each subscription. Each subscription database needs to be an **exact copy of the publication database**. The copy can be created using [backup](#) and [restore](#) in SQL Server Management Studio.

1. In **SQL Server Management Studio**, expand the **Replication** node and right-click the **Local Subscriptions** folder. Choose **New Subscriptions** from the context menu.

2. The **New Subscription Wizard** starts. Click **Next** in the first step.

3. In the **Publication** step, you need to select the publication to which you want to subscribe. Select the server where the publication is located from the **Publisher** drop-down list. All publications on the selected server will be listed in the **Databases and publications** section below.

Select the required publication and click **Next**.

4. In this step, you need to decide where the Merge Agent will be run. You have the following two options:

- **Run all agents at the Distributor (push subscription)** - if selected, the Merge Agent will run at the distributor (the server where the publication is)
- **Run each agent at its Subscriber (pull subscription)** - if selected, the Merge Agent will run at the subscriber (the server where the subscription is)

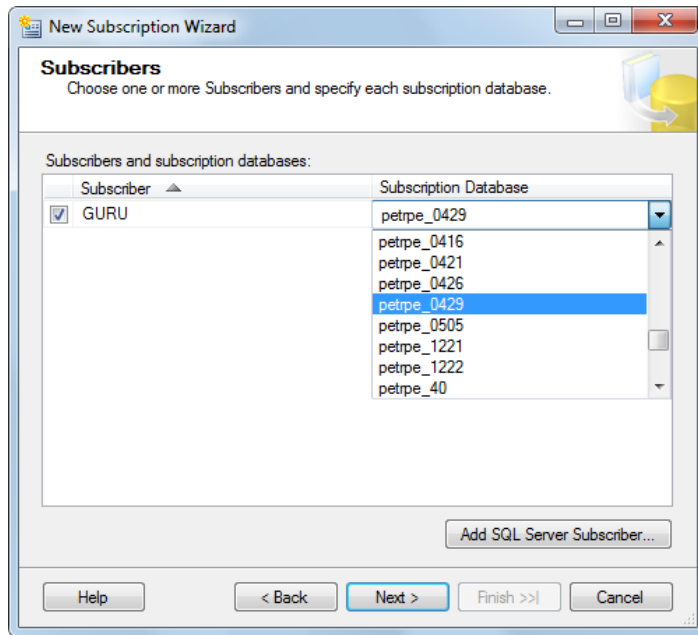

Make your choice (running the agent at the Distributor is recommended for most cases) and click **Next**.

5. Now you need to select the subscription database(s).

The currently managed database server will be offered in the **Subscriber** column. Using the **Add SQL Server Subscriber** button, you can add other servers to the list, which enables you to create subscriptions on a different server than the currently managed one. Next to each server, you can find a drop-down list containing all databases on the server.

Choose the subscription database(s) that you prepared before starting this wizard (as described at the beginning of this page) and click **Next**.

6. In the **Merge Agent Security** step, you are asked to specify the process account and connection options for the Merge Agent. This can be specified for each server by clicking the appropriate "...." button.

Specify the required information according to your environment and click **Next**.

7. In the **Synchronization Schedule** step, you need to specify when will synchronization between the subscriber and the publisher be performed. You have the following options:

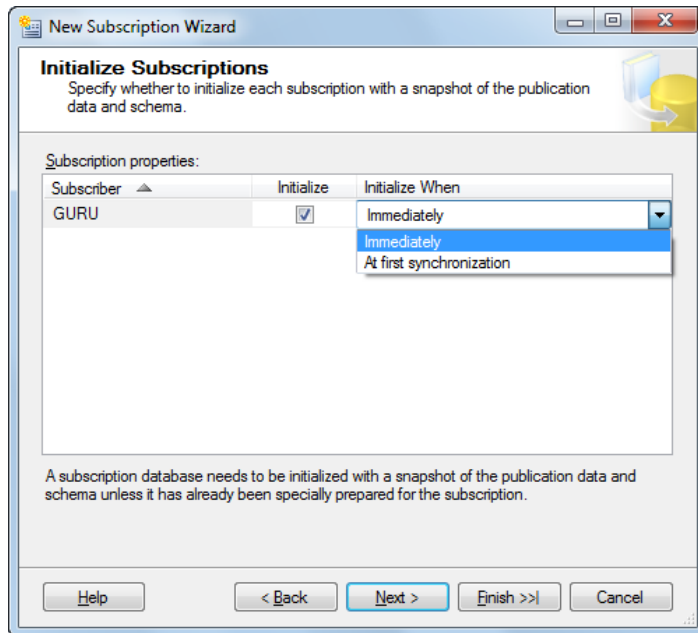

- **Run continuously** - synchronizes immediately whenever a change is made
- **Run on demand** - synchronization is performed only when executed manually from **Replication Monitor** in **SQL Server Management Studio**
- **Run on schedule** - synchronization is performed on a regular basis after a set interval

Select the required schedule and click **Next**.

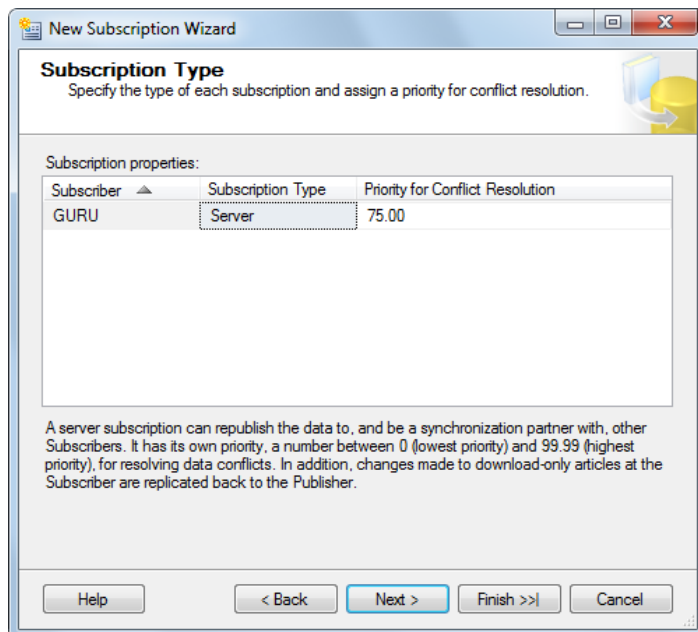

8. This step lets you initialize the subscription, i.e. fill the subscription database with data from the

publisher database snapshot. To perform this, the database snapshot needs to be already created. You can select from the following two options defining when will the synchronization be performed:

9. The **Subscription Type** step lets you decide if you want the subscription to be of the **Server** or **Client** type. For the purposes of our example, leave the default values (*Server* subscription with *75.00* priority) and click **Next**.

10. The **Wizard Actions** step lets you decide what happens when you finish the wizard. You have the following two options:

- **Create the subscription(s)** - if enabled, the subscription(s) will be created as defined throughout the

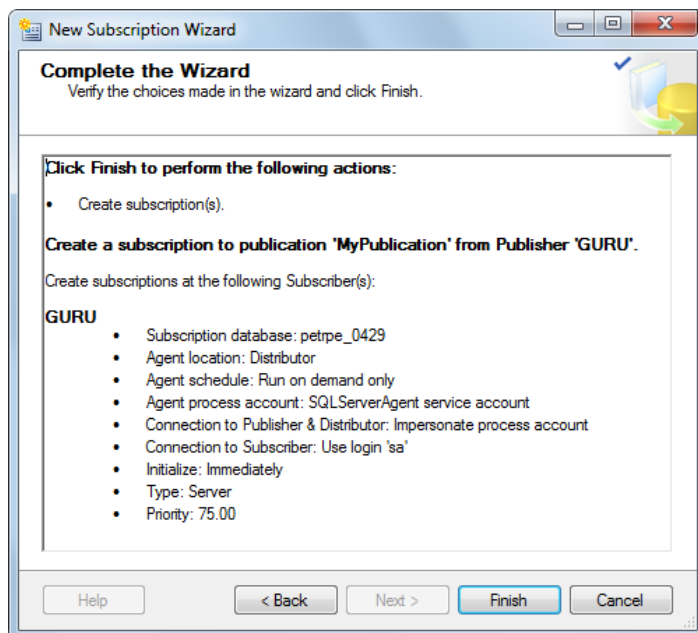

wizard

- **Generate a script file with steps to create the subscription(s)** - if enabled, the wizard generates a script which, when executed, creates the subscription(s) as defined throughout the wizard

Click **Next**.

11. The final step is only informational. It gives you an overview of the options that you selected throughout the wizard. Click **Finish** to create the publication based on the listed options.

3.5.13.4 Modifying structure of a replicated DB

It is possible to make some changes to the DB structure even without disestablishing the existing replication.

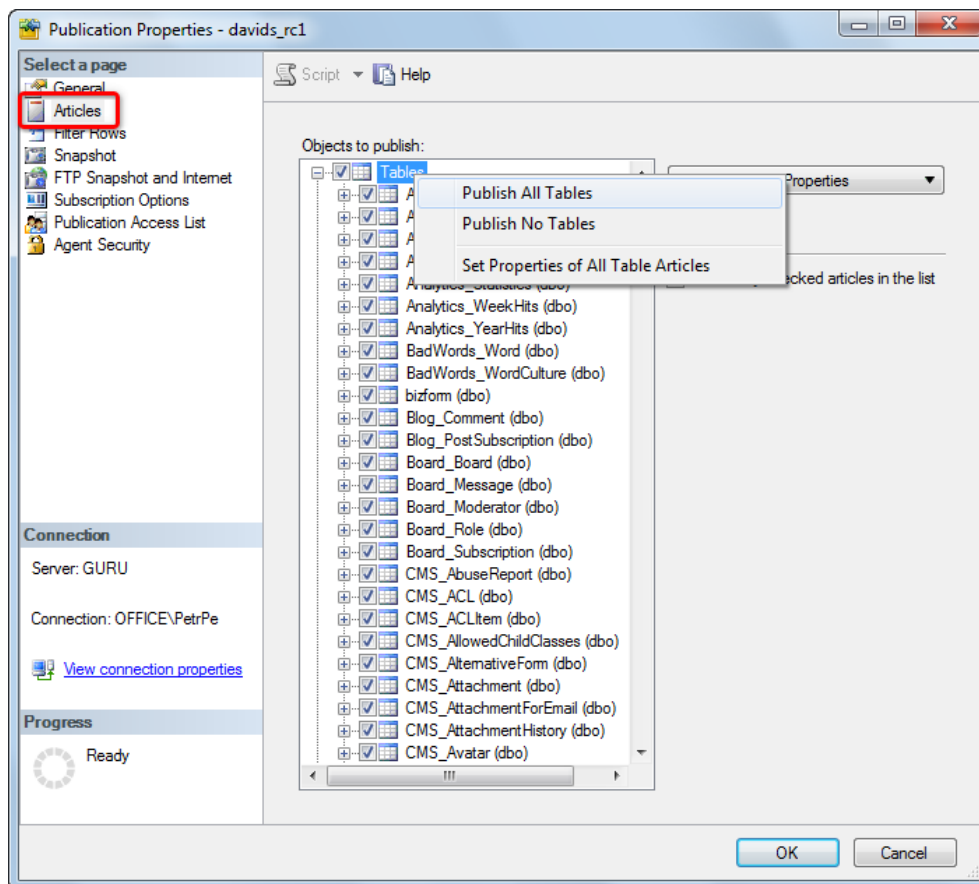

Adding forms, custom tables or document types

Forms, custom tables and document types can be created even when database replication is established. You only need to follow the steps below to

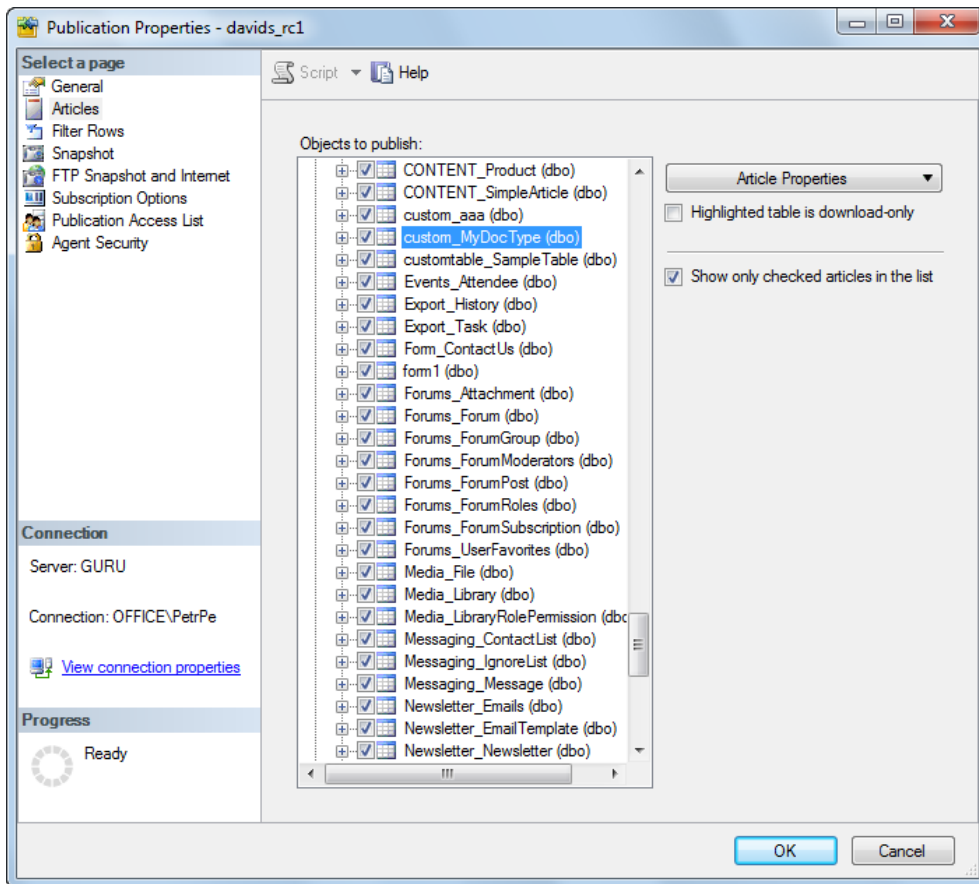

1. Create the form, custom table or document type from within the publisher's Kentico CMS user interface.
2. Open **SQL Server Management Studio**. In **Object Explorer**, expand the **Replication -> Local publications** node, right-click your publication and choose **Properties** from the context menu.

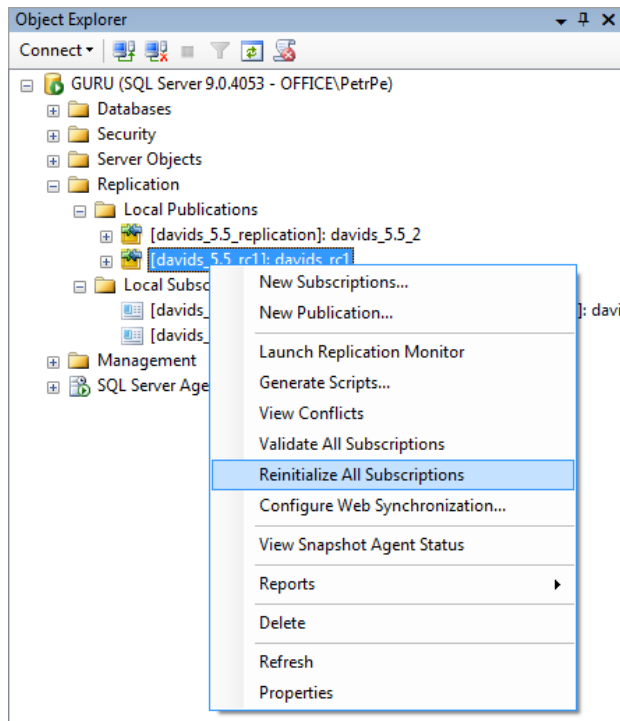

3. In **Publication Properties**, select **Articles** from the right menu. You will see a tree of database tables which are synchronized to the subscribers. You can verify that the new table created in step 1 is missing, i.e. it is not synchronized. Right-click **Tables** (the root of the tree) and click **Publish All Tables**.

4. In case that a new table is found, you are displayed with a confirmation window where you need to confirm that you really want to add the table (article) to the publication. Click **Yes**. The table will be added and you should be able to find it in the tree. Click **OK**.

5. Now back in **Object Explorer**, right-click the publication again and choose **Reinitialize All Subscriptions** from the context menu.

6. A dialog window will be raised, telling you that all subscriptions need to be reinitialized from a snapshot the next time its Merge Agent runs. For the changes to be reflected, you need to reinitialize the subscriptions from a snapshot of the new database structure, i.e. from a snapshot which has been taken after steps 1-4 have been performed.

If you haven't created the snapshot since you finished step 4, choose **Use a new snapshot** and **Generate the new snapshot now**. If you already have the snapshot, choose **Use the current snapshot**.

Click **Mark For Reinitialization**. Next time the subscriptions' Merge Agent runs, the subscriptions will be reinitialized with the new database structure.

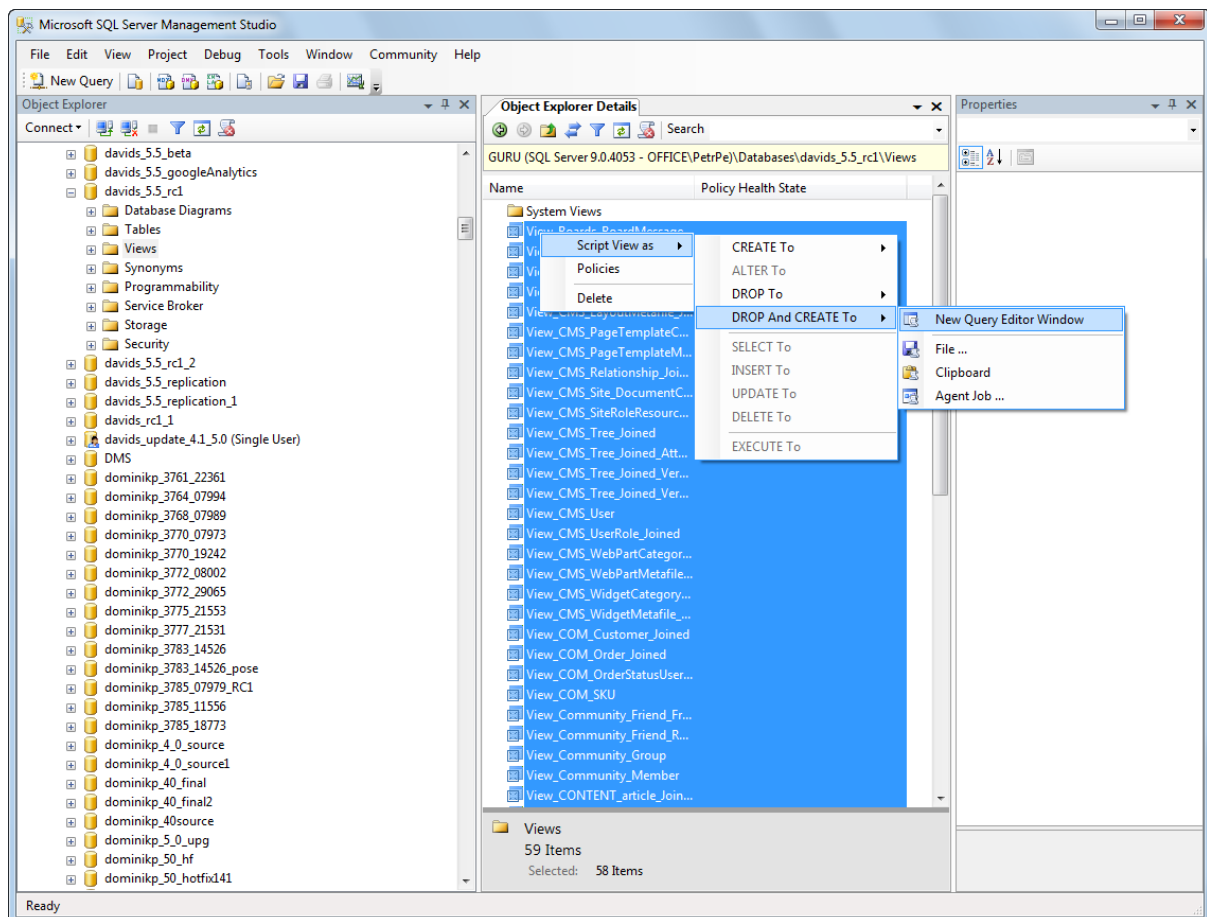

Field changes in system tables

It is also possible to make changes to the fields of System tables without disestablishing an existing replication. In this case, you need to replace all views on the subscription databases with views from the

modified publisher database.

The easiest way to do this is to generate a DROP And CREATE script on the publication database and run it on the subscription databases.

1. Click **F7** to open **Object Explorer Details** view and select the **Views** folder of the publication database.
2. Select all listed views, right-click and select **Script View as -> DROP And CREATE To -> New Query Editor Window** from the context menu.
3. Execute the generated script on the subscription databases.

Field changes in document types

Changes to document type fields can also be made without disestablishing an existing replication. The solution in this case is almost identical to the solution for system tables (described above). The only difference is that you don't need to DROP And CREATE all views, but only the view related to the particular document type.

3.5.14 Configuration of full-text search in files

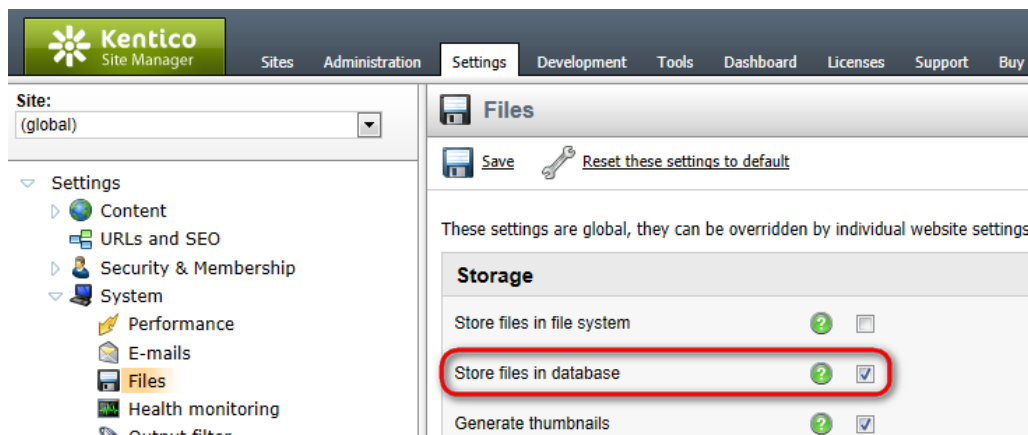

3.5.14.1 Overview

Kentico CMS allows you to search the content of files (document attachments) uploaded into the database. The attachment search uses the standard Microsoft SQL Server full-text search engine, which supports a wide variety of files. The search is available for all supported versions of SQL Server:

- SQL Server 2005
- SQL Server 2008
- SQL Server 2008 R2
- SQL Server 2012

Prerequisites

- Full-text search support must be installed on your SQL Server. The full-text search is available for all supported editions of Microsoft SQL Server, including the Express Edition with Advanced Services.
- Your Kentico CMS website must be configured for storing files in the database (**Site Manager -> Settings -> System -> Files -> Store files in database**).

Use one of the following guides to configure your installation of Kentico CMS for search in files:

- [Manually configuring full-text search on MSSQL Server](#)
- [Enabling full-text search on MSSQL Server \(Script\)](#)

Supported file types

The standard full-text search engine delivered with Microsoft SQL Server can search TXT, HTML, DOC, XLS and PPT files.

- To search in PDF files, install a free driver from Adobe: [Searching PDF files](#)
- To search Microsoft Office Open XML documents, such as DOCX or XLSX, install a free IFilter pack: [Searching Microsoft Office documents](#)

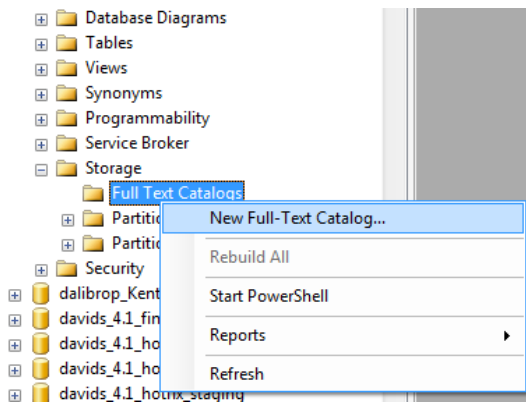

If you want to search other types of documents, you need to install appropriate IFilter

libraries. You can download or purchase IFilter libraries from third-party vendors.

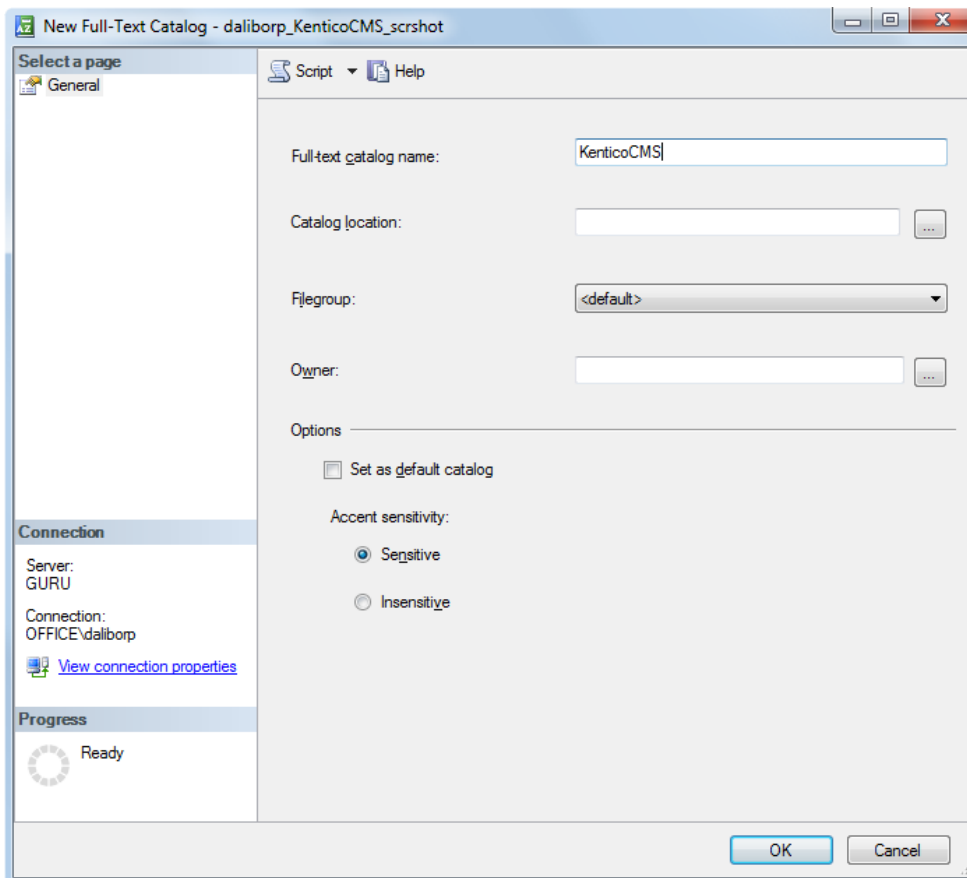

3.5.14.2 Manually configuring full-text search on MSSQL Server

Use the following steps to configure your Kentico CMS database for full-text search in file attachments:

1. Start **Microsoft SQL Server Management Studio**.
 - o If you cannot use SQL Server Management Studio on your database server, you can configure the full-text search through a [script](#) instead.
2. Locate your Kentico CMS database.
3. Unfold the **Storage** sub-folder, right-click **Full Text Catalogs** and click **New Full-Text Catalog**.

4. Type a **Full-text catalog name** and click **OK**.

5. Right-click the new full-text catalog and choose **Properties**.
6. In the Full-Text Catalog Properties dialog, click the **Tables/Views** tab.
7. Assign the *CMS_Attachment* table to the catalog.
 - a. Check the box next to the *AttachmentBinary* column
 - b. Set the **Language for Word Breaker** to *English* or another value
 - c. Set the **Data Type Column** to *AttachmentExtension*

8. Click **OK**.

You can now [search](#) through the content of basic files types stored in the database. See also:

- [Searching PDF files](#)
- [Searching Microsoft Office documents](#)

Enabling attachment search for the SQL search

Perform the following steps if you wish to search attachments using the [SQL search](#):

Note

The SQL search engine is obsolete. It is recommended to use the [Smart search](#) instead. In that case you only need to enable the **Search in attachments** property of the relevant smart search results web parts.

1. Sign in to **Site Manager** and go to **Development -> Document types**.
2. Edit the **Root** document type.
3. Open the **Queries** tab.

4. Edit the `searchattachments` query and uncomment the following part of the code:

```
SELECT View_CMS_Tree_Joined.*, View_CMS_Tree_Joined.NodeName AS SearchResultName
FROM CMS_Attachment INNER JOIN View_CMS_Tree_Joined
ON View_CMS_Tree_Joined.DocumentID = CMS_Attachment.AttachmentDocumentID
WHERE (##WHERE##) AND
((([AttachmentName] Like N'%'+ @Expression + N'%') OR ([AttachmentTitle] Like N'%'+
@Expression + N'%') OR ([AttachmentDescription] Like N'%'+ @Expression + N'%'))
OR (FREETEXT(AttachmentBinary, @expression))
ORDER BY ##ORDERBY##
```

3.5.14.3 Enabling full-text search on MSSQL Server (Script)

If you cannot use SQL Server Management Studio to configure the full-text search, run the following script against your Kentico CMS database:

```
-- Allows IFilter library loading
exec sp_fulltext_service 'verify_signature', 0
exec sp_fulltext_service 'load_os_resources', 1

-- Creates the Full Text Catalog
exec sp_fulltext_catalog 'KenticoCMSCatalog', 'create'

-- Adds the CMS_Attachment table to the catalog
exec sp_fulltext_table
'CMS_Attachment', 'create', 'KenticoCMSCatalog', 'PK_CMS_Attachment'

-- Sets the data column of the CMS_Attachment table in the catalog
exec sp_fulltext_column 'CMS_Attachment', 'AttachmentBinary', 'add',
NULL, 'AttachmentExtension'

-- Populates the catalog
exec sp_fulltext_table 'CMS_Attachment', 'start_full'
```

You can now [search](#) through the content of basic files types stored in the database. See also:

- [Searching PDF files](#)
- [Searching Microsoft Office documents](#)

Enabling attachment search for the SQL search

Perform the following steps if you wish to search attachments using the [SQL search](#):

Note

The SQL search engine is obsolete. It is recommended to use the [Smart search](#) instead. In that case you only need to enable the **Search in attachments** property of the relevant smart search results web parts.

1. Sign in to **Site Manager** and go to **Development -> Document types**.
2. Edit the **Root** document type.
3. Open the **Queries** tab.
4. Edit the **searchattachments** query and uncomment the following part of the code:

```
SELECT View_CMS_Tree_Joined.*, View_CMS_Tree_Joined.NodeName AS SearchResultName
FROM CMS_Attachment INNER JOIN View_CMS_Tree_Joined
ON View_CMS_Tree_Joined.DocumentID = CMS_Attachment.AttachmentDocumentID
WHERE (##WHERE##) AND
(((AttachmentName) Like N'%'+ @Expression + N'%') OR ([AttachmentTitle] Like N'%'+
@Expression + N'%') OR ([AttachmentDescription] Like N'%'+ @Expression + N'%'))
OR (FREETEXT(AttachmentBinary, @expression))
ORDER BY ##ORDERBY##
```

3.5.14.4 Searching PDF files

Kentico CMS does not support searching in PDF files by default. To enable it, you need to install the free **Adobe PDF IFilter** on your machine. The installation process is different for 32-bit and 64-bit systems.

Note: Adobe PDF IFilter is not a product of Kentico Software and we cannot guarantee its functionality.

Configuration on 32-bit platforms

Use the following procedure to enable searching in PDF files on 32-bit platforms:

1. Download the free Adobe PDF IFilter 6.0 from the Adobe website: <http://www.adobe.com/support/downloads/detail.jsp?ftpID=2611>
2. Run the installer and follow the instructions.
3. Rebuild the full-text search catalog that you created for Kentico CMS.
4. If you are using MS SQL Server 2005, run the following SQL commands to ensure that the server can load the PDF IFilter libraries:

```
sp_fulltext_service 'verify_signature', 0
GO
sp_fulltext_service 'load_os_resources', 1
```

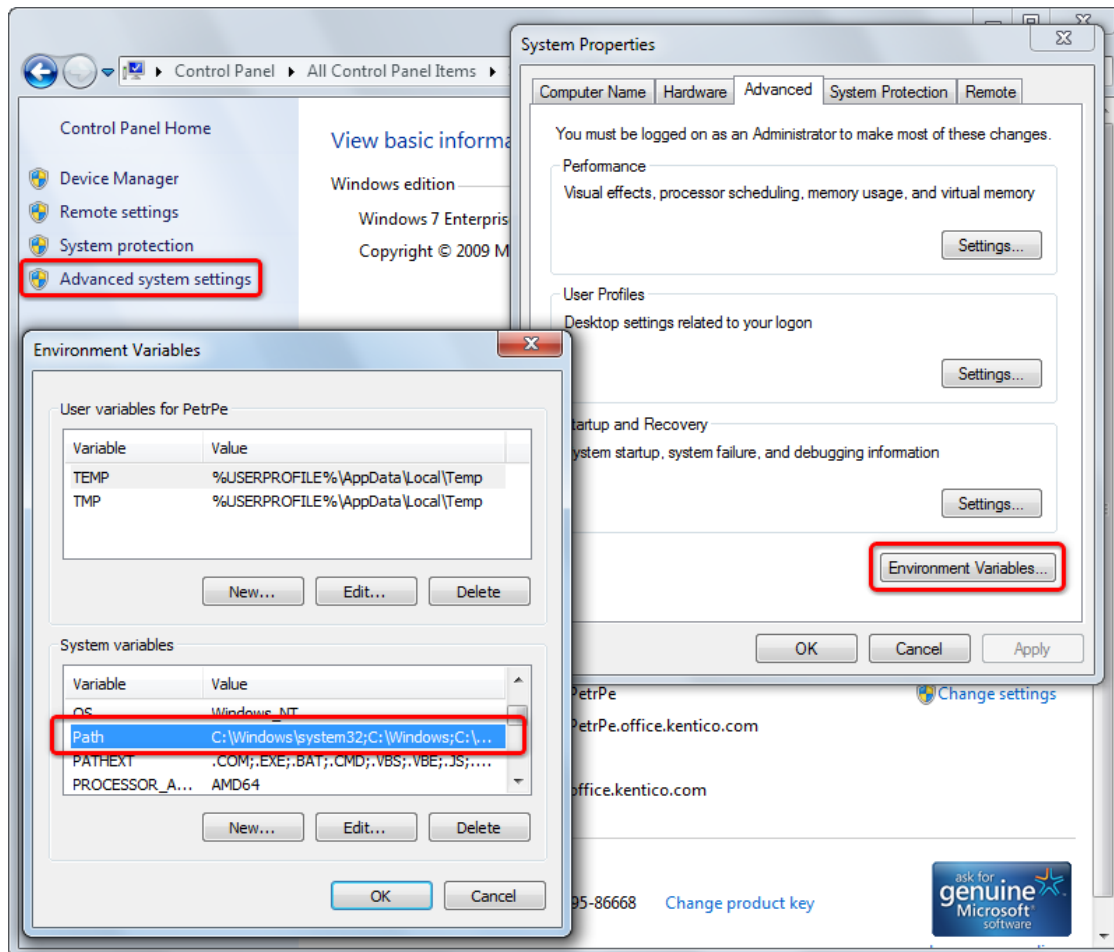

You can now [search](#) for PDF files stored in the database.

Configuration on 64-bit platforms

Use the following procedure to enable searching in PDF files on 64-bit platforms:

1. Download Adobe PDF IFilter 9 for 64-bit platforms from the following location: <http://www.adobe.com/support/downloads/detail.jsp?ftpID=4025>
2. Make sure that no other version of IFilter is installed on your machine.
3. Run the installer and follow the instructions.
4. After installing the PDF IFilter, it is recommended to add the **bin** folder of the IFilter installation directory to your system **Path** environment variable:

- a. Go to **Control Panel** -> **System** -> **Advanced system settings** -> **Environment Variables**.
- b. Append `C:\Program Files\Adobe\Adobe PDF IFilter 9 for 64-bit platforms\bin\` to the value of the **Path** variable.

5. Restart the computer.
6. Check whether Adobe IFilter is registered with the server — run the following query against your server:

```
SELECT * from sys.fulltext_document_types
```

You should see a list of supported file types that have filters installed. Verify that you can see an entry for **.pdf**.

7. If you do not see an entry for **.pdf**, execute the following two lines:

```
EXEC sp_fulltext_service 'load_os_resources', 1  
EXEC sp_fulltext_service 'verify_signature', 0  
GO
```

8. Restart the SQL Server.
9. Run the query from step 6 again and verify that you can see the entry for **.pdf**.

You can now [search](#) for PDF files stored in the database.

3.5.14.5 Searching Microsoft Office documents

Kentico CMS does not support searching in Microsoft Office Open XML files by default (documents created in Office 2007 or newer — .docx, .xlsx, .pptx etc.). To enable search in these files, you need to install and configure **Microsoft Filter Pack** IFilters on your machine.

Note: Microsoft Filter Pack is not a product of Kentico Software and we cannot guarantee its functionality.

Perform the following steps to enable searching in Microsoft Office Open XML files:

1. Download the Microsoft Filter Pack installer that matches the architecture of your operating system from the Microsoft website:

- [Microsoft Office 2007 Filter Pack](#)
- [Microsoft Office 2010 Filter Pack](#)

2. Run the installer and follow the instructions.

3. After you finish the installation, start SQL Server Management Studio, access your Kentico CMS database and run the following command in that instance:

```
sp_fulltext_service 'load_os_resources', 1
```

This allows the server to load the IFilter libraries.

4. Check whether the IFilters are registered with the server. Type and execute the following in a new query window:

```
SELECT * from sys.fulltext_document_types
```

You should see a list of supported file types that have filters installed. Verify that the list contains entries for all desired file extensions.

5. Restart the SQL Server service.
6. **Rebuild** the full-text search catalog that you created for Kentico CMS.

You can now [search](#) for Microsoft Office Open XML files stored in the database.

3.5.15 Custom URL extensions and extensionless URLs

3.5.15.1 Overview

This chapter describes how to configure the system for using custom URL extensions and extensionless URLs. Custom URL extensions let you have the extensions rendered with a different extension than the default `.aspx`, like `.html`, `.php`, `.xxx` or any other.

So for example, instead of the default `http://www.example.com/news.aspx`, you can have URLs ending with `.html`:

`http://www.example.com/news.html`

you can also configure an empty extension, which results in an **extension-less URL**:

`http://www.example.com/news`

To achieve this result you have to take the following two steps:

1. Adjust your `web.config` or IIS to handle the custom extensions. This step is different for [IIS 7 or higher](#) and [IIS 6](#).
2. Configure custom URL extensions in Kentico CMS. It is described in [this chapter](#).

3.5.15.2 IIS 7 and higher

If your instance of Kentico CMS is running on a server with IIS 7 or higher installed, you only need to add or modify several keys in your project's `web.config` file.

Note: This procedure only works for IIS 7 sites that use an **Application Pool** with **Managed Pipeline Mode** set to *Integrated*.

Required configuration

1. Edit your application's `web.config` file.
2. Find the `<modules>` element inside the `system.webServer` section directly under the `web.config` root (i.e. not under a specific `<location>` element).
3. Modify the the opening `<modules>` tag to match the following code:

```
<system.webServer>
  ...
  <modules runAllManagedModulesForAllRequests="true">
```

```
...  
</system.webServer>
```

4. With this modification in your web.config, proceed to [configuring the extensions](#) in the administration interface of Kentico CMS.

You can also perform additional configuration as described below.

Optional configuration (recommended)

5. It is recommended to configure a custom *Page-not-found* (404) error page when using custom URL extensions, otherwise a blank page may be displayed in some browsers if a user attempts to access a non-existing resource. This can be achieved by entering the URL of the appropriate document or aspx page as the value of the **Page not found URL** setting in **Site Manager -> Settings -> Content**, for example: `~/CMSMessages/PageNotFound.aspx`. Please read the [Configuring custom error pages](#) topic to learn more.

Alternatively, you can add a **<httpErrors>** element into the *system.webServer* section of your **web.config** file according to the following:

```
<httpErrors existingResponse="Auto" errorMode="Custom">  
  <clear/>  
  <error statusCode="404" responseMode="ExecuteURL" path="/<Virtual_Directory>/  
  CMSMessages/PageNotFound.aspx" />  
</httpErrors>
```

Replace the `<Virtual_Directory>` string in the value of the **path** attribute of the **<error>** element with the name of the virtual directory where you run Kentico CMS.

6. You can also add the following key to the *AppSettings* section, which ensures that URLs remain the same even after postback.

```
<add key="CMSUseExtensionOnPostback" value="false" />
```

7. If you are using trailing slashes (enabled by the **Use URLs with trailing slash** option in **Site Manager -> Settings -> URLs and SEO**), you can use the following extra key to have only extensionless URLs ending with the trailing slash. URLs ending with an extension are rendered without the slash when the key is used.

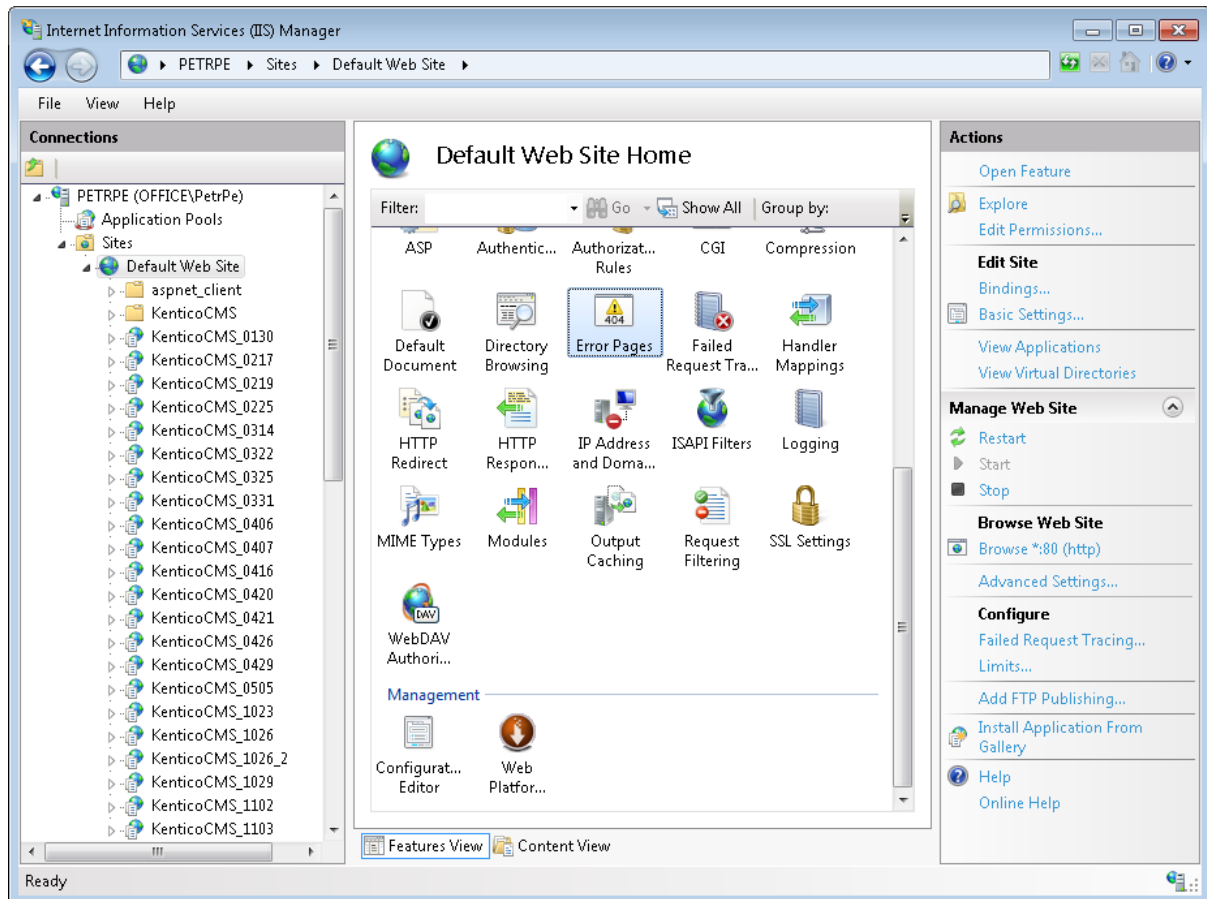

```
<add key="CMSUseTrailingSlashOnlyForExtensionLess" value="true" />
```

Using the `cmspages/handler404.aspx` special page (obsolete)

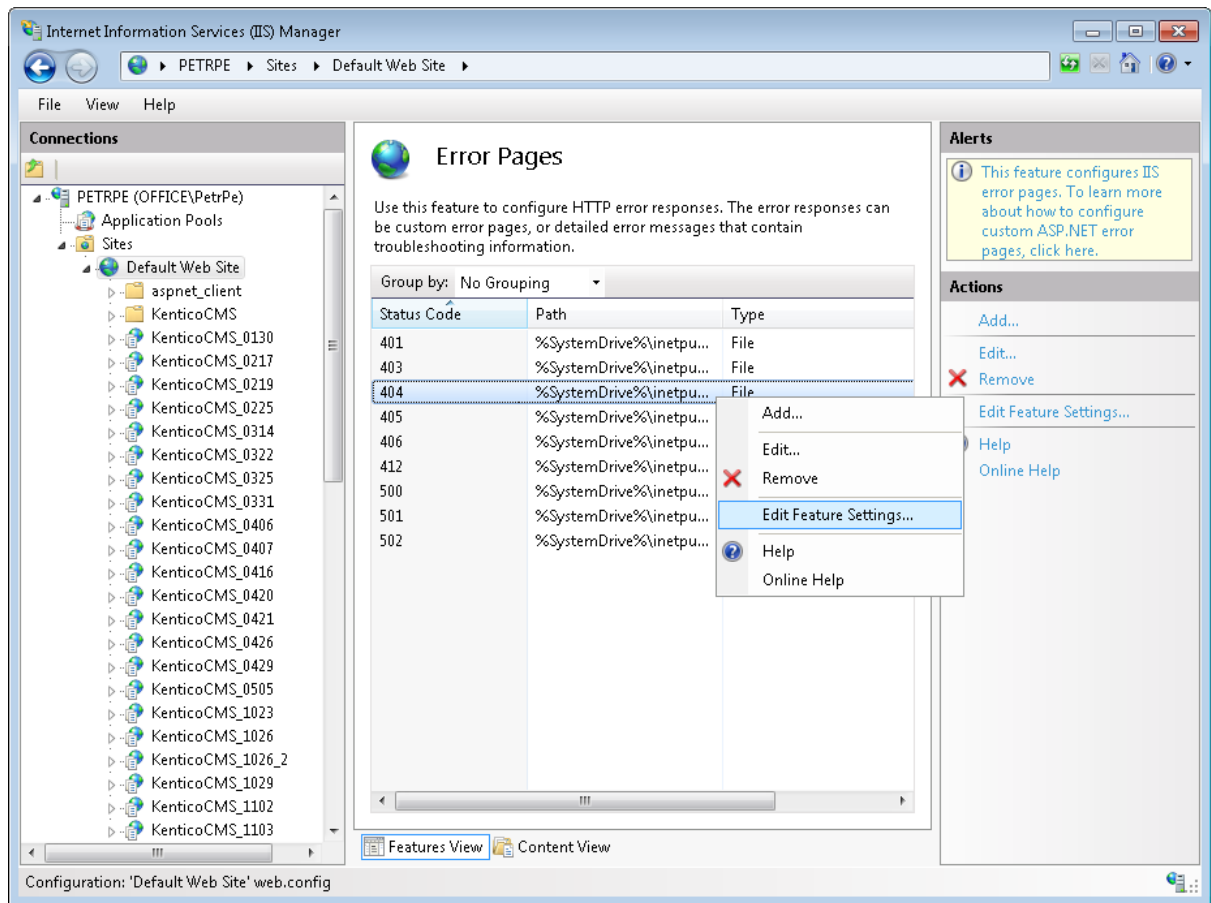

Due to backward compatibility, you can also enable custom URLs by configuring your IIS manually. It is not recommended now as it is obsolete. If you receive the **Lock violation error** during the procedure, try the solution described [here](#).

The setup procedure on IIS 7 is the following:

1. Open **Start -> Control Panel -> Administrative Tools -> Internet Information Services (IIS) Manager**.
2. Select your website from the tree on the left and open the **Error pages** section.

3. Right-click the **404 error** and choose **Edit Feature Settings**.

4. Enter the following values:

- **Path:** enter the URL of the **cmspages/handler404.aspx** page according to your application's URL.
Example: if you run your web project in virtual directory `/kenticocms`, you need to enter `/kenticocms/cmspages/handler404.aspx`
- **Path type:** Execute URL

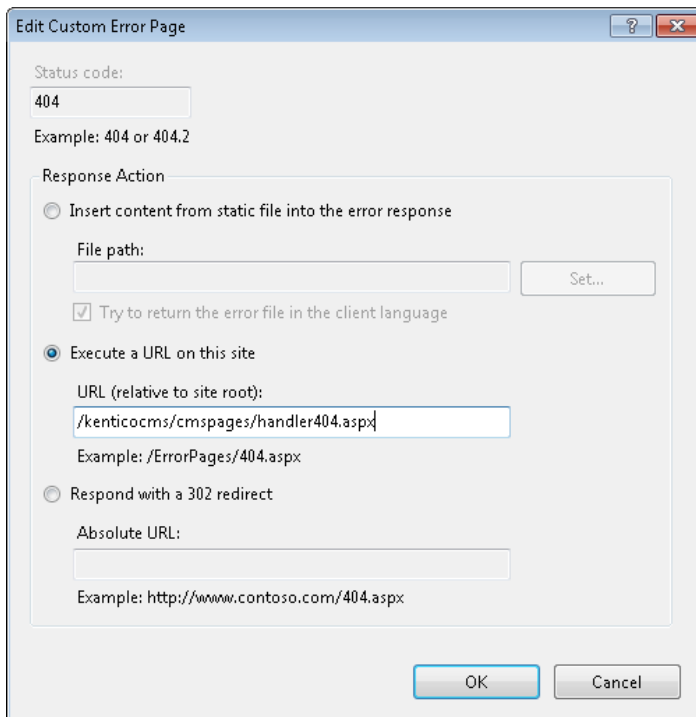

Click **OK**.

5. Now right-click the **404 error** again and choose **Edit** from the context menu.

6. Select **Execute a URL on this site** and enter the same URL that you entered in step 4. Click **OK**.

7. Go back to step 3 and repeat the same procedure for the **405 error**.
8. Click **OK** on all dialogs to save the changes. It's not necessary to restart the application.

Setting up the .html extension on IIS manually (obsolete)

The following approach is also possible, but not recommended and considered obsolete now. To use the **.html** extension, go through the following steps:

1. Run **IIS Manager** .
2. Select your web.
3. Open **Handler mappings**.
4. Click to **Add managed handler...** .
5. Enter the following values:
 - **Request path:** *.html
 - **Type:** System.Web.DefaultHttpHandler
 - **Name:** HTML

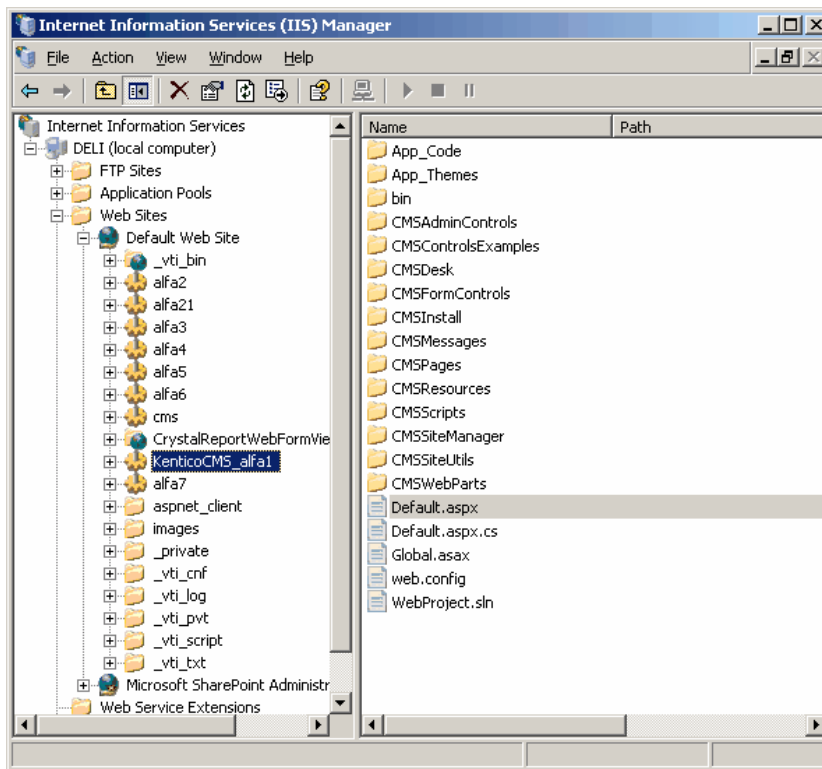

Click **OK**.

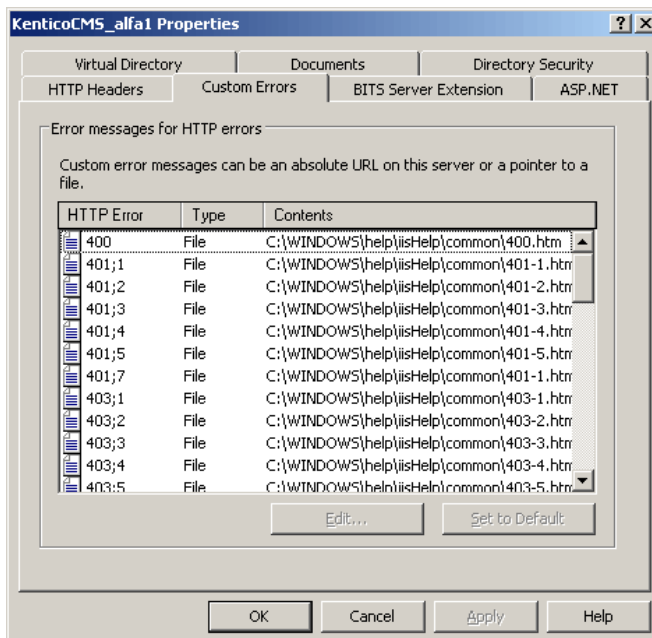

3.5.15.3 IIS 6

This procedure needs to be performed to configure IIS 6 to handle Kentico CMS's custom URL extensions. You can use this configuration on **Windows XP** and **Windows Server 2003** with Internet Information Services (IIS) 6 installed. It's not possible to use it with Visual Studio's built-in web server.

1. Go to **Start -> Control Panel -> Administrative Tools** and launch the **Internet Information Services (IIS) Manager**. Locate the appropriate website and virtual directory (if you installed Kentico CMS into the root, you will make this change on the website level only).

2. Right-click the directory (or website) and choose **Properties** and then click the **Custom Errors** tab:

3. Edit the 404 error and enter the following values:

- **Message type:** URL
- **URL:** enter the URL of the cmspages/handler404.aspx page according to your application's URL.
E.g. if you run your web project in virtual directory /kenticocms, you need to enter /kenticocms/

cmspages/handler404.aspx

4. Now repeat the same for the 405 error, using the same custom URL: /kenticocms/cmspages/handler404.aspx

Click **OK** on all dialogs to save the changes. It's not necessary to restart the application.

3.5.15.4 Configuration of custom URL extensions (.html or other)

When you have performed the required configuration for your version of IIS, you can proceed with entering the actual extensions.

This can be done in **Site Manager -> Settings -> URLs and SEO**. For example, try to set the **Friendly URL extensions** value to **.html** and click **Save**.

Now when you go to the live website, you will see that all URLs in menus and listings are rendered with **.html** extensions. In some cases, you may need to update some static links which were created with the default **.aspx** extension.

Using multiple extensions

You can enter multiple extensions into the **Friendly URL Extension** field mentioned above. The

following format should be used:

.html;.htm;;.xxx;.abc

- The first extension is used as the default one and the links will be generated with it in the browser.
- Other extensions are entered divided by semicolons (;). Pages can be accessed through URLs ending with all entered extensions.
- If you enter a semicolon without any extension in front of it, like in the middle of the sample entry above, extension-less URLs can be achieved.

The **Redirect documents to main extension** setting, which can also be found at **Site Manager -> Settings -> URLs and SEO**, causes URLs with non-default extensions to be redirected to corresponding URLs with the current default extension. This can be useful for SEO purposes. For example, if you want to change the extensions of your documents and want them to be used when the documents are accessed from a search engine that has your website indexed with the old extension.

Document-level extensions settings

Apart from the global settings described above, document extensions under which the document can be accessed can also be set separately for each document. The default extension with which the pages are **rendered** in the browser is always taken from the **global** settings.

1. Select the document from the content tree.
2. Switch to its **Properties -> URLs** tab.
3. Enable the **Use custom URL extensions** check-box.
4. Enter the required extension(s) using the same rules as described above.

Please note: Even if the **Use custom URL extensions** option is disabled, files (**cms.file** documents) can be accessed under their physical extensions.

3.5.15.5 Lock violation on IIS7

When configuring your IIS 7 (or later) to allow custom extensions or extension-less URLs, especially if you're running Kentico CMS in a virtual directory, you may receive the **Lock violation** error message. This typically doesn't allow you to specify the path settings in step 4 of the instructions for using `cmspages/handler404.aspx` described on [this page](#).

The reason is most probably a locked **defaultPath** attribute in the **httpErrors** section. You can check and unlock it in **IIS Manager**. Select your site (IIS site) and open **Configuration Editor** (it is included in the *Management* section in the standard installation of IIS 7.5; if you are using IIS 7, you can download and install it as a part of the [IIS7 Administration Pack](#)).

In Configuration Editor, choose **webServer/httpErrors** from the **Section** drop-down list.

If there is a **lock icon** next to the **defaultPath** attribute name, right-click on the attribute name and select the **'defaultPath' Attribute -> Unlock Attribute** action from the context menu. If the option is missing in the context menu, you will probably have to unlock it on a higher level in the IIS tree, i.e. on the parent site or on the root of the server.

Click **Apply** to save the changes and from now, the *Lock violation* errors shouldn't appear.

3.6 Visual Studio integration

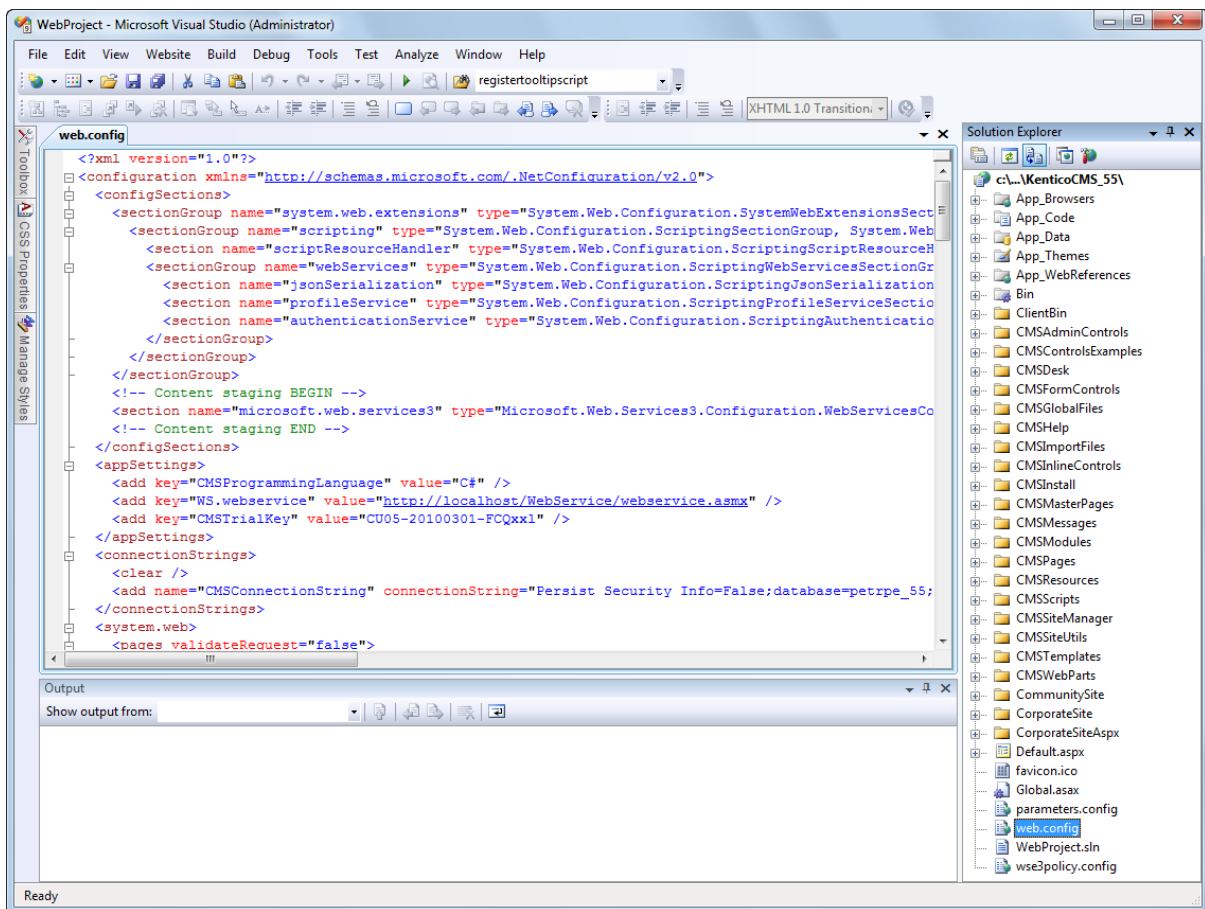

3.6.1 Opening the project

After you create a new Kentico CMS web project, you can open it in Visual Studio by double-clicking the `WebProject.sln` file in Windows Explorer:

If this option doesn't work, you can start **Visual Studio** and choose **File -> Open -> website** in the main menu and navigate to the folder which contains the *WebProject.sln* file.

The project looks like this:

Making modification to the standard code

Although Kentico CMS is delivered with source code of the administration interface (CMS Desk, CMS Site Manager), it's recommended that you do NOT modify the default files to avoid problems when upgrading to a higher version (your changes may be overwritten by new code).

If you need to modify some dialog, note down its name and merge your modifications with the new version during the upgrade to a higher version of Kentico CMS.

If you need to modify some web part, create its copy and then modify it.

Source Code Options

There are two levels of source code:

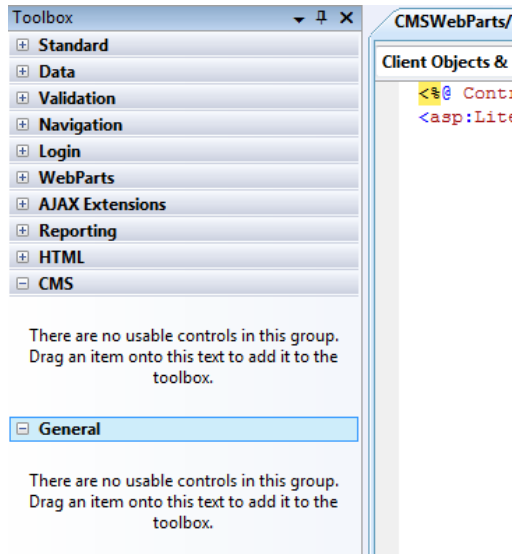

- the **source code of the website**, administration interface and web parts - this source code is delivered with every license (even in the trial version)
- the **full source code** of all libraries, including data layer, business layer and Kentico CMS Controls - this source code is only available as a part of the 1 website Ultimate or 1 Server Ultimate licence with Source Code.

You're allowed to modify the source code you receive (in both options) and deploy the modified version into production environment, provided you meet all other licensing conditions.

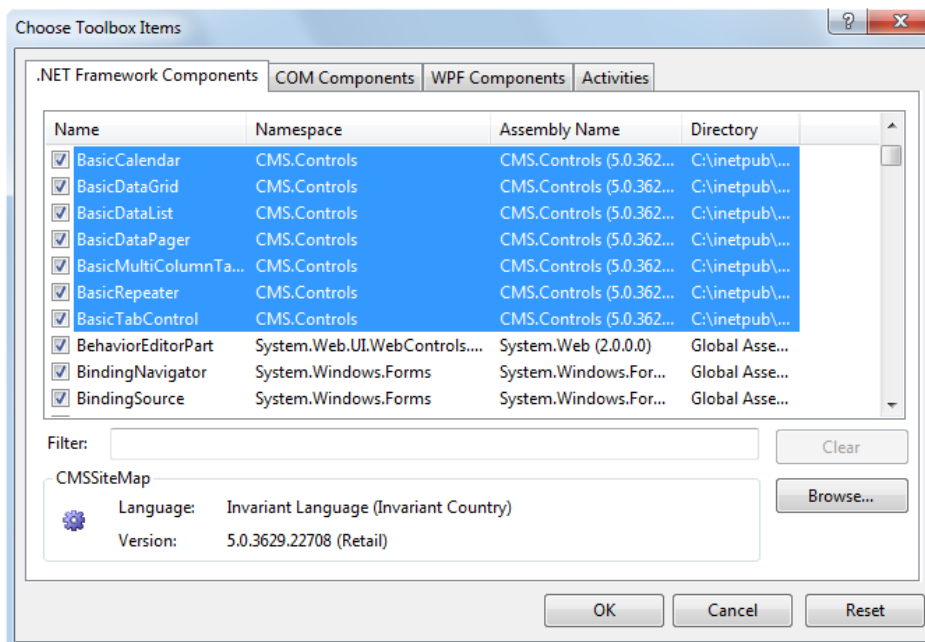

3.6.2 Adding Kentico CMS Controls to the Toolbox

Before you start using Kentico CMS Controls in your ASP.NET project, it is recommended to add the controls to the **Toolbox**:

1. Open the web project in Visual Studio and edit any ASPX web form or ASCX user control file, for example *Default.aspx* under the project root. This is necessary, because the controls will only be offered in the toolbox when working with ASPX markup.
2. Right-click the **Toolbox** and choose **Add tab** from the context menu.
3. Type the name of the new tab (e.g. *CMS*) and press Enter:

4. Right-click the new tab and choose **Choose items...** from the context menu.
5. In the **Choose Toolbox Items** dialog, click **Browse** and locate the **CMS.Controls.DLL** library in the **bin** folder under your website. Click **Open** and then click **OK**.

6. The controls are now added to the Toolbox, as you can see in the following screenshot. Now you can easily drag and drop the controls into the content of your web forms or user controls.

3.6.3 Debugging

If you're adding custom code using Visual Studio into Kentico CMS, you can easily debug it in Visual Studio as you're used to since Kentico CMS is a standard Visual Studio application. Simply click on the left next to your method or command and it will create a red breakpoint:

Now choose **Debug -> Start debugging** in the main menu or press **F5**. The website starts and you can track the code flow. You may get a message like this:

You will need to choose to **Modify the web.config file to enable debugging** and click **OK**. It's recommended that you disable debugging before deploying the website to a production environment by

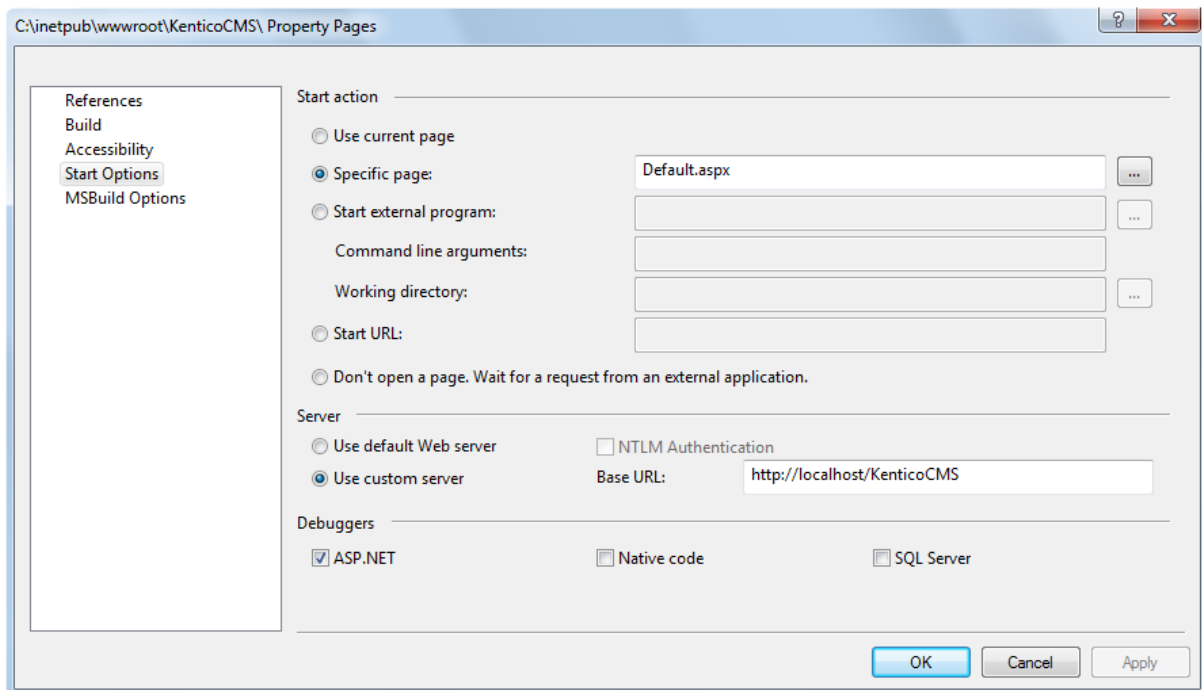

setting the value

```
<compilation debug="true" .... />
```

to **false** in your *web.config* file for better performance.

Debugging using IIS website

The debug mode starts in built-in web server by default. You can change this in the **website -> Start** options dialog by choosing the Use custom server option like this:

Please note that you need to be local administration and the website or virtual directory must be configured for both anonymous and Windows authentication (see [Additional configuration tasks -> Creating a virtual directory](#) for details).

Debugging from within Kentico CMS UI

Kentico CMS provides certain debugging possibilities directly from within its user interface in **Site Manager -> Administration -> System -> Debug**. Further information on this topic can be found in the [Development -> Debugging](#) chapter of this guide.

3.6.4 Precompilation (Publish function)

When deploying a website, you have the option of [precompiling](#) the web project before you place it on a server. This compiles the source code into assemblies, which provides several advantages:

- Faster initial response times - resources do not need to be compiled dynamically when they are requested for the first time.

- Source code protection - you can create a compiled version of the website without any accessible source code.
- Efficient deployment - using the **Publish** function, you can compile and deploy the website at the same time.

Limitations of precompiled websites

Only use precompilation to deploy completed websites. Precompiled instances of Kentico CMS have limited website development features.

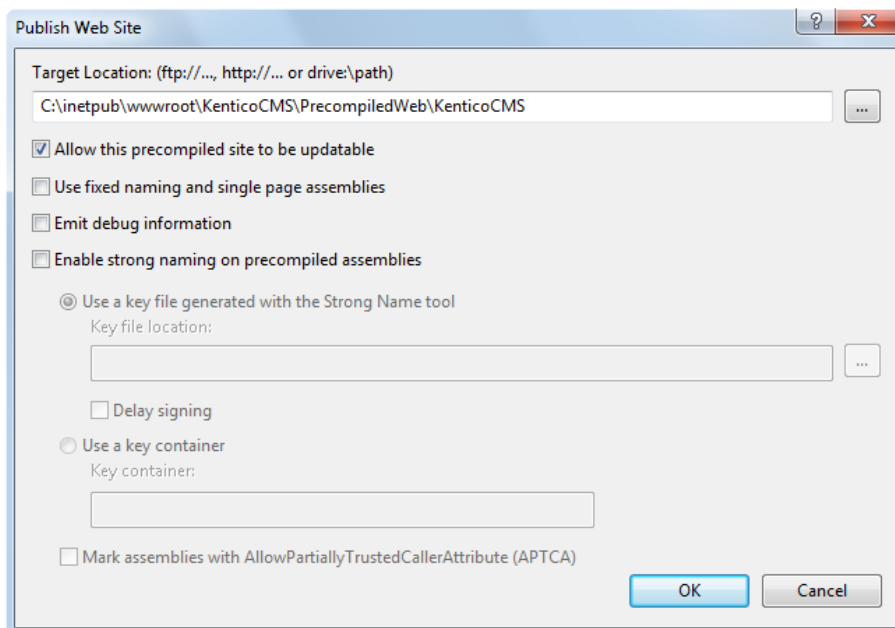

You cannot edit, create or import virtual objects that contain ASP.NET markup and require compilation:

- [Page layouts](#) (ASCX type)
- [Transformations](#) (ASCX type)
- [Web part layouts](#)

If you wish to [import](#) physical files that require compilation (such as *cs*, *vb*, *aspx*, *ascx*), you need to run the import process on the original project, and then create the precompiled site again.

Pre-compiling a web project

1. Rename the **Microsoft.Web.Services3.dll.rename** file in the `~\Bin` directory to **Microsoft.Web.Services3.dll**.
 - This allows you to use [content staging](#) on the precompiled site.
2. Go to **Site Manager -> Administration -> System -> Virtual objects** and click **Store all virtual objects in file system**.
 - This saves all virtual objects into the web project as physical files, so they can be included in the precompilation.
 - The system cannot load virtual objects from the database in a precompiled environment (the Virtual path provider is not available).
3. Right-click your web site project in the Solution Explorer in Visual Studio and select **Publish Web Site**.
 - This function is not present in the Express versions of Visual Studio, but you can use the command line ASP.NET Compilation Tool.
 - The following dialog box opens:

4. Enter a path outside of your current web project where the precompiled version will be placed.

5. Choose between two compilation modes using the **Allow this precompiled site to be updatable** checkbox:

- checked - compiles the code behind of all web forms and controls, but stores the markup files (.aspx, .ascx) in their original code form.
- unchecked - the compilation also includes markup files. The website contains only empty "stub" .aspx/.ascx files without any code.

We generally recommend using non-updatable sites for optimal performance.

6. Click **OK**.

Once the process is complete, you can deploy the precompiled site to your server.

Moving the database

You may need to copy the database to the server using the standard **backup/restore** procedure, since the compiled website cannot be used to install an SQL Server database. Other options are:

- Install a non-compiled website on the server first, go through the setup wizard and then replace the non-compiled files with compiled ones, while keeping the web.config file as is.
- Install a Kentico CMS website locally and run the database setup against the remote SQL Server on the live server.

Testing the website before compilation

To check if your website runs without using the **Virtual path provider** (to simulate a precompiled environment), you can disable the provider by adding the following key into the *appSettings* section of your web.config file:

```
<add key="CMSUseVirtualPathProvider" value="false" />
```

If your application runs correctly with the virtual path provider disabled, you should be able to run it after the precompilation.

Related topics:

- [Additional configuration tasks -> Configuration for Medium Trust environment](#)
- [Installation procedure -> Deployment to the live server](#)
- [Additional configuration tasks -> Installation on shared hosting server](#)

3.6.5 Visual Source Safe and Team Development

Kentico CMS can be used in team development environment as any other website project in Visual Studio. You can also use Microsoft Visual Source Safe (VSS) as you're used to: you simply add the website to VSS and then you need to check out/check in the files you want to modify.

In this case, all developers have their local copy of Kentico CMS installed, but they use the same VSS code and the same database as shown on the following picture:

Synchronization of memory objects between development machines

Kentico CMS caches some system objects (such as transformations, templates, etc.) in memory. It means that the memory on multiple development machines may not be synchronized and the developers may not see the latest version and they may even overwrite the work of other developers.

We recommend you to synchronize the memory objects between development machines using the [Web farm synchronization module](#).

Team Development without Visual Studio

If the developers do not modify the source code and use the portal engine development model, they do not even need to have the local copies of the web project and they do not need to use VSS. In this case, they can install a single instance of Kentico CMS on their web server and develop the website through the browser-based interface.

3.6.6 Opening a VS2005 project in VS2008

If you were using Visual Studio 2005 for your web project and wish to convert to Visual Studio 2008, all you need to do is:

1. Start **Visual Studio 2008**.
2. Click **File -> Open website...**
3. Choose the folder with your web project on the disk and click **OK**.

4. If you're asked if you wish to upgrade the project to a newer version of .NET Framework and Visual Studio, click **Next** and go through the wizard.

Compilation error

You may receive a compilation error saying there are different versions of the **System.Web.Extensions.dll** library in the Global Assembly Cache (GAC) and a temporary folder. In this case, you need to locate the file **bin/System.Web.Extensions.dll** in your web project and delete it.

3.7 Troubleshooting installation issues

3.7.1 Overview

You may encounter various issues during the installation. The following chapters may help you sort them out.

You may encounter problems in following areas:

- [SQL Server connection problems](#)
- [ASP.NET not working on Windows Server 2003](#)
- [Disk permissions problems](#)

Click one of the links to learn how to solve the issues.

3.7.2 SQL Server connection problems

You may encounter problems when entering the database connection details in the first step of database setup:

Error 1: Establishing connection to the server

Error message:

An error has occurred while establishing a connection to the server. When connecting to SQL Server 2005, this failure may be caused by the fact that under the default settings SQL Server does not allow remote connections. (provider: Named Pipes Provider, error: 40 - Could not open a connection to SQL Server)

Troubleshooting:

1. Make sure the SQL Server name or IP address is correct. In some cases, using one of the following values may help:

- your computer name
- localhost

- 127.0.0.1
- (local)

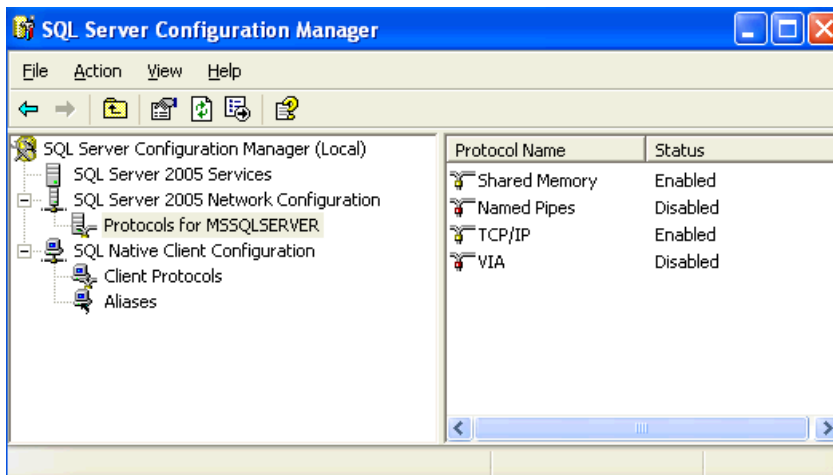

2. Make sure the server has Microsoft SQL Server 2005 or 2008 installed and running.

3. Make sure you are using the appropriate instance of the SQL Server in case you are using different instances of SQL Server. The instance name must be entered as `myserver\myinstance` (please note there's a backslash \).

4. If you're using Microsoft SQL Server Express 2005 with default installation settings, the correct server name is `.\sqlexpress` or `computername\sqlexpress`.

5. Make sure the access to the database server is not blocked by some firewall (the default port number for TCP/IP protocol is 1433).

6. If you're using **SQL Server 2005** (especially the Express Edition), some protocols are disabled by default. You may need to go to **Start menu -> All Programs -> Microsoft SQL Server 2005 -> Configuration Tools** on the computer where the SQL Server is installed and start **SQL Server Configuration Manager**. Then, go to SQL Server 2005 Network Configuration and enable the TCP/IP protocol:

7. You may also need to enable the TCP/IP protocol in the **SQL Native Client Configuration -> Client Protocols** section:

Error 2: Login failed for user 'xy'

Error message:

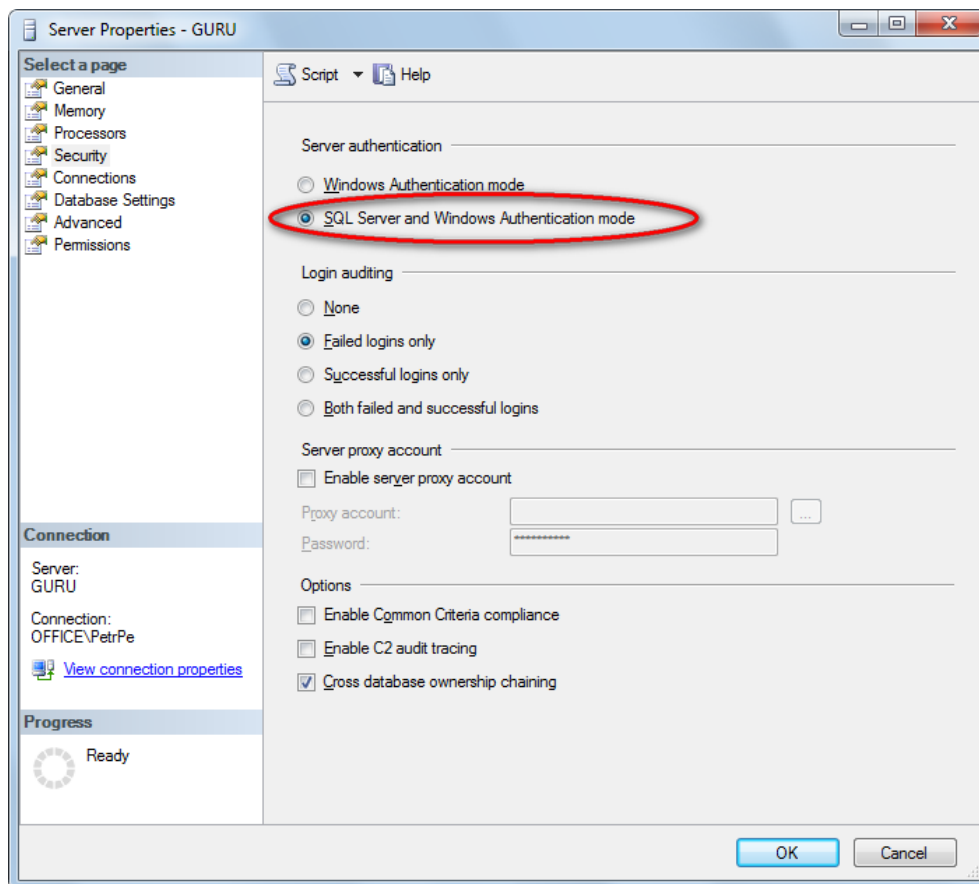

Login failed for user 'xy'

Troubleshooting for SQL Server account

If you're using SQL Server account with password, make sure you are using a valid user name and password. The login must be created on the server, it must be enabled and permissions to connect to the server must be granted to it. You can check the user account in Enterprise Manager/SQL Server Management Studio -> Server -> Security -> Logins:

Also, check the **Server Properties -> Security** dialog in Enterprise Manager/SQL Server Management Studio and make sure your server supports **SQL Server and Windows Authentication mode**:

Troubleshooting for Windows Authentication account

If you're using Windows Authentication account, the situation may be a little more complex and may require you to contact your network administrator. ASP.NET applications run under some particular local or domain account. This current account is displayed on the screen:

Use integrated Windows authentication (ASP.NET account: NT AUTHORITY\NETWORK SERVICE)

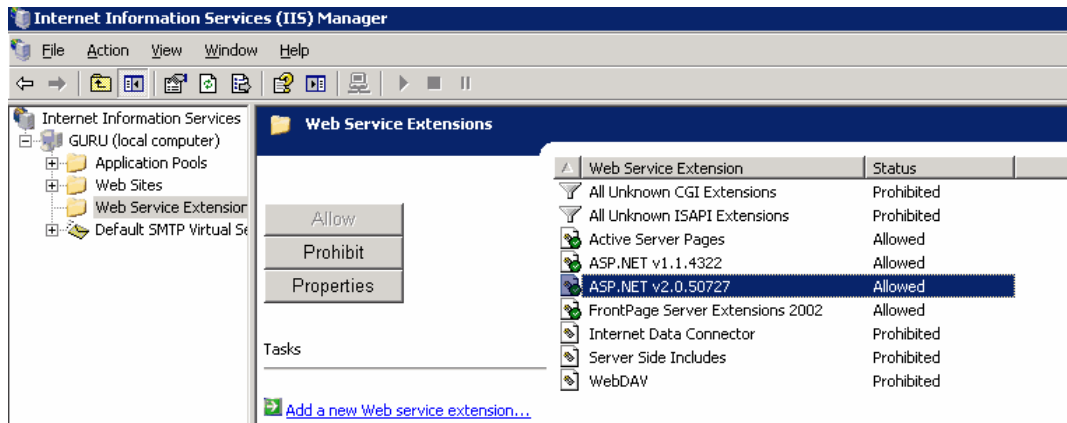

This account must have its own login with Windows authentication in the SQL Server. You can create the login in **Enterprise Manager\SQL Server Management Studio -> Security -> Logins** and grant appropriate permissions on the server to it. If your SQL Server is located on a different machine than your web server, you may need to configure your web application so that it runs under some domain account, rather than local account so that you can the login in the remote SQL Server.

If you do not succeed to configure Windows authentication, you may want to enable Windows and SQL Server Authentication on your SQL Server and use SQL Server account instead. You can learn more about SQL Server authentication in the **Troubleshooting for SQL Server account** section earlier in this chapter.

3.7.3 ASP.NET not working on Windows Server 2003

If you get the *404: Page not found* error or a similar error every time you request some ASPX page on your server and this is the first ASP.NET application installed and running on your server, it may be caused by configuration of Web Services Extensions on Windows Server 2003.

Go to **Control Panel -> Administrative tools -> Internet Information Services (IIS) Manager**, click **Web Service Extensions** and make sure that **ASP.NET 3.5** (or higher depending on the version you use) is **Allowed** (IIS 6 may display the **ASP.NET version as 2.0.50727** even if you have a higher one installed and registered) as shown in the following screenshot:

3.7.4 Disk permissions problems

3.7.4.1 Disk permissions problems

Kentico CMS is able to perform most operations without writing to disk. However, there are situations when the web application needs to write to the disk for optimal operations or performance, such as importing/exporting a site or storing uploaded files in the file system (which is optional).

If you receive the error message depicted below, saying that the web application cannot write to disk, you need to grant the **Modify** permissions on the whole website folder to the appropriate user account.

User account of the web application

The web application runs under a user account that depends on your environment. Please note that the accounts listed below are just the default ones, they may be different in your environment. However, the

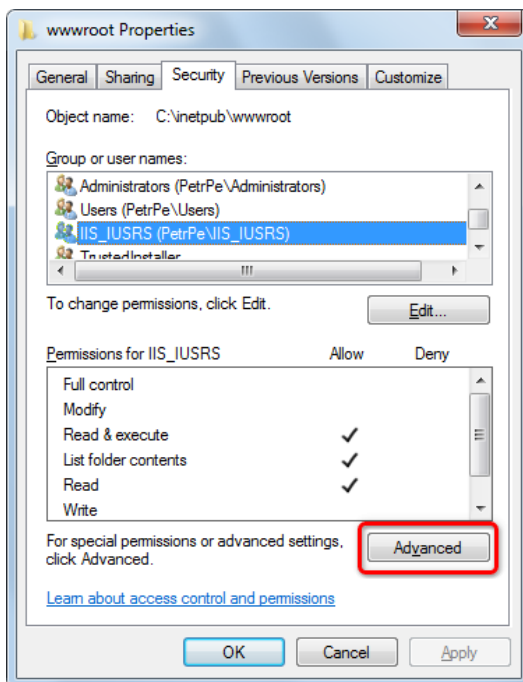

name of the account is always displayed with the error message, as highlighted in the screenshot above.

- On [Windows 7](#), the user account is the local **IIS_IUSRS** account by default.
- On [Windows Vista or Server 2008](#), the user account is the local **NETWORK SERVICE** account by default.
- If you're using **Visual Studio's** built-in web server, it is running under your account.

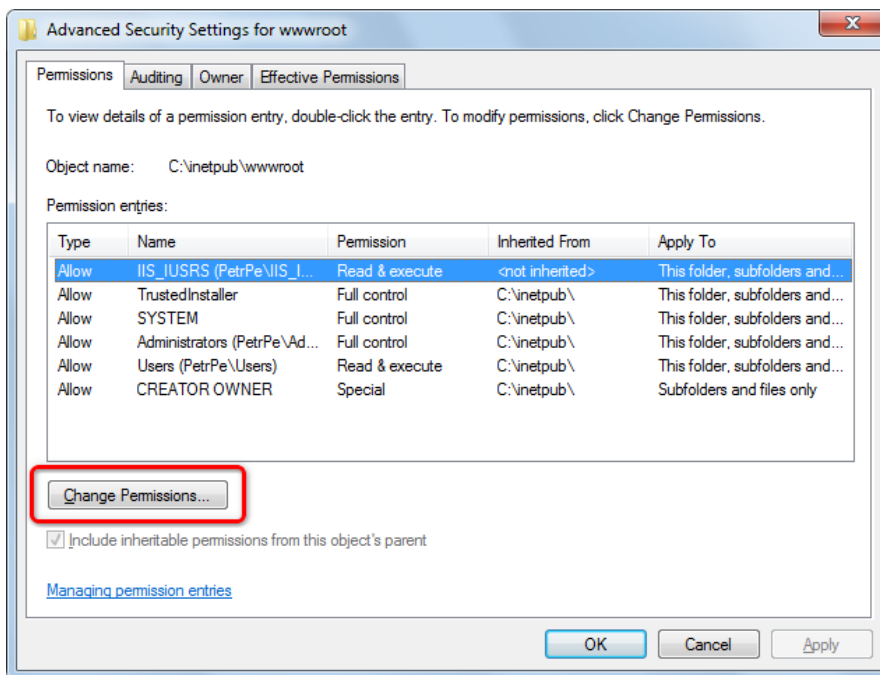

You can see the name of the user account under which the application runs in **Site Manager -> Administration -> System** dialog.

3.7.4.2 Solution on Windows 7

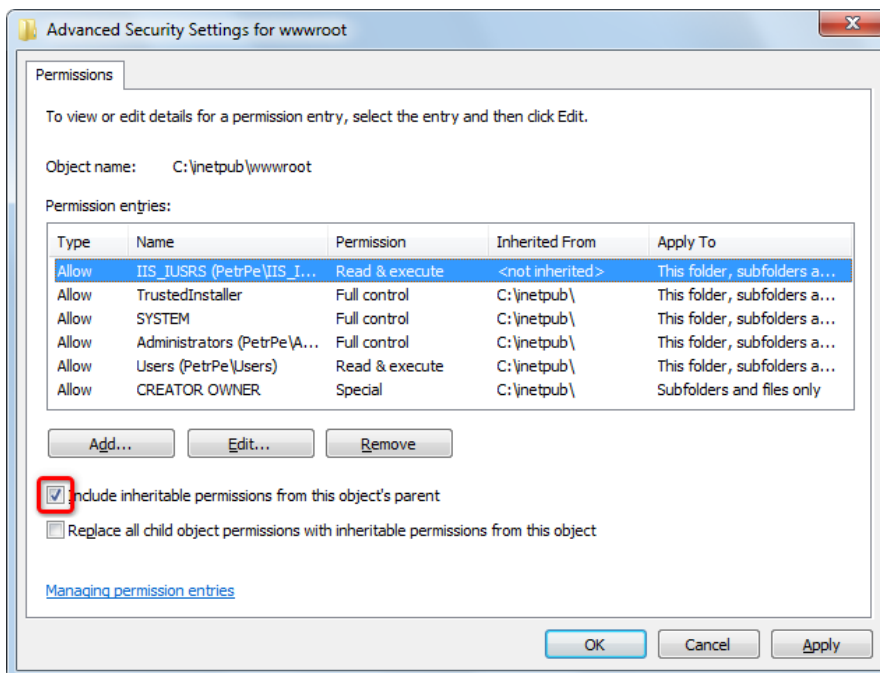

1. Open Windows Explorer, locate the folder with your website, right-click the folder and display its **Properties**. Choose the **Security** tab.
2. Verify that the account that you need to grant the permissions to (the name was displayed with the error message) is present in the **Group or user names** list. If not, click **Edit**, click **Add** in the pop-up dialog and add the required account to the list. Close the pop-up dialog when finished.
3. Back on the **Security** tab of the folder properties, select the appropriate account and click **Advanced**.

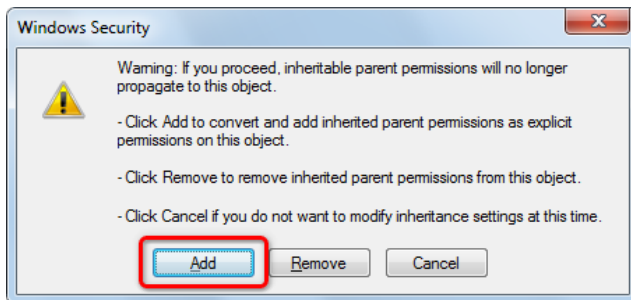

4. In the pop-up dialog, select the account again and click **Change Permissions**.

5. Disable the **Include inheritable permissions from this object's parent** option.

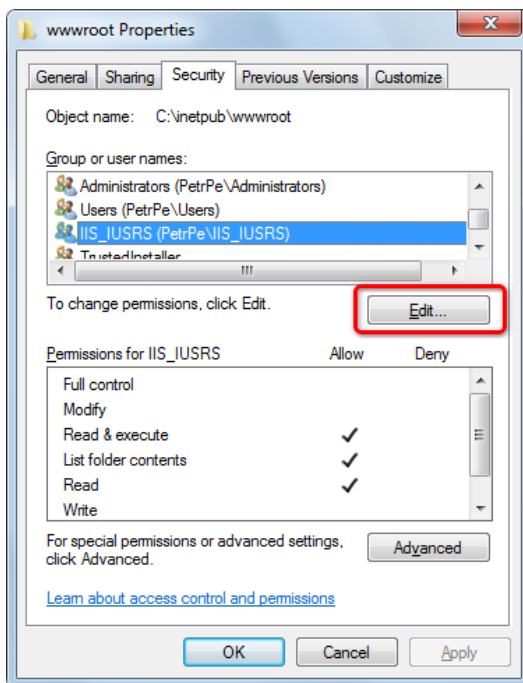

6. In the pop-up dialog, click **Add**.

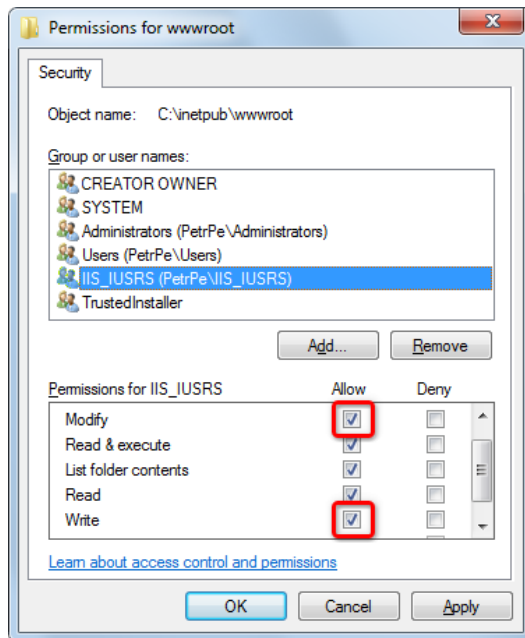

7. When the dialog closes, click **OK** to close the dialog under it. Click **OK** again to close the dialog under the previous one.

You are back in the folder properties dialog now. Select the account and click **Edit**.

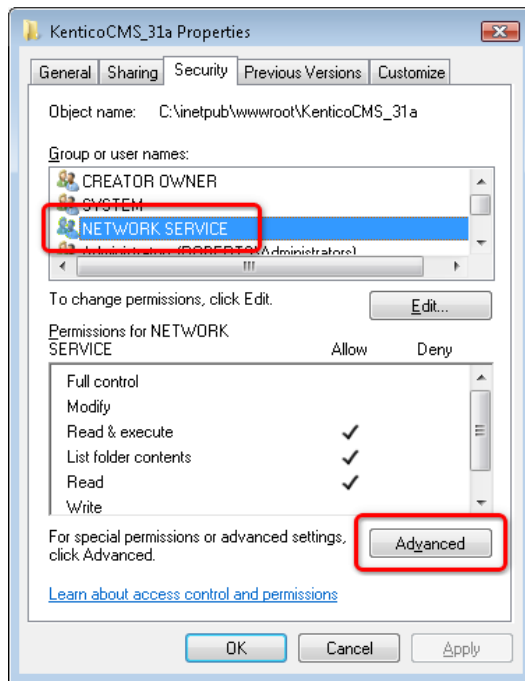

8. Check the **Allow** check-box for the **Write** and **Modify** permissions and click **OK**.

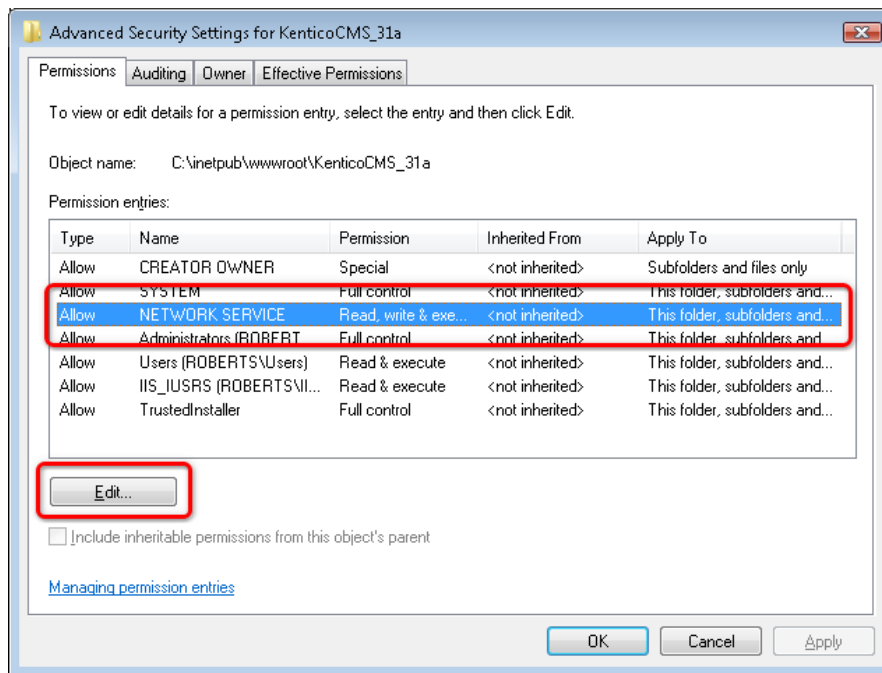

9. You have assigned the account with the required permissions. Kentico CMS should now be able to perform all disk write operations and therefore work correctly.

3.7.4.3 Solution on Windows Vista or Server 2008

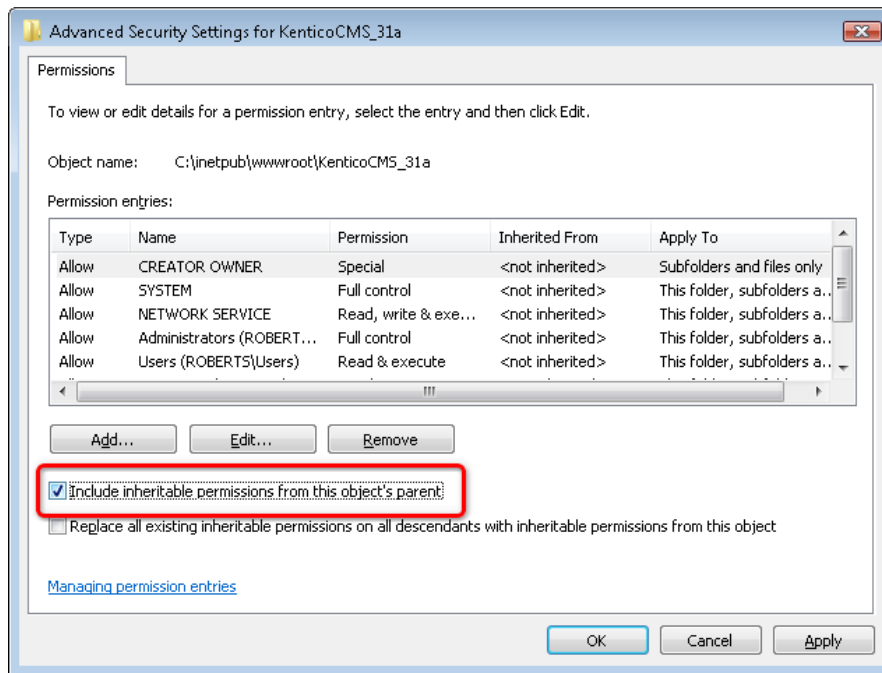

1. Open Windows Explorer, locate the folder with your website, right-click the folder and display its **Properties**. Choose the **Security** tab.
2. Verify that the account that you need to grant the permissions to (the name was displayed with the error message) is present in the **Group or user names** list. If not, click **Edit**. In the pop-up dialog, click **Add** and add the required account to the list. Close the pop-up dialog when finished.
3. Select the required account and click **Advanced**.

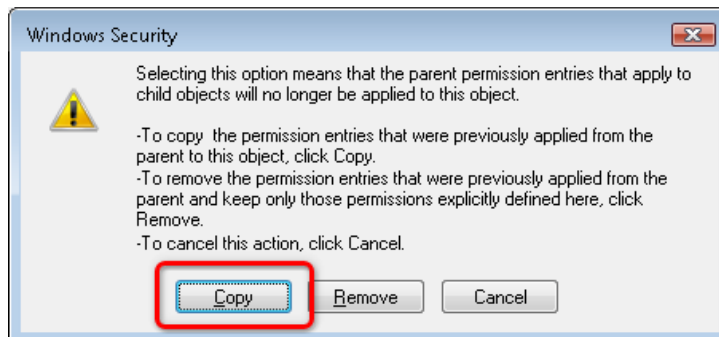

4. In the pop-up dialog, select the account again and click **Edit**.

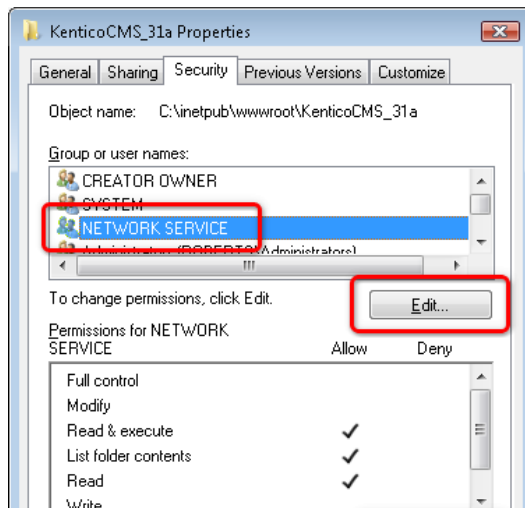

5. Disable the **Include inheritable permissions from this object's parent** option.

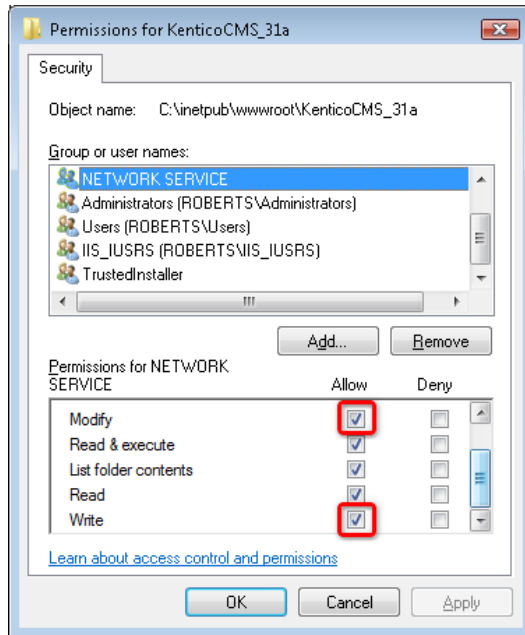

6. On the pop-up dialog, click **Copy**.

7. When the dialog closes, click **OK** to close the dialog under it. Click **OK** to close the dialog under the previous one. You are back in the folder properties dialog now. Select the account again and click **Edit**.

8. Check the **Allow** check-box for the **Write** and **Modify** permission and click **OK**.

9. You have assigned the account with the required permissions. Kentico CMS should now be able to perform all disk write operations and therefore work correctly.

3.8 System backup and recovery

Backup

To backup the data of Kentico CMS instance, you need to:

1. Backup the Kentico CMS database.
2. Backup the files of the Web application.

Recovery

To recover the system, you need to:

1. Recover the Kentico CMS database.
2. Recover the website files and create a virtual directory for it.

3.9 Silent Install

3.9.1 Overview

Silent Install is a tool which enables you to install Kentico CMS directly from a command line, without any user interface and user interaction involved. It also allows you to modify an existing installation and add or remove components contained in this installation. You only need to prepare a configuration XML file and execute a command from the command line with this XML file as a parameter.

The main purpose of the tool is the possibility of automated installation and modification of Kentico CMS.

Silent Install is capable of substituting the whole installation procedure including:

- [Setup \(KenticoCMS.exe\)](#) - Silent Install installs the program files to a specified location on your hard drive.
- [Web Installer](#) - Silent Install creates a new web project and optionally configures IIS.
- [Database setup](#) - Silent Install creates a new database with system tables and basic data on your SQL server.
- [New site wizard](#) - Silent Install allows you to install websites based on available web templates.

You can download a ZIP package containing the Silent Install tool and sample XML files from the following location:

- <http://www.kentico.com/downloads/SilentInstall.zip>.

Silent installation procedure

1. Create a configuration XML file using a text editor.
 - You can use any of the sample XML files stored in the *Examples* folder within the *SilentInstall.zip* package and edit it to suit your needs.
 - The *Examples* folder also contains the *SilentInstall.xsd* file, which is an XML schema file defining the configuration XML file format. You can use it to validate the XML configuration file you have created.
 - You can find a reference on the required format of the configuration XML file in the [XML configuration](#) topic.
2. Copy the XML file to the folder containing Kentico CMS installation files.
3. Execute a command with the **SilentInstall.exe <configuration XML file name>.xml** syntax in the folder.

```
SilentInstall.exe CorporateSite.xml
```

The installation will be executed and carried out according to the configuration in the XML file.

3.9.2 XML configuration

This topic provides reference on the format of the XML file used as a source of the Silent install configuration.

Instead of creating one from scratch, it is highly recommended to use one of the sample XML files located in the *Examples* folder within the *SilentInstall.zip* package and customize it according to your specific needs.

The *Examples* folder also contains the *SilentInstall.xsd* file, which is an XML schema file defining the configuration XML file format. You can use it to validate the XML configuration file you have created.

Boolean attribute values

You can enter the boolean attribute values in these ways:

True value	False value
TRUE	FALSE
Yes	No
1	0

Supported macros in attribute values

You can use macros in the following XML attributes to get the respective values dynamically:

- SilentInstall -> LogFile
- Setup -> SetupFolder
- IIS -> TargetFolder
- SQL -> Database

Macro expression	Description	Sample resolved value
{%shortversion%}	Build number of the installed Kentico CMS version.	4709.166
{%longversion%}	Full version number of the installed Kentico CMS version.	7.0.4709.166
{%programfiles%}	Path to the <i>Program Files</i> folder on your local drive.	c:\Program Files (x86)\
{%machine%}	Name of the current machine.	PC-01
{%username%}	User name of the currently used account.	Andy
{%date%}	Current date in format <i>yyyy-mm-dd</i> .	2012-12-21

{%time%}	Current time in format <i>hh:mm:ss</i> .	14:53:23
----------	--	----------

Note that these macros are completely independent of standard Kentico CMS macros that can be used in the system's user interface.

SilentInstall XML element

The root element of the XML file is *SilentInstall*. Using the attributes of this element, you can configure general options of the installation:

Attribute name	Description	Accepted values
ShowProgress	Determines if the Silent Install tool displays the progress of the installation or not. <ul style="list-style-type: none"> • COMMAND_PROMPT - the progress is shown in the command line. • NO - the progress is not shown anywhere. 	NO COMMAND_PROMPT
Log	Enables logging of import progress to a file.	TRUE FALSE
OnError	Determines the action the tool performs when an error occurs during the installation.	STOP CONTINUE
LogFile	File where the log is saved. The default value is <i><installation path>\setup.log</i> .	full path to a file
CheckRequirements	Indicates, if the tool checks whether the correct .NET version is installed on the target machine before executing the installation. If the installed .NET version is not matching, the installation is aborted.	TRUE FALSE

Setup XML element

The first sub-element that should be present under *SilentInstall* is *Setup*. This element allows you to configure the general options by means of attributes:

Attribute name	Description	Accepted values
NET	.NET version installed on the target machine.	3.5 4.0 4.5
SetupFolder	Folder where the tool installs the Kentico CMS setup files (not the web project).	full path to a folder
WebProject	Determines if the project is installed as an ASP.NET web site, ASP.NET web application, or as a Windows Azure project.	WebSite WebApplication WindowsAzure
InstallContextHelp	Indicates, if Context help (built-in documentation accessible by clicking the icon throughout the user interface) is installed with the project.	TRUE FALSE

OpenAfterInstall	Indicates, if the tool opens the newly installed website in a new browser window when the installation finishes.	TRUE FALSE
RegisterCounters	Indicates, if performance counters for Health Monitoring should be registered. This option has the same functionality as the Register performance counters for Health Monitoring option in Step 4 of Kentico CMS Web Installer.	TRUE FALSE
InstallWinServices	Indicates, if the tool installs Kentico CMS Windows services in Windows.	TRUE FALSE
DeleteExisting	Indicates, if the the tool deletes the existing setup files in a folder with the same name as set in the <i>SetupFolder</i> attribute.	TRUE FALSE

IIS XML element

The *IIS* sub-element is also located directly under *SilentInstall*. Its attributes allow you to adjust IIS-related settings of the installation:

Attribute name	Description	Accepted values
AppPool	Type of IIS application pool which the new website will use. <ul style="list-style-type: none"> • Native - the application pool uses the mode that is default in the installed IIS version (<i>Classic</i> for IIS versions prior to 7 and <i>Integrated</i> for IIS 7 and higher). 	Native Classic Integrated
WebSite	Name of the website in IIS.	string value
TargetFolder	Path to the folder where IIS websites are stored (typically <i>C:\inetpub\wwwroot</i>).	full path to a folder
RootFolder	Indicates, if the tool installs the website into the IIS root. <ul style="list-style-type: none"> • TRUE - the website is installed into the IIS root and no virtual directory is created. • FALSE - the website is installed into a new virtual directory. 	TRUE FALSE
DeleteExisting	Indicates, if the the tool deletes an existing website with the same name as set in the <i>WebSite</i> attribute.	TRUE FALSE
Location	Determines where will the tool install the web files: <ul style="list-style-type: none"> • Local - on a local IIS server. • VisualStudio - on a build-in server which is 	Local VisualStudio Remote Modify

	<p>included in Visual Studio or Visual Web Developer Express Edition.</p> <ul style="list-style-type: none"> • Remote - copies the files into a temporary folder on your disk. You will need to copy these files to your production server. • Modify - modifies an existing installation (adds or removes components) on a local machine. <p>See Kentico CMS Developer's Guide -> Installation procedure -> Web installer for more details.</p>	
--	---	--

SQL XML element

The *SQL* sub-element of the *SilentInstall* element allows you to configure database-related settings of the installation. It covers the configuration that is normally performed in Step 1 and Step 2 of the **Database setup**.

Attribute name	Description	Accepted values
Database	Name of the target database.	string value
SqlName	User name of the account used for access to the SQL server.	string value
SqlPswd	Password for the SQL server account.	string value
Server	Name of the target SQL server.	string value
Operation	Determines whether the tool creates a new database modifies an existing one. The default value is New .	New Modify
Authentication	Type of the authentication used to access the SQL server.	SQL WINDOWS WIN
DeleteExisting	Indicates, if the tool deletes an existing database with the same name as set in the <i>Database</i> attribute.	TRUE FALSE

Notification XML element

The *Notification* sub-element allows you to configure the automatic notification e-mail messages. The system sends them to the specified e-mail address when an error occurs during the installation.

Attribute name	Description	Accepted values
Enabled	Indicates, if the tool sends notification e-mails when an error occurs during the installation.	TRUE FALSE

From	E-mail address of the sender of the notification e-mail. This value is required in the <i>Notification</i> element.	e-mail address
To	E-mail address of the recipient of the notification e-mail. This value is required in the <i>Notification</i> element.	e-mail address (or multiple addresses separated by a semicolon (;))
Server	Name of the SMTP server used to send out the notification e-mail.	string value
Subject	Subject of the notification e-mail message.	string value
UserName	User name of the SMTP server account used to send out the notification e-mail.	string value
Password	Password for the SMTP server account used to send out the notification e-mail.	string value
SSL	Indicates, if SSL is used when sending the notification e-mail.	TRUE FALSE
AttachLogFile	Indicates, if the tool includes a compressed installation log file as an attachment.	TRUE FALSE

WebTemplates, UICultures, Modules and Dictionaries XML elements

The *WebTemplates*, *UICultures*, *Modules* and *Dictionaries* elements allow you to configure which web templates, UI cultures, modules and dictionaries will be installed by the Silent Install tool. If you chose to modify an existing Kentico CMS installation (by specifying the *Modify* value for the *Location* attribute), you can also use these elements to add new components to the existing installation or to remove unwanted components.

Each of these elements only has a single attribute:

Attribute name	Description	Accepted values
type	<ul style="list-style-type: none"> • InstallAll - the tool adds all components of the type to the installation. However, you can limit added components in the sub-elements by specifying <i>No</i> or <i>Remove</i> in their <i>operation</i> attribute. • RemoveAll - the tool removes all components of the type from the installation. However, you can limit removed components in the sub-elements by specifying <i>No</i> or <i>Add</i> in their <i>operation</i> attribute. • Mix - only configuration in the <i>operation</i> attribute of the sub-elements will be taken into account. 	Mix InstallAll RemoveAll

Each of the *WebTemplates*, *UICultures*, *Modules* and *Dictionaries* elements can have any number of sub-elements named *WebTemplate*, *UICulture*, *Module* or *Dictionary*. These sub-elements represent particular web templates, UI cultures, modules or dictionaries and have the following attributes:

Attribute name	Description	Accepted values
name	Name of the web template, UI culture, module or dictionary.	string value
operation	The operation that should be performed with the component: <ul style="list-style-type: none"> • Add - the component is added to the installation. • Remove - the component is removed from the installation. • No - no action is taken. 	Add Remove No

WebSites XML element

The *WebSites* element lets you configure which websites will be installed based on available web templates. It has no attributes itself — it only contains *WebSite* sub-elements representing particular websites to be installed. Each *WebSite* sub-element has the following attributes:

Attribute name	Description	Accepted values
domain	Domain used by the website.	string value
displayname	Name of the website used in Kentico CMS user interface.	string value
codename	Name of the website used in code.	string value
webtemplatename	Code name of the chosen web template.	available web template code name
runsite	Indicates, if the tool should run the website after it is imported to the system.	TRUE FALSE

Licenses XML element

You can add any number of *License* sub-elements under the *Licenses* element. These sub-elements represent particular licenses for separate domains. You should state the domain in the *domain* attribute and add the actual key as a sub-element wrapped in a CDATA enclosure.

Example

Here you can find an example of the configuration file. It installs Kentico CMS 7.0 with the sample Corporate site website and all the available web templates, UI cultures, modules and dictionaries.

```

<SilentInstall ShowProgress="COMMAND_PROMPT" Log="TRUE"
OnError="STOP" LogFile="{%programfiles%}\KenticoCMS\7.0\setup.log"
CheckRequirements="TRUE">
  <Setup NET="4.5" SetupFolder="{%programfiles%}\KenticoCMS\7.0"
InstallContextHelp="TRUE" />
  <IIS AppPool="Native" Website="Default Web Site" TargetFolder="c:
\inetpub\wwwroot\KenticoCMSCorporateSite70" RootFolder="FALSE"
Location="Local" />
  <Sql SqlPswd="password" Database="KenticoCMSCorporateSite70"
Operation="New" SqlName="login" Server="Artemis"

```

3.10 Uninstallation

To uninstall Kentico CMS from your computer, open **Start -> Control Panel -> Programs and Features**. Right-click **Kentico CMS** and choose **Uninstall** from the context menu.

The uninstaller will delete files created on your computer except the deployed instances of Kentico CMS - it means that the database instances and the website folders will not be removed and you have to delete them manually if needed.

Part

IV

Content management

4 Content management

4.1 Overview

The content of a website's pages can be managed through a browser-based, WYSIWYG user interface. Editors need to have the appropriate permissions and must first authenticate themselves by signing in with a user name and password.

Links for accessing the user interface

The Kentico CMS user interface, i.e. **CMS Desk**, **On-site editing mode** and **Site Manager**, can be accessed via the links described below, where the first part of the link URL is dependent on the site's domain name and the virtual directory specified during the installation. If the default URL of your website is *http://localhost/KenticoCMS*, then the following URLs may be used:

- **CMS Desk**: *http://localhost/KenticoCMS/CMSDesk*
- **On-site editing**: *http://localhost/KenticoCMS/CMSEdit*
- **Site Manager**: *http://localhost/KenticoCMS/CMSSiteManager*

Default user name and password

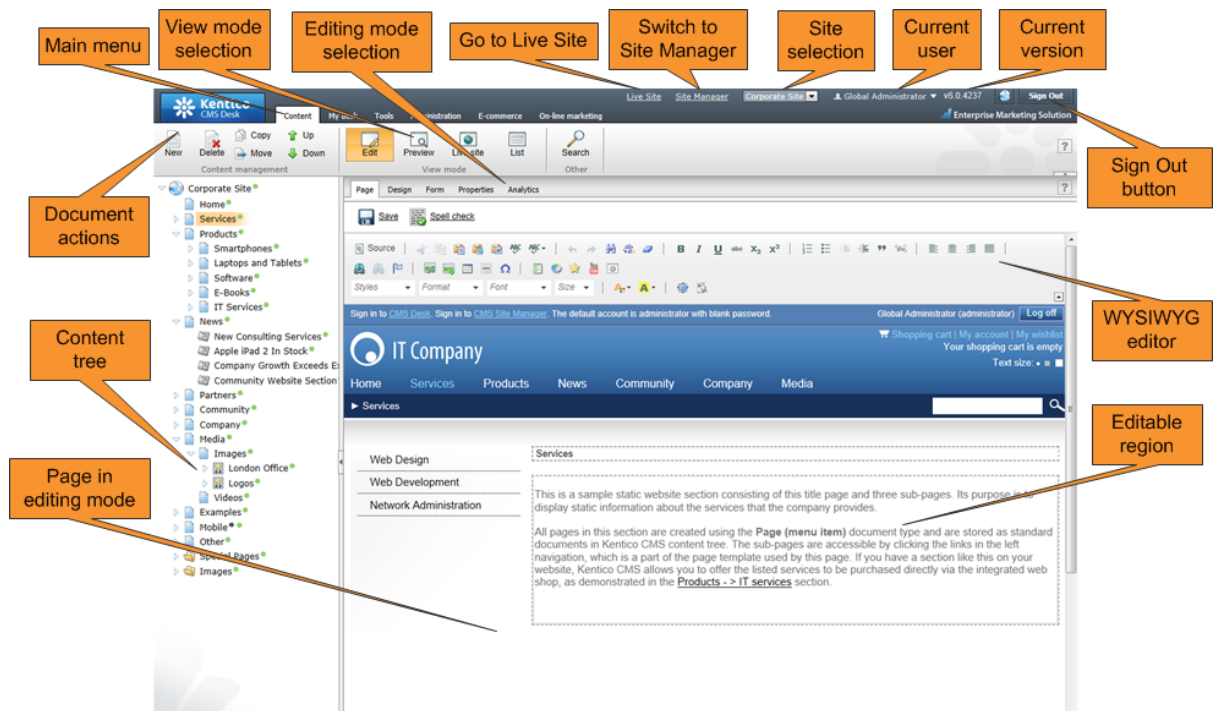

To log in to a website's Kentico CMS interface for the first time, use the default logon credentials:

- The default user name is **administrator**.
- The default password is **blank (no password)**.

It is highly recommended to change the password after you finish the installation.

User interface overview

The following figure shows the CMS Desk user interface.

The user interface consists of the following main sections and features:

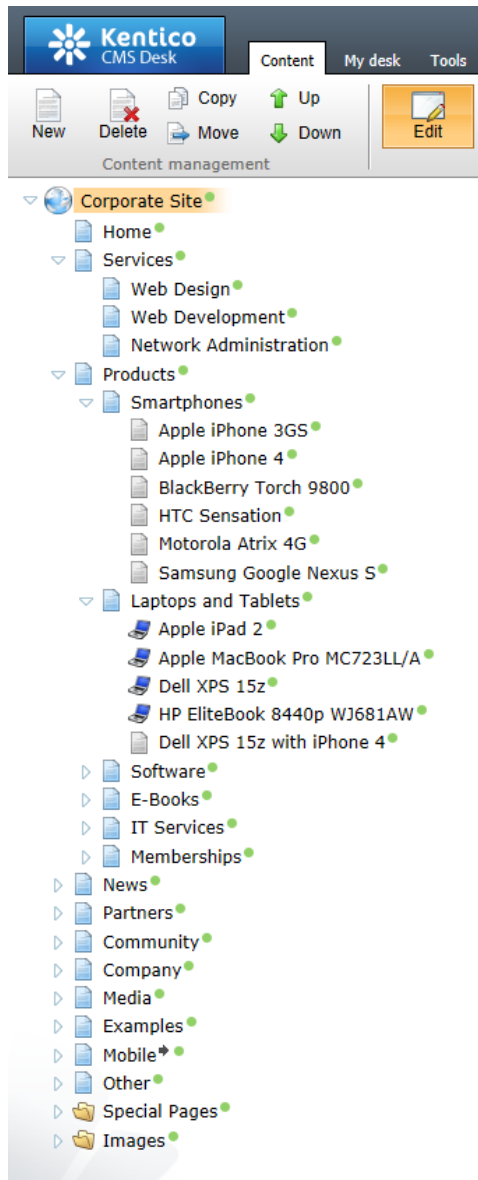

- **Main menu** with Content, My Desk, Tools, Administration, E-commerce and On-line marketing tabs.
- **Content tree** that represents the site map of the website. It allows you to organize the site's structure or select a specific document for editing in the content section.
- **Document actions** toolbar with buttons for creating new documents, deleting, copying, moving and sorting documents.
- **View mode selection** - allows you to choose between editing, preview, live site view and list view.
- **Editing mode selection** - you can choose to edit page content, design the page template, edit the document's fields, product properties or document properties.
- **Live Site** - this action redirects you to the title page of the currently edited website, logged under the same user account that you used to log into CMS Desk. This is a more convenient way than using the **Sign out** button and logging in on the live site afterwards.
- **Site Manager** - redirects you to Site Manager, the other part of the system's administration interface. This option is only available for global administrators.
- **Site selection** - this drop-down list is used to select the currently edited website. Only those websites that the current user can edit are available in the list.
- **Current user** - displays the name of the current user.
- **Current version** - version number of the Kentico CMS installation.
- **Sign Out button** - clicking this button logs you out of the user interface and redirects you to the title page of the live site. This button is only displayed if *Forms authentication* is used. When using *Windows authentication*, the link is not displayed.
- **WYSIWYG editor** - allows you to edit text, change its formatting and insert graphics or other items. It is available for **Editable regions** on the *Page* tab, as well as when editing document fields on the *Form* tab.
- **Page in editing mode** - this is where you can view and edit the document selected in the content tree, in the mode selected in the view mode and editing mode toolbar.

[edit content?](#)

4.2 Organizing pages, files and documents

All content in Kentico CMS is stored in a **tree hierarchy**. You can see the content tree on the left in **CMS Desk -> Content**:

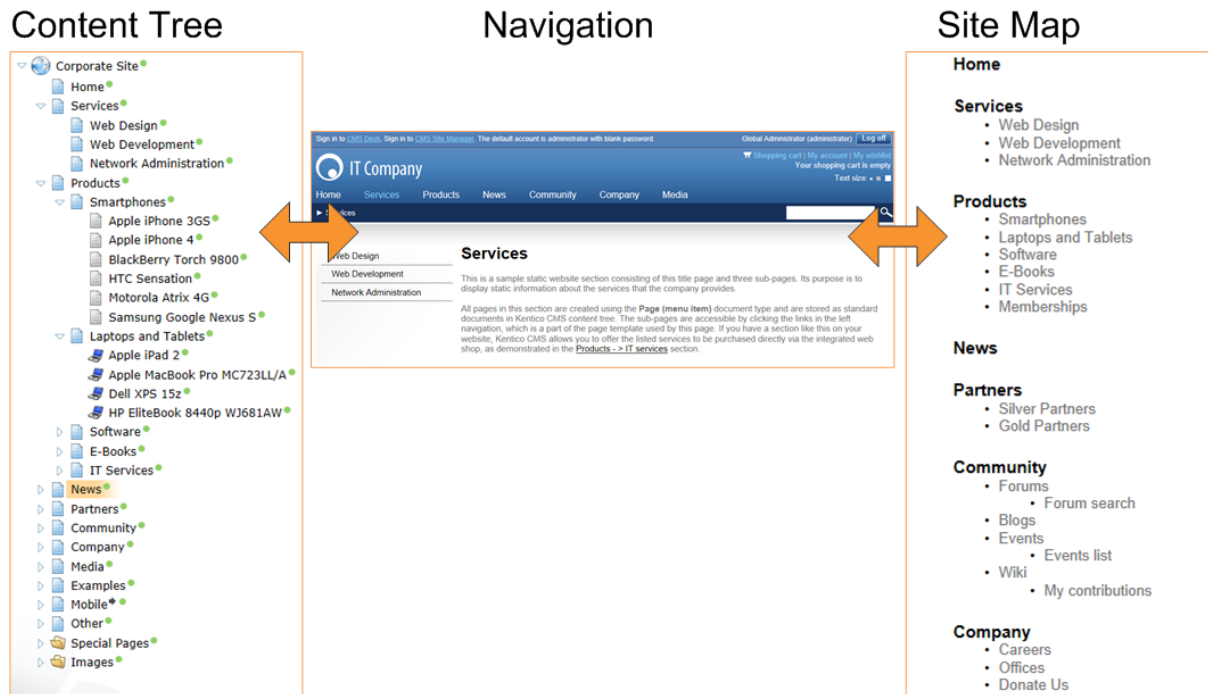

The tree hierarchy provides many advantages:

- It organizes the page in a logical structure that represents the (dynamic) site map.
- It ensures easy-to-navigate information architecture.
- It provides a logical categorization of pages and documents.
- The content of sub-pages can be nested inside the parent pages.
- The position of the document is reflected in its URL, which consists of the document path in the tree

hierarchy,
such as `/products/lcd-displays/nec-52vm.aspx`.

- The structure allows you to define permissions (and other types of settings) for a particular site section and have underlying items inherit them.

The following figure shows how the content tree defines the navigation and site map of the website:

Document types

Each document is of some type - it can be a page, a news item, an article, a product specification, etc. Each document type has its own:

- fields (data structure)
- editing form layout
- transformations (appearance and design)
- queries

and other settings.

Document types are fully customizable - you can add, modify and delete custom fields. The advantage of using custom document types is that you can define custom structure of documents and store content (data) separated from design. This can be done in **Site Manager -> Development -> Document types**.

More details can be found in the [Document types](#) chapter.

Pages and documents

All items in the content tree are in fact documents. However, there is a special type of documents

called **pages**. The pages (such as */Home*, */Products*, */Services*) display the content and they are displayed as menu items by default (this can be also customized).

Unlike pages, structured documents (such as the news items under the */News* section of the sample Corporate Site) contain structured data that can be displayed on the pages.

While pages usually contain unstructured content in the form of editable regions that can be edited on the **Page** tab, the structured documents contain structured and typed data stored in document type-specific database tables and edited on the **Form** tab.

You will typically use **structured documents** when you need to display a **list of items**, such as list of news, list of products, etc.

Page versus Form

There are two types of content: content stored in editable regions on the page and content stored in forms. The following table compares both approaches:

	Editable regions on the page	Form
Content structure	Simple content structure, only text-based content.	Complex content structures, typed data, such as text, date-time, numbers, etc.
Validation	Only basic validation rules for minimum and maximum length.	Complex validation rules, including regular expressions and custom form controls with custom validation code.
Display	The content is displayed in the context of the page providing truly WYSIWYG editing.	The content is displayed using XSLT or ASCX transformations using special controls or web parts.
Storage	The content is stored in a single XML document in the document properties.	The content is stored in a separate database table. Each field has its own column. The data can be easily modified using SQL queries or API.
Examples of use	<p>Home page, contact page.</p> <p>Generally: pages with simply structured or unstructured, text-only content.</p> <p>The editable regions are usually used only in connection with documents of type Page (menu item).</p>	<p>News, product specification, event details, job opening, etc.</p> <p>Generally: pages with structured content where you need to separate content from design and keep the content in its original data type.</p> <p>The form-based content is usually used in connection with documents of type News, Product, Article, etc.</p>

Organizing media files

There are two types of files you need to manage on the website:

- **Website design files** - images and flash files that are a part of the website's design, such as logo, background or menu images, etc. These should be stored in the file system as a part of the application theme as explained in the [App themes](#) topic.
- **Media files and document files** - images, flash movies, word documents, PDFs, etc. that are published on the website and are part of the content editable by editors. These should be uploaded to the content tree as documents so that they can be managed by the content editors and so that you can apply all content-related features (permissions, workflow, versioning, multilingual support) to files as well.

You can find more details on files in the [File management](#) chapter.

See also: [Where is the content stored?](#)

4.3 Storing data effectively

When storing data in Kentico, you should consider whether you want to store it in **Documents**, **Custom tables** or **Media libraries**. Each of the options was created with different use in mind and thus provides various advantages over the others. Refer to the following text to see a comparison of the approaches:

Documents

Documents offer a hierarchical tree data structure for storing data. You can use them in a workflow or to hold multilingual content without having to use localization macros.

Custom tables

Custom tables provide you with better performance than Documents when storing data in a flat structure. Consider using custom tables when you need to store a large amount of structured items. To localize custom table data, you need to use localization macros.

[Learn more about custom tables.](#)

Media libraries

Media libraries are designed to store large files — not exclusively of media character — such as videos, high-res images or packaged files. You can access media library files without overhead as there is no need to query a database in order to access them.

[Learn more about Media libraries.](#)

Comparing documents with custom tables

	Documents	Custom tables
Can hold traditional data types (int, float, ...)	✓	✓
Can hold binary stream data (files)	✓	✗
Can hold one-to-many data (radio buttons, drop-down lists)	✓	✓

Data can be formatted using transformations	✓	✓
Can be used as an E-commerce product	✓	✗
Can be displayed by 'Listings' web parts	✓	✓
Can be displayed by 'Navigation' web parts	✓	✗
Workflow	✓	✗
Versioning	✓	✗
Multilingual content	✓	✓ ¹
Hierarchical data structure	✓	✗
Each record has its own URL	✓	✗ ²
Data can be accessed using API	✓	✓
Importable / Exportable	✓	✓
Performance		
Recommended for large data sets when using flat data structure	✗	✓
Number of database tables that store the data	3+	1
Recommended for large binary data	✗	✗
Binary data can be stored in file system	✓	✗

1) You can translate custom table data using localization macros only.

2) You can access custom table records via listing web parts and query string URL parameters.

Comparing documents with media libraries

	Documents	Media libraries
Recommended for large binary data	✗	✓
Direct access to the data without querying database	✗	✓
Number of database tables that store the data	3+	2
Binary data can be stored in file system	✓	✓

4.4 Editing content (CMS Desk)

4.4.1 Basic content tree actions

This topic gives an overview of actions that can be performed with documents in the content tree. The actions can be executed either from the ribbon above the content tree or from a **context menu** displayed by right clicking a document.

The ribbon offers the following actions:

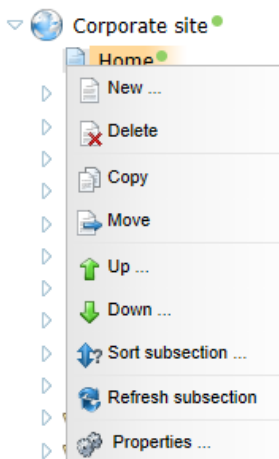

-  **New** - creates a new document under the currently selected one
-  **Delete** - deletes the currently selected document
-  **Copy** - creates a copy of the currently selected document in a location specified in a pop-up dialog

-  **Move** - moves the currently selected document to a location specified in a pop-up dialog
-  **Up** - moves the currently selected document above the one which is above it at the same level
-  **Down** - moves the currently selected document below the one which is below it at the same level
-  **Refresh content tree** - displayed only on mouse over of the content tree's top right corner; refreshes the content tree so that it shows the current content (useful e.g. for multi-user editing or when blog posts are published using [MetaWeblog API](#))

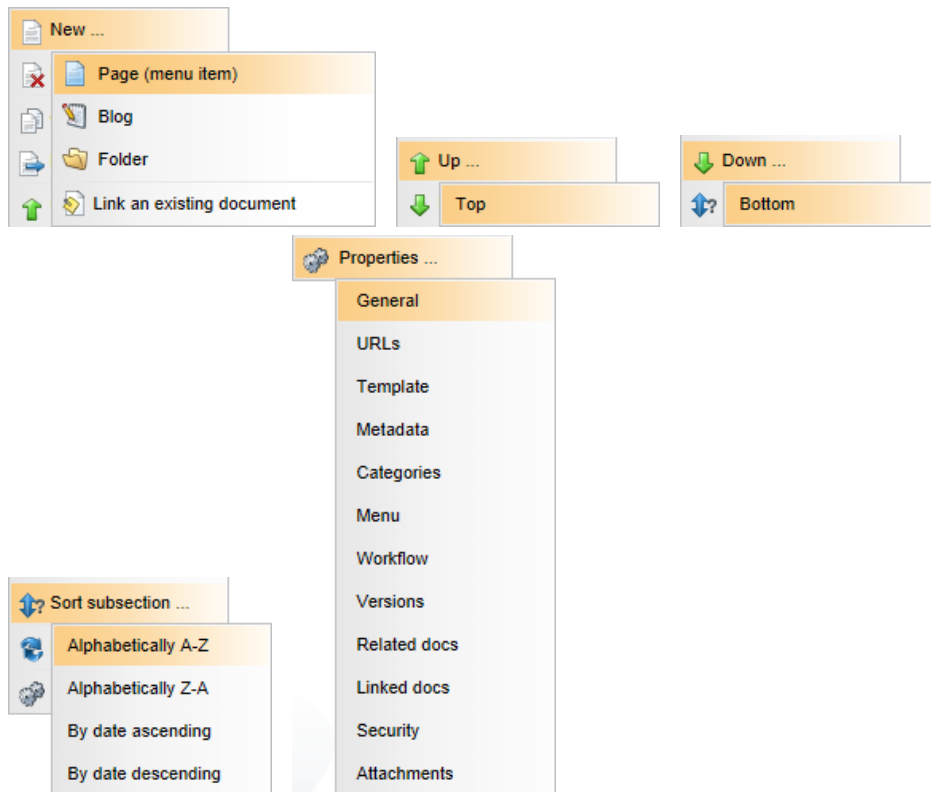

If you right-click a document in the content tree, a **context menu** appears. The menu offers the same actions as listed above, while the following extra options are available on top of the ones from the ribbon:

-  **Sort subsection** - sorts documents under the clicked one, while both ascending and descending order by date or alphabet is achievable
-  **Refresh subsection** - refreshes the content tree subsection under the clicked document (useful e.g. for multi-user editing or when blog posts are published using [MetaWeblog API](#))
-  **Properties** - opens the document's **Properties** -> **General** tab

If you right-click some of the items in the context menu or hold the mouse pointer above it, a **sub-menu with additional options** appears:

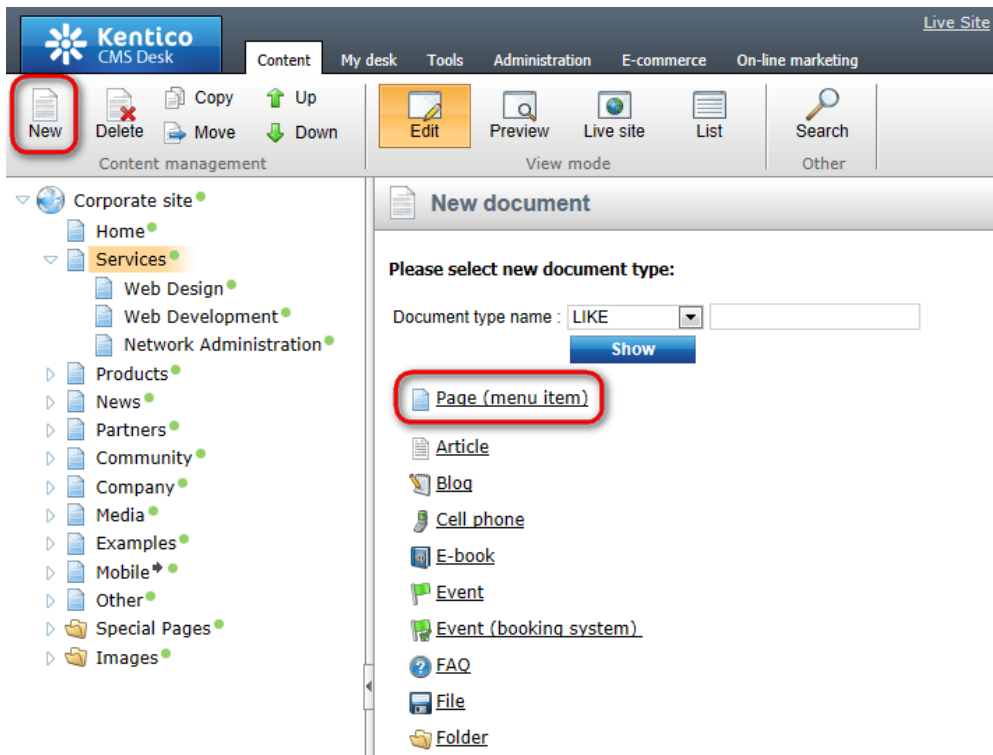

-  **New** - the sub-menu offers you the document type of the new document, while only allowed child document types are offered
-  **Up** - the sub-menu offers only the  **Top** option, which moves the document to the first position in the current tree level
-  **Down** - the sub-menu offers only the  **Bottom** action, which moves the document to the last position in the current tree level
-  **Sort subsection** - the sub-menu offers alphabetical sorting from A to Z and Z to A, and both ascending and descending sorting by date
-  **Properties** - the sub-menu offers shortcuts to open the document on particular sub-tabs of the **Properties** tab

4.4.2 Creating a new page

To create a new page, you need to go through the following steps:

1. In the content tree, select the document under which you want to place the new one. Click the **New** button in the main toolbar and choose the **Page (menu item)** document type.

2. Enter the new page's name into the **Page name** field and select the page template that will be used by the page.

The page template defines the layout and design of the new page. When creating a new page, you can choose from the following options using the check-boxes below the **Page name** field:

- **Use existing page template** - displays the catalog of reusable page templates and allows one to be chosen for the new page.
- **Use parent page template** - if selected, the new page will inherit the template used by its parent document.
- **Create a blank page with layout** - creates a new ad-hoc portal page template using the page layout selected below, and assigns it to the new page. If the **Copy this layout to my page template** box below the layout list is checked, a unique copy of the chosen layout will be generated for the template. Otherwise the template will use the specified shared layout. Any changes made to a shared layout affect all page templates that use it.
- **Create a blank page** - creates a new ad-hoc portal page template for the new page with a single web part zone and no other formatting (the same as the *Simple* page layout). You can learn more in [Content tree and page templates](#).

Choose **Use existing page template**, select the **Corporate Site - Simple text** template from the **Corporate Site** category, enter **IT training** into the **Page name** field and click **Save**.

The screenshot shows a web interface for selecting a page template. At the top, there is a text input field labeled "Page name:" containing the text "IT training". Below this, there are four radio buttons for selection: "Use existing page template" (which is selected), "Use parent page template", "Create a blank page with layout", and "Create a blank page".

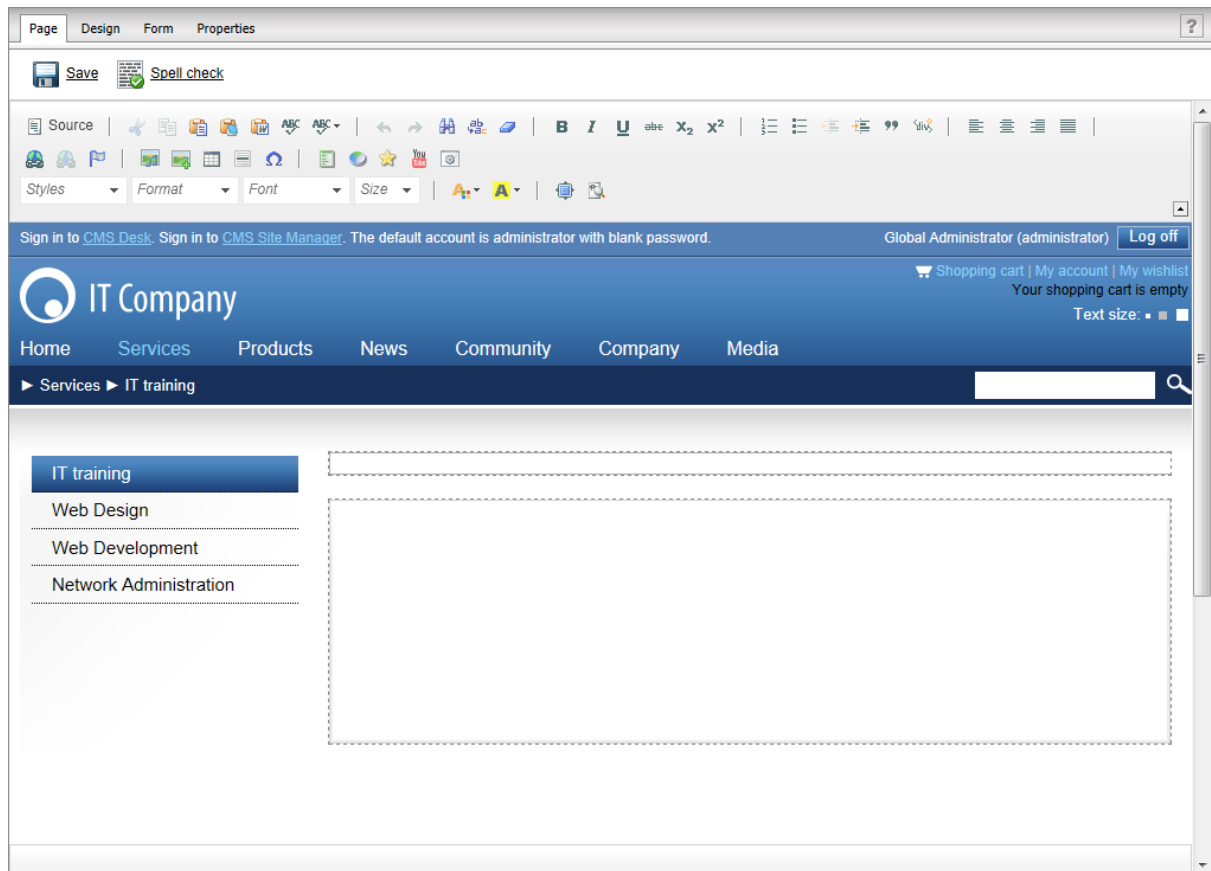

On the left side, there is a tree view of "All page templates" with the following categories listed: Articles, Blank, Blogs, Corporate site (highlighted), E-commerce, Events, FAQs, Forums, General, Home pages, Images, Job openings, Knowledge base, Master templates, Membership and security, News, Newsletter, Offices, Press releases, Products, Templates with editable region, and Wiki.

The main area displays a grid of template thumbnails. Each thumbnail has a placeholder image labeled "no image" and a title. The titles are:

- Corporate Site - Search page
- Corporate Site - Shopping cart
- Corporate Site - Simple text (highlighted with a yellow border)
- Corporate Site - Text and placeholder with left menu
- Corporate Site - Text and placeholder with left menu (personalised)
- Corporate Site - Video gallery
- Corporate Site - Web Part (sample)
- Corporate Site - Web Parts

At the bottom of the grid, there is a pagination control with numbers 1 through 8, where 1 is underlined. Below the pagination, the text "Corporate Site - Simple text" is displayed.

3. The **Page** tab opens and you can enter some content. Click  **Save** to confirm the changes.

4.4.3 Creating a new structured document

You can create new documents in **CMS Desk -> Content**.

1. Click the document under which the new item should be placed, click **New** and choose the required document type.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The 'Content management' toolbar contains buttons for 'New', 'Delete', 'Copy', 'Move', 'Up', 'Down', 'Edit', 'Preview', 'Live site', 'List', and 'Search'. The 'New' button is highlighted with a red circle. The left sidebar shows a tree view of the site structure, with 'News' selected. The main area displays the 'New document' dialog box, which prompts the user to select a document type. The 'Document type name' is set to 'LIKE'. A 'Show' button is visible. A list of document types is displayed, with a red box highlighting the entire list. The list includes: Page (menu item), Article, Blog, Cell phone, E-book, Event, Event (booking system), FAQ, File, Folder, Image gallery, IT Service, Job opening, Knowledge base article, Laptop, News, Office, PDA, Press release, Product, Product - Cell phone, Product - Laptop, Simple article, Smartphone, Software, and Wireframe.

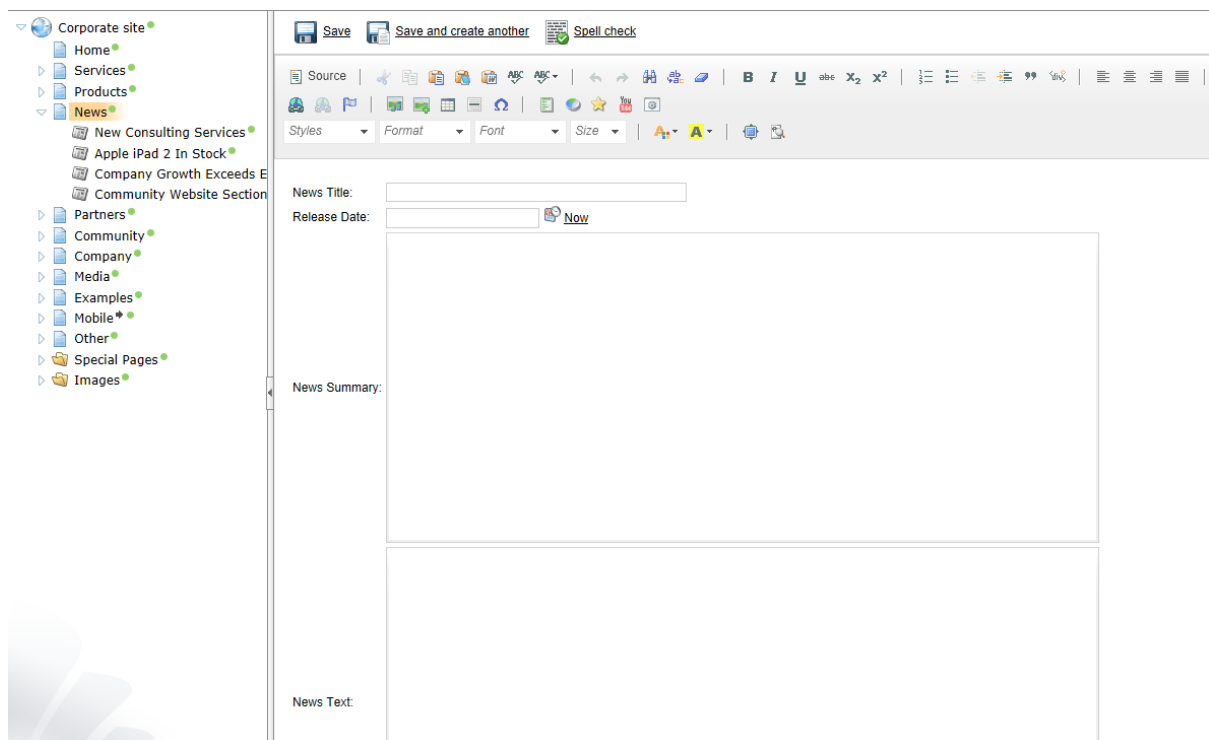

Available document types

The types of documents that can be created under the selected document depend on the type of the selected document. If the required document type is not available, the site administrator needs to add it in Site Manager -> Development -> Document types -> ... edit parent document type ... -> Child types.

2. You are then redirected to the appropriate editing form. For example, if you chose to create a new **News** document in the previous step, you would get an editing form like in the screenshot below. Enter some sample values like the following:

- **News title:** My testing news
- **Released date:** 8/15/2011 (the release date displayed on the website)
- **News summary:** Some news summary.
- **News text:** Some news text.
- **Publish from:** <leave empty for now, it can be used to specify when the document goes live>
- **Publish to:** <leave empty for now, it can be used to specify when the document expires>

Now you can click  **Save** to save the document and continue editing. You can also click  **Save and create another** to save the news document and immediately create another news document in the same location. The latter option can help save time if you need to create multiple documents of the same type under the same parent.

4.4.4 Creating a linked document

A linked document is a "stub" or "shortcut" of some existing document. It allows you to place a single document to multiple places in the content tree instead of creating its copies. Such a document is then displayed in the given part of the website, but when you edit it, you actually update the original document.

This feature is useful if you need to include a document (product) in multiple site sections (product categories), but keep only one instance of the document.

In order to create a linked document, select the document under which you want the linked one to be placed, click **New** and choose **Link an existing document** in the bottom of the screen:

 **New document**

Please select new document type:

Document type name :

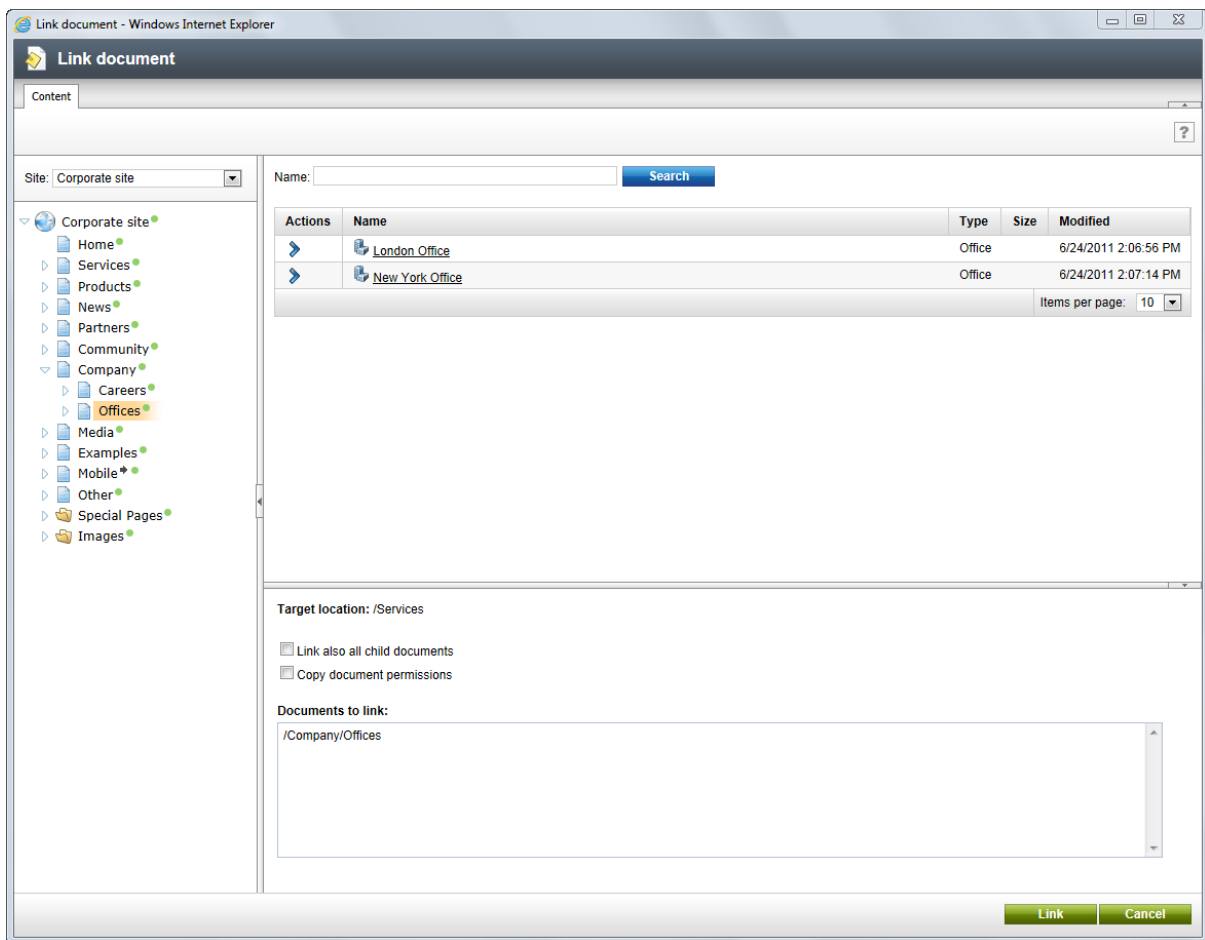

-  [Page \(menu item\)](#)
-  [Article](#)
-  [Blog](#)
-  [Cell phone](#)
-  [E-book](#)
-  [Event](#)
-  [Event \(booking system\)](#)
-  [FAQ](#)
-  [File](#)
-  [Folder](#)
-  [Image gallery](#)
-  [IT Service](#)
-  [Job opening](#)
-  [Knowledge base article](#)
-  [Laptop](#)
-  [News](#)
-  [Office](#)
-  [PDA](#)
-  [Press release](#)
-  [Product](#)
-  [Product - Cell phone](#)
-  [Product - Laptop](#)
-  [Simple article](#)
-  [Smartphone](#)
-  [Software](#)

 [Link an existing document](#)

Then, choose the document that should be linked. You have two additional options to configure:

- **Link also all child documents** - this option is displayed only when the selected document has some child documents stored under itself; if enabled, all child documents will be linked along with the selected document
- **Copy document permissions** - if enabled, document-level permissions will be preserved on the linked document; if disabled, the document will inherit permissions from its parent in the target location

Click **Link** to create the new linked document.

Unless the **Site Manager -> Settings -> Content -> Content management -> Display linked icon** option is disabled, the linked document will appear with the icon in the content tree:

You can see a list of all linked documents for the currently selected document in the [Properties -> Linked docs](#) dialog.

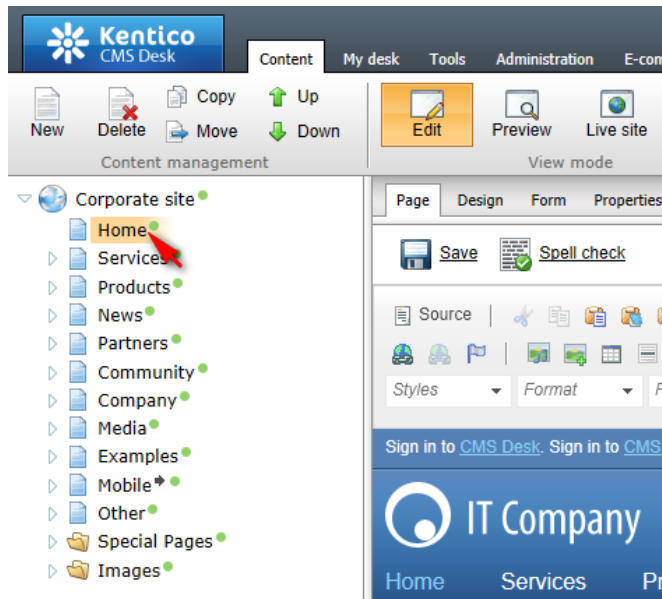

4.4.5 Drag-and-drop operations with documents

You can perform the following operations with documents quickly by dragging and dropping in the content tree.

- **Move** - just drag and drop the document
- **Copy** - drag and drop while holding CTRL
- **Create linked document** - drag and drop while holding down CTRL+SHIFT

The following steps describe the process of dragging and dropping a document:

1. Select the document that you want to move.

2. Move the mouse to the target location while still holding down the mouse button.

3. Release the mouse button. The document will be moved to the location where you dropped it.

4. If you drag the document a bit to the right ...

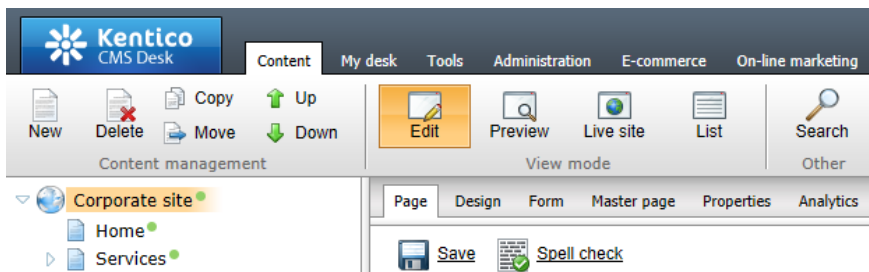

5. ... it will be placed under the document above it.

4.4.6 Previewing documents

When you open the page in **CMS Desk -> Content** section, the default mode is **Edit**. This mode allows you to edit the page's content, design and properties.

The other view modes are:

- **Live site** - this mode shows the page as it currently appears to visitors on the live site.
- **Preview** - this mode also displays the current version of the page, but it may be used even for documents that are not actually published on the live site yet.
- **List** - this mode shows a list of all documents under the currently selected document. This can be useful if there is a large number of documents under a single parent, or if you wish to perform an action for multiple documents simultaneously.

The following points summarize the difference between the **Live site** and **Preview** view modes:

- The **Live site** and **Preview** modes display the same content when a document is published and no

further changes have been made to it since it was published.

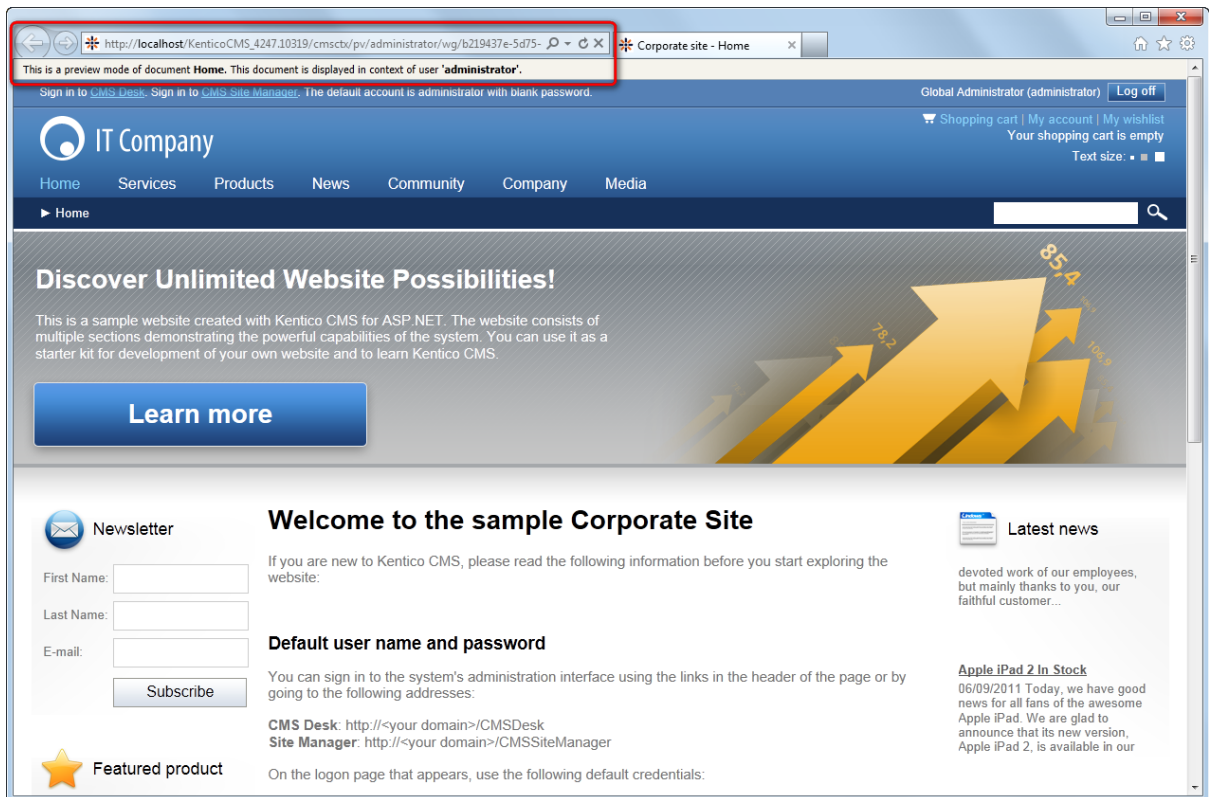

- The **Preview** mode does not use caching, so it may display published changes that are not visible in **Live site** mode yet due to caching.
- If a document does not use [workflow](#) and its **Publish from** property is set to a future date and time, the **Live site** mode does not display any content, while the **Preview** mode displays the content that will be published after the specified date and time.
- If the document uses workflow and has not yet reached the **Published** step, the **Live site** mode doesn't display any content, while the **Preview** mode displays the content created in the current workflow step.
- If the document uses workflow, is already in the **Published** workflow step and its workflow cycle has been restarted (i.e. it was switched from the **Published/Archived** workflow step back to the **Edit** step and is going through the workflow cycle again), the **Live site** mode displays the last published version, while the **Preview** mode displays content from the current workflow step.

Preview URLs

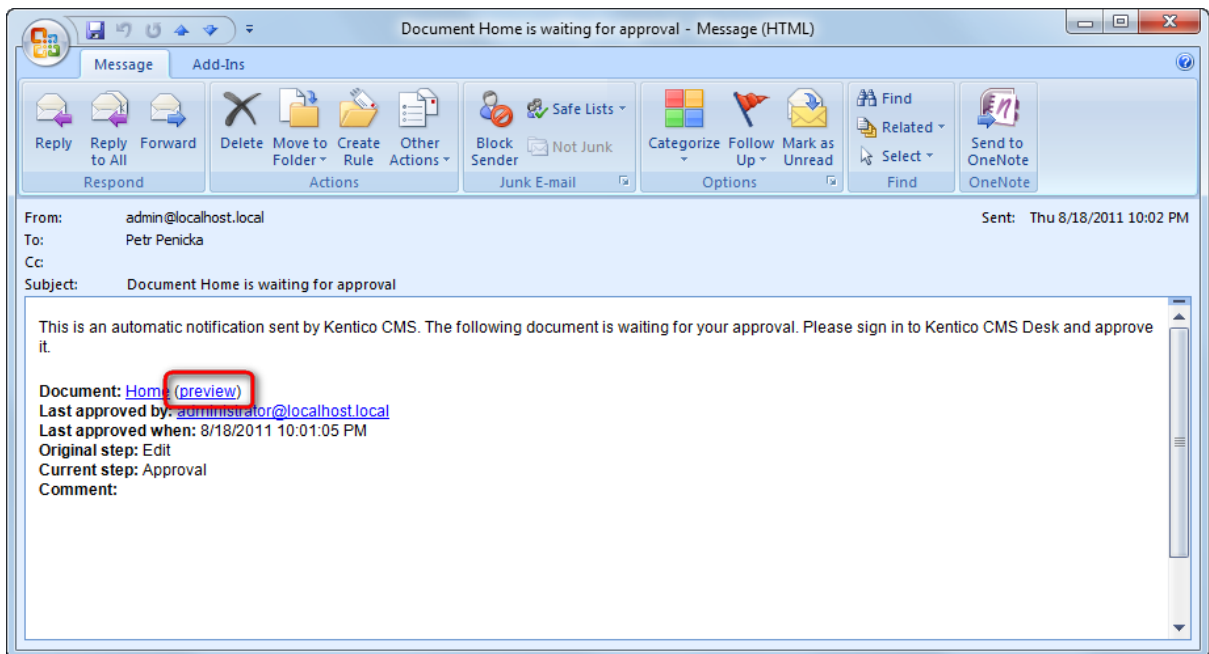

On the **Properties -> General** tab of an edited document, you can find the **Preview URL** property. If you click the **Show preview** link next to it, a new window will be opened, displaying the current document in **Preview** mode outside Kentico CMS user interface.

The screenshot shows the Kentico CMS interface. The top navigation bar includes 'Kentico CMS Desk', 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The left sidebar shows a tree view of the 'Corporate site' with folders like Home, Services, Products, News, Partners, Community, Company, Media, Examples, Mobile, Other, Special Pages, and Images. The main content area is divided into 'Page', 'Design', 'Form', and 'Properties' tabs. The 'Properties' tab is active, and the 'General' sub-tab is selected. The 'General' sub-tab contains a list of properties: URLs, Template, Metadata, Categories, Menu, Workflow, Versions, Related docs, Linked docs, Security, and Attachments. The 'Other properties' section is expanded, showing details for the 'Home' document, including its name, type, creator, creation date, last modified date, rating, and various IDs. The 'Preview URL' property is highlighted with a red box, and the 'Show preview' link is visible next to it.

The document will be displayed on a special page with a dedicated URL. The URL can be sent to a person without access to Kentico CMS user interface to let them view content that is not published yet. At the top of the page, an info line is displayed, informing that the page is displaying a document preview in context of a specific user (the **Show preview** link is always leading to preview in context of the current user). Links on the page are intentionally not working, so the person who accesses the preview URL can only see the preview of the particular document.

Preview links are also included in [workflow notification e-mail templates](#). In this case, the preview is displayed in context of the user who performed the workflow action about which the e-mail is notifying.

Generating new preview URLs

If you do not want the document's preview to be accessible under a link that you already sent to someone, you can generate a new preview URL for the document. This can be done by clicking on **Generate preview** (🌐) next to the **Show preview** link on the document's **Properties -> General** tab. By doing so, the document gets a new preview URL and the original one is no longer functional.

Depending on the **Allow permanent preview links** setting in **Site Manager -> Settings -> Content -> Content management**, new preview URLs can also be generated automatically for documents under [workflow](#) when their workflow cycle is restarted (i.e. when they are switched from the **Published/Archived** workflow step to the **Edit** step). If disabled, new preview URLs are generated in this situation and the original ones are no longer usable. If enabled, original preview links are preserved when the workflow cycle is restarted.

Additional configuration for long URLs in .NET 3.5

URLs in ASP.NET can have a maximal length of 260 characters. This may cause problems with links in previewed documents (e.g. links to attachments of documents which are nested deep in the content tree). If these URLs are long on their own, they may potentially exceed the length limit because the preview URL prefix is pre-pended to in document preview.

If you are running Kentico CMS on .NET 4.0, handling of such URLs is pre-configured in the default *web.config* file, so you should not encounter any problems. If you are running Kentico CMS on .NET 3.5, you need to perform the following steps in order to avoid problems with such URLs:

1. You need to install the URL Rewrite Module into the IIS. It can be downloaded from the following location: <http://www.iis.net/download/urlrewrite>.
2. Add the following rewriting rule into the `<system.webServer>` section of the project's *web.config* file:

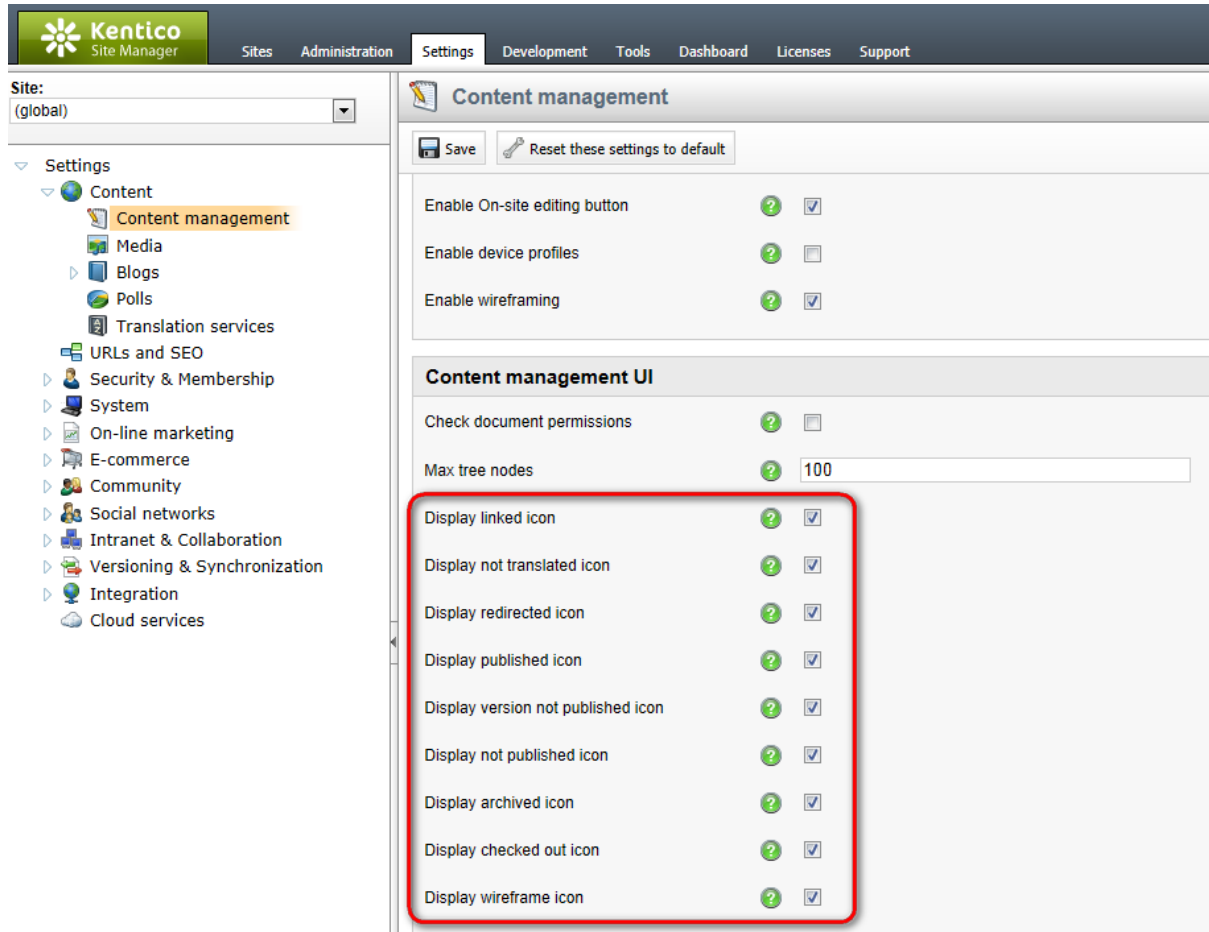

```
<system.webServer>
  <rewrite>
    <rules>
      <rule name="Remove virtual context prefix" stopProcessing="false">
        <match url="^cmsctx/(.+)/-(.+)$" />
        <action type="Rewrite" url="cmsctx/{R:2}" />
      </rule>
    </rules>
  </rewrite>
  ...
</system.webServer>
```

4.4.7 Document status icons

It is possible to have status icons displayed next to documents in the content tree, as you can see in the screenshot below.

These icons give additional information about the document and its current status. You can have them displayed by enabling a set of settings in **Site Manager -> Settings -> Content -> Content management**.

The following table gives information on what each icon indicates and which setting needs to be enabled in order for the particular icon to be displayed.

Icon	Description	Required settings
	This icon is displayed next to linked documents, i.e. documents that only represent a link pointing to another document in the content tree. See the Creating a linked document topic for more details.	Display linked icon
	This icon appears next to documents that are not available in the currently edited culture.	Display not translated icon

➔	This icon appears next to documents that have a redirection configured in Properties -> Navigation -> URL redirection .	Display redirected icon
●	This icon indicates that the document is not published on the live site. When a document is not under workflow, it indicates that the Publish to property is set to a past date and time. Under workflow, it indicates that the document has not yet been published, i.e. that it has no previously published version.	Display not published icon
●	This icon appears next to documents that are scheduled to be published in the future. Without workflow, this happens when the Publish from value on their Form tab is set to a future date and time. Under workflow, the same applies, while a document must also not have a previously published version (if it has one, the ● icon is displayed instead).	Display not published icon or Display published icon
●	This icon indicates that the document is currently published on the live site. by means of configuration of the Publish from and Publish to properties on the document's Form tab. If the document is under workflow, it also needs to be in the Published workflow step for this icon to appear next to it.	Display published icon
●	This icon only appears next to documents under workflow that already have a published version and a new version of the document is being created, but is not published yet. In other words, it is displayed next to documents next to documents in any workflow step before the Published step.	Display version not published icon
●	This icon only appears next to documents under workflow that already have a published version and another version is scheduled to be published. This happens when the new version already is in the Published workflow step and the Publish from value on its Form tab is scheduled to some future date and time.	Display published icon or Display version not published icon
●	This icon appears next to documents that have been submitted to a Translation service and are waiting for the translation to be completed.	N/A (this icon is always enabled)
●	This icon appears next to documents that are archived. Archived documents are no longer visible on the live site, but are still present in the content tree and can be restored when needed. You can archive a document by clicking the Archive button on the Properties -> Workflow tab.	Display archived icon
🔒	This icon indicates that the document is currently checked-out, i.e. that it is being edited by another user. You can't edit a document while it is checked out, you have to wait until the user finishes editing and checks the document back in. See Development -> Workflow and versioning -> Content locking for more details.	Display checked out icon
☰	This icon is displayed next to documents (of any type) that contain a wireframe definition. It is not added to dedicated wireframing documents of the <i>CMS.Wireframe</i> type, which can already be identified by their main document type icon. Please see the Development -> Wireframing chapter to learn more.	Display wireframe icon

4.5 On-site editing

4.5.1 On-site editing overview

Kentico CMS also provides a way to work with the content of websites through a convenient on-site editing interface. This allows editors to make changes to page content and manage documents directly while viewing the website from the live site perspective.

All actions that can be done via on-site editing are also available in CMS Desk. It simply offers a different way to edit the website that may be quicker and easier in many cases (particularly for users who prefer a minimal interface). It is recommended to use CMS Desk for creating the core structure of new sites or when performing complex changes. On-site editing is most suitable for adding or adjusting the content of an existing website that is already running.

To open the title page of a website in on-site editing mode, access it through the following URL:

<http://<domain>/<virtual directory>/cmsedit>

Just like CMS Desk, on-site editing mode requires authentication and a logon screen opens if you are not signed in yet.

Alternatively, editors who are already logged in on the live site may switch to on-site editing mode simply by clicking the **Edit page** button displayed in the corner of the page. This opens the on-site editing interface for the page that is currently being viewed.

On-site editing mode works just like the standard live site, with the addition of a toolbar shown above the page. The content and configuration of pages can be modified through the buttons on this toolbar, along with a special interface displayed when hovering over specific editable sections of the currently viewed page (as described in the [Editing content](#) topic).

To move between pages, simply use the site's standard navigation. All other functionality of the website is also available in on-site editing mode. However, there are several important differences from the regular live site that should be considered:

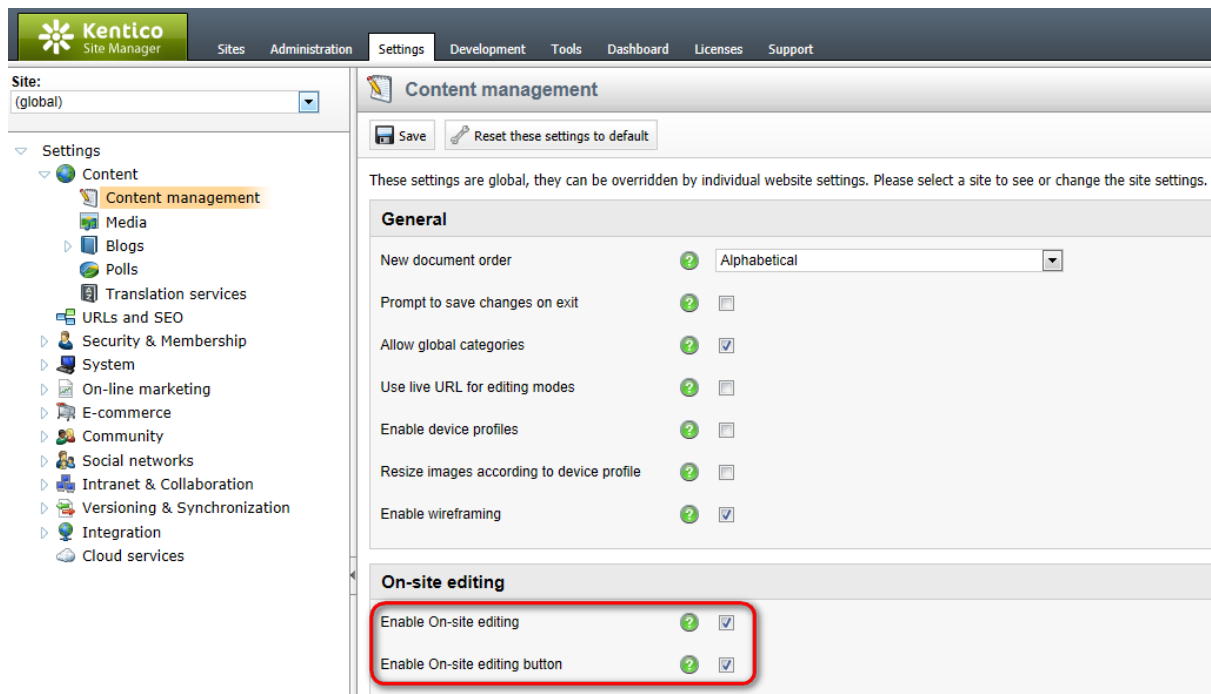

- Pages are always displayed in their current editing state, even if they are not published on the actual live site yet (like in the Preview and Edit view modes of CMS Desk). This makes it possible to view and modify pages before they are presented to the website's regular visitors.

- All forms of page redirection are disabled. This allows editing of pages that would normally be forwarded to a different address on the live site. Pages that are configured for redirection can be identified by the presence of a message box, which also provides a link to the target page.
- If a *Page not found* error occurs while browsing in on-site editing mode, it is handled by a special system page that contains a link to the root of the website.

On-site editing settings

The on-site editing interface is not a required part of the system and can be disabled globally or for specific sites. System administrators may do so by configuring the appropriate settings in **Site Manager -> Settings -> Content -> Content management**:

- **Enable On-site editing** - on-site editing is only available for websites that have this field checked.
- **Enable On-site editing button** - determines whether the *Edit page* button should be displayed in the corner of pages on the live site for users who are authorized as editors. If you do not wish to use this button, users can alternatively access on-site editing mode through its dedicated URL, or by following a link provided by the [Edit document link](#) or [Admin actions](#) web part.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The 'Settings' section is expanded, showing a tree view of settings categories: Content, Content management, Media, Blogs, Polls, Translation services, URLs and SEO, Security & Membership, System, On-line marketing, E-commerce, Community, Social networks, Intranet & Collaboration, Versioning & Synchronization, Integration, and Cloud services. The 'Content management' settings page is displayed, showing a 'Save' button and a 'Reset these settings to default' button. The settings are organized into sections: 'General' and 'On-site editing'. The 'On-site editing' section is highlighted with a red box, showing two settings: 'Enable On-site editing' and 'Enable On-site editing button', both of which are checked.

Setting	Help	Value
Enable On-site editing	?	<input checked="" type="checkbox"/>
Enable On-site editing button	?	<input checked="" type="checkbox"/>

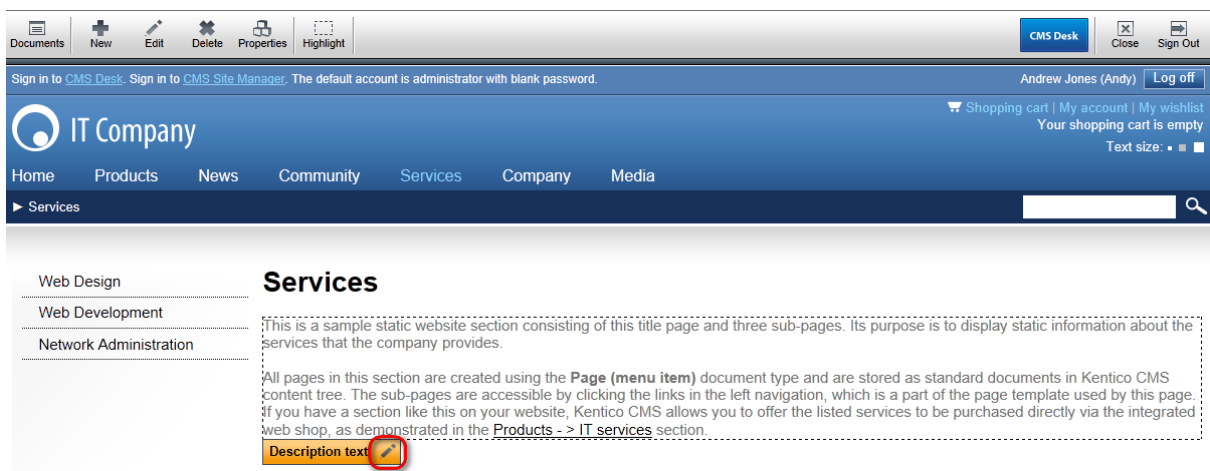

4.5.2 Editing content

The following steps demonstrate how to edit various types of page content through the on-site editing interface:

1. Open the sample Corporate site and log on to the live website as a user who is an editor. For example, you can use the default editor account — user name *Andy* with a blank password. Do not sign in to CMS Desk, simply enter the credentials into the logon form at the top right of the site's header.
2. Click the  **Edit page** button in the corner of the page to open on-site editing mode. The system displays the button because the current user is authorized as an editor.

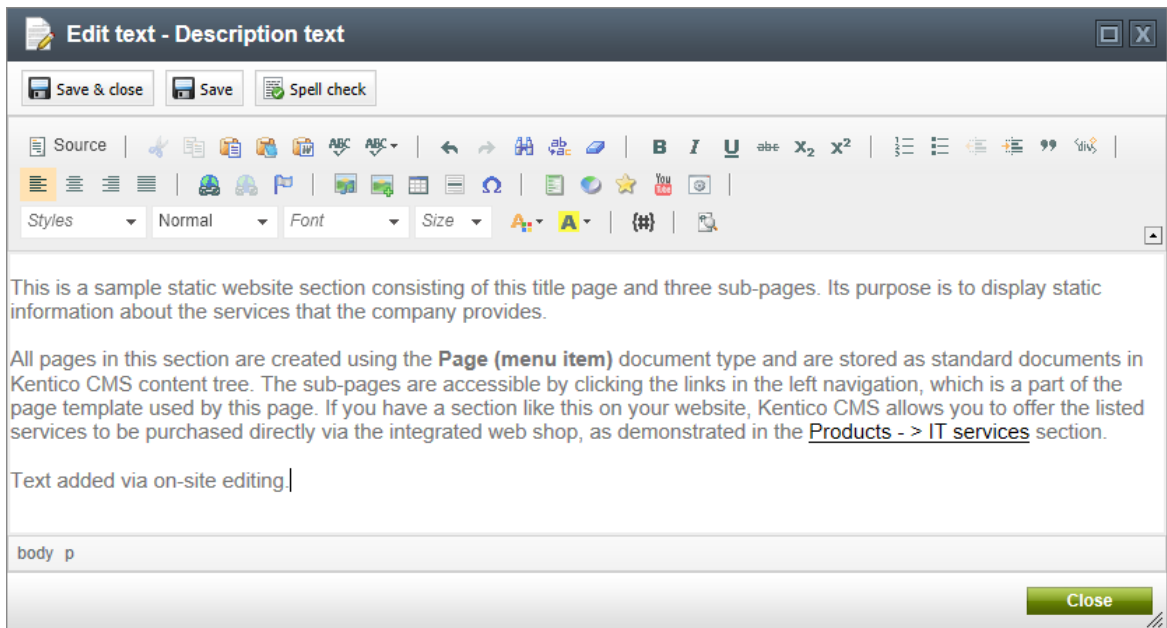

3. Navigate to the **Services** page through the website's main menu. Try moving the mouse over the sections of text displayed on the page. In on-site editing mode, hovering over editable text regions causes them to be highlighted by a dotted outline, with a box showing the title of the given region. Do this for the main text area and then click edit (✎) in the title box.

Tip

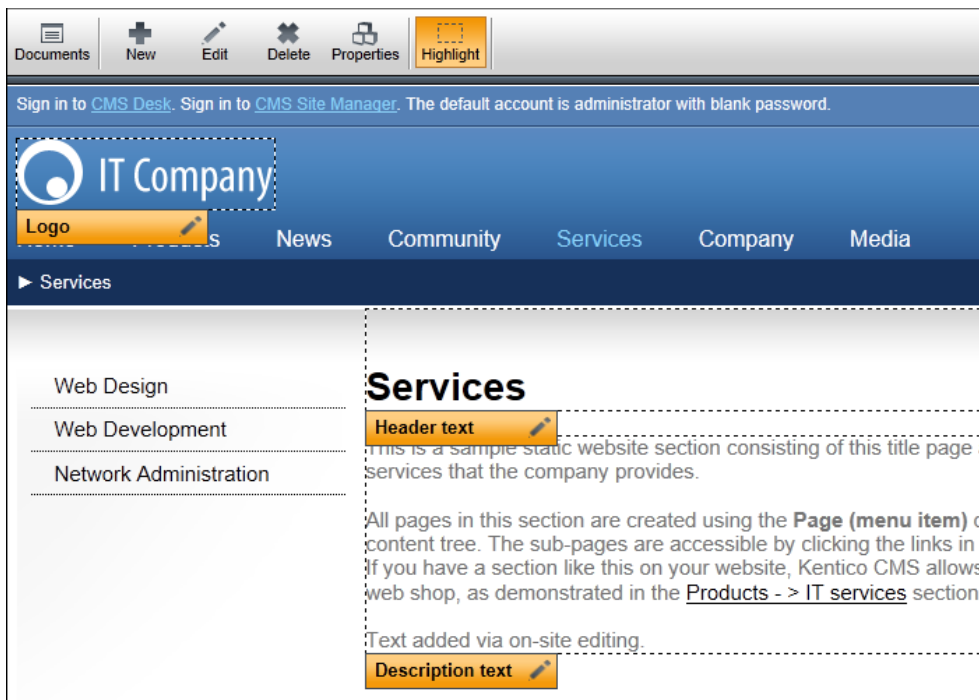

If you encounter a situation where the highlight feature is blocking a part of the page that you wish to click, you can bypass it by holding down the **CTRL** key while moving your mouse. This way, you can reach the required location without triggering the highlight.

4. A new dialog opens, where the content of the region can be edited as needed using the [WYSIWYG editor](#). Add some new text below last paragraph and confirm the change by clicking **Save & close**.

This automatically refreshes the page and displays the new content.

5. Continue by clicking the **Highlight** action on the on-site editing toolbar above the page. When this button is toggled on, all editable items placed on the page are highlighted at the same time. This way you can easily find all editable text regions and editable images and modify them as necessary.

To change an editable image, click the edit (✎) action next to its title and then select a different image in the displayed dialog. Please note that the company logo on the Corporate site is not actually a part of the *Services* page. It is defined in the website's root document, which provides the header content

shared by most pages. As a result, changing the image here also changes it for the entire website.

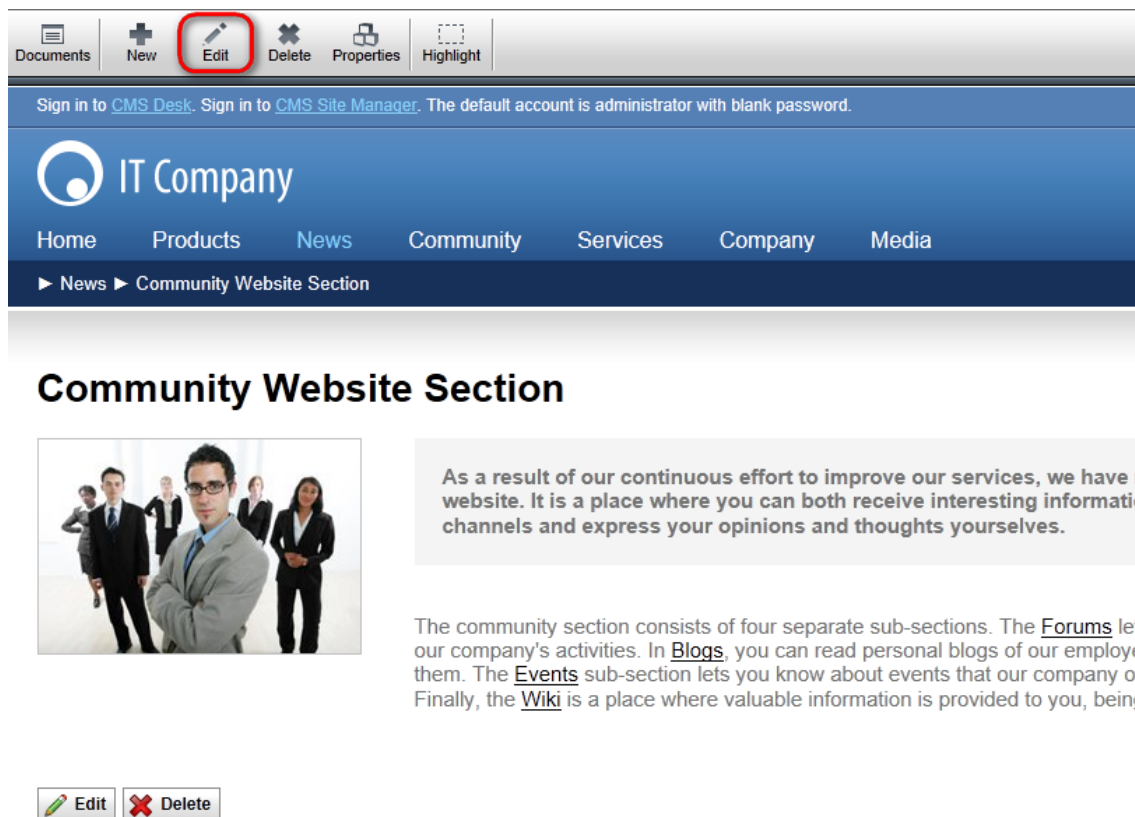

On-site editing with Design permissions

If the current user is also authorized to design the website, the system additionally highlights individual [Web parts](#) placed on the page. In this case, on-site editing also offers the option to configure (⚙️) the properties of these web parts.

Editing structured documents

Now we will edit a page that loads its content from the fields of a structured document.

1. Go to the **News** section of the website and view the first news article in the list, titled **Community Website Section**. Once the page is loaded, click the  **Edit** action on the on-site editing toolbar.

The screenshot shows the on-site editing toolbar at the top, with the 'Edit' button (pencil icon) highlighted in a red box. Below the toolbar is a navigation menu for 'IT Company' with links for Home, Products, News, Community, Services, Company, and Media. The current page is 'Community Website Section'. The main content area features a large image of a group of business professionals and a text block that reads: 'As a result of our continuous effort to improve our services, we have n website. It is a place where you can both receive interesting informatio channels and express your opinions and thoughts yourselves.' Below this is a paragraph of text: 'The community section consists of four separate sub-sections. The [Forums](#) let our company's activities. In [Blogs](#), you can read personal blogs of our employe them. The [Events](#) sub-section lets you know about events that our company or Finally, the [Wiki](#) is a place where valuable information is provided to you, being'. At the bottom of the page, there are two buttons: 'Edit' (pencil icon) and 'Delete' (red X icon).

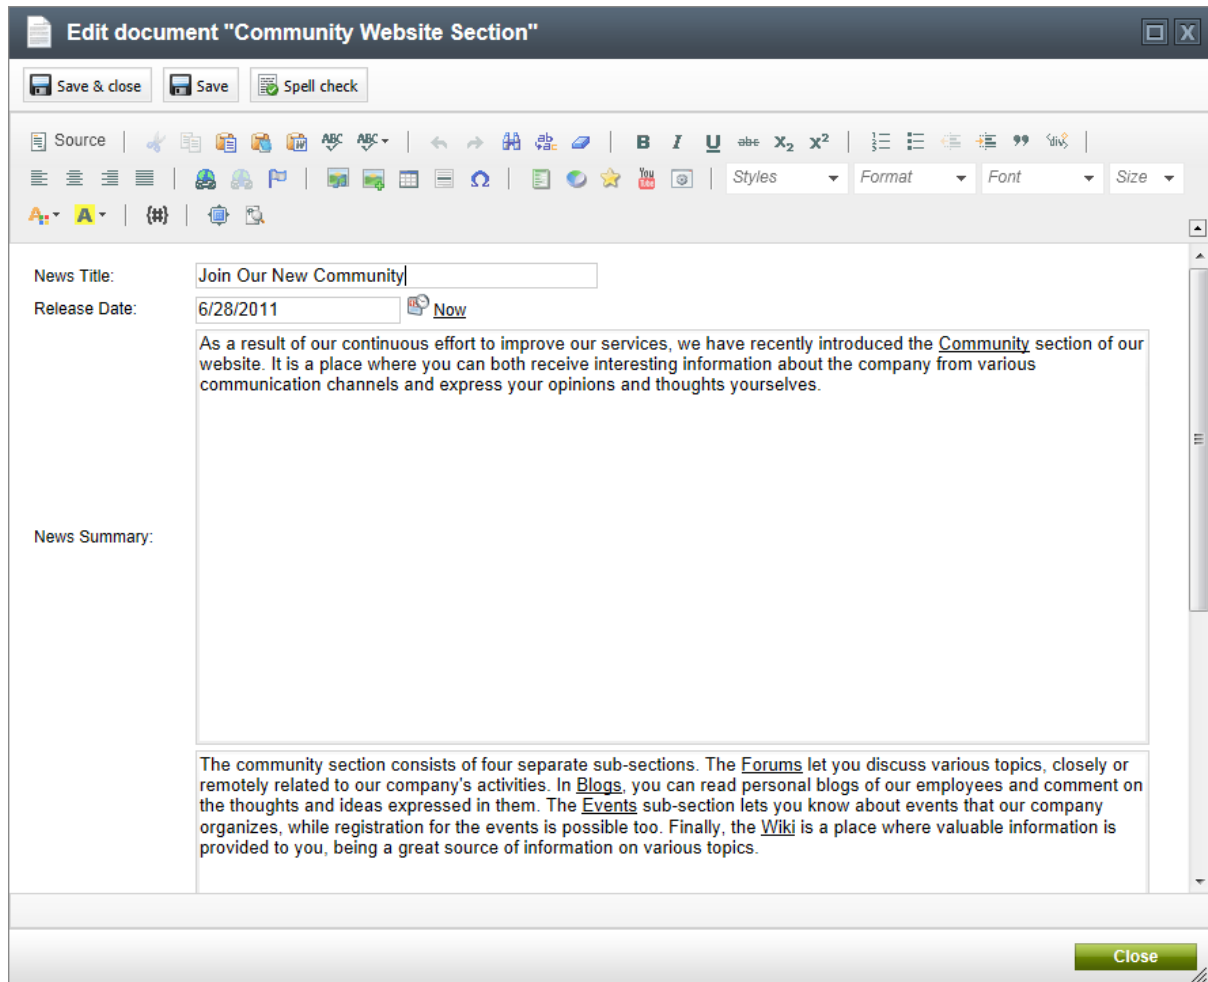

Edit mode buttons

In many cases, document lists are configured to provide edit mode buttons, which are also visible in on-site editing mode. Such buttons are shown both on the list page next to individual items and when viewing the details of a specific document.

The  **Edit** button works the same way as the corresponding action on the main toolbar.

2. An editing dialog opens, where you can work with the values of the given document's fields. This is the equivalent of the *Form* tab in CMS Desk. You can make any required changes to the news document. For example, set the **News Title** field to *Join Our New Community*. Confirm the change by clicking  **Save & close**.

The screenshot shows a web-based editing interface titled "Edit document 'Community Website Section'". At the top, there are buttons for "Save & close", "Save", and "Spell check". Below these is a rich text editor toolbar with various icons for text formatting (bold, italic, underline, strikethrough, subscript, superscript), alignment, bulleted and numbered lists, indentation, link, unlink, and media insertion. The main editing area contains several fields: "News Title:" with the text "Join Our New Community", "Release Date:" with "6/28/2011" and a "Now" button, and a large text area for the "News Summary:" containing two paragraphs of placeholder text. The first paragraph reads: "As a result of our continuous effort to improve our services, we have recently introduced the Community section of our website. It is a place where you can both receive interesting information about the company from various communication channels and express your opinions and thoughts yourselves." The second paragraph reads: "The community section consists of four separate sub-sections. The Forums let you discuss various topics, closely or remotely related to our company's activities. In Blogs, you can read personal blogs of our employees and comment on the thoughts and ideas expressed in them. The Events sub-section lets you know about events that our company organizes, while registration for the events is possible too. Finally, the Wiki is a place where valuable information is provided to you, being a great source of information on various topics." A "Close" button is located at the bottom right of the dialog.

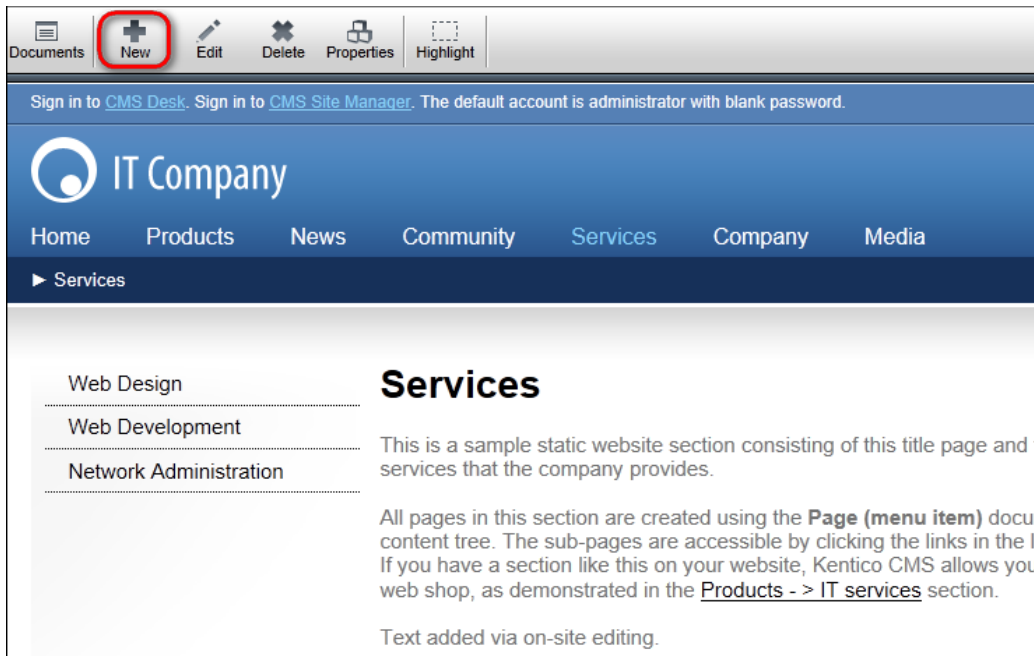

The new title is shown on the detail page of the news article, as well as in the main list of items on the **News** page.

4.5.3 Adding new pages

This topic contains an example describing the typical steps that need to be performed when creating new pages (documents) through the on-site editing interface.

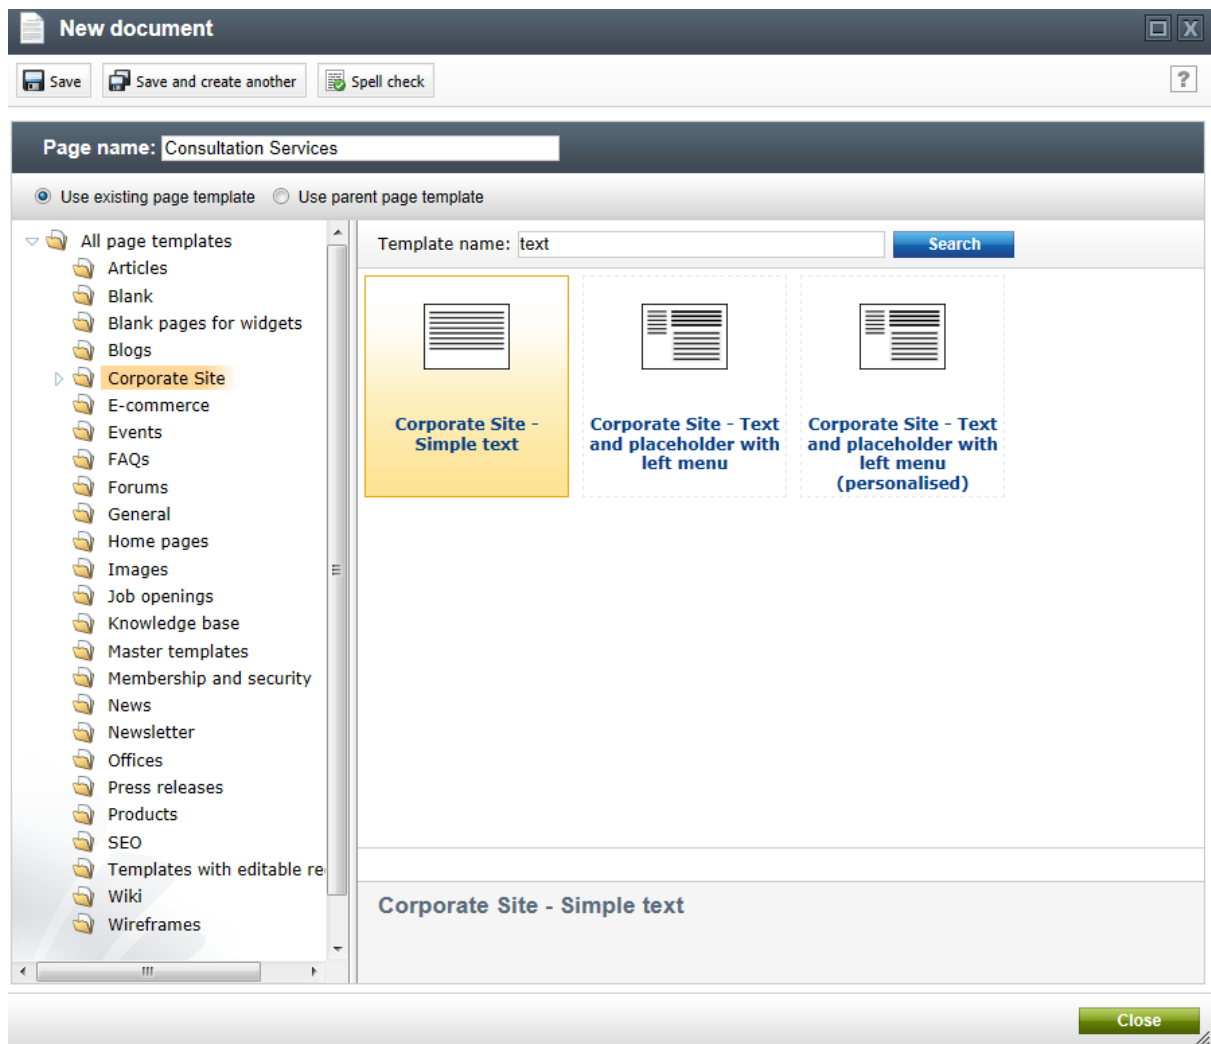

1. Open the sample Corporate site, log on to the live website as an editor (for example user name *Andy* with a blank password) and switch to on-site editing mode.

2. Select the **Services** page in the website's main navigation menu and then click **+ New** on the on-site editing toolbar. This action creates a child document under the page that is currently being viewed.

3. In the displayed document creation dialog, choose the **Page (menu item)** document type. You must then select a template for the new page. Click the **Corporate Site** category in the tree, enter the word *text* into the **Template name** filter and then choose the **Corporate Site - Simple text** template.

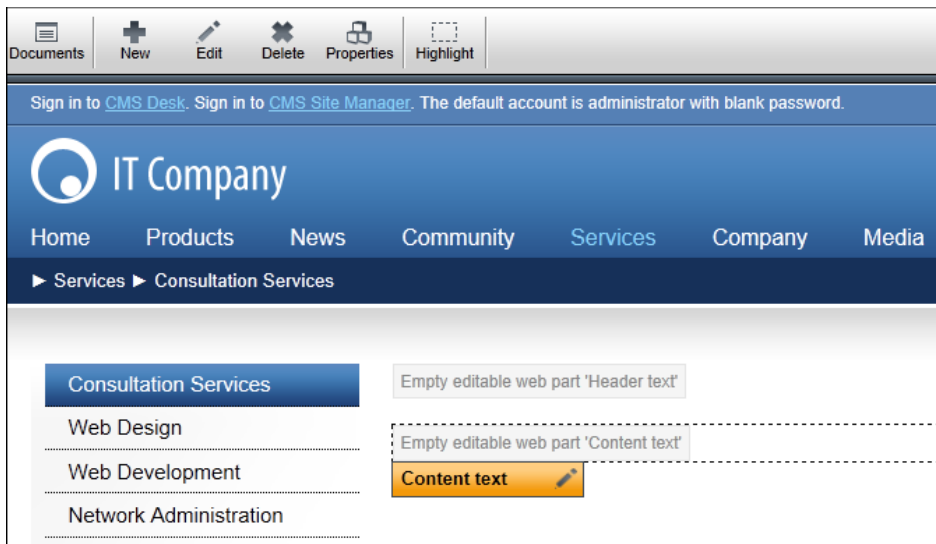

4. Type *Consultation Services* into the **Page name** field and click **Save**.

The new page is added under the *Services* section of the website. Visitors can now access it through the site's navigation menus.

5. The content of new pages is often empty. In this example, the page template contains two editable regions without any text. Empty editable regions are represented by placeholder boxes in on-site editing mode, so you can easily find them on the page and edit their content.

Hover over the placeholders and use the edit action to enter some text into the page's header and content areas.

Creating structured documents

1. Navigate to the **Community -> Events** page through the main menu. You can add structured documents to the website in the same way as standard pages.
2. Click the **+** **New** action on the toolbar and select the **Event (booking system)** document type. Alternatively, the same could be achieved using the **New event** button provided in the list of upcoming events on the right side of the page.
3. Instead of selecting a page template, you need to specify values for the document's fields in the creation dialog. For example, you can use the following:
 - **Event name:** New Version Release Conference
 - **Event summary:** Learn everything you need to know about the new version of our product at this two day conference. All customers and partners are invited.
 - **Start date / End date:** Use the calendar (📅) to enter a date in the future

4.5.4 Document management

In addition to basic editing of page content, on-site editing may also be used to manage the document structure of the website. This is done via a separate dialog that can be accessed by clicking the  **Documents** button on the on-site editing toolbar. The overall structure of the website may not always be obvious from the live site point of view and it can be difficult or even impossible to access some documents using only the natural on-site navigation. For these reasons, the dialog offers an alternative way to explore the website based on document lists.

Documents button on the on-site editing toolbar. The overall structure of the website may not always be obvious from the live site point of view and it can be difficult or even impossible to access some documents using only the natural on-site navigation. For these reasons, the dialog offers an alternative way to explore the website based on document lists.

When opened, the list initially displays all sibling documents of the page that is currently being viewed in on-site editing mode (i.e. the documents on the same content level that share the same parent).

Editing the website root

The **Document listing** dialog also provides an easy way to access the *root document* of the website. You can find it as a special item at the top of the list on the first level of the site's content (it is marked by the  document type icon).

You can navigate deeper into the site structure by clicking on the name of any listed document, which displays the child documents of the given item. To return to a previous content level, click on one of the parent documents shown in the breadcrumb navigation at the top of the dialog. This way, you can quickly access any section of the website.

Selected documents (select an action) OK

Close

The following actions are available for individual documents in the list:

- **View** - navigates to the page represented by the given document on the live site (in on-site editing mode).
- **Edit** - clicking this action opens a dialog where the fields of the given document can be edited.
- **Delete** - removes the given document from the website.
- The ▾ action opens a context menu with further options that may be used to change the position of the document on the given level of content:
 - **Top**
 - **Up**
 - **Down**
 - **Bottom**

Additionally, the dialog may be used to perform various types of document management operations via the two drop-downs below the list. First, you need to select one of the following options:

- **Selected documents** - the action is performed only for the documents selected through the checkboxes (.
- **All documents** - the action is done for all documents listed on the given content level.

Then you can choose one of the available actions:

- **Move** - moves the documents to a new location specified through a separate dialog.
- **Copy** - creates copies of the selected documents at the specified location.
- **Link** - creates linked versions of the selected documents at the specified location.

- **Delete** - removes the documents from the site.
- **Translate** - submits the selected documents to a [Translation service](#) specified via a separate dialog.
- **Publish/Archive** - may be used to publish or archive documents under [Workflow](#).

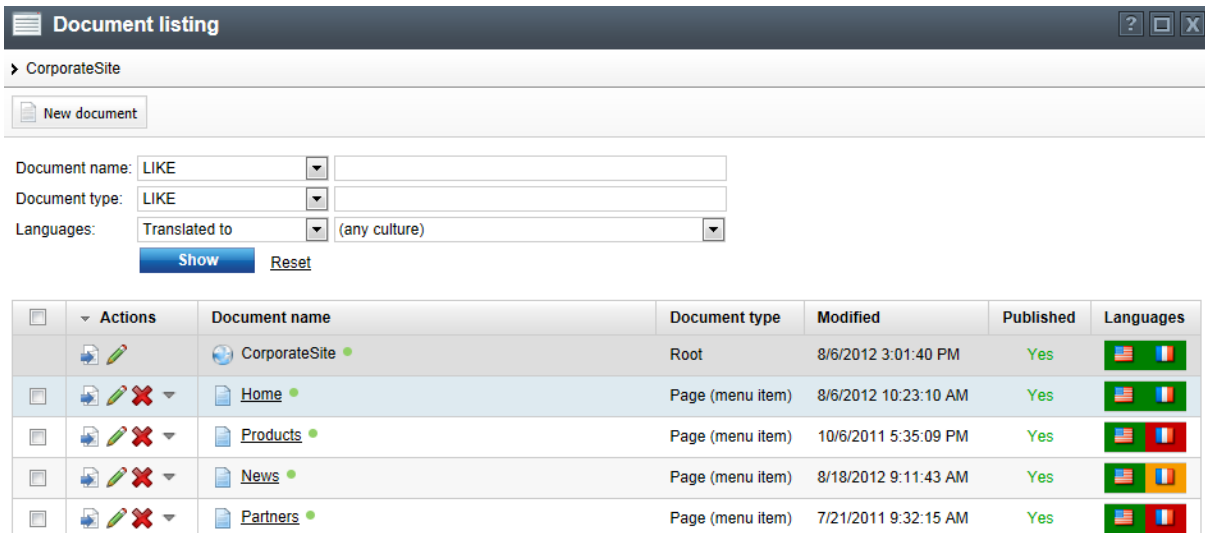

Click **OK** to perform the selected action.

You can also add a new document to the currently selected location by clicking the  **New document** button above the list. This opens a creation dialog that works the same way as described in the [Adding new pages](#) topic.

Managing multilingual websites

If the website's content is available in more than one language, the document list also provides a **Languages** column with additional data. It displays the status of the documents in all languages assigned to the website. The colors surrounding the flags of individual languages indicate the following possible language statuses:

- **Green - Translated** - the document is available in the given language and up-to-date. The actual language of the document's content has no effect on the status, the system only checks whether the language version exists.
- **Orange - Outdated** - the language version exists for the document, but is outdated. The system considers language versions to be outdated if the default language version of the document has been modified (or published when using workflow) more recently.
- **Red - Not available** - the document does not exist in the given language.

Actions	Document name	Document type	Modified	Published	Languages
	CorporateSite	Root	8/6/2012 3:01:40 PM	Yes	
	Home	Page (menu item)	8/6/2012 10:23:10 AM	Yes	
	Products	Page (menu item)	10/6/2011 5:35:09 PM	Yes	
	News	Page (menu item)	8/18/2012 9:11:43 AM	Yes	
	Partners	Page (menu item)	7/21/2011 9:32:15 AM	Yes	

Clicking a **Translated** or **Outdated** flag redirects you to the matching language version of the document on the live site (in on-site editing mode). If you click a **Not available** flag, a dialog opens instead where you can create a new version of the document in the given language.

You can also switch between languages and create translated page versions directly while viewing the page content using the selector on the main toolbar.

Refer to the [Multilingual content](#) chapter to learn more about creating websites in multiple languages.

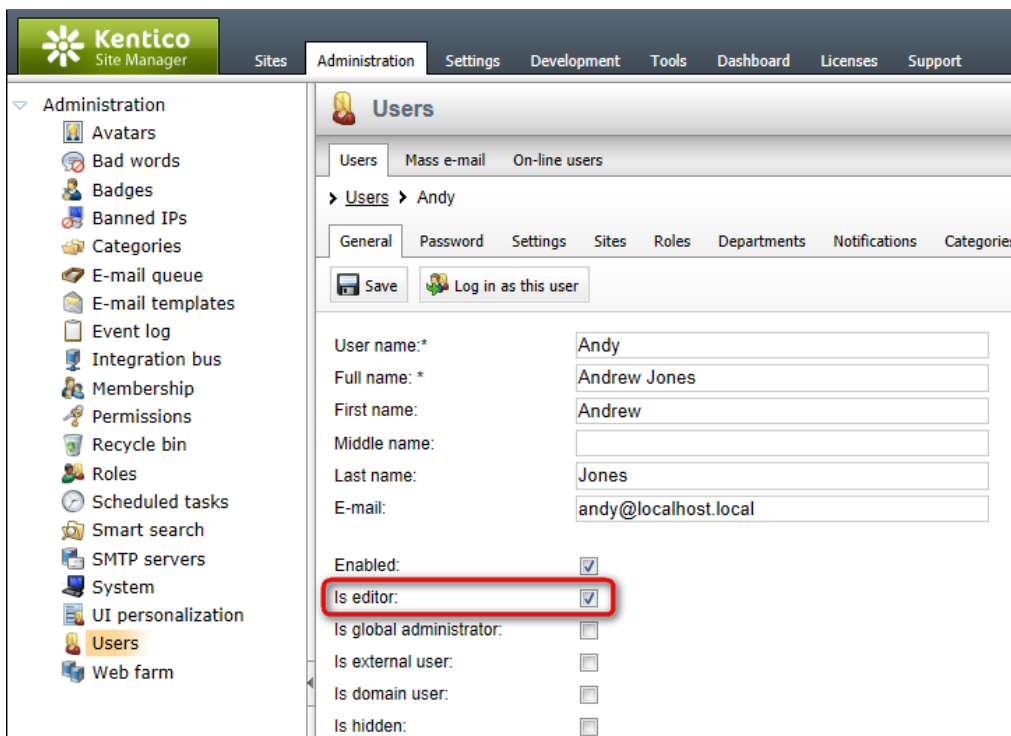

4.5.5 Security

This topic describes the [permissions](#) and other security requirements related to the on-site editing interface. The information here is primarily intended to help system administrators correctly set up user accounts for on-site editing.

Editor prerequisite

Like with CMS Desk, users need to be designated as editors to access on-site editing mode.

1. Go to **Site Manager** (or **CMS Desk**) -> **Administration** -> **Users**.
2. Edit a user on the **General** tab.
3. Check the **Is editor** box.
4. Click **Save**.

The system now recognizes the given user as an editor.

Permissions

There are several module permissions that affect on-site editing. You can configure these permissions for specific roles in **Site Manager / CMS Desk** -> **Administration** -> **Permissions**.

Module	Permission	Description
Content	Read	Only users who belong to roles that have this permission are able to enter on-site editing mode.
	Modify	Allows users to edit document fields and the content of editable regions.
	Create	Allows users to create new pages (documents).
	Delete	Allows users to delete existing pages from the website.
	Browse tree	Users need this permission to perform document management actions, such as creating and deleting pages or viewing the document list. It is not required for basic work with editable region content.
Design	Design website	Users need this permission to configure the properties of web parts through the on-site editing interface. The system only highlights editable regions and images for users without this permission.

 **Permissions**

Site:

Permissions for:

Report for user: Show only this user's roles

CMS Editors	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
CMS Readers	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Additionally, all permissions configured for document types or individual documents also apply in on-site editing mode. You can find more information in the [Development -> Membership, permissions and security -> Permissions](#) chapter.

UI personalization

You can also customize the visibility of individual elements on the on-site editing toolbar and in the related dialogs for particular roles via UI personalization.

1. Go to **Site Manager / CMS Desk -> Administration -> UI personalization**.
2. Select the appropriate **Site** and **Role**.
3. Choose the *CMS On-site editing* **Module**.
4. Configure the checkboxes as required. The available options match individual buttons on the main on-site editing toolbar.

Members of the selected role can now see only the specified UI elements.

**Note**

All of the UI personalization options set for the *Content Module* also apply (e.g. various document property tabs, the web part properties dialog etc).

You can find additional details in the [Development -> Membership, permissions and security -> UI personalization](#) chapter.

4.6 WYSIWYG editor

4.6.1 Overview

Kentico CMS comes with a built-in WYSIWYG editor. It is based on [CKeditor](#), which is one of the best browser-based editors available on the market.

Where the editor is available

You can come across the WYSIWYG editor in many parts of the system. However, its main use is related to the **Editable text** web part, which enables content editors to enter page content via the **Page** tab.

Another example of the use of the WYSIWYG editor is the **HTML area** form control that can be displayed e.g. on the **Form** tab of a document, as a part of **Form** or in web part properties dialogs of certain web parts (e.g. **Static HTML** or **Silverlight application**).

WYSIWYG editor toolbar

The default toolbar looks like this:

As you can see, it provides functionality similar to Microsoft Word. Still, there are several icons that may require additional explanation:

	Paste as plain text - this command pastes the content of your clipboard while cleaning out all formatting.
	Paste from Word - this command allows you to clean-up content pasted from Microsoft Word. It cleans up the HTML code so that it does not contain extra code and fits your website design. You can find more details in the Copy & Paste from Microsoft Word topic.
	Insert/Edit link - creates a link from the selected text or inserts a link into the text. Please refer to the WYSIWYG editor -> Insert link subchapter for more details.
	Insert/Edit image or media - inserts an image or other media into the text. Please refer to the Insert image or media topic for more details.
	Quickly insert image or media - inserts an image, video, document or any other type of file

	from a disk in a quick way, without any additional settings when inserting. Please refer to the Quickly insert image or media topic for more details.
	Insert Form - inserts an on-line form into the text. You can find more details on forms in the Modules -> Forms chapter.
	Insert Poll - inserts a poll into the text. You can find more details on polls in the Modules -> Polls chapter.
	Insert/Edit YouTube video - inserts a YouTube video. Please refer to the Insert YouTube video topic for more details.
	Insert/Edit widget - inserts an inline widget into the text. You can find more details about widgets in the Development -> Widgets chapter.

4.6.2 Insert image or media

4.6.2.1 Overview

The **Insert image or media** dialog can be used to insert the following types of files:

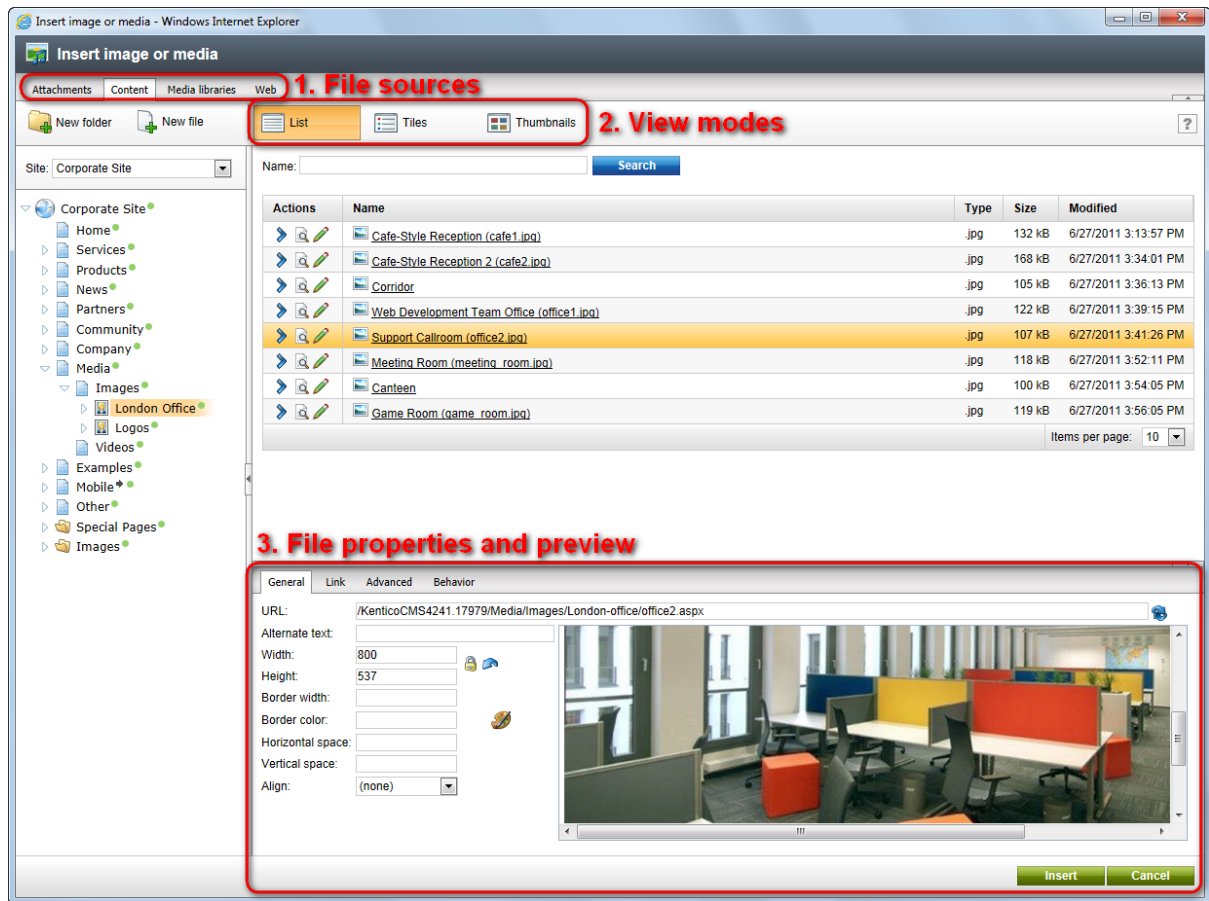

- **Images** - bmp, gif, ico, png, wmf, jpg, jpeg, tiff, tif.
- **Audio** - wav, wma, mp2, mp3, mid, midi, mpga.
- **Video** - avi, mp4, mpg, mpeg, wmv, qt, mov, rm.
- **Flash** - swf.

Custom types can be added as described in the [Configuring custom file types](#) topic of the **Modules -> Media libraries** chapter.

The dialog can be opened by clicking the **Insert/edit image or media** () icon, as highlighted in the screenshot below.

After clicking the icon, the following dialog will be displayed:

The highlighted parts of the dialog have the following functions. Their position may vary based on the selected file source:

1. **File sources** - using these four tabs, you can select from where the inserted files should be taken. Please refer to the [File sources](#) topic for more details.
2. **View modes** - using these buttons, you can switch between different modes of viewing files listed in the dialog. Please refer to the [View modes](#) topic for more details.
3. **File properties** - in this section, you can define properties of a file inserted into the text; the properties are different for [images](#), [audio/video](#) and [flash](#).

General process of inserting an image or media

1. Place the cursor in the appropriate position in the WYSIWYG editor.
2. Click the **Insert/edit image or media** (🖼️) icon.
3. The dialog window opens. Select the appropriate file source tab according to from where you want to add the file.
4. Locate and select the file on the tab.
5. Appropriate properties according to the file type are displayed. Specify the required properties and click the **Insert** button.
6. The required code is inserted into the WYSIWYG editor.

4.6.2.2 File sources

Using the four tabs at the top of the dialog window, you can choose from where the image or media should be inserted. The following tabs are available:

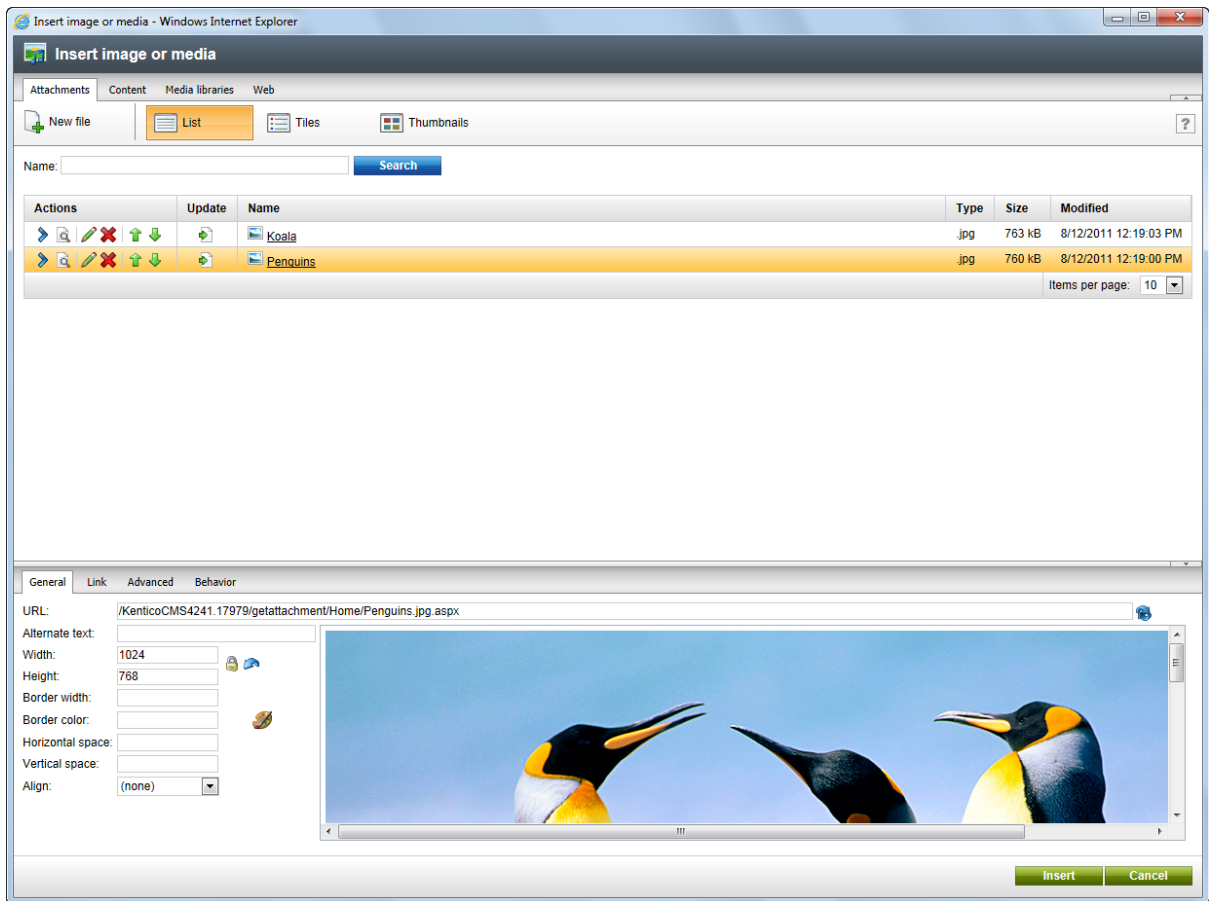

Attachments

The selection of files available on this tab depends on the location where the WYSIWYG editor is being used. When editing documents (e.g. on the **Form** tab, through user contributions etc.), the unsorted file attachments of the current document are offered. For more information about document attachments, please refer to the [Document attachments](#) chapter of this guide. When editing the content of other objects in the CMS (various types of layouts, e-mail templates etc.), this tab provides a way to insert the given object's metafile attachments.

From this tab, you can insert image attachments of the document into the text. You can select an attachment using the **Select** (🔍) icon or by simply clicking the appropriate line (or tile/thumbnail in the other view modes).

You can upload new attachments using the  **New file** button. The following actions can be performed with the listed attachments:

- After clicking the **View** (🔍) icon, the attachment will be opened in a new window.
- Using the **Delete** (✖) icon, you can remove the attachment from the document.
- Using the **Move up** (⬆) and **Move down** (⬇) icons, you can change the order of document attachments. This option is available only in the **List** view mode. The order is stored in the **AttachmentOrder** property of each attachment. You can enter *AttachmentOrder* into the **ORDER BY expression** property of a displaying web part to have the attachments ordered accordingly.
- Using the **Edit** (✎) icon, you can edit the metadata of the file. However, clicking this icon placed beside an image opens the image in the built-in image editor.
- Using the **Update** (🔄) icon, you can replace the original attachment with a new one.

Content

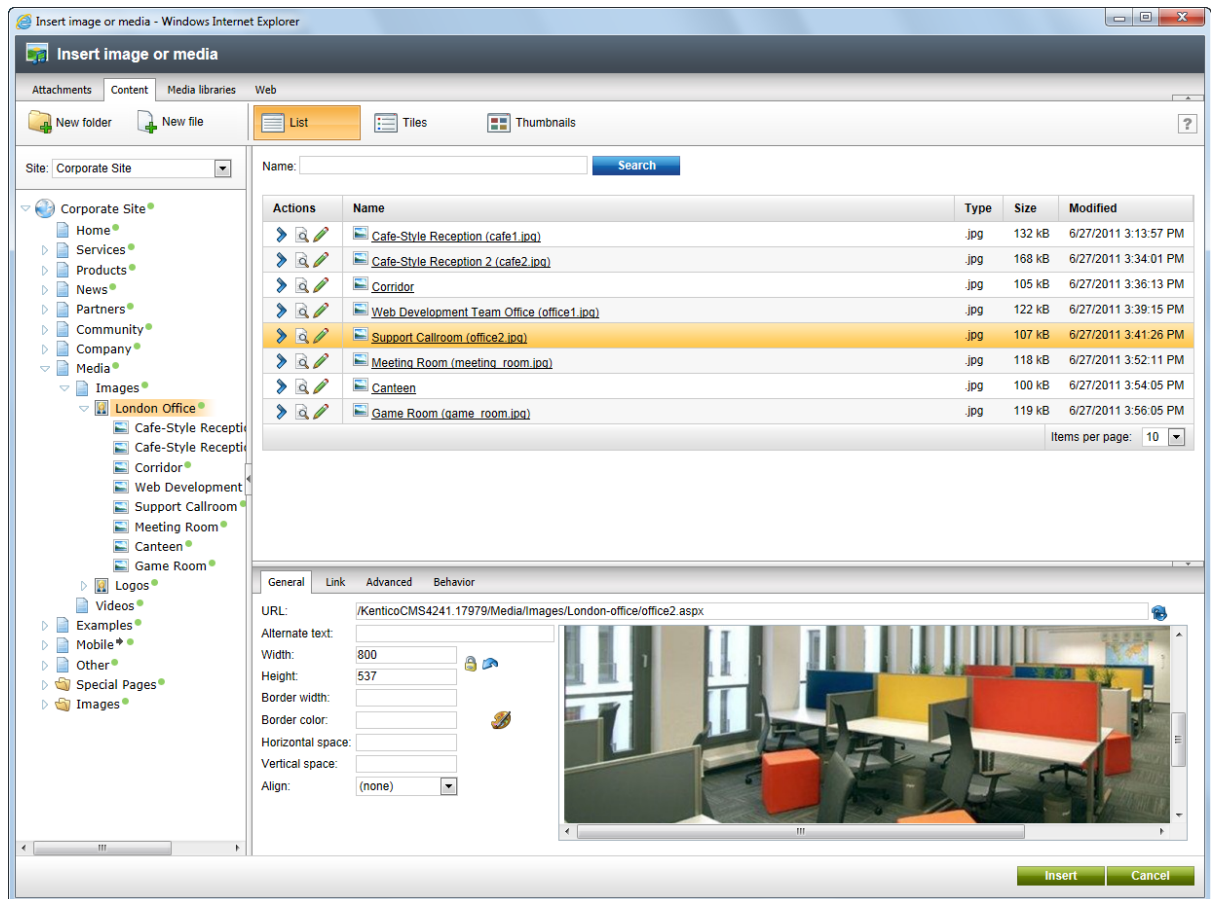

From this tab, you can insert files stored in the content tree of any of the sites running in the system. The site to insert from can be selected using the **Site** drop-down list, while its content tree will be displayed below. You can define which sites will be available. You can also define the starting alias path of the displayed content tree when defining a field in the field editor, as described in the [Dialog configuration](#) topic.

If you select a node of the content tree, all insertable files stored under it will be listed in the main area. You can filter the listed files by **Name**, **Type**, **Size** and the time when the files were **Modified** using the filter above the list.

You can select a file using the **Select** () icon or by simply clicking the appropriate line (or tile/thumbnaill in the other view modes).

New folders (*cms.folder* documents) can be created in the content tree via this dialog using the **New folder** () button. You can also upload new files (*cms.file* documents) into the content tree using the **New file** () button. The following actions can be performed with the listed files:

- After clicking the **View** () icon, the file will be opened in a new window.
- Using the **Edit** () icon, you can edit metadata of the file. However, clicking this icon placed beside an image opens the image in the built-in image editor.

Media libraries

From this tab, you can insert files stored in a media library. Depending on the settings described in the [Dialogs configuration](#) topic, you can select a library using the set of three drop-down lists - **Site**, **Group** and **Library** - in the top right part of the dialog.

More information about Kentico CMS Media libraries can be found in the [Modules -> Media libraries](#) chapter.

When a library is selected, its folder structure is displayed below the drop-down lists. After selecting a folder, its content will be offered in the main area. You can filter the listed files by **Name**, **Type**, **Size** and the time when the files were **Modified** using the filter above the list.

You can select a file using the **Select** () icon or by simply clicking the appropriate line (or tile/thumbnaill in the other view modes).

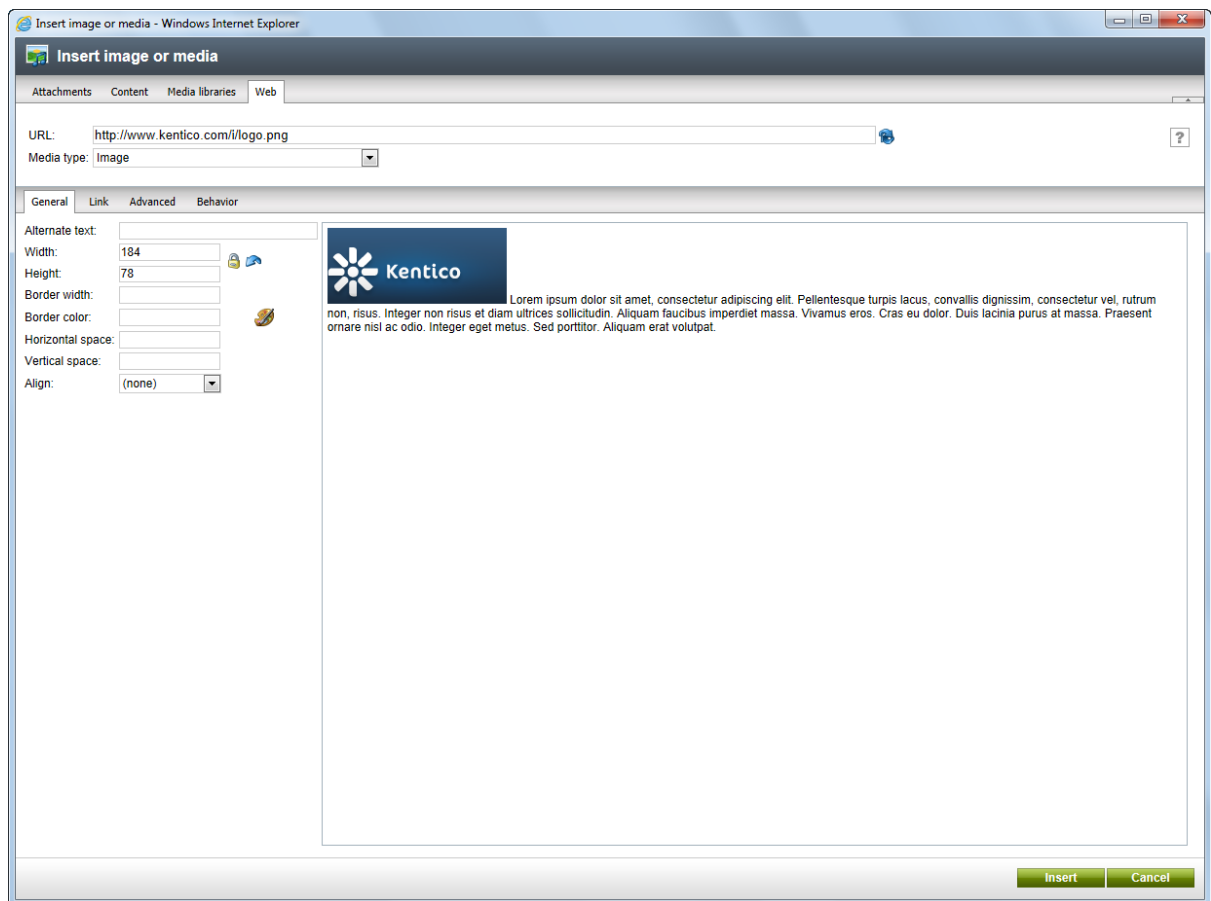

You can also perform the following actions with the listed files:

- After clicking the **View** () icon, the file will be opened in a new window.
- Using the **Edit** () icon, you can edit metadata of the file. However, clicking this icon placed beside an image opens the image in the built-in image editor.

Web

From this tab, you can enter an image, audio, video or flash from the web by entering its URL. More information on how to use this tab can be found in the [Inserting images or media from the Web](#) topic.

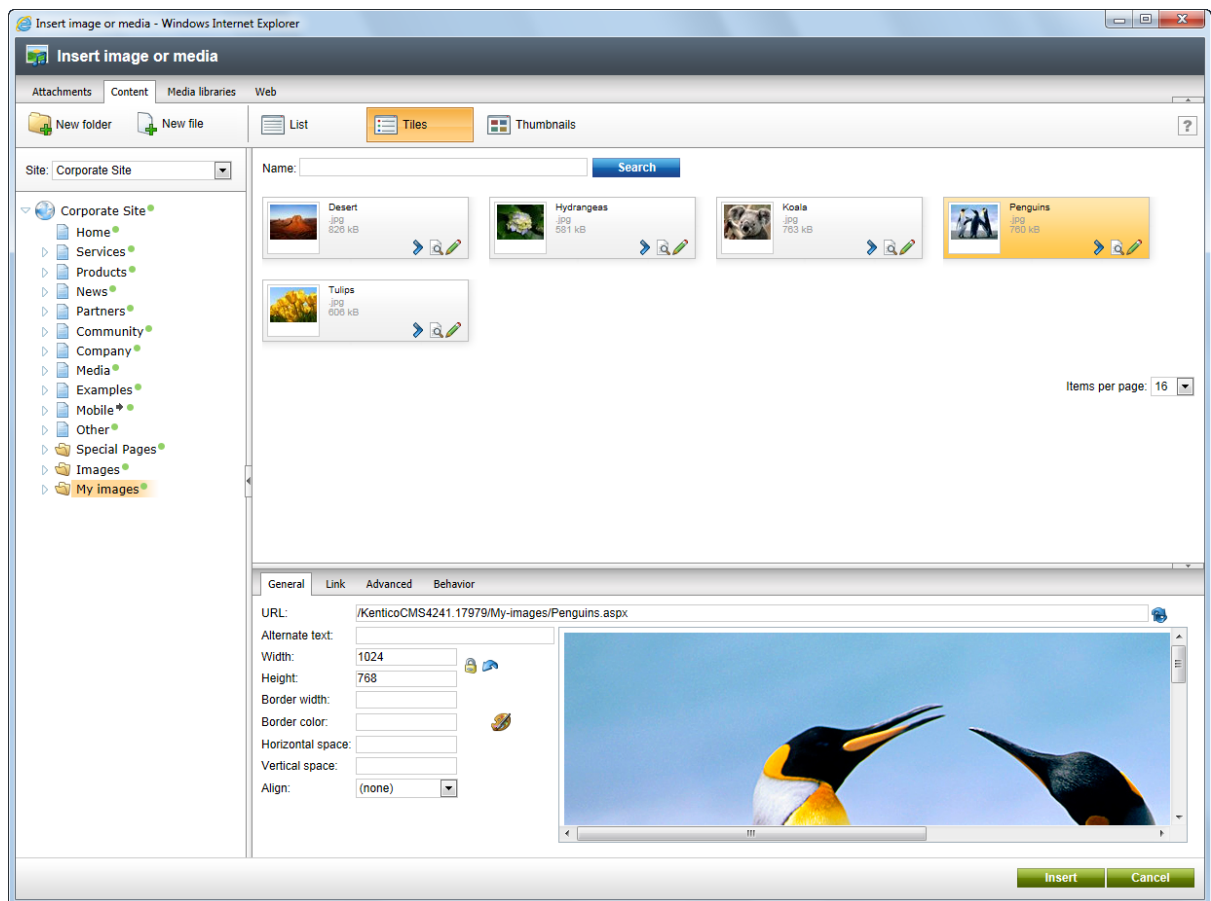

4.6.2.3 View modes

The following three view modes are available on the **Attachments**, **Content** and **Media libraries** tabs:

List

Tiles

Thumbnails

4.6.2.4 Inserting images

Inserting images via this dialog enables you to set a number of properties of the image. If you want to insert an image from the disk in a quick way, without specifying any properties, you can use the **Quickly insert image or media** (📎) icon as described in the [Quickly insert image or media](#) topic.

When inserting an image, its properties can be set on the following four tabs:

General

- **URL** - URL of the attached image.
- **Alternate text** - the text displayed when the image cannot be loaded correctly. Using alternative text improves the accessibility of your website for visitors with screen readers or browsers that do not support images or have them disabled. It is also a good SEO practice.
- **Width, Height** - the width and height of the displayed image; in pixels.
 - Aspect ratio can be locked (🔒), which makes the second dimension recalculated automatically when you change one dimension, while the ratio between the two dimensions is kept.
 - If unlocked (🔓), dimensions can be entered manually into both fields, without the ratio being kept.
 - You can also reload the default dimensions using the **Reset size** (🔄) icon.
- **Border width** - the width of the border around the displayed image.
- **Border color** - the color of the border around the image; has no effect when border width is not set.
- **Horizontal space** - horizontal space between the image and the surrounding text.
- **Vertical space** - vertical space between the image and the surrounding text.
- **Align** - image alignment.

Link

- **URL** - if set, the image will become a link to the resource defined by the entered URL. Settings on the **Behavior** tab are overridden.
- **Target** - the destination where the linked resource should be displayed when the image is clicked.

Advanced

- **ID** - the identifier of the image HTML element.
- **Tooltip** - the text displayed when the mouse cursor is placed over the image.
- **Class** - the image element CSS class.
- **Style** - image element additional styles.

Behavior

- **None** - the image is inserted as a standard image. When the image is clicked, no action is performed.
- **Open full size in the same window** - the image will become a link. When the image is clicked, its full size is displayed in the same window.
- **Open full size in a new window** - the image will become a link. When the image is clicked, its full size is displayed in a new window.
- **Show larger size on mouse-over** - when the mouse cursor is placed over the image, the image is displayed in a "floating window" in the defined size. It will be inserted as the **Image** inline control.
 - **Width** - the width of the displayed image; in pixels.
 - **Height** - the height of the displayed image; in pixels.
 - Aspect ratio can be locked (🔒), which makes the second dimension recalculated automatically when you change one dimension, while the ratio between the two dimensions is kept.
 - If unlocked (🔓), dimensions can be entered manually into both fields, without the ratio being kept.
 - You can also reload the original dimensions using the **Reset size** (🔄) icon.

6 ways how images can be inserted

1. Standard image

- **Behavior tab** - *None*.
- **Link tab** -> **URL** - an empty field.

The image is inserted as a standard image with no special behavior. No action is performed when the image is clicked or mouse-overed.

The output code looks like the following code sample:

```

```

2. Image with link

- **Behavior tab** - *None*.
- **Link tab** -> **URL** - a URL is specified.

The image functions as a link to the specified URL. When the image is clicked, the user is redirected to the URL in the same browser window.

The output code looks like the following code sample:

```
<a href="www.kentico.com"></a>
```

3. Image with special behavior - full size in the same window

- **Behavior tab** - *Open full size in the same window*.
- **Link tab** -> **URL** - an empty field.

When the image is clicked, it is displayed in full size in the same browser window.

The output code looks like the following code sample:

```
<a target="_self" href="/KenticoCMS41/MyImages/Waterfall.aspx"></a>
```

4. Image with special behavior - full size in a new window

- **Behavior tab** - *Open full size in a new window*.
- **Link tab** -> **URL** - an empty field.

When the image is clicked, it is displayed in full size in a new browser window.

The output code looks like the following code sample:

```
<a target="_blank" href="/KenticoCMS41/MyImages/Waterfall.aspx"></a>
```

5. Image with special behavior - larger size on mouse-over

- **Behavior tab** - *Show larger size on mouse-over*, **Height** = *xx*, **Width** = *yy*.
- **Link tab** -> **URL** - an empty field.

When the image is mouse-overed, it is displayed in a new layer in size defined on the **Behavior** tab as shown in the screenshot below.

In this case, the image is inserted as the **Image** inline control. The output code looks like the following code sample:

```
<object codetype="CMSInlineControl" height="265" type="Image" width="400">
<param name="mouseoverwidth" value="400" />
<param name="ext" value=".jpg" />
<param name="mouseoverheight" value="265" />
<param name="behavior" value="hover" />
<param name="url" value="~/Images-(1)/Services_webdevelop.aspx" />
<param name="cms_type" value="image" />
</object>
```

6. Image with special behavior - larger size on mouse-over with link

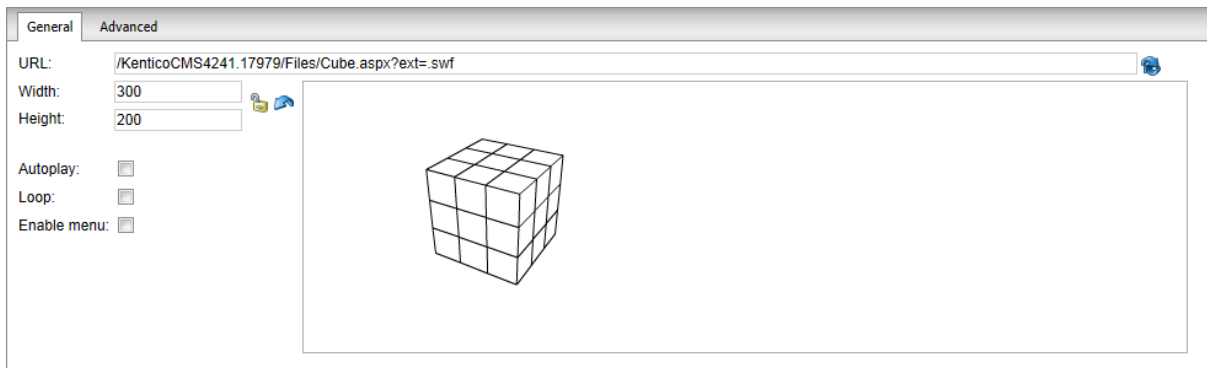

- **Behavior tab** - *Show larger size on mouse-over*, **Height** = *xx*, **Width** = *yy*.
- **Link tab** -> **URL** - a URL is specified.

When the image is mouse-overed, it is displayed in a new layer in size defined on the **Behavior** tab as shown in the screenshot above. The image is clickable and when clicked, the user is redirected to the specified URL in the same browser window.

In this case, the image is inserted as the **Image** inline control. The output code looks like the following code sample:

```
<a href="www.kentico.com">{^Image | (behavior)hover | (url)~/MyImages/Waterfall.aspx?width=200&height=150 | (width)200 | (height)150 | (mouseoverwidth)400 | (mouseoverheight)300^}</a>
```

4.6.2.5 Inserting flash

When inserting flash, its properties can be specified on the following two tabs:

General

- **URL** - URL of the attached flash file.
- **Width, Height** - the width and height of the flash player; 300x200px is used by default.
 - Aspect ratio can be locked (🔒), which makes the second dimension recalculated automatically when you change one dimension, while the ratio between the two dimensions is kept.
 - If unlocked (🔓), dimensions can be entered manually into both fields, without the ratio being kept.
 - You can also reload the default dimensions using the **Reset size** (🔄) icon.
- **Autoplay** - indicates if the video plays automatically when the player loads.
- **Loop** - indicates if the player plays the video repeatedly in a loop.
- **Enables menu** - indicates if flash options are available in the flash context menu. The flash context menu is displayed on right click of the flash player.

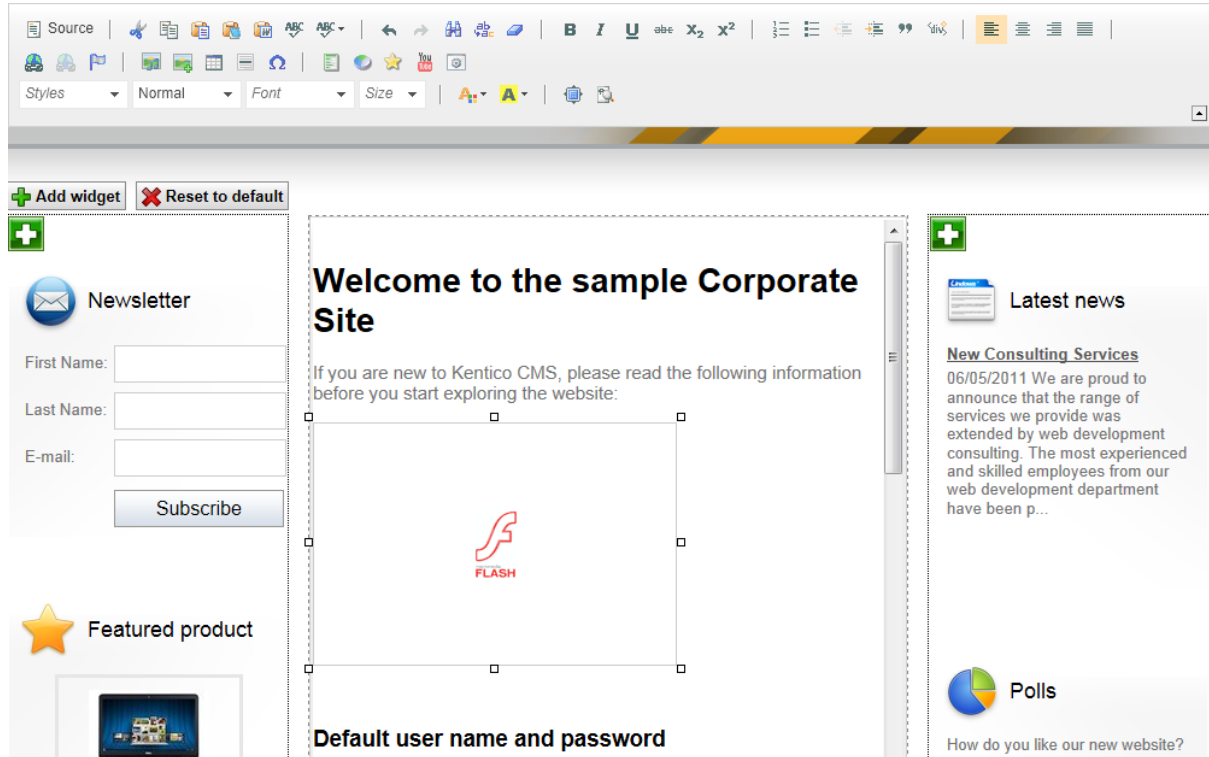

Advanced

- **Scale** - defines how the flash player stretches, shrinks and resizes when the browser window is resized.
- **ID** - the identifier of the flash HTML object.
- **Advisory title** - the text displayed when mouse cursor is placed over the flash player.
- **Class** - the flash element CSS class.
- **Style** - flash element additional styles.

Flash is inserted into the output code as the **Media** inline control. The following code sample shows what the output code looks like:

```
<object codetype="CMSInlineControl" height="200" type="Media" width="300">
<param name="url" value="http://127.0.0.1/KenticoCMS/Files/Cube.aspx?ext=.swf" />
<param name="ext" value=".swf" />
<param name="cms_type" value="flash" />
</object>
```

In the WYSIWYG editor, the flash is displayed only in the form of a box with the Flash logo, giving information about the size of the player:

And this is the result on the live site:

4.6.2.6 Inserting audio/video

General

URL:

Width:  

Height:  

Autoplay:

Loop:

Show controls:

When inserting both audio and video, the following properties can be set:

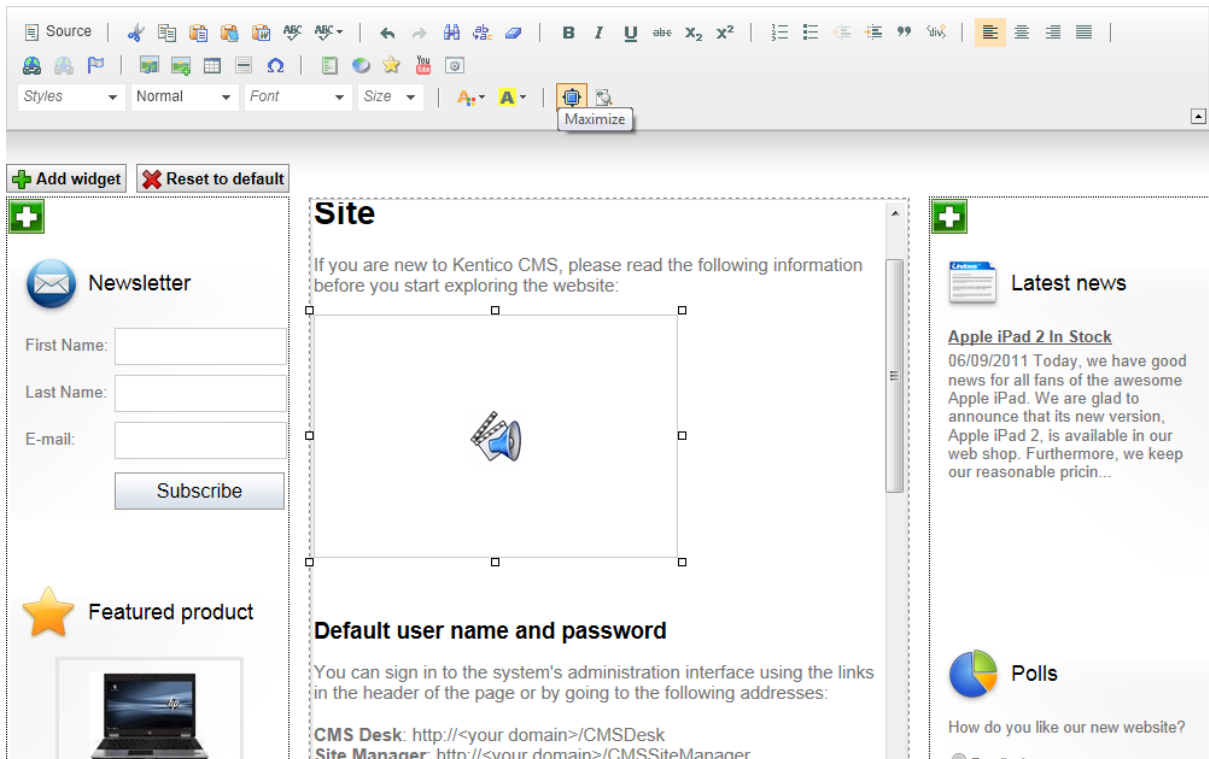

- **URL** - URL of the attached audio/video file.
- **Width, Height** - the width and height of the media player; 300x200px is used by default.
 - Aspect ratio can be locked (🔒), which makes the second dimension recalculated automatically when you change one dimension, while the ratio between the two dimensions is kept.
 - If unlocked (🔓), dimensions can be entered manually into both fields, without the ratio being kept.
 - You can also reload the default dimensions using the **Reset size** (🔄) icon.
- **Autoplay** - indicates if playback starts automatically when the page is loaded.
- **Loop** - indicates if playback is performed repeatedly in a loop.
- **Show controls** - indicates if playback controls (play, stop, fast forward, ...) are displayed. In some browsers, the controls may not be displayed if the player size is too small even if this option is enabled.

Audio and video is inserted into the output code as the **Media** inline control. The output code looks like

the following code sample:

```
<object codetype="CMSInlineControl" height="200" type="Media" width="300">
<param name="ext" value=".avi" />
<param name="cms_type" value="audiovideo" />
<param name="url" value="~/getattachment/Sample.avi.aspx" />
</object>
```

In the WYSIWYG editor, the player is not displayed. Instead, only a box with the audio/video icon can be seen, giving information about the size of the player on the live site:

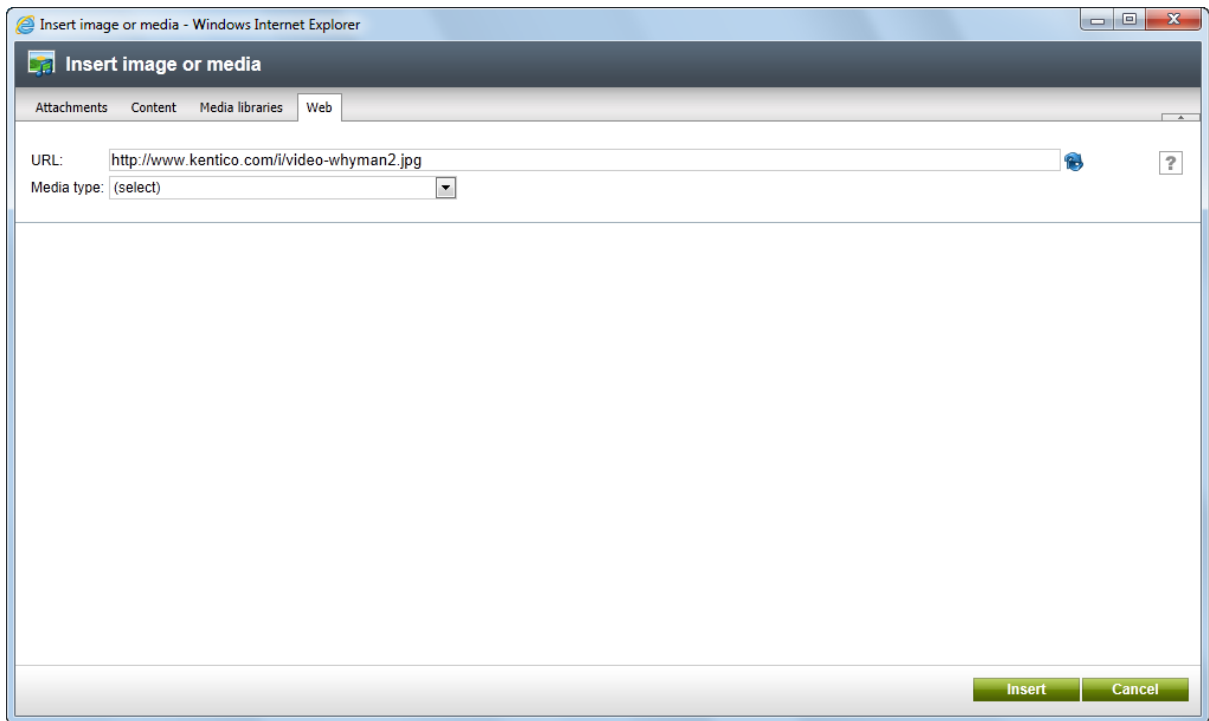

And this is how it looks on the live site:

The screenshot displays a sample Corporate Site homepage. On the left, there is a 'Newsletter' section with a blue envelope icon, followed by input fields for 'First Name', 'Last Name', and 'E-mail', and a 'Subscribe' button. Below this is a 'Featured product' section with a yellow star icon, showing a smartphone image and a price of '\$799.99'. The main content area is titled 'Welcome to the sample Corporate Site' and includes a video player with a play button and a volume icon. To the right, there is a 'Latest news' section with a document icon, a 'Community Website Section' header, and a news item dated '06/29/2011'. Below the news is a 'Polls' section with a pie chart icon, asking 'How do you like our new website?' with three radio button options: 'Excellent', 'Well done', and 'Nothing special'. The 'Default user name and password' section provides login instructions and URLs for 'CMS Desk' and 'Site Manager'.

4.6.2.7 Inserting images or media from the Web

Via the **Web** tab you can insert from the web any of the file types enumerated in the [Insert image or media -> Overview](#) topic, just by entering the respective URL. The generated code depends on the type of linked media and looks as the code samples mentioned in the previous three chapters.

The dialog initially looks like this on the tab:

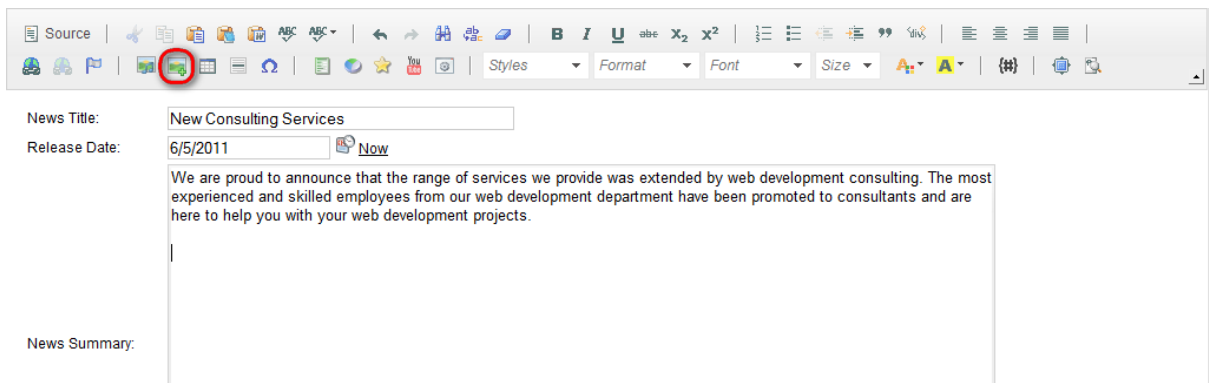

The general process of adding images or media from the web is as follows:

1. Enter the URL of the resource into the **URL** field.
2. Try automatic file type detection using the **Refresh** (🔄) icon. In case that the file type cannot be detected, you can still choose it manually from the **Media type** drop-down list.
3. Based on the file type, its properties will be loaded into the main area. The properties of individual file types are described in the [Inserting images](#), [Inserting flash](#) and [Inserting audio/video](#) topics.
4. Enter the properties and click the **Insert** button. The image or media file is inserted into the text.

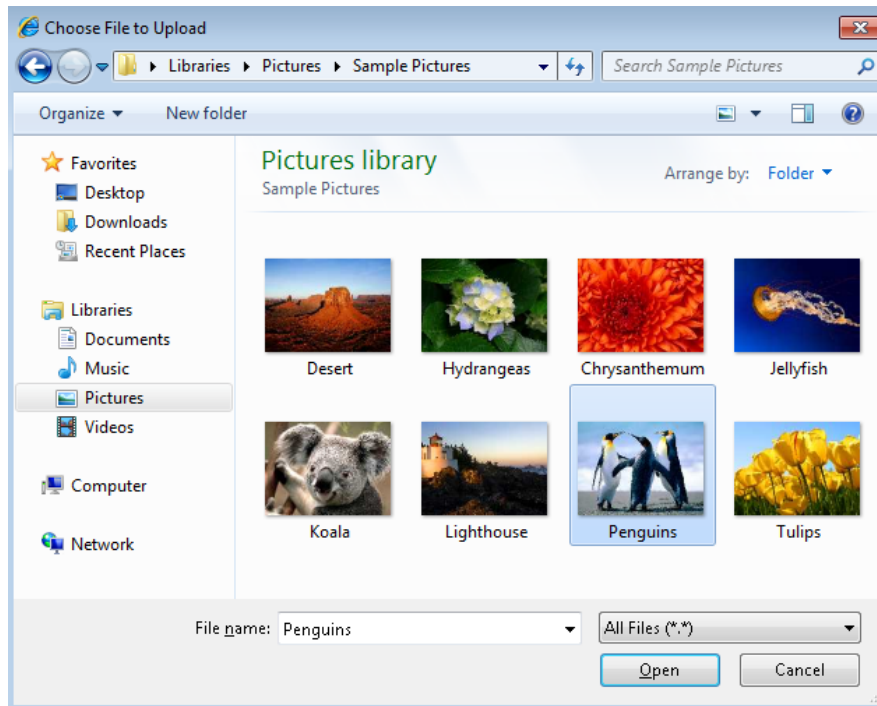

4.6.3 Quickly insert image or media

The Quickly insert image or media action can be used to insert an image, video, flash video or document from a disk in a quick way. The following three steps need to be taken to insert media this quick way:

1. Place the cursor in the appropriate position and click the **Quickly insert image or media** (🖼️) icon on the WYSIWYG editor toolbar.

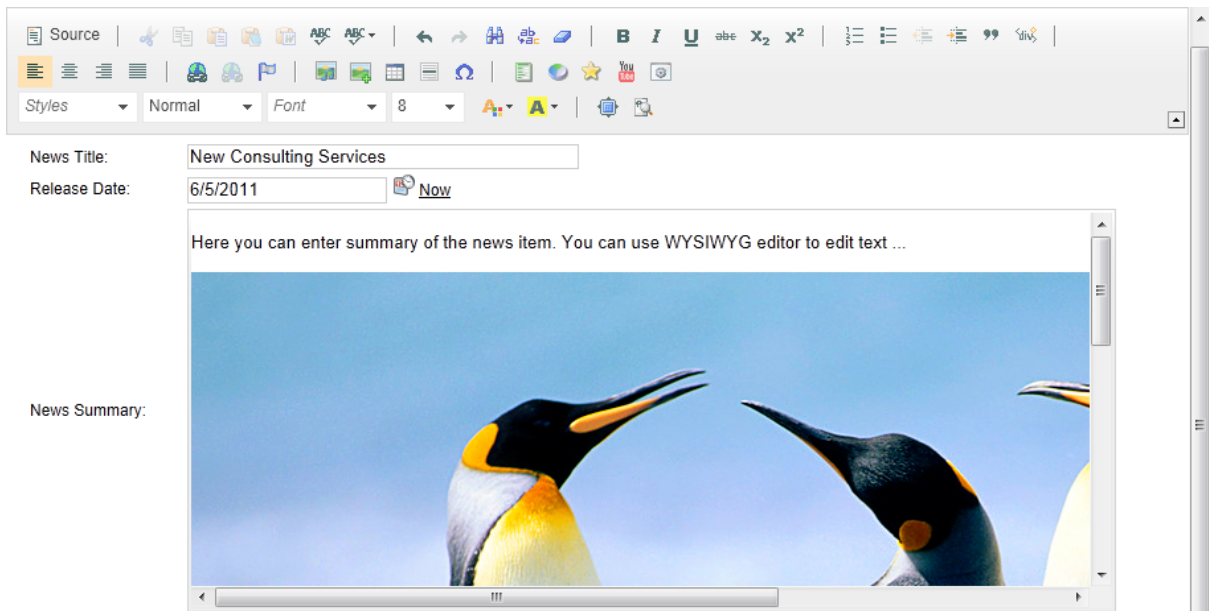

2. The **Choose file** dialog of your browser opens. Locate the file on the disk and click **Open**.

3. Result

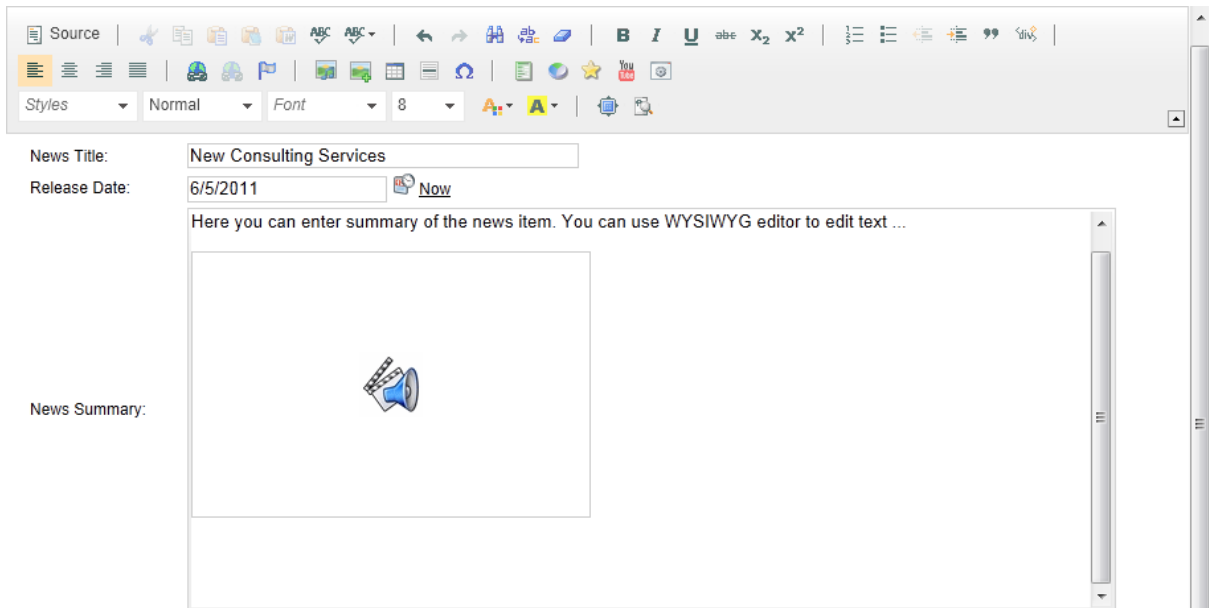

Image

An image is inserted into the text in its original size; to learn how to change this setting, please refer [here](#). At the same time, it is uploaded to the document as its [attachment](#). However, you can edit the image just as images inserted via the **Insert image or media** dialog. For more information, please refer to the [Editing inserted items](#) topic.

Video and flash video

Same as images, videos are inserted into the text and uploaded to the document as its [attachments](#). The size of an inserted video is 300x200px by default; to learn how to change this setting, please refer [here](#). Videos inserted this way can be edited just as videos inserted via the **Insert image or media** dialog. For more information, please refer to the [Editing inserted items](#) topic.

Please note

To change the default size of the inserted audio/video player, you need to modify the `DEFAULT_OBJECT_WIDTH` and `DEFAULT_OBJECT_HEIGHT` constants in the `DirectFileUploaderControl.ascx.cs` control located in `<your web project folder>/CMSModules/Content/Controls/Attachments/DirectFileUploader`.

Document

A document file or any other type of file except for an image, video or flash video is inserted into the text as a link tag.

News Title:

Release Date:

Here you can enter summary of the news item. You can use WYSIWYG editor to edit text ...

News Summary:

Please note

The link to a document file has the following format: `<attachment name.file extension>`.

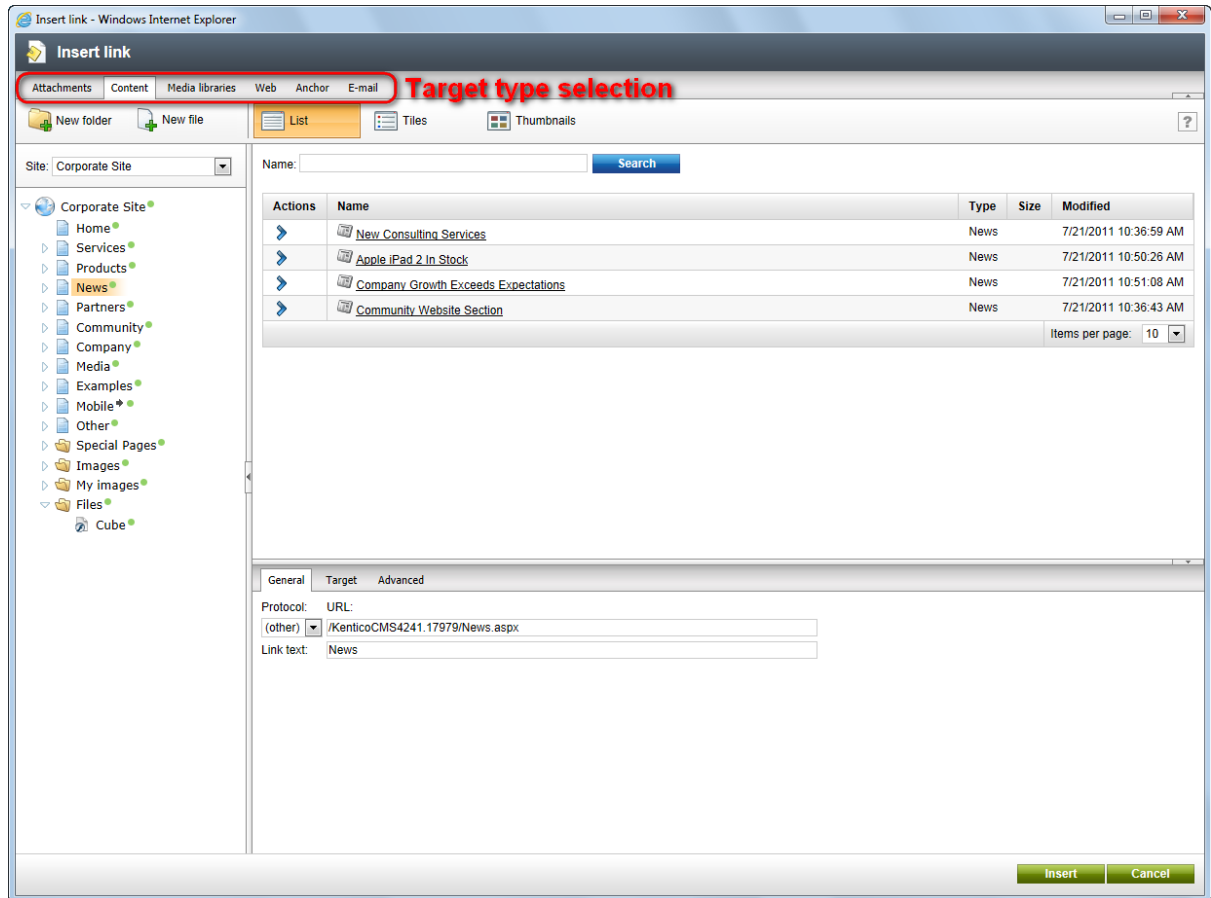

4.6.4 Insert link

4.6.4.1 Overview

The **Insert link** dialog is accessible by clicking the **Insert link** (🔗) icon on the WYSIWYG editor toolbar:

All links are inserted using `<a>` tags and the following types of targets can be linked:

- [Content within the CMS](#) - via the **Attachments**, **Content** and **Media libraries** tabs.
- [Content anywhere on the Web](#) - via the **Web** tab.
- [Anchors in documents](#) - via the **Anchor** tab.
- [Mailto links](#) - via the **E-mail** tab.

General process of inserting a link

1. Select the text that should become a link or place the cursor to the position where the link text should be inserted.
2. Click the **Insert link** () icon on the WYSIWYG editor toolbar.
3. Choose the appropriate tab and specify where the link should be leading.
4. Specify link properties and click the **Insert** button.
5. The link is inserted into the text.

4.6.4.2 Link properties

On the **Attachments**, **Content**, **Media libraries** and **Web** tabs, you can see the following section for setting up link properties:

General	Target	Advanced
Protocol: URL:		
(other) ▾	/KenticoCMS4241.17979/News.aspx	
Link text:	News	

You can specify the following properties on the respective tabs:

General

- **Protocol + URL** - the address of the linked resource.
- **Link text** - the text of the link that will appear in the text. This field is visible only when inserting a link into an empty space in the text area, i.e. when no text or object is selected.

Please note

On the **Web** tab, only the **Target** and **Advanced** tabs are displayed and the general properties are displayed above them.

Target

- **Target** - using this drop-down list, you can define where the link will be opened.
- **Target frame name** - the name of the frame where the target should be opened. This option is displayed only if the **Target** property is set to *(frame)*.

Advanced

- **ID** - the identifier of the link HTML element.
- **Name** - the name of the link HTML object.
- **Tooltip** - the text displayed when the mouse cursor is placed over the link.
- **Class** - the link element CSS class.
- **Style** - additional link element styles.

4.6.4.3 Links to content within the CMS

Links to content within the CMS can be inserted via the **Attachments**, **Content** and **Media libraries** tabs. Detailed descriptions of all possible actions that can be performed on the tabs can be found in the [File sources](#) topic of the **WYSIWYG editor -> Insert image or media** subchapter.

Attachments

Via this tab, you can insert links to attachments of the current document. For more information about document attachments, please refer to the [Document attachments](#) chapter of this guide.

The following code sample shows what the output code looks like:

```
<a href="/3644_9682/getattachment/News/Your-first-news/NewsPhoto1.JPG.aspx">NewsPhoto1.JPG</a>
```

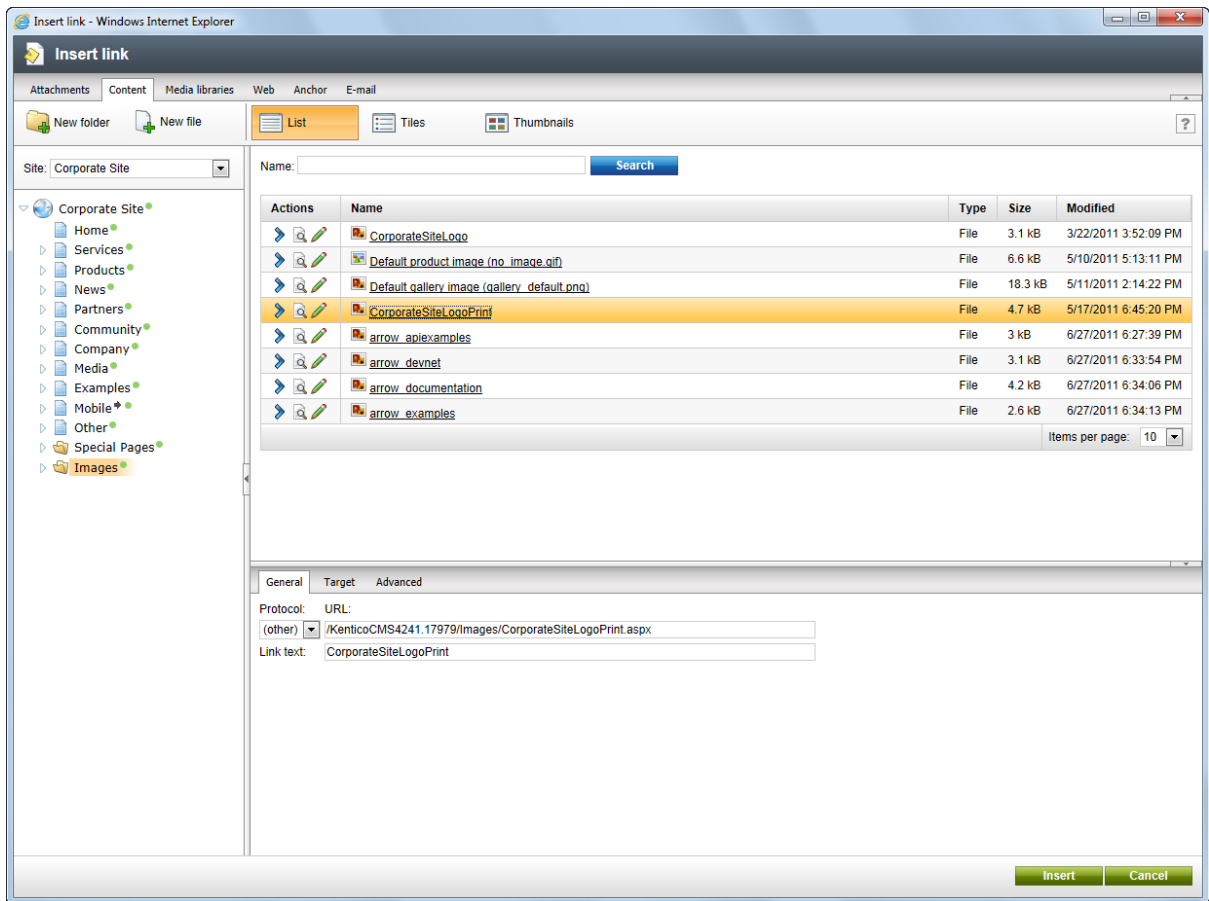

Content

Via this tab, you can insert links to any pages, documents or files within the content tree of a site. The site can be selected using the **Site** drop-down list, while its content tree will be displayed below. You can define which sites will be available. You can also define the starting alias path of the displayed content tree when defining a field in the field editor, as described in the [Dialog configuration](#) topic.

The following code sample shows what the output code looks like:

```
<a href="/3644_9682/Images-(1)/Services_webdesign.aspx">Services webdesign</a>
```

Media libraries

Via this tab, you can insert links to files stored within media libraries. Depending on the settings described in the [Dialogs configuration](#) topic, you can select a library using three drop-down lists - **Site**, **Group** and **Library** - in the top right part of the dialog.

The following code sample shows what the output code looks like:

```
<a href="/3644_9682/CorporateSite/media/CzechCities/IM002595.JPG">IM002595</a>
```

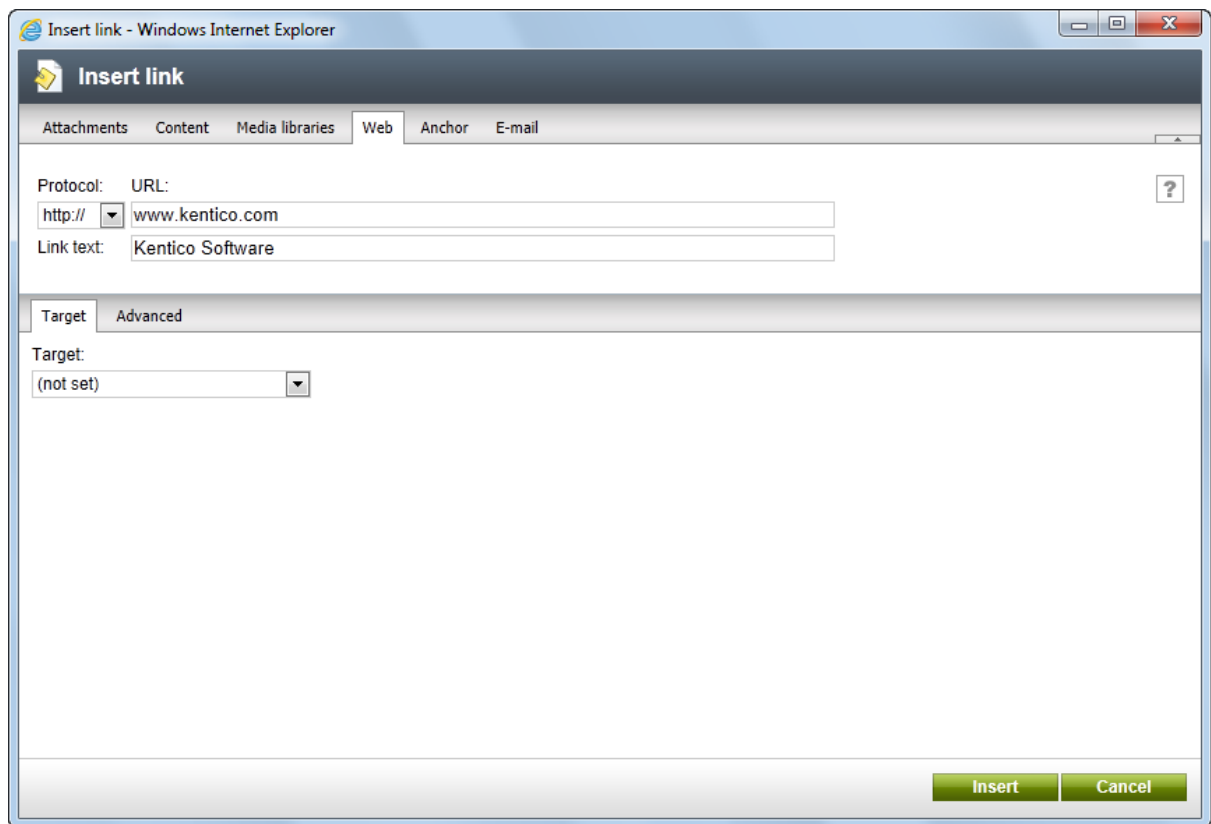

4.6.4.4 Links to the Web

On the **Web** tab, you can link any resource on the web by entering its URL. The output code is generated as an `<a>` HTML element:

```
<a href="http://www.kentico.com">Kentico Software</a>
```

On this tab, you can specify the same properties as described in the [Link properties](#) topic, with the difference that the content of the **General** tab is displayed above the two other tabs.

4.6.4.5 Links to anchors

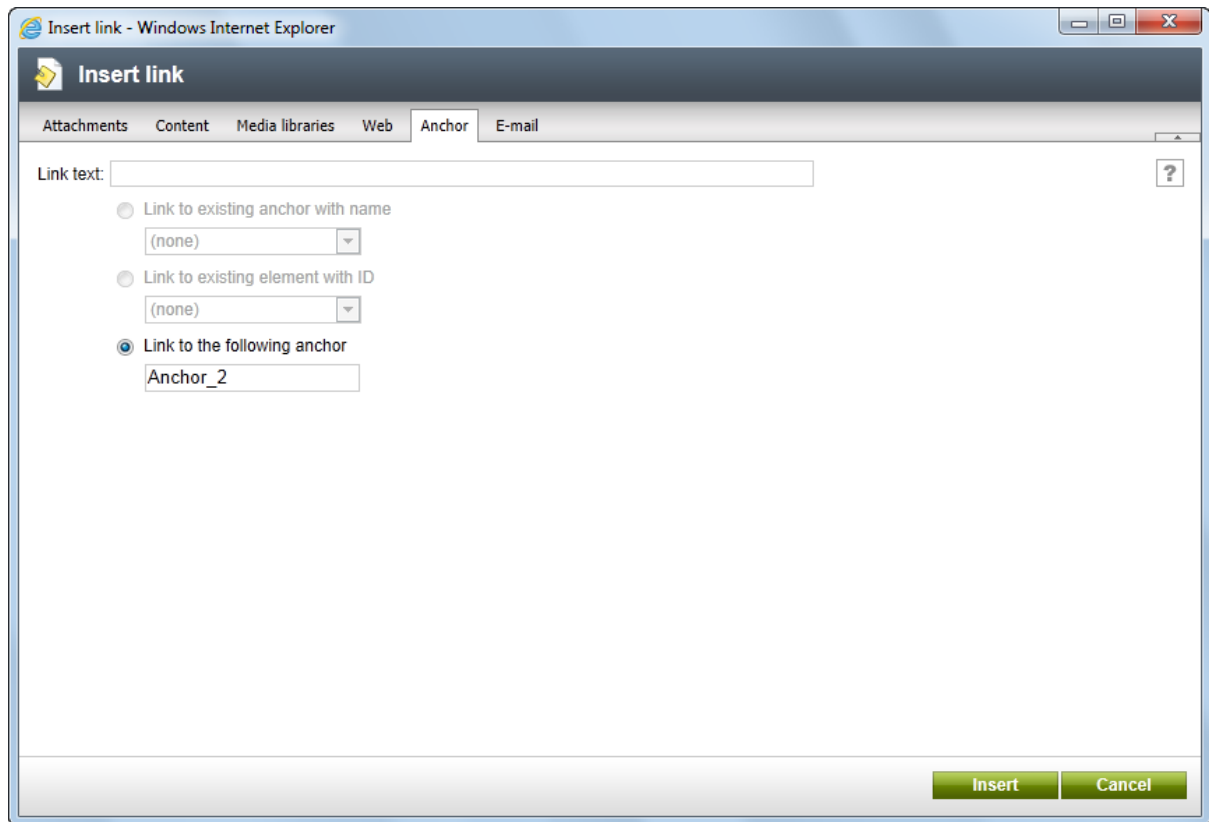

Via the **Anchor** tab, users can insert links to any anchor or any HTML element with a specified ID attribute on the current page. Anchors are `<a>` HTML elements with the **Name** attribute specified. They can be inserted using the **Anchor** (📌) icon on the WYSIWYG editor toolbar. If you link to an anchor, the page will scroll to it after clicking the link.

You have the following options on this tab:

- **Link text** - the text of the link that will appear in the text. This field is visible only if inserting a link into an empty space in the text area, i.e. if no text or object is selected.
- **Link to existing anchor with name** - if selected, you can choose an anchor from the drop-down list below as the target.
- **Link to existing element with ID** - if selected, you can choose an HTML element from the drop-down list below as the target.
- **Link to the following anchor** - if selected, you can type in the name of the target anchor or ID of the target element manually.

The output code looks like the following code sample, while the text after `#` is the name of the anchor or the value of the ID attribute:

```
<a href="#Anchor_2">Second chapter</a>
```

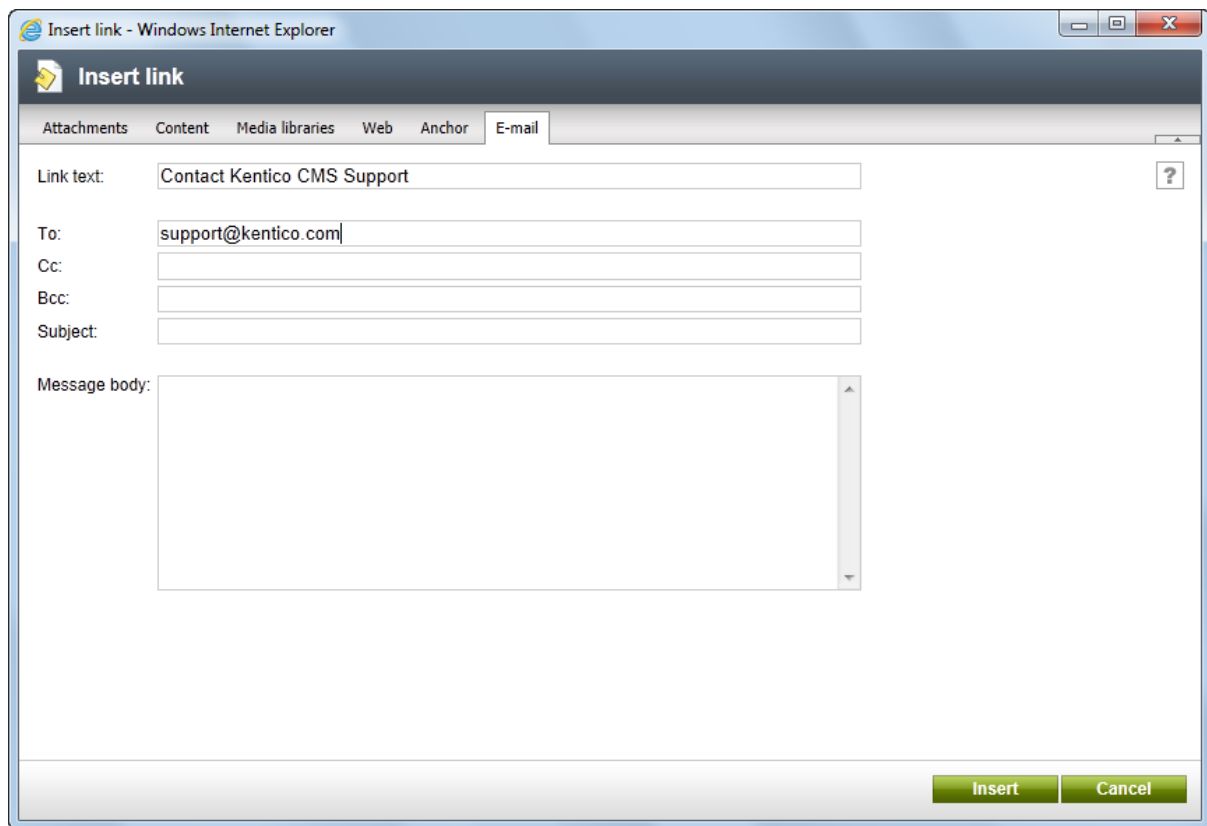

4.6.4.6 Mailto links

Via the **E-mail** tab, you can insert standard "mailto" links. After clicking such a link, a new message window of the user's e-mail program (e.g. Outlook) is opened, while some details may be pre-filled based on what is specified in the following properties:

- **Link text** - the text of the link that will appear in the text. This field is visible only when inserting a link into an empty space in the text area, i.e. when no text or object is selected.
- **To** - e-mail recipient's address; a required field. Multiple addresses can be entered divided by semicolons.
- **Cc** - e-mail copy recipient's address. Multiple addresses can be entered divided by semicolons.
- **Bcc** - e-mail blind carbon copy recipient's address. Multiple addresses can be entered divided by semicolons.
- **Subject** - the subject of the e-mail.
- **Message body** - the text of the e-mail.

The output code looks like the following code sample:

```
<a href="mailto:support@kentico.com">Contact Kentico CMS Support</a>
```

4.6.5 Insert YouTube video

Using this dialog, a video from YouTube can be easily added to a page. The dialog can be opened using the **Insert YouTube video** (📺) icon on the WYSIWYG editor toolbar, as you can see in the screenshot below:

Inserting YouTube video

The general process of inserting a YouTube video is as follows:

1. Place the cursor at the appropriate position in the text area and click the **Insert YouTube video** (📺) icon.
2. The dialog opens.
3. Insert the URL of the YouTube video into the **URL** field and click the **Refresh** (🔄) icon.
4. The entered URL is checked and if it is valid, default properties are loaded and the preview displayed.
5. Specify the properties of the video according to your needs. The changes you make are reflected in the preview in the right part of the dialog.
6. When you are finished with the properties, click the **Insert** button.
7. The video is inserted into the text area.

If you click on **Go to YouTube** (🌐) in the dialog, you will be redirected to the YouTube home page. This

home page will be opened in a new browser tab.

YouTube video properties

The following properties can be specified in this dialog:

- **URL** - URL of the YouTube video. You can copy&paste it from the address line of your browser or from the **URL** field on the video page.
- **Allow full screen** - indicates if the control to switch playback to full screen will be available in the video toolbar.
- **Autoplay** - indicates if playback starts automatically when the page is loaded.
- **Loop** - indicates if playback is continuously repeated in a loop.
- **Include related videos** - indicates if related videos will be displayed when playback finishes.
- **Enable delayed cookies** - indicates if delayed cookies should be used.
- **Play in HD** - indicates if the video will be played in HD by default. The user can switch back to normal quality by pressing the **HD** button while playing the video.

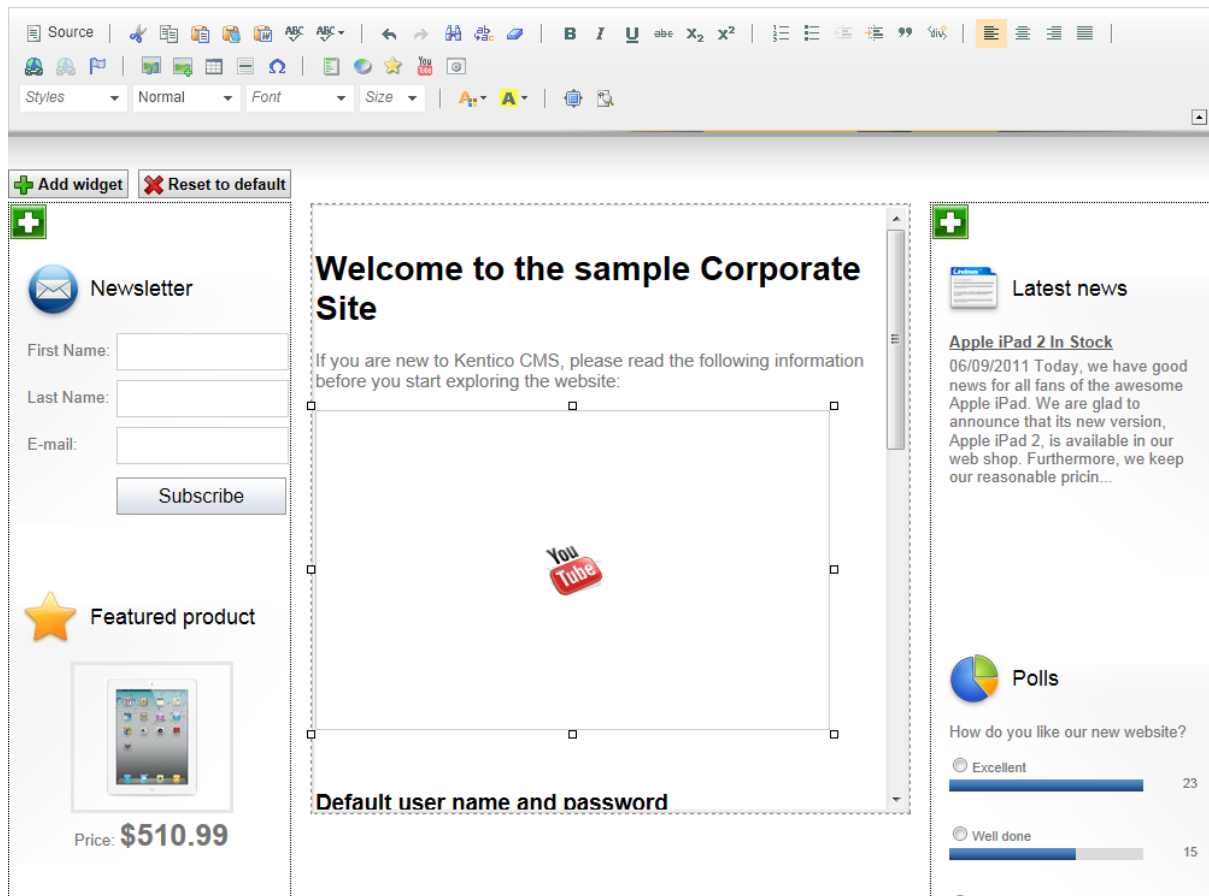

- **Default color** - you can choose one of the default color combinations, which will be used in the **Color 1** and **Color 2** properties.
- **Color 1** - the color of the border around the player, relevant only if the **Show border** property is enabled.
- **Color 2** - the color of the player toolbar.

- **Default size** - you can choose one of the default sizes of the video player, which will be used in the **Width** and **Height** properties.
- **Width** - the width of the video player.
- **Height** - the height of the video player.
- **Show border** - indicates if border should be shown around the player. Enabling this option adds 20px to both the width and height of the player.

This is what the dialog window looks like when a video is loaded:

In the WYSIWYG editor, the actual video is not displayed. You can only see a box with the YouTube logo in the middle to give you information about the player size:

The YouTube video is generated as the **YouTubeVideo inline control**, as you can see in the code sample below:

```
{^YouTubeVideo|(url)http://www.youtube.com/watch?v=VtzdJrKmUhs|(width)320|(height)198|(fs>true|(autoplay>false|(loop>false|(rel>true|(cookies>false|(border>false|(color1)#3A3A3A|(color2)#999999^}
```

On the live site, the video is displayed in the player:

4.6.6 Editing inserted items

Properties of images, audios, videos, flash videos, YouTube videos and links that are already inserted in the WYSIWYG editor can be edited. The same dialog that was displayed when you inserted the items can be opened again the following three ways:

1. Double-click the item.

2. Right-click the item and choose Properties from the context menu.

3. Select the item and click the appropriate button on the WYSIWYG editor toolbar.

4.6.7 Copy & Paste from Microsoft Word

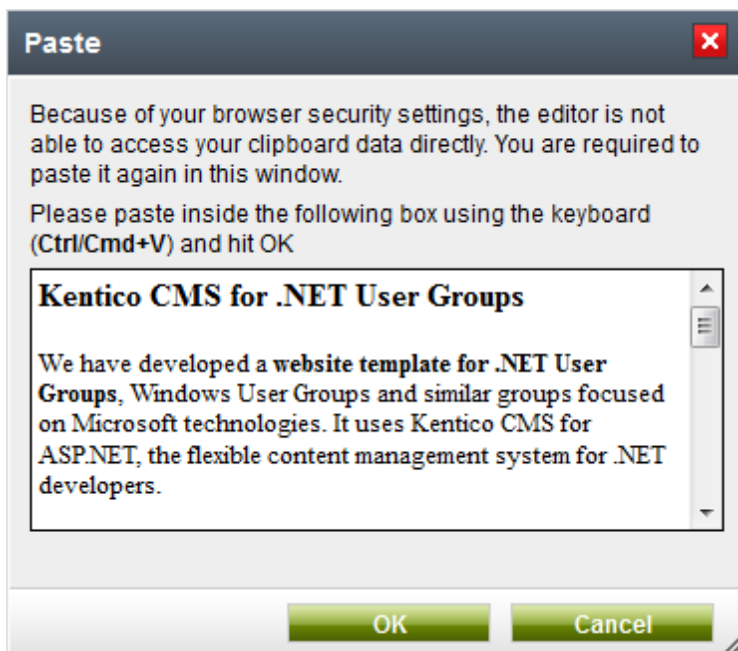

When copying a text from Microsoft Word, the text is encapsulated with many unnecessary tags that may break your web page design. That is why the built-in WYSIWYG editor allows you to clean the pasted text so that it contains only basic formatting.

1. Select the text in a Microsoft Word document and copy it to clipboard (**CTRL+C**):

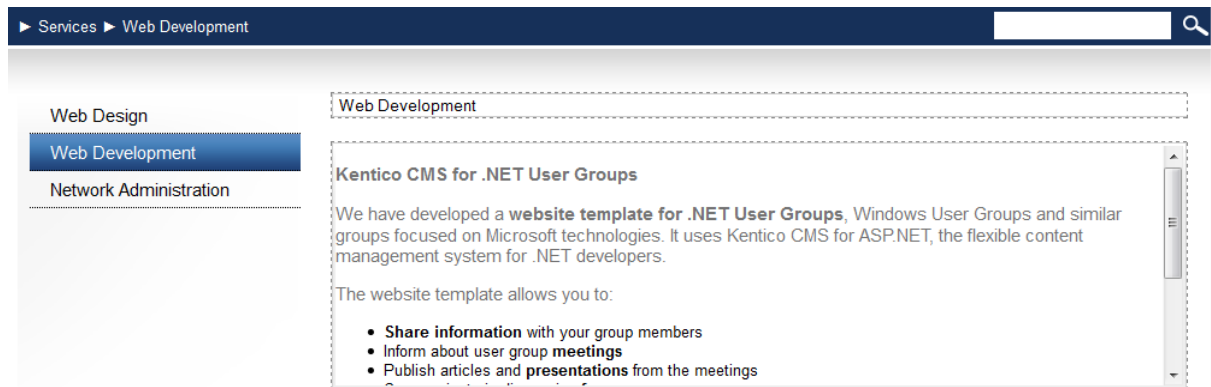

2. Now place the cursor into a Kentico CMS text area and click the **Paste from Word** (📄) icon on the WYSIWYG editor toolbar. The behaviour depends on the browser that you are using:

- If you are using Microsoft Internet Explorer, the text will be pasted into the text area automatically.
- If you are using a different browser, the **Paste from Word** dialog opens. Paste the text into the box using **CTRL+V** and check both the check boxes and click **OK**.

3. The text gets pasted into the text area and looks like this:

As you can see, the style follows your website design. However, since Word does not provide appropriate tagging information, some formatting may not be preserved and you may need to apply the design manually - e.g. the header in the sample text.

4. Finally, click **Save** (📁) to save the changes.

4.6.8 Defining custom toolbars

The WYSIWYG editor toolbar is customizable so that content editors can be prevented from using certain formatting features. This helps to keep the website design consistent and clean.

1. Defining toolbar sets

You can define toolbar sets in `<web project>\CMSAdminControlsCKEditor\config.js`.

The following code sample shows a definition of the default toolbar set containing all available icons. However, you can create your custom toolbar sets by modifying it or by using icon names contained in it.

```
config.toolbar_Full = config.toolbar_Default =
[
  ['Source', '-', 'Preview'],
  ['Cut', 'Copy', 'Paste', 'PasteText', 'PasteFromWord', '-', 'SpellChecker',
  'Scayt'],
  ['Undo', 'Redo', '-', 'Find', 'Replace', '-', 'SelectAll', 'RemoveFormat'],
  ['Bold', 'Italic', 'Underline', 'Strike', '-', 'Subscript', 'Superscript'],
  ['NumberedList', 'BulletedList', '-', 'Outdent', 'Indent', 'Blockquote',
  'CreateDiv'],
  ['JustifyLeft', 'JustifyCenter', 'JustifyRight', 'JustifyBlock'],
  ['InsertLink', 'Unlink', 'Anchor'],
  ['InsertImageOrMedia', 'QuicklyInsertImage', 'Table', 'HorizontalRule',
  'SpecialChar', 'PageBreak'],
  ['InsertBizForms', '-', 'InsertPolls', '-', 'InsertRating', '-',
  'InsertYouTubeVideo', '-', 'InsertWidget'],
  '/',
  ['Styles', 'Format', 'Font', 'FontSize'],
  ['TextColor', 'BGColor'],
  ['Maximize', 'ShowBlocks']
]
```

```
];
```

As you can see, the toolbar set definition consists of several arrays, e.g. `['Source', '-', 'Preview']`. This array displays a group of three icons: *Source* and *Preview*, with the first icon separated by a vertical line (defined by the `'-'` string).

If you need to insert a line break between the icon groups, use the `'/'` string.

If you want to define your own toolbar set, add a command in the **`config.toolbar_ToolbarName`** format to the **`config.js`** file. When you have done this, save the changes you made to the file.

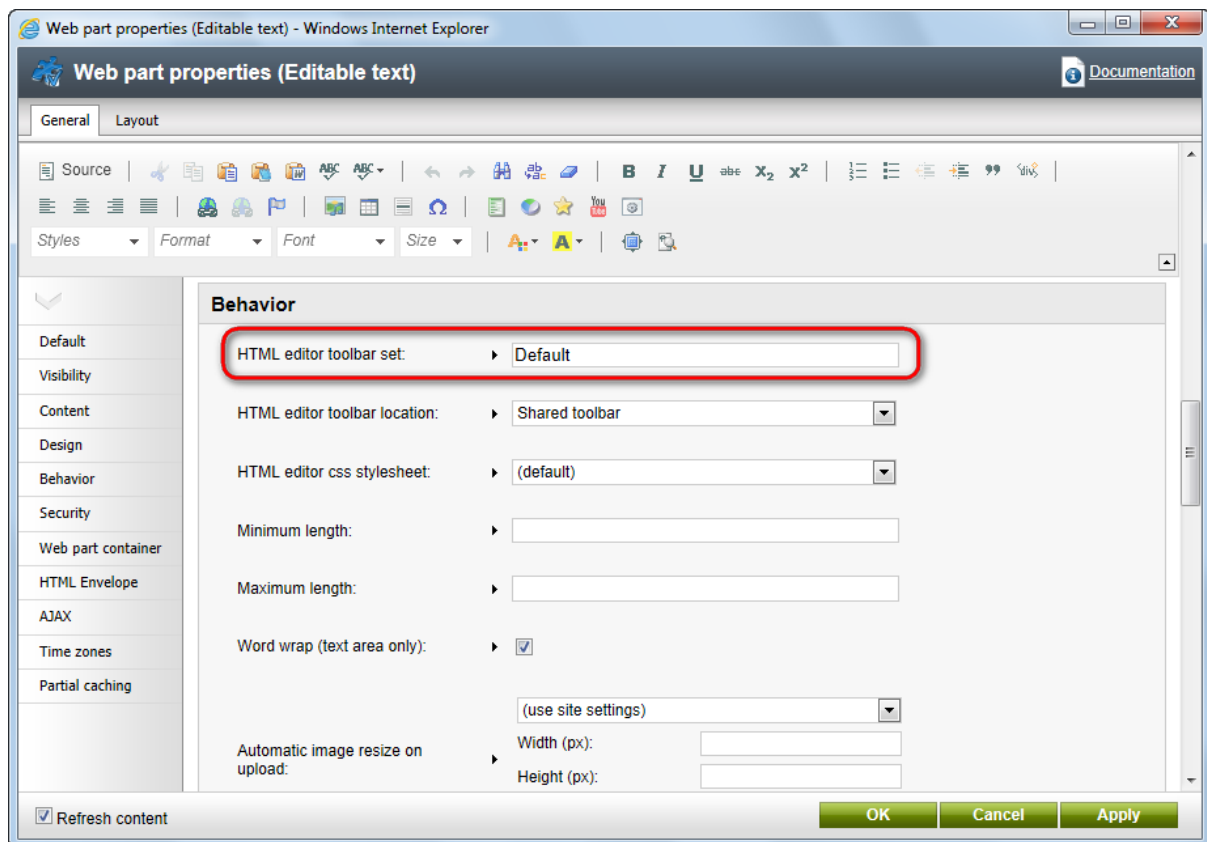

Every time you modify the `config.js` file (or any other file that is used for the WYSIWYG editor), you need to clear the cache of your browser so that the changes are applied.

Now you need to configure a page or document type in order for it to use your new toolbar set.

2. Assigning the toolbar set to a page

To assign the toolbar set to a page with editable regions (edited on the **Page** tab), you need to configure web parts of the *Editable region* type on the page template. Specifically, you need to set their **Toolbar set** property values to the name of your toolbar set (in the above example, it is *Default*).

Toolbar set used for structured documents

If you want to modify a toolbar set used for **structured documents** (edited on the **Form** tab), you need to set the **Toolbar set** property value of the custom field. If you share the toolbar between multiple fields, the first field toolbar set will be used.

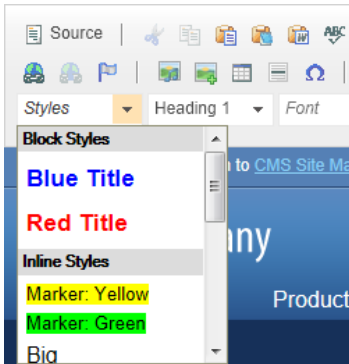

Standard toolbar sets

Kentico CMS comes shipped with several standard toolbar sets that are used by the Kentico CMS modules:

- **Full/Default** - used for structured documents.
- **Basic** - the simplest toolbar set; should not be used as default.
- **ProjectManagement** - used for project management.
- **BizForm** - used for Form module forms.
- **Forum** - used for the WYSIWYG editor in forums (if enabled).
- **Newsletter** - used for newsletters.
- **Reporting** - used for reporting.
- **SimpleEdit** - used for simple editing.
- **Invoice** - used for invoicing.
- **Group** - used for groups.
- **Widgets** - used for widgets.

4.6.9 Defining styles

The WYSIWYG editor allows you to apply a selected style to the text using the **Style** drop-down list. You can use either built-in styles or your custom styles:

The styles offered in the list are defined in the minified `<web project>\CMSAdminControls\CKeditor\plugins\styles\styles\default.js` file. For illustration purposes, the structure of the unminified file looks like this:

```
CKEDITOR.stylesSet.add( 'default',
[
  { name : 'Blue Title'      , element : 'h3', styles : { 'color' : 'Blue' } },
  { name : 'Red Title'      , element : 'h3', styles : { 'color' : 'Red' } },
  { name : 'Marker: Yellow' , element : 'span', styles : { 'background-color' :
'Yellow' } },
  { name : 'Marker: Green'  , element : 'span', styles : { 'background-color' :
'Lime' } },
  { name : 'Big'            , element : 'big' },
  { name : 'Small'         , element : 'small' },
  { name : 'Typewriter'    , element : 'tt' },
  { name : 'Computer Code' , element : 'code' },
  { name : 'Keyboard Phrase' , element : 'kbd' },
  { name : 'Sample Text'   , element : 'samp' },
  { name : 'Variable'      , element : 'var' },
  { name : 'Deleted Text'  , element : 'del' },
  { name : 'Inserted Text' , element : 'ins' },
  { name : 'Cited Work'    , element : 'cite' },
  { name : 'Inline Quotation' , element : 'q' },
  { name : 'Language: RTL'  , element : 'span', attributes : { 'dir' : 'rtl' } },
  { name : 'Language: LTR' , element : 'span', attributes : { 'dir' : 'ltr' } },
  {
    name : 'Image on Left',
    element : 'img',
    attributes :
    {
      'style' : 'padding: 5px; margin-right: 5px',
      'border' : '2',
      'align' : 'left'
    }
  }
]
```

```

},
{
  name : 'Image on Right',
  element : 'img',
  attributes :
  {
    'style' : 'padding: 5px; margin-left: 5px',
    'border' : '2',
    'align' : 'right'
  }
},
{ name : 'Borderless Table', element : 'table', styles: { 'border-style':
'hidden', 'background-color' : '#E6E6FA' } },
{ name : 'Square Bulleted List', element : 'ul', styles : { 'list-style-type' :
'square' } }
]);

```

If you need to set more styles for one object, separate individual style definitions with a comma:

```

{ name : 'Object', element : 'element', styles : { 'style 1' : 'value' , 'style
2' : 'value' } }

```

Every style has its name and element for which it is used. The styles are offered in the drop-down list based on the current position of the cursor. If you select some image, the styles for the *img* element will be offered. If you select some text, the styles for the *h3* or *span* element will be offered.

If you choose to apply e.g. the **Red Title** style to the following HTML code:

```

We provide web development services.

```

the result will be as follows:

```

<h3 style="color: red">We provide web development services.</h3>

```

As you can see, the text was encapsulated with the *h3* element with the **style** attribute set to **color: red**.

However, you may want to apply CSS class names instead of hard-coded styles. If you want to add a new style, the definition of the style needs to be inserted into the *default.js* file in front of the last square bracket. In this case, your style definition will look like this:

```

name : 'Green text',
element : 'div',
attributes :
{
  'class' : 'GreenText'
}

```

```
}
```

and the result will be:

```
<div class="GreenText">We provide web development services.</div>
```

In your CSS stylesheet, you need to define the *GreenText* class name like this:

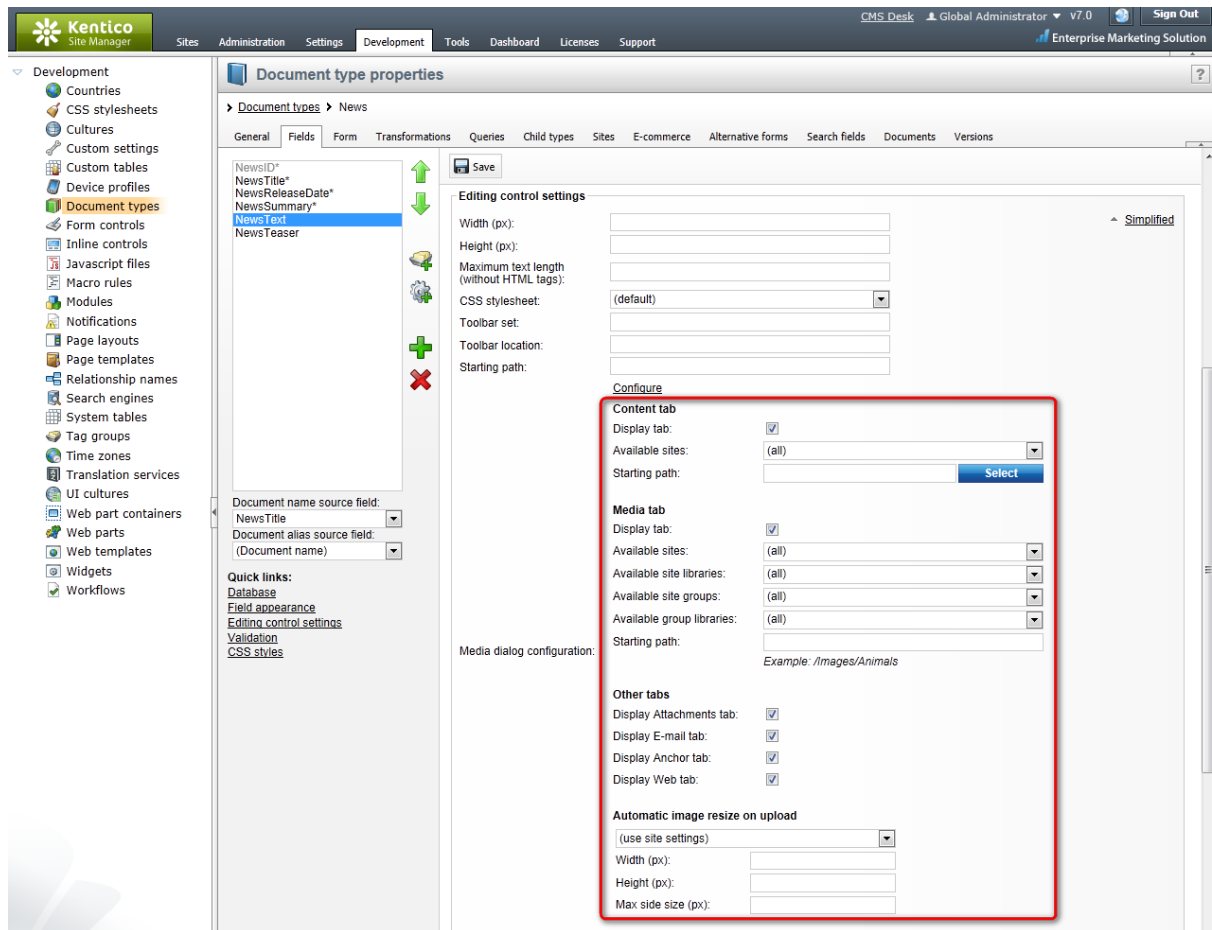

```
.GreenText { color: green; }
```

Every time you modify the *default.js* file (or any other file that is used for the WYSIWYG editor), you need to clear the cache of your browser so that the changes are applied.

4.6.10 Dialog configuration

When defining a new field that uses the **HTML area (Formatted Text) form control**, you can access advanced dialog settings by clicking the **Configure** link next to the **Media dialog configuration** parameter. Please note that it is only displayed if the **Editing control settings** of the form control are viewed in **Advanced** mode.

The following properties can be set. They are organized in categories related to the respective tabs in the dialogs:

Content tab

- **Display tab** - indicates if the **Content** tab should be displayed in the **Insert image or media** and **Insert link** dialogs.
- **Available sites** - defines which sites will be used and therefore also which content trees will be available in the dialogs.
- **Starting path** - the alias path from where the content tree should be displayed. If not relevant for the selected site, its whole content tree will be displayed.

Media tab

- **Display tab** - indicates if the **Media libraries** tab should be displayed in the **Insert image or media** and **Insert link** dialogs.
- **Available sites** - defines from which sites the media libraries can be selected.
- **Available site libraries** - defines which media libraries from the above selected site can be used.
- **Available site groups** - defines from which groups the media libraries can be selected.
- **Available group libraries** - defines which group libraries can be selected.
- **Starting path** - the path within the library from where the content should be offered. If not relevant for the selected library, the whole library will be offered.

Other tabs

- **Display Attachments tab** - indicates if the **Attachments** tab should be displayed in the **Insert image or media** and **Insert link** dialogs.
- **Display E-mail tab** - indicates if the **E-mail** tab should be displayed in the **Insert link** dialog.
- **Display Anchor tab** - indicates if the **Anchor** tab should be displayed in the **Insert link** dialog.
- **Display Web tab** - indicates if the **Web** tab should be displayed in the **Insert image or media** and **Insert link** dialogs.

Automatic image resize on upload

- *(do not resize)* - if selected, images will not be resized and will be pasted in full size.
- *(use site settings)* - if selected, images will be resized according to settings made in **Site Manager -> Settings -> System -> Files**.
- *(use custom settings)* - if selected, the settings specified in the three properties below will be used. The settings have the same effects as described in the [Resizing images on upload](#) topic in the **Content management system** section of this guide.
- **Width (px)** - the width of the image on upload; in pixels.
- **Height (px)** - the height of the image on upload; in pixels.
- **Max side size (px)** - if one of the sides of the image is larger than this value, the image will be resized so that its larger side dimension matches the entered value. The aspect ratio is kept and the width and height settings are not applied.

Some of the properties have the **(current)** values (e.g. current site, current library etc.). This means that the current value from the page context will be taken - e.g. if you are on a page belonging to a group and have the **Available group libraries** set to **(current group)**, the group to which the page belongs will be used.

Setup on last insertion

The dialog remembers the selection setup on last insertion for each user. This means that when a particular user opens the **Insert image or media** or **Insert link** dialog, all of the following properties are in the same state as on last insertion:

- Selected tab.
- Selected view mode.

Content tab only:

- Selected site.
- Selected path in the content tree.

Media libraries tab only

- Selected site.
- Selected group.
- Selected media library.
- Selected path within the library.

Dialogs-related settings

The following settings in the categories under **Site Manager -> Settings** are related to WYSIWYG

editor dialogs:

- **URLs and SEO -> Use permanent URLs** - if enabled, URLs of documents and document attachments will be generated in a permanent format. If disabled, friendly URLs will be used.
- **Content -> Media -> Use permanent URLs** - indicates if links in a permanent format should be used for files stored in media libraries.
- **System -> Files -> Automatic image resize on upload** - for more information on image resizing, please refer to the [Resizing images on upload](#) topic.

4.6.11 Dialog security

The following tables show which permissions are required to perform the listed actions on the particular tabs.

Media libraries tab

In this table, you can see that three types of permissions may enable users to perform the required action:

[Media library module permissions](#) and [groups module permissions](#) are those permissions that can be set in the permissions matrices in **Site Manager -> Administration -> Permissions**.

[Media library permissions](#) are those permissions that can be set on the **Security** tab when editing a particular media library in **CMS Desk -> Tools -> Media**.

Action/Permission	Media library module permissions		Groups module permissions			Media library permissions							
	Read	Manage	Read	Manage		File			Folder			See content	
						Create	Delete	Modify	Create	Delete	Modify		
Global administrator in group/global media library													
Creating new media file	No permissions are required												
Creating new media folder	No permissions are required												
See media library content in dialogs	No permissions are required												
Group admin in group media library													
Creating new media file	No permissions are required												
Creating new media folder	No permissions are required												
See media library content in dialogs	No permissions are required												
Any other user in global media library													
Creating new media file		X			or	X							
Creating new media folder		X			or				X				
See media library content	X												X

in dialogs												
Any other user in group media library												
Creating new media file			X	or	X							
Creating new media folder			X	or				X				
See media library content in dialogs			X	or								X

Attachments tab - the document already exists

To perform the following actions on the **Attachments** tab, the user needs to have the appropriate [document permissions](#) for the particular document.

Action/Permission	Document permissions			
	Read	Create Manage	Modify	Delete
Creating new attachment (New file)			X	
Replacing source file of the attachment (Update)			X	
Deleting attachment (Delete)			X	
Moving attachment up or down (Move up/Move down)			X	
See attachments of the specified document	X			

Attachments tab - the document does not exist yet

To perform the following actions on the **Attachments** tab, the user needs to have the appropriate [document permissions](#) for the particular document.

Action/Permission	Document permissions			
	Read	Create Manage	Modify	Delete
Creating new attachment		X		
Replacing attachment		X		
Deleting attachment		X		
Moving attachment up or down		X		
See attachments of the specified document		X		

Content tab

To perform the following actions on the **Content** tab, the user needs to have the appropriate [document permissions](#) and the listed document types (*CMS.File* and *CMS.Folder*) need to be allowed to be created in the location.

The last two columns indicate if the **cms.file** and **cms.folder** document types are **allowed child types** of the document under which they should be created. This can be set separately for each document type in **Site Manager -> Development -> Document types -> Edit (✎)** the particular document type on the **Child types** tab.

Action/Permission	Document permissions					
	Browse tree	Create	Modify	Delete	CMS.File is allowed	CMS.Folder is allowed
		Manage				
Creating new cms.file		X			X	
Creating new folder		X				X
See child documents of the specified document	X					

4.6.12 HTML5 media tags

In **Site Manager -> Settings -> Content -> Media**, you can find the following two settings related to rendering of HTML 5 media tags:

- **Render HTML5 media tags** - if enabled, the system renders HTML5 `<audio>` and `<video>` tags for media content inserted using WYSIWYG editor dialogs.
- **Media extensions to be rendered with HTML5** - specifies a list of media extensions to be rendered with HTML5 media tags. Enter a list of extensions separated by a semicolon, e.g. `.mp4;.ogg`.

The screenshot shows the Kentico CMS 7.0 Site Manager interface. The left sidebar shows the navigation menu with 'Settings' expanded and 'Media' selected. The main content area displays the 'Storage' and 'HTML5 support' settings. The 'HTML5 support' section is highlighted with a red box, showing the following settings:

- Render HTML5 media tags**:
- Media extensions to be rendered with HTML5**: ogg;ogv;oga;wav;mp3;mp4;webm

4.7 Document properties

4.7.1 Overview

You can edit document properties in **CMS Desk -> Content** after selecting a document in the content tree and opening the **Properties** tab in **Edit** mode.

The same options may also be accessed for a specific document when viewing the corresponding page in [On-site editing](#) mode. In this case, the properties can be configured by clicking the **Properties** button on the toolbar.

4.7.2 General

On this tab, you can see general information about the currently edited document:

General	
CSS Stylesheet	The CSS stylesheet used for this particular page. You can choose some particular stylesheet or use the default site stylesheet. You can also choose to inherit the stylesheet from the parent document.

	By clicking the New button or selecting the (new stylesheet...) option from the drop-down list, you can create a new CSS stylesheet. The created stylesheet will be added to the list of stylesheets in Site Manager -> Development -> CSS stylesheets .
Other properties	
Document name	Name of the document.
Type	Document type on which the document is based.
Created by	User who created the document.
Created	Date and time when the document was created.
Last modified by	User who last edited the document.
Last modified	Date and time when the document was last edited.
Rating	Rating of the document's content posted evaluated by site visitors. You can reset the value using the Reset button. See Modules -> Content rating for more details.
Node ID	Identifier of the document's node in the content tree (common for all language versions).
Document ID	Identifier of the document in the currently edited language version.
Node GUID	Globally unique identifier of the document's node in the content tree (common for all language versions).
Document GUID	Globally unique identifier of the document in the currently edited language version.
Alias path	Unique path to the document in the content tree structure.
Culture	Culture (language) of the currently edited language version of the document.
Name path	Friendly version of the document's Alias path (without blank spaces replaced with dashes, etc.).
Live URL	URL under which the document is accessible on the live site.
Preview URL	<p>If you click the Show preview link, a new window will be opened, displaying the current document in Preview mode outside Kentico CMS user interface. The document will be displayed on a special page with a dedicated URL. The URL can be sent to a person without access to Kentico CMS user interface to let them view content that is not published yet.</p> <p>If you do not want the document's preview to be accessible under a link that you already sent to someone, you can generate a new preview URL for the document by clicking the Generate preview link (🔗) button.</p> <p>See Editing content -> Previewing documents for more details.</p>
Published	Indicates if the document is currently published.

Owner	
Owner	<p>Document owner is the user responsible for its editing.</p> <p>This feature doesn't imply any special permissions for the owner, but it allows for easier orientation in documents. The owner can see all their documents in the My Desk -> My Documents section.</p> <p>The owner is by default set to the user who created the document. The owner can be changed only by users with the <i>Modify permissions</i> permission.</p>
Owned by group	<p>This field shows which group is the owner of the document (this is particularly the case of group pages). This field is mainly informative, but in some special situations, you might find it useful to change the group that the document belongs to by using the Change button.</p>
Output cache	
Use output cache	<p>Indicates if the system caches the full HTML output of the page. Output caching can greatly improve the performance of the page, but is not suitable for pages with dynamic content.</p> <p>You can inherit the output cache settings from the parent document.</p> <p>Important: Output caching must also be allowed in the website's settings. Administrators can enable output caching in Site Manager -> Settings -> System -> Performance.</p>
Cache minutes	<p>Determines how long the system keeps the output code of the page in the cache (if output caching is enabled).</p> <p>The page's output cache is automatically cleared if someone modifies the page. You can manually remove the page from the output cache by clicking Clear output cache.</p>
Allow file system cache	<p>Indicates if the system stores the page's output cache on the server's file system. This provides persistent caching in case of application restarts.</p> <p>If disabled, the application only caches the page output in its memory. If enabled, the system checks both types of cache.</p> <p>You can inherit the setting from the parent document.</p> <p>The file system cache is stored for the number of minutes specified in the Cache output in file system (minutes) setting in Site Manager -> Settings -> System -> Performance.</p>
On-line marketing	
Log on-line marketing activity	<p>Indicates if page-related on-line marketing activities (e.g. Page visit, Landing page or Content rating activity types) should be logged for this document.</p>

	If the Inherit field is checked, the document loads the value of this setting from the parent document.
Advanced	
 Edit regions & web parts	This button opens a window that displays a list of all Editable text and Editable image web parts (or Editable regions for pages based on ASPX templates) placed on the current document and allows them to be edited.
 Add wireframe to this page	Inserts a wireframe schematic into the document. This can be used to plan out the page's structure and design. The document's wireframe can be defined on the Wireframe tab, which will become available in the main Edit mode menu.
 Remove wireframe	If the document has a wireframe definition, this action may be used to delete it.

4.7.3 URLs

URLs tab fields:

Document alias	<p>The unique name of the document in the given section of the website. By default, this alias is not changed when you modify the document name. The alias is used for the following purposes:</p> <ol style="list-style-type: none"> 1. To define the alias path, which is the unique path to the document. Developers typically use the alias path in the Path property of certain web parts and controls. 2. For the URL of the document. The URL of the document is like: <i>www.kentico.com/products/cms.aspx</i> Where <i>/products/cms</i> is the alias path of the document. <p>Forbidden characters</p> <p>Some characters are forbidden in URLs and thus they are replaced by a safe character (by default, it's a dash -). You can specify the forbidden characters and the replacement character in Site Manager -> Settings -> URLs and SEO through the Forbidden URL characters and Forbidden characters replacement properties.</p>
Document URL path	<p>If you want to use a specific URL for a document that doesn't depend on its Alias path, you need to check the Use custom URL path box and enter a different value.</p> <p>You can choose from the following Path types for the custom URL:</p> <ul style="list-style-type: none"> • Standard URL or wildcard - the URL will be handled by the standard Kentico CMS rewriting engine. • Route - the URL will be processed as an ASP.NET Route pattern. • MVC - requests to the URL will be handled as requests for an MVC

	<p>page. Please see the MVC development model chapter for more information.</p> <p>The selection made here determines how the value of the Path or pattern field will be processed. For <i>MVC</i> or <i>Route</i> patterns, it is always necessary to include the URL extension at the end of the path. If you leave the path without an extension, the document will automatically be available under an extensionless URL.</p> <p>If MVC is selected, you must also specify the following values:</p> <ul style="list-style-type: none"> • Default controller - the name of the MVC controller containing the action that should be performed when the alias URL is accessed, without the <i>Controller</i> part at the end. For example, if the class is called <i>NewsMVCController</i>, enter <i>NewsMVC</i>. The system first searches for the specified class in the <i>CMS.Controllers.<current site code name></i> namespace. If it is not found there, the <i>CMS.Controllers.Global</i> namespace is searched. • Default action - specifies the action defined within the controller that should be performed when the document is accessed under this URL. <p>The URL path must always start with /. When entered, the document will be accessible under two URLs. This can be useful if you need to define a short URL for a page or need to optimize the URL for search engines.</p> <p>The URL path is culture-specific, unlike the alias path. This means that if you use URL paths: /product (for the English version) /produkt (for the German version)</p> <p>Then when the user comes to /produkt.aspx, the language of the website will automatically be switched to German.</p> <p>The URL path may contain wildcard URLs or MVC or Route patterns. Wildcards use the following format: <i>{wildcard}</i> or <i>{wildcard;defaultvalue}</i>, where <i>wildcard</i> is the name of the wildcard and <i>defaultvalue</i> its value if the URL is used without a wildcard being entered. More information can be found in the Wildcard URLs topic.</p>
URL extensions	<p>Default URL extensions are defined in Site Manager -> Settings -> URLs and SEO -> Friendly URL extensions. If you check the Use custom URL extensions check box, you can define other extensions under which the document can be accessed.</p> <p>In case that the option is disabled, physical file extensions can also be used for cms.file documents.</p> <p>Multiple extensions can be entered divided by a semicolon. If you enter a semicolon without any extension, extensionless URLs will be allowed.</p> <p>Example: entering <i>.htm;</i> for a document with a URL path set to <i>/test</i></p>

	<p>will allow the document to be accessed through both of the URLs below:</p> <ul style="list-style-type: none"> • <i><site path>/test.htm</i> • <i><site path>/test</i> <p>For this to work, you also need to set up your IIS for handling 404 and 405 errors as described in the Installation and deployment -> Additional configuration tasks -> Custom URL extensions chapter.</p>
Document aliases	<p>This section displays a list of other document aliases under which the document can be accessed. One document can have an unlimited number of aliases. You can edit () and delete () aliases in the list or  Add new alias.</p> <p>If the Remember original URLs when moving documents setting is enabled in Site Manager -> Settings -> URLs and SEO, new document aliases containing the original URL properties will automatically be created whenever the Document URL path or URL extensions properties are changed.</p> <p>More information about document aliases can be found in the Multiple document aliases topic in the Development -> Page processing and URLs chapter of this guide.</p>

4.7.4 Template

In the Template dialog, you can specify the [page template](#) that will be used for the selected document and configure its content inheritance.

Template

The textbox in this section displays the name of the page template currently assigned to the document. The options above determine what type of template will be used:

- **Inherit from parent**
- **All culture versions use the same page template**
- **Each culture version uses its own page template**

If the first option is selected, the page template set for the parent document will automatically be loaded.

With the other two options, you can assign a specific template to the document via the **Select** button. If the document is available in [multiple languages](#), you can choose whether all versions should share the same template or if it should be possible to specify a different one for each language. By selecting the third option, you can configure the template settings on this tab separately for each document version by switching between cultures using the language toolbar in the main menu of the **CMS Desk -> Content** tab.

Changes need to be confirmed by clicking  **Save**.

Setting the template of the website's root document

The website's root document has no parent from which the template could be inherited, so the first radio button option (**No master page template**) may instead be used if you wish to have an empty root page.

In most scenarios, it is highly recommended to assign an appropriate template to the root document and use content inheritance.

Additionally, the following actions may be used to manage the document's template:

-  **Save as new template** - saves the current template as a new re-usable page template. This can be useful if you wish to use an ad-hoc template for other pages.
-  **Clone template as ad-hoc** - creates a copy of the current page template as a new ad-hoc template. This allows you to modify the design of the page without affecting other documents that use the original template.
-  **Edit template properties** - opens a new window where you can configure the properties of the currently assigned page template.

Inherit content

In this section, you can configure how the document should inherit content from its parent pages (if it is not a [master page](#)). Select one of the following options:

Use page template settings	The inheritance is determined by the settings of the assigned page template. To manage the template's configuration, click the  Edit template properties button and set the Inherit content property on the General tab.
Do not inherit any content	The document does not inherit any content from parent documents in the content tree.
Inherit only master page	The document inherits content from the first master page above the document in the content tree. If there are multiple master pages, the document only inherits from the closest one in the hierarchy.
Select inherited levels	You can select exactly from which parent documents the page should inherit via the checkboxes below.

4.7.5 Metadata

Here you can manage the information describing the page. You can choose to inherit the values from the parent document or enter document-specific values.

Page settings	
Page title	The page title is displayed to users in the header of their browser (or tab) when the page is viewed. It is also an important factor for Search engine optimization . Many search engines use this title for the page in their

	<p>search result lists.</p> <p>The content of the field is added into the <code><title></code> element in the HEAD section of the page's output.</p>
Page description	<p>A brief description of the page and its purpose that can be used for SEO purposes and when performing searches on the website.</p> <p>The content of this property is added as a description meta element in the HEAD section of the page. This tag may be indexed by some search engines.</p>
Page keywords	<p>Adds meta keywords to the page, which may be used when searching the content of the website (for example by the built-in Smart search). Multiple keywords need to be separated by commas.</p>
Tags	
Page tag group	<p>Tag group that will be used for tagging this document using the Page tags parameter below.</p>
Page tags	<p>Enter the Tags that you want to tag the document with.</p> <p>When entering more than one tag into the Page tags field, the tags should be separated with a comma or a blank space. A combination of both in a single entry is also valid. The following examples are all valid entries for adding three tags - <i>tag1</i>, <i>tag2</i> and <i>tag3</i>:</p> <p><i>tag1, tag2, tag3</i> <i>tag1 tag2 tag3</i> <i>tag1, tag2 tag3</i></p> <p>In case that you are entering a tag consisting of more than one word, you should enclose it within quotation marks. Multiple long tags can also be entered and can be also divided by both blank spaces and commas:</p> <p><i>"long tag1", tag, "long tag2"</i> <i>"long tag1" tag "long tag2"</i></p> <p>Quotation marks can also be used for tags containing special characters that couldn't be used otherwise:</p> <p><i>"tag@1", "tag#2", "long, strange: tag@#"\$</i></p> <p>The page tags field also has an autocompletion function implemented. This functions offers you tags from the selected tag group while you are writing.</p>

Global Settings

You can configure a prefix for the page title, description and keywords for all documents on the website using the corresponding settings in **Site Manager -> Settings ->**

Content. Here you can set the prefixes and also the standard format of the page title.

The default page title format is: {%prefix%} - {%pagetitle_orelse_name%}

It means that the format consists of the prefix followed by the page title value. If the page title value is not set, the document name is used.

Macro expressions in metadata

You can use macros in format {%ColumnName%} to insert the values of the current document's fields into the title or other metadata properties. See [Development -> Macro expressions](#) for more information about macro expressions.

4.7.6 Categories

Categories are topic-related groups of documents. On this page, you can assign the selected document to an unlimited number of categories. There are two lists of categories:

- **My categories** - this list shows the current user's custom categories. Each of the categories can be edited (✎) or deleted (✖). By clicking on **New category**, you can create your own category. The following details will be required:

Display name	Display name of the category.
Description	Text describing the category.

- **Global categories** - this list shows global categories that can be defined in **Site Manager -> Development -> Categories**. These categories can only be edited (✎) from this page.

In case that you want to assign the selected document to some of the categories, check the category's **Select** check-box in the list and click **Save**.

See the [Modules -> Categories](#) chapter for more details.

4.7.7 Navigation

This dialog allows you to specify how the current document should be displayed in navigation elements.

Basic properties

Menu caption	The name of the document as it's displayed in navigation. It may be different compared to the document name. If no value is entered, the document name is used.
Show in navigation	Indicates if the document should be displayed by navigation web parts (in the menus). Please note: the document is displayed in the navigation if all of the following conditions are met:

	<ol style="list-style-type: none"> 1. The Show in navigation box is checked. 2. The document is published. 3. The type of the document matches the document types configured in the appropriate navigation control (web part) - by default, only Page (menu item) documents are displayed in navigation. 4. If you turn on the Check permissions property of the menu control, the current user must be allowed to read the given document or it will not appear in the navigation controls/web parts.
Show in site map	Indicates if the document should be included in the website's Google sitemap and displayed by the Site map web part.

Menu actions

You can choose from the following menu item behavior options:

Standard behavior	The menu item redirects the user to the page as expected.
Inactive menu item	<p>Clicking the menu item doesn't cause any action - the item is disabled. This option is useful if you need to create a menu item that cannot be clicked, but has sub-items that can be clicked.</p> <p>If selected, the Redirect to URL field appears, where you can enter the URL of a page to which users will automatically be redirected if they access the given page, e.g. through a link.</p>
Javascript command	<p>If you enter some JavaScript command, it will be run when this menu item is clicked.</p> <p>Example: <code>alert('hello');return false;</code></p>
URL redirection	<p>The user is redirected to the target location when they try to access the given page. Redirected documents are marked with the  icon in the content tree.</p> <p>Example: <code>http://www.domain.com</code> or <code>~/products.aspx</code></p>

Search & SEO

Exclude from search	<p>If enabled, the current document and its content (including attachments) will be ignored by all forms of search. This affects both the Smart search module and the SQL search.</p> <p>Additionally, it instructs web crawlers (robots) not to index the page by adding the following meta tag into the HEAD section, which should exclude it from search engine listings:</p> <pre><meta name="robots" content="noindex,nofollow" /></pre> <p>Enabling this setting also ensures that the page is excluded from Google sitemaps by default, but this can be overridden by individual Google Sitemap (XML Sitemap) web parts.</p>
---------------------	---

	Please note: Objects or documents displayed by web parts will not be excluded by enabling this property for the page that contains them.
Sitemap change frequency	Determines the value of the document's <code><changefreq></code> element in the website's Google sitemap , which provides a suggestion to search engines about how often the page should be indexed. This value should reflect the frequency of the page's content modifications.
Sitemap priority	Allows you to inform web crawlers which pages you consider to be the most important. The selected priority is converted to a decimal number between 0 and 1 and added as the value of the document's <code><priority></code> element in the website's Google sitemap. The priority is only measured in relation to other pages on the website.

Menu design

The menu item design properties are available in three alternatives:

- standard design
- mouse-over design - style used when a user hovers their mouse over the menu item,
- highlighted design - style applied if the page represented by the menu item is currently selected.

These values override the settings of individual navigation web parts (or controls) as long as their **Apply menu design** property is enabled. The CSS styles defined in the CSS stylesheet are overridden as well.

Please note: some of the following properties may not be applied to some navigation web parts or controls.

Menu item style	Style definition of the menu item. Values can be entered the same way as when defining a CSS class in a stylesheet. <u>Sample value:</u> <code>color: orange; font-size: 140%</code>
Menu item CSS class	CSS class defined in the website's stylesheet. <u>Sample value:</u> <code>h1</code>
Menu item left image	Image that will be displayed next to the menu caption on the left side. Sample values as below.
Menu item image	Image that will be displayed in the menu instead of the menu caption. You can enter either an absolute URL or a relative path in the content tree. <u>Sample values:</u> <code>http://www.domain.com/image.gif</code> <code>~/Images-(1)/icon.aspx</code>
Menu item right image	Image that will be displayed next to the menu caption on the right side. Sample values as above.

4.7.8 Workflow

On this tab, you can approve or reject document if it uses **workflow** and you're authorized to approve/reject given document in the given workflow step. See the [Workflow and versioning](#) chapter for more details.

Approve section

- **Comment** - you can add a comment which will be added to the e-mail message to the editor whose work you are approving
- **Send e-mail** - if the box is checked, a message can be sent to the editor whose work is currently being approved; if not, no message is sent to the editor

Workflow steps

This table displays the workflow steps of the current document's workflow, while pointing out the current step

Workflow history

This list displays the current document's workflow steps history.

4.7.9 Versions

On this tab, you can view the previous versions of the document if it uses a workflow. You can also roll back to a previous version of the document by clicking the  icon, delete () the older versions or destroy the whole document history.

When you click on the  icon, you can preview the particular document version.

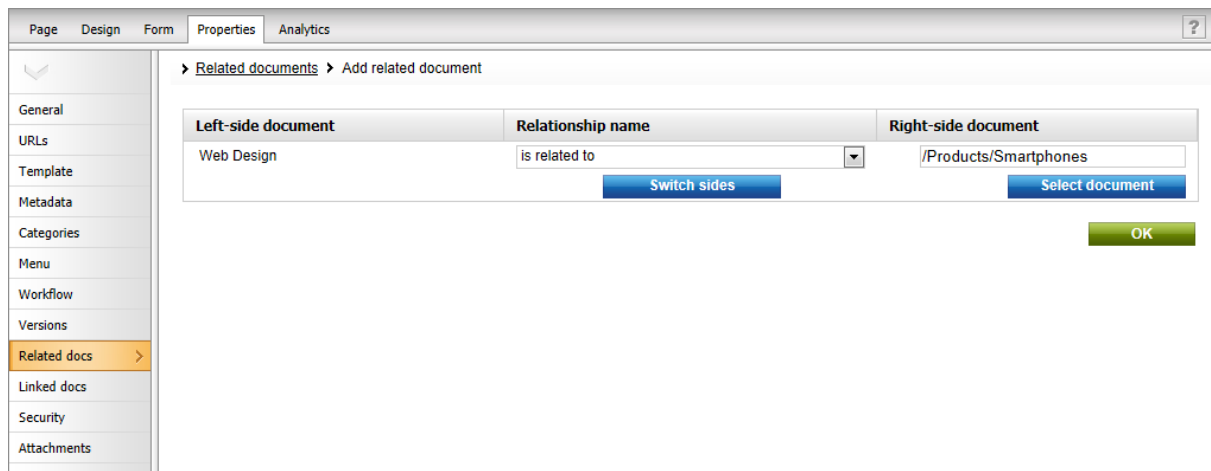

See chapter [Workflow and versioning](#) for more details.

4.7.10 Related docs

This dialog allows you to specify documents that are related to the selected document. Click () **Add related document**.

Now you can:

- select the related document using the Select button
- switch the sides of the relationship
- select the type of the relationship

Left-side document	Relationship name	Right-side document
Web Design	is related to	/Products/Smartphones

Buttons: **Switch sides**, **Select document**, **OK**

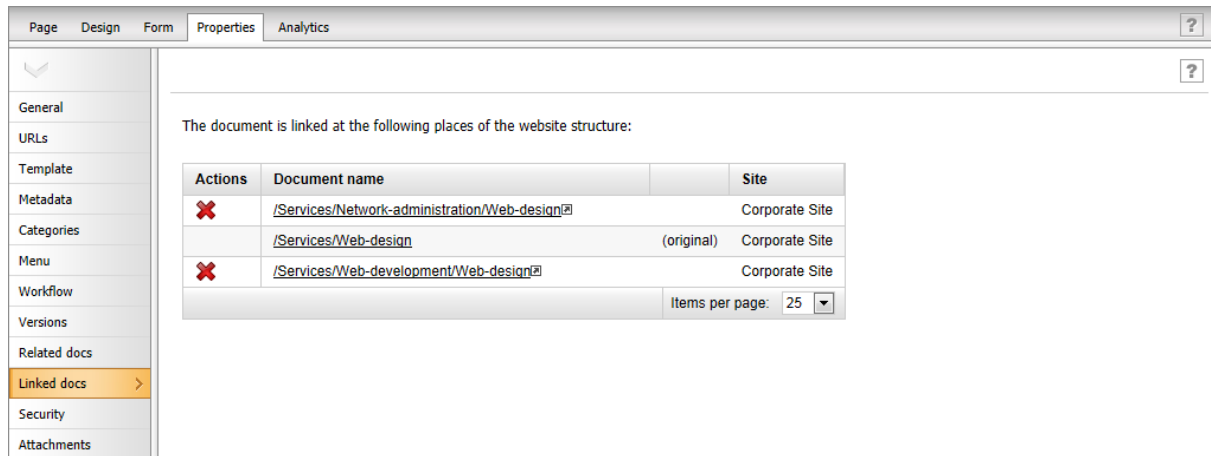

You can view related documents using controls (web parts). Refer to [Kentico CMS Web parts and Controls reference -> Displaying related documents](#) for more information.

You need to define the relationship names in **Site Manager -> Development -> Relationship names**. Only relationship names enabled for the current website are available in the drop-down list.

4.7.11 Linked docs

This dialog displays the linked documents (see [Creating a linked document](#) for explanation of the concept of linked documents).

You can delete the linked documents using the **Delete** (✘) icon or navigate to other linked documents or to the original document by clicking the link:

4.7.12 Security

This dialog is divided into two independent sections - **Permissions** and **Access**

Permissions

Here you can specify the document-level permissions for the given document. Please see the [Authorization \(permissions\)](#) chapter for more details.

Local and global permissions

Please remember that the local permissions are combined with global permissions defined for roles in the **CMS Desk -> Administration -> Permissions** dialog as described in the [Authorization \(permissions\)](#) chapter.

Access

Here you can configure if the page is accessible by public (anonymous) visitors or if it's only available to users who sign in with their user name and password. If you choose the option **Inherits**, the value is

inherited from the parent document.

Please read the [Secured website areas](#) chapter for more details.

You can also specify if the give page or website section **requires SSL** (HTTPS) protocol. If you set it to Yes, the CMS automatically redirects the user to the URL with **https://** protocol.

Requires authentication

- **Yes** - authentication is required to access the page
- **No** - authentication is not required to access the page
- **Inherits** - value of the setting is required from the parent page

Requires SSL

This setting indicates if users who access the page should automatically be redirected to the version of the page that is secured through the SSL protocol (i.e. the target URL will use the **https** scheme). You can choose one of the following options:

- **Yes** - users attempting to access the page will always be redirected to the HTTPS version of the page's URL.
- **No** - users will not be explicitly redirected to a secured URL when they access the page, but the protocol used in the current URL will remain unchanged (i.e. if a user navigates to the page from another page that is secured, this page will also use SSL).
- **Inherits** - the settings defined for the parent document will be used.
- **Never** - users trying to access the page through a secured URL will be explicitly redirected to the unsecured version of the page.

Please note: Kentico CMS does not configure your website for SSL/HTTPS. It may only be used to automatically redirect users to the appropriate URL. You need to perform the configuration itself manually using the standard IIS settings, as described in IIS documentation or in this article: [http://msdn.microsoft.com/cs-cz/magazine/cc301946\(en-us\).aspx](http://msdn.microsoft.com/cs-cz/magazine/cc301946(en-us).aspx)

4.7.13 Attachments

On this tab, files can be attached to the document.

On this page, you can see a list of the currently selected document's unsorted attachments. Grouped attachments can be added to the document on the Form tab in case that the appropriate field(s) are defined for the particular document type.

You can upload **New attachment** (). You can also perform the following actions with the attachments in the list:

- Using the **Delete** () icon, you can remove the attachment from the document.
- Using the **Move up** () and **Move down** () icons, you can re-order the attachments. The order is stored in the **AttachmentOrder** property of each attachment. You can enter AttachmentOrder into the ORDER BY expression property of a displaying web part to have the attachments ordered accordingly.

**Please note**

The order of attachments is **not versioned** with documents' workflow. This means that if you change the order of attachments in one version of a document, the order is changed in all other versions too.

- Images have also the **Edit** (✎) icon available. This icon opens the image in the built-in image editor.
- Using the **Update** (↻) icon, you can replace the original attachment with a new one.
- After clicking an attachment's name, the attachment will be opened.

For more information on the Attachments module, please refer to the [Document attachments](#) chapter of this guide.

4.7.14 Languages

This tab only appears on multilingual sites (i.e. those that have more than one content culture assigned). See the [Multilingual content](#) chapter for more details.

Here you can view the language versions of the selected document. A document can have one of the following statuses for each language:

- **Translated** - the document is translated and up-to-date. The actual language of the document's content has no effect on the status, the system only checks whether the language version exists.
- **Outdated** - the language version exists for the document, but is outdated. The system considers language versions to be outdated if the default language version of the document has been modified (or published when using workflow) more recently.
- **Not available** - the document does not exist in the given language.
- **Waiting for translation** - the document exists in the given language, but its content has not been translated yet. It is currently submitted to a [translation service](#). You can manage the translation submission in *CMS Desk* -> *Tools* -> *Translations*.

You can use the following actions for individual language versions:

-  **Edit culture version** - allows you to edit the fields for the given language version of the document (i.e. opens the **Edit** -> **Form** tab in *CMS Desk*).
-  **Create new culture version** - shown for languages in which the document is not available. Clicking the action creates a new version of the document in the given language.
-  **Translate document** - opens a dialog where you can submit the document for translation to the given language, using a specified [Translation service](#).

4.8 File management

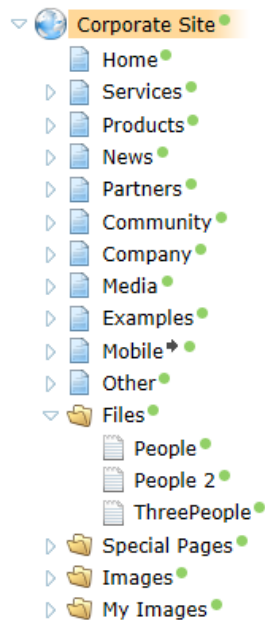

4.8.1 File management overview

Kentico CMS allows you to upload files (such as GIF, JPG, SWF, PDF, XLS, DOC, etc.) to the Kentico CMS database or file system and manage them as any other content.

File management approaches

There are four types of files from the file management perspective:

- **CMS.File documents** - these files are uploaded by the content editors as new *CMS.File* documents into the content tree. You will typically use this type for files that are used as part of unstructured documents, such as document links or images inserted into editable regions of pages. It is advisable to have files stored within folders (*CMS.Folder* document type). You can also use the [File import](#) module when uploading multiple files. The [Document library](#) module allows convenient management of CMS.File documents on the live site.

- **Document attachments** - these files are stored as a part of a structured document and their life cycle is also bound with the document (including workflow and versioning). You can have an unlimited number of files attached to a document. A detailed description of the whole concept and examples of typical usage can be found in the [Document attachments](#) sub-chapter.
- **Media Libraries** - the Media Libraries module allows storage of large amounts of files, while large file sizes are supported; the whole module and its typical usage is described in [Modules -> Media libraries](#).
- **Unmanaged files** - these files are part of the website theme and they should be stored in the `<web project>\app_themes\<theme>\images` folder on the disk. They usually include images and Flash animations used throughout the site. These files are not managed by the CMS system.

For performance optimization tips related to file management, please refer to the [Development -> Caching and performance -> File management and performance](#) chapter of this guide.

4.8.2 Document attachments

4.8.2.1 Overview

Kentico CMS allows users to attach files to the website's documents. This concept greatly simplifies the way you work with files. Each document can have any number of attached files, which is a great step forward compared to the previous use of the [File field](#), which allowed only one uploaded file per one

defined File field.

Attachments are directly bound to a document's life cycle. So if a document gets published, its attachments get published too. If you delete a document, its attachments will also be deleted.

There are two types of attachments:

- **Unsorted** - added via the **Properties -> Attachments** tab; using this approach, you can easily add attachments to any document; all attachments added this way are taken as **one group** and displayed together using the web parts
- **Grouped** - added by defining a 'Document attachments' field for a document type and then uploading a file on a document's **Form** tab; for each Document attachments field, you can have an unlimited number of files attached; you can also define more fields of this type to have several groups of attachments which can be displayed separately on the live site
- **File field** - another type of field that can be used for file upload via the **Form** tab; the difference from Grouped attachments is that only one file can be uploaded into one File field

The attachments can be displayed with the document using one of the following web parts:

- **Attachment image gallery** - using the default transformation, the web part displays thumbnails of the document's image attachments. After a thumbnail is clicked, a lightbox will display the attachment in full size. For non-image attachments, a file type icon will be displayed instead. If clicked, the file will be offered for download. Of course, this behaviour can be modified by defining a custom transformation.
- **Document attachments** - displays a list of document's attachments. After an attachment is clicked, it is opened in a new window or offered for download in case that it is not an image.
- **Attachments data source** - data source web part for providing attachments to a connected displaying web part; see also [Using Data source web parts](#).

More information about the web parts can be found in the [Available web parts](#) topic.

You can also display a document's unsorted attachments using the following two inline widgets that can be added via the **Editable text** web part:

- **Attachment image gallery** - displays thumbnails of the document's unsorted attachments in a gallery. After a thumbnail is clicked, the attachment will be displayed in a lightbox.
- **Document attachments** - displays the document's unsorted attachments. After an attachment is clicked, it will be displayed on a new page if it is an image and non-image attachments will be offered for download.

More information about the inline widgets can be found in the [Available inline widgets](#) topic.

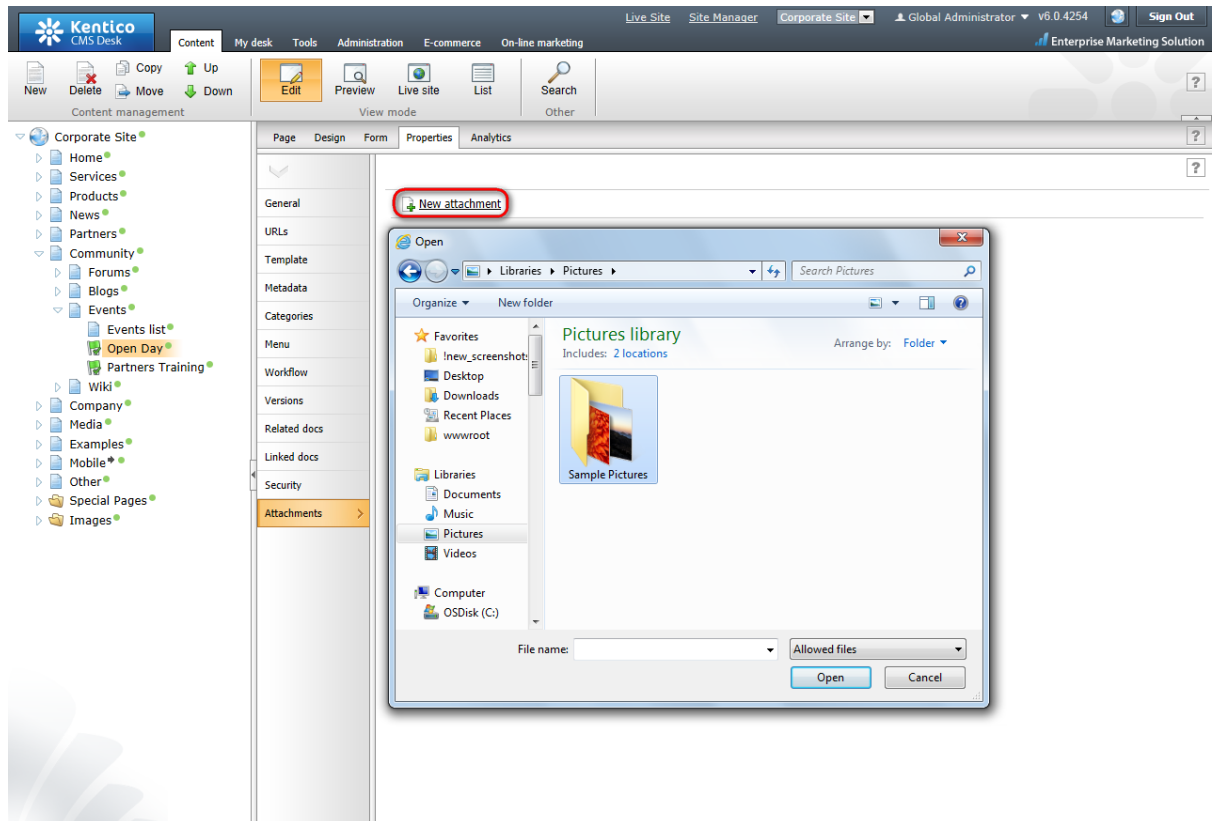

Settings which can be configured in **Site Manager -> Settings -> System -> Files** are applied to document attachments. You can learn about available settings in the [Files-related settings](#) chapter.

4.8.2.2 Example: Unsorted attachments

In the following example, you will learn how to add attachments to a document via the **Properties -> Attachments** tab and display them on the live site. We will use the **Events** section of the sample **Corporate Site**. First, we will upload the attachments to some of the events in the section. Then we will add the **Attachments image gallery** web part to the **Events** page, which will display the attachments for each displayed event.

1. Adding attachments to a document this way is quite simple. First, you need to select a document from the content tree and switch to its **Properties -> Attachments** tab.
2. On the tab, click the **New attachment** (📎). The familiar **Choose file** dialog will be displayed. Choose any file from your local drive and click the **Open** button.

Please note: The mouse pointer doesn't change when you hover the **New attachment** (📎). This is by design and you needn't be worried about it.

3. Repeat the same procedure so that you have a few files attached to at least one document. Preferably, include some images among them. The document's attachments tab should look similarly to the screenshot below after the attachments' upload. Note that if you hover an image in the list, its thumbnail is displayed as in the screenshot.

In the list of attachments, you can do several things with each attachment:

- **Delete** (✖) - removes the attachment from the document.
- **Move up** (⬆) and **Move down** (⬇) - re-orders the attachments. The order is stored in the **AttachmentOrder** property of each attachment. You can enter *AttachmentOrder* into the **ORDER BY expression** property of a displaying web part to have the attachments ordered accordingly.

Please note

The order of attachments is **not versioned** with documents' workflow. This means

that if you change the order of attachments in one version of a document, the order is changed in all other versions too.

- **Edit** (✎) - if the attachment is an image, clicking the icon opens it in the built-in [image editor](#). If the attachment is not an image, the [metadata editor](#) is opened after clicking the icon.
- **Edit in client application** (🖱) - is displayed only when [WebDAV integration](#) is enabled and only next to file types supported by WebDAV. Clicking the icon opens the document for editing in an external application installed on the client computer (the application must support WebDAV for this to work). Saving the document in the client application updates the attachment with the new version automatically.
- **Update** (↕) - enables you to replace the original attachment with a new one.
- After clicking an attachment's name, the attachment is opened.

Actions	Update	Name	Size
✎ ✕ ↕ ↴	↕	Koala.jpg	763 kB
✎ ✕ ↕ ↴	↕	Penguins.jpg	760 kB
✎ ✕ ↕ ↴	↕	sample-docum	0 B
✎ ✕ ↕ ↴	↕	sample-docum	4.5 MB
✎ ✕ ↕ ↴	↕	sample-docum	8.5 kB

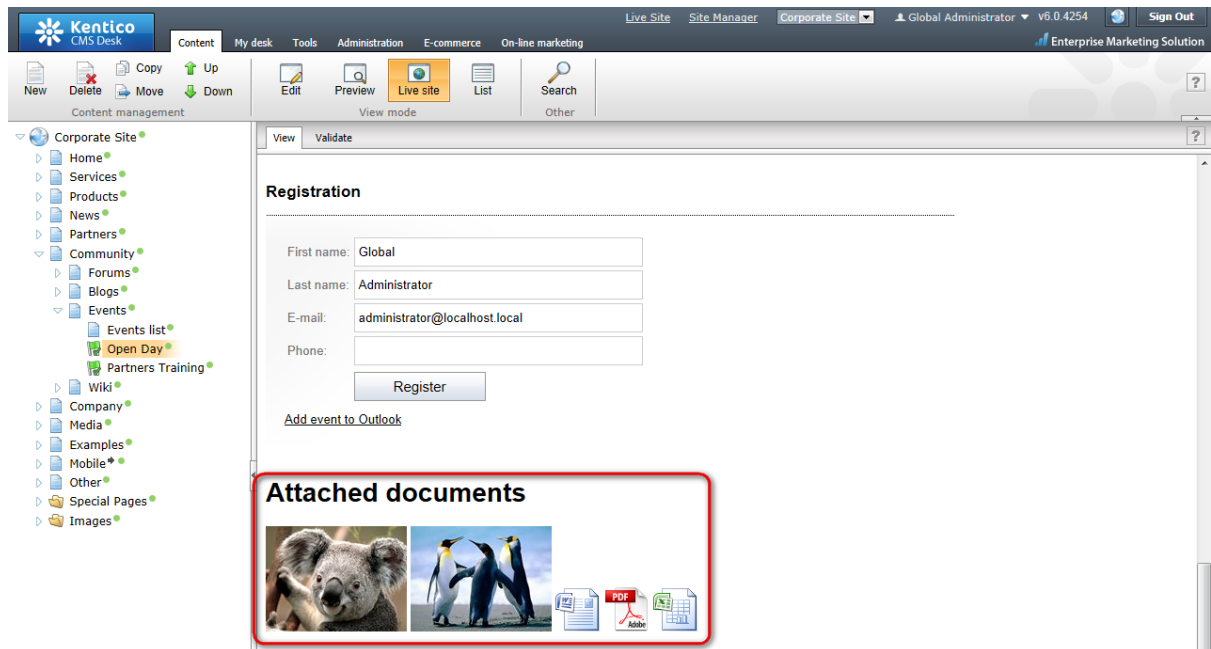

Items per page: 25

4. Now that we have the attachments uploaded, we can display them on the live site. The events are displayed by a repeater on the **Events** page, so we will have to add the **Document attachments** web part to this page.

Select the **Events** page from the content tree and switch to the **Design** tab. Click the **Add web part** (+) icon of the **Main zone** web part zone and choose the **Attachments -> Attachments image gallery** web part. You do not need to set any web part properties in order for the web part to display the attachments. However, you can add some heading via the **Content before** property:

- **Content before:** <h1>Attached documents</h1>

Click **OK**. If you switch to the live site now, you should see its attachments' thumbnails as in the screenshot below.

4.8.2.3 Example: Grouped attachments

In the [previous example](#), you learned how to add attachments to a document via the **Properties -> Attachments** tab. This is the easier approach, however, in some situations, you may want to have more groups of attachments.

In this example, you will learn how to add two **Document attachments** fields to a document type and how to use them on the live site. Again, we will use the **Events** section of the sample **Corporate Site**. So if you completed the previous example right before, please delete the **Document image gallery** web part from **Main zone** in order to get the page to the original appearance.

1. The events' document type is **CMS.BookingEvent**. We will need to add the fields to it. Go to **Site Manager -> Development -> Document types** and choose to **Edit** (✎) the **Event (booking system)** document type.

The screenshot shows the Kentico Site Manager interface. The left sidebar contains a navigation menu with 'Development' expanded, listing various tools like 'Countries', 'CSS stylesheets', 'Cultures', etc. The main content area is titled 'Document types' and features a 'New document type' form. The form has three input fields: 'Display name' (set to 'LIKE'), 'Code name' (set to 'LIKE'), and 'Site name' (set to '(all)'). A 'Show' button is located below the form. Below the form is a table with the following columns: 'Actions', 'Display name', and 'Code name'. The table lists various document types, each with edit and delete icons. The 'Event (booking system)' row is highlighted with a red box.

Actions	Display name	Code name
	Article	CMS.Article
	Blog	CMS.Blog
	Blog month	CMS.BlogMonth
	Blog post	CMS.BlogPost
	Bundle	CMS.Bundle
	Cell phone	CMS.CellPhone
	Chat - Transformations	Chat.Transformations
	Community - Transformations	Community.Transformations
	Corporate site - Transformations	CorporateSite.Transformations
	E-book	CMS.Ebook
	E-commerce - Transformations	Ecommerce.Transformations
	Event	CMS.Event
	Event (booking system)	CMS.BookingEvent
	FAQ	CMS.Faq
	File	CMS.File

2. Switch to the **Fields** tab. Use the **New attribute** (+) icon to add the following two fields. For each attribute, set only the following properties and leave the default values for the rest. Click the **Save** button to confirm the creation of each field.

- **Column name:** AttachedImages
 - **Attribute type:** Document attachments
 - **Field caption:** Attached images
 - **Form control:** Document attachments control
-
- **Column name:** AttachedDocuments
 - **Attribute type:** Document attachments
 - **Field caption:** Attached documents
 - **Form control:** Document attachments control

Finally, use the **Move up** (↑) and **Move down** (↓) arrows to move the two attributes to the bottom of the list so that they will be displayed at the bottom of the **Form** tab.

3. Optionally, you can set the following additional parameters for the fields in their **Editing control settings** section (most of the parameters are only available if you switch to **Advanced** mode using the link on the side of the section):

- **Allow change order** - indicates if the order of attachments can be changed.
- **Paging** - indicates if paging should be used for the list of attachments.
- **Page size** - defines the page size options that will be selectable in the attachments pager. Values must be separated by commas, e.g. *25,50,100,##ALL##*.
- **Default page size** - sets the amount of attachments displayed per page by default (if paging is allowed).
- **Allowed extensions** - sets which file types can be uploaded as attachments. Uploading files that do not match the specified extensions will not be permitted. Check *Inherit from settings* to use the values specified in *Site Manager -> Settings -> System -> Files -> Upload extensions*
- **Automatic image resize on upload:**
 - **(do not resize)** - uploaded images will not be resized.
 - **(use site settings)** - uploaded images will be resized according to site settings in *Site Manager -> Settings -> System -> Files -> Automatic image resize on upload*.
 - **(use custom settings)** - uploaded images will be resized according to the Width, Height and Max side size values set below.

Depending on which values you fill in the **Width**, **Height** and **Max side size** fields, the functionality is the following:

- **Only width or only height** - images will be resized so that the width/height matches the entered value. The other dimension is also resized so that the aspect ratio is kept.
- **Both width and height** - images will be resized so that both dimensions match the entered values. The aspect ratio will not be kept in this case
- **Max side size** - if one of the image's sides is larger than this value, the image will be resized so that the its larger side matches the entered value. The aspect ratio is kept and width and height settings are not applied.

4. Now that we have the two fields defined, we can upload some attachments to the existing events on the site. Switch to **CMS Desk** and select the **Events -> Open day** from the content tree. Switch to its **Form** tab. If you scroll down the page, you should see the two fields defined in the previous step.

5. Use **New attachment** () to add attachments into both fields. According to the name of the field, upload some documents into the first one and some images into the second one.

Just as on the **Properties -> Attachments** tab, you can perform the following actions with the attachments in the lists:

- **Delete** () - removes the attachment from the document.
- **Move up** () and **Move down** () - re-orders the attachments. The order is stored in the **AttachmentOrder** property of each attachment. You can enter *AttachmentOrder* into the **ORDER BY expression** property of a displaying web part to have the attachments ordered accordingly.

Please note

The order of attachments is **not versioned** with documents' workflow. This means that if you change the order of attachments in one version of a document, the order is changed in all other versions too.

- **Edit** () - if the attachment is an image, clicking the icon opens it in the built-in [image editor](#). If the attachment is not an image, the [metadata editor](#) is opened after clicking the icon.
- **Edit in client application** () - is displayed only when [WebDAV integration](#) is enabled and only next to file types supported by WebDAV. Clicking the icon opens the document for editing in an external application installed on the client computer (the application must support WebDAV for this to work). Saving the document in the client application updates the attachment with the new version

automatically.

- **Update** (↻) - enables you to replace the original attachment with a new one.
- After clicking an attachment's name, the attachment is opened.

6. Now that we have the attachments uploaded, it's time to have them displayed on the live site. The events are displayed by a repeater on the Events page, so we will have to add the displaying web parts to this page. First, we will add the **Document attachments** web part. We will configure it so that it will display attachments from **Attached documents** field.

Select the **Events** page and switch to the **Design** tab. Click the **Add web part** (+) icon of the **Main zone** web part zone and choose the **Attachments -> Document attachments** web part. Set the following properties of the web part, leave the rest at the default values.

- **Show for document types:** CMS.BookingEvent
- **Attachment group:** Event (Booking system) -> Attached documents
- **Content before:** <h2>Attached documents</h2>

Click **OK**.

7. Below the documents, we will want the attached images to be displayed. For the images, it will be better to use the **Attachment image gallery** web part. Click the **Add web part** (+) icon of the **Main zone** web part zone and choose the **Attachments -> Attachment image gallery** web part. Set the following properties of the web part, leave the rest at the default values.

- **Show for document types:** CMS.BookingEvent
- **Attachment group:** Event (Booking system) -> Attached images

- **Content before:** <h2>Attached images</h2>

Click **OK**.

8. If you switch to the live site now, you should see the two web parts displaying the attachments, each web part one group defined earlier in this example. If you add attachments to any other event, they would be displayed with the event too.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Live Site', 'Site Manager', 'Corporate Site', 'Global Administrator', 'v6.0.4254', and 'Sign Out'. The main content area displays a registration form for an event titled 'Open Day' at the 'NEW YORK OFFICE' on '6/23/2012'. The form includes fields for 'First name' (Global), 'Last name' (Administrator), 'E-mail' (administrator@localhost.local), and 'Phone'. A 'Register' button is present. Below the form, there are sections for 'Attached documents' and 'Attached images'. The 'Attached documents' section lists three files: 'sample-document.docx', 'sample-document.pdf', and 'sample-document.xlsx'. The 'Attached images' section displays three images: a landscape with a rock formation, a koala, and two penguins.

4.8.2.4 Available web parts

In this chapter, you can see an overview of the web parts that can be used to display document attachments. Only the most important web part properties are explained here. For a complete list of web part properties, please refer to [Kentico CMS Web Parts](#) reference guide or click the **Documentation** link at the top right corner of the web part properties window.

Document attachments

The web part is located in the **Attachments** web part category. This web part displays a list of files attached to a document. After clicking an attachment, it is opened in a new window.

The following properties of the web part are the most important:

- **Path:** alias path of the document whose attachments should be displayed; if blank, the currently displayed document's attachments will be displayed
- **Attachment group:** specifies the field from which the attachments should be displayed; if blank, ungrouped attachments from the Properties -> Attachments tab will be used
- **Transformation:** transformation used for displaying the attachments; the default transformation is *CMS.Root.AttachmentList*

Attachments image gallery

The web part is located the **Attachments** web part category. The web part is particularly useful for image attachments. It displays thumbnails of images attached to the document. After clicking a thumbnail, the clicked image is displayed in its full size by a **lightbox**. For non-image attachments, its file type icon is displayed. After clicking such an icon, the file is offered for download.

The following properties are the most important:

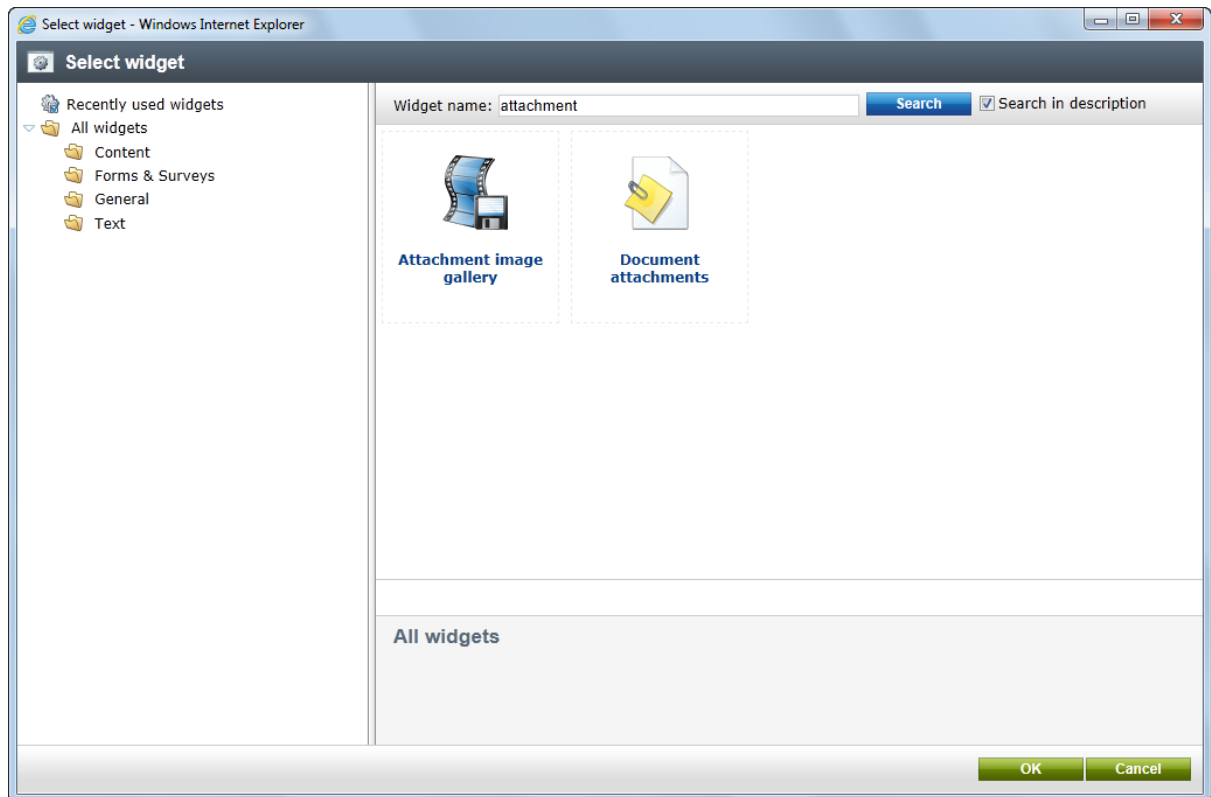

- **Path:** alias path of the document whose attachments should be displayed; if blank, the currently displayed document's attachments will be displayed
- **Attachment group:** specifies the field from which the attachments should be displayed; if blank, ungrouped attachments from the Properties -> Attachments tab will be used
- **Transformation:** transformation used for displaying the attachments; the default transformation is *CMS.Root.AttachmentLightbox*
- **Selected item transformation:** transformation used to display the selected item; the default transformation is *CMS.Root.AttachmentLightboxDetail*
- **LightBox Configuration:** the properties in this section can be used to customize the used LightBox

Attachments Data Source

This is a special web part - a data source. It is not visible on the live site. It only provides data to another connected web part (e.g. Basic Repeater), which will display the provided data. More information on data source web parts can be found in [this chapter](#).

4.8.2.5 Available inline widget

There are two [inline widgets](#) that can be used for displaying unsorted attachments of documents. The inline widgets can be added to a page via the **Editable text** web part, using the WYSIWYG editor on the **Page** tab. To add a widget to the page, just place the cursor in the appropriate position and click the **Insert/Edit widget** (📎) button. You can choose one of the following two widgets from the **Content** category for displaying attachments, which are based on the document attachment web parts:

Attachment image gallery

Displays thumbnails of the document's unsorted attachments in a gallery. After a thumbnail is clicked, the attachment will be displayed in a lightbox. By default, the widget uses the `cms.root.attachmentLightbox` transformation for the gallery and `cms.root.attachmentLightboxDetail` for the lightbox.

Document attachments

Displays the document's unsorted attachments. After an attachment is clicked, it will be displayed on a new page if it is an image and non-image attachments will be offered for download. By default, images are displayed based on the `cms.root.attachment` transformation.

In the Editable text's text area, the widgets are represented by matching placeholder images.

4.8.2.6 Handling attachments in transformations

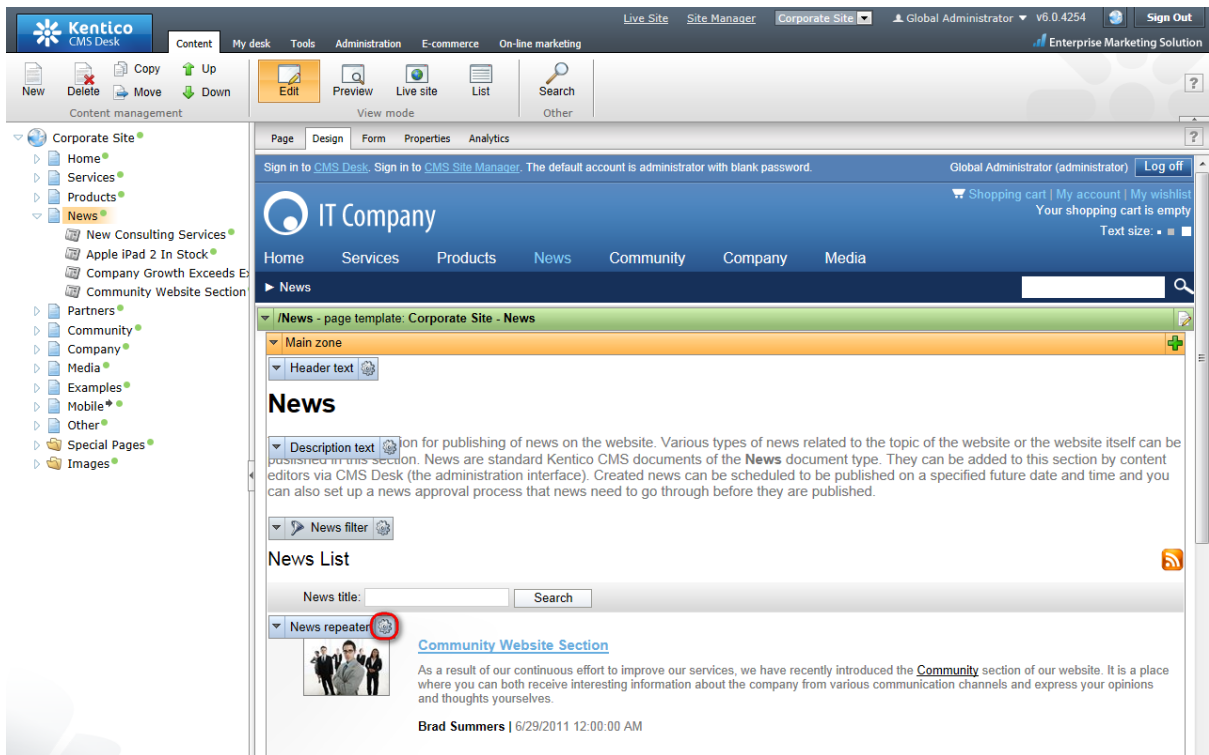

You can display document's unsorted attachments by adding one of the following two controls directly into the transformations:

- `~/CMSAdminControls/Attachments/DocumentAttachments.ascx`
- `~/CMSAdminControls/Attachments/AttachmentLightboxGallery.ascx`

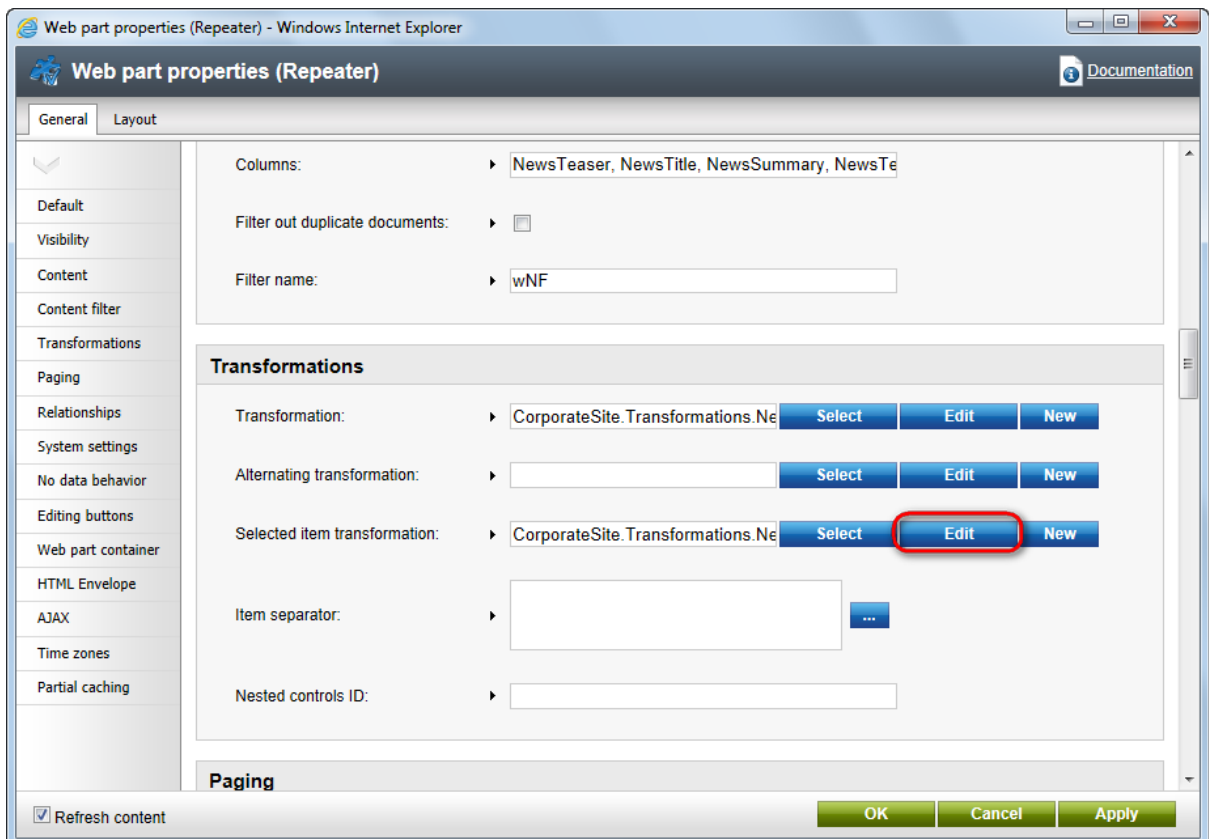

In the following example, you will learn how to use these controls in transformations. The news in the **News** section of the sample **Corporate Site** have some images attached by default. In [this example](#), you have learned how to display these attachments using a web part. Another way of displaying the attachments is by modifying the particular transformation for the document type.

The news are displayed on the News page using a **Repeater**. Detail view of each news item is displayed using the **CMS.News.NewsDetail** transformation. We will modify this transformation so that it displays the attachments along with the news summary and text.

1. Go to **CMS Desk** and select the **News** page from the content tree. Switch to **Design** tab and choose to **Configure** (⚙️) the **News repeater** web part.

2. In the web part properties window, choose to **Edit** the **Selected item transformation**.

3. Replace the original transformation with the following code, which is the original transformation with the highlighted parts added.

```
<%@ Register Src="~/CMSInlineControls/DocumentAttachments.ascx"
TagName="DocumentAttachments" TagPrefix="cms" %>

<div class="listDetail">
<h1 class="newsTitle"><%# Eval("NewsTitle", true) %></h1>
<div class="teaser"><%# IfEmpty(Eval("NewsTeaser"), "<img src='~/App_Themes/
CorporateSite/Images/no_image_news.png' alt='Default news teaser image' />",
GetImage("NewsTeaser", 230, 230, 500, Eval("NewsTitle"))) %></div>
<div class="contentText contentTextTeaser">
<div class="summary">
<p><%# Eval("NewsSummary") %></p>
</div>
<div class="text">
<p><%# Eval("NewsText") %></p>
</div>
</div>
<div class="clear"></div>

<div class="NewsBody">
<cms:DocumentAttachments ID="ucDocAttachments" runat="server"
TransformationName="cms.root.attachment" Path='<%# Eval("NodeAliasPath") %>' />
</div>

</div>
```

Click **Save**. Click **OK** in the web part properties window.

4. If you go to the live site now and view some of the news, you should see the attachments displayed below the news text, just as in the screenshot below.

New Consulting Services

We are proud to announce that the range of services we provide was extended by web development consulting. The most experienced and skilled employees from our web development department have been promoted to consultants and are here to help you with your web development projects.

We are proud to announce that the range of services we provide was extended by web development consulting. These services will be provided by highly skilled and experienced employees coming from our web development team. With extensive professional background and hundreds of successful projects in their portfolio, our consultants are here to provide valuable advice on your running or forthcoming web development projects. No matter how complicated your projects are or how tight are the upcoming deadlines, you can be sure that we will help you turn any project into clear success.

Penguins.jpg

- Let's try the other control now. Choose to **Configure** (⚙️) the **NewsRepeater** again and choose to **Edit** its **Selected item transformation**. Replace the transformation with the code below. Again, it is the original transformation with the highlighted parts added.

```
<%@ Register Src="~/CMSInlineControls/AttachmentLightboxGallery.ascx"
TagName="AttachmentLightboxGallery" TagPrefix="cms" %>

<div class="listDetail">
<h1 class="newsTitle"><%# Eval("NewsTitle", true) %></h1>
<div class="teaser"><%# IfEmpty(Eval("NewsTeaser"), "<img src='~/App_Themes/
CorporateSite/Images/no_image_news.png' alt='Default news teaser image\' />",
GetImage("NewsTeaser", 230, 230, 500, Eval("NewsTitle"))) %></div>
<div class="contentText contentTextTeaser">
<div class="summary">
<p><%# Eval("NewsSummary") %></p>
</div>
<div class="text">
<p><%# Eval("NewsText") %></p>
</div>
</div>
<div class="clear"></div>

<div class="NewsBody">
<cms:AttachmentLightboxGallery ID="ucDocAttachments" runat="server"
TransformationName="cms.root.attachmentLightbox"
```

```
SelectedItemTransformationName="cms.root.attachmentLightboxDetail" Path='<%# Eval  
("NodeAliasPath") %>' />  
</div>  
  
</div>
```

Click **Save**. Click **OK** in the web part properties window.

6. If you go to the live site now, you should see the result as in the screenshot below. After clicking one of the images, it will be displayed in the lightbox.

New Consulting Services

We are proud to announce that the range of services we provide was extended by web development consulting. The most experienced and skilled employees from our web development department have been promoted to consultants and are here to help you with your web development projects.

We are proud to announce that the range of services we provide was extended by web development consulting. These services will be provided by highly skilled and experienced employees coming from our web development team. With extensive professional background and hundreds of successful projects in their portfolio, our consultants are here to provide valuable advice on your running or forthcoming web development projects. No matter how complicated your projects are or how tight are the upcoming deadlines, you can be sure that we will help you turn any project into clear success.

Please note: the appearance shown in this example is based on the controls' default transformations. You can fully customize the appearance by modifying the default transformations or creating your own transformations and specifying them in the **TransformationName** and **SelectedItemTransformationName** properties of the controls.

4.8.2.7 Using the File field

In the overview, we mentioned the **File** field used in the previous versions. Use of this field is still possible and could be particularly useful if you want to have a field where only one file can be uploaded. The default **CMS.File** document type is based on the use of this type of field.

If you want to define a new **File** field, choose **File** from the **Attribute type** drop-down list when defining a new field.

The screenshot shows the 'Document type properties' configuration page for an 'Event (booking system)'. The 'Form' tab is selected, and the 'Field appearance' section is expanded. The 'Form control type' is set to 'Uploader', and the 'Form control' is set to 'Direct uploader'. The 'Field description' is 'Upload file'. The 'Database' section shows the column name 'File' and attribute type 'File'. The 'Editing control settings' section shows 'Inherit from settings' checked and 'Allowed extensions' set to 'pdf;doc;docx;ppt;ppb;xls;'. The 'Automatic image resize on upload' is set to '(use site settings)'. The 'Form' tab is selected, and the 'Field appearance' section is expanded. The 'Form control type' is set to 'Uploader', and the 'Form control' is set to 'Direct uploader'. The 'Field description' is 'Upload file'.

As you can see in the screenshot above, the **Form control** drop-down list can be used to choose between two available controls for file uploading which will be displayed on the **Form** tab:

• Upload file

This is the original control which was used in the previous versions.

• Direct uploader

This is the same control that is used for uploading attachments via the **Form** tab. The only difference is that it allows only one file to be uploaded.

This is how it looks like when no file is uploaded:

And here is the control after file upload:

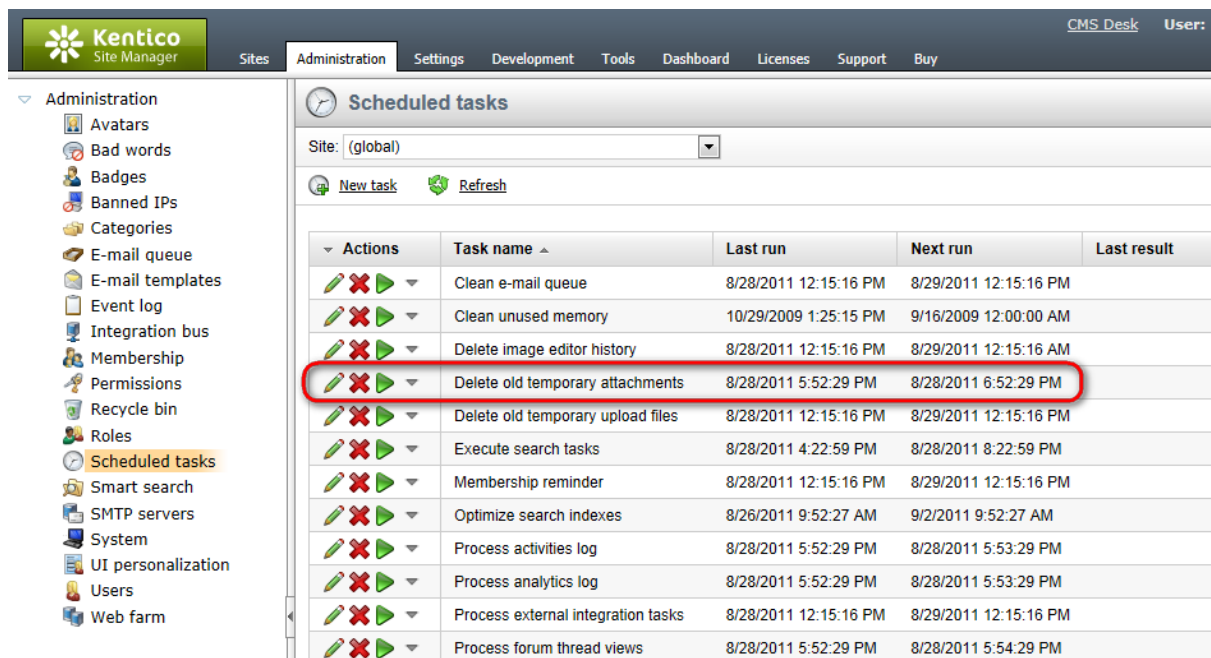

Actions	Update	Name	Size
 		 Desert-(1).jpg	826 kB

4.8.2.8 Temporary attachments handling

If you create a new document and start attaching files to it, temporary attachments are created. When the document is saved, the temporary attachment becomes a real attachment. If the document is not saved, the temporary attachments remain on the disk or in the database. To handle the unused files, there is a scheduled task pre-defined.

In **Site Manager -> Administration -> Scheduled tasks**, you can find the **Delete old temporary attachments** scheduled task. By default, this task is performed on a daily basis and deletes all temporary attachments older than 24 hours.

You can customize the interval by adding the `<add key="CMSDeleteTemporaryAttachmentsOlderThan" value="1"/>` key into the `<appSettings>` section of your site's `web.config` file. The value specifies the interval in hours.

The screenshot shows the Kentico Site Manager Administration interface. The left sidebar contains a navigation menu with 'Scheduled tasks' highlighted. The main content area displays a table of scheduled tasks for the '(global)' site. The 'Delete old temporary attachments' task is circled in red.

Actions	Task name	Last run	Next run	Last result
  	Clean e-mail queue	8/28/2011 12:15:16 PM	8/29/2011 12:15:16 PM	
  	Clean unused memory	10/29/2009 1:25:15 PM	9/16/2009 12:00:00 AM	
  	Delete image editor history	8/28/2011 12:15:16 PM	8/29/2011 12:15:16 PM	
  	Delete old temporary attachments	8/28/2011 5:52:29 PM	8/28/2011 6:52:29 PM	
  	Delete old temporary upload files	8/28/2011 12:15:16 PM	8/29/2011 12:15:16 PM	
  	Execute search tasks	8/28/2011 4:22:59 PM	8/28/2011 8:22:59 PM	
  	Membership reminder	8/28/2011 12:15:16 PM	8/29/2011 12:15:16 PM	
  	Optimize search indexes	8/26/2011 9:52:27 AM	9/2/2011 9:52:27 AM	
  	Process activities log	8/28/2011 5:52:29 PM	8/28/2011 5:53:29 PM	
  	Process analytics log	8/28/2011 5:52:29 PM	8/28/2011 5:53:29 PM	
  	Process external integration tasks	8/28/2011 12:15:16 PM	8/29/2011 12:15:16 PM	
  	Process forum thread views	8/28/2011 5:52:29 PM	8/28/2011 5:54:29 PM	

4.8.2.9 Attachment names

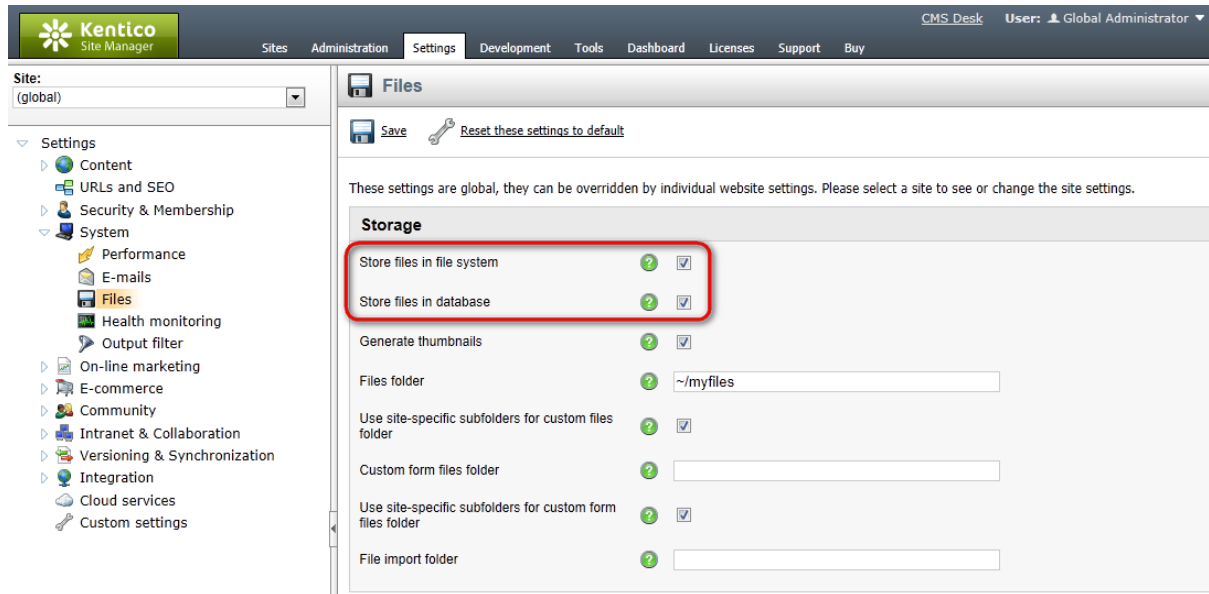

Attachment names are unique for a document (or its version). If you try to upload an attachment that has the same name as some already existing attachment of the particular document, the new attachment gets a number in the **-(1)** format attached to its name.

This happens for the attachments to be accessible via friendly URLs in the following format:

- `~/getattachment/<node_alias_path>/<safe_filename>.<extension>`

4.8.3 Where the files are stored

Document attachments and CMS.File documents can be physically stored in the file system, in the database, or in both. You can define this in **Site Manager -> Settings -> System -> Files**, using the **Store files in file system** and **Store files in database** options.

The following three combinations can be achieved using the settings:

- **File system** - the files are stored in the configured folder on your disk. This option provides the best performance. However, the **Modify** permissions on the disk must be granted to the ASP.NET account on your machine, which is not always possible. The process of granting the Modify permission is described in [this chapter](#).
- **Database** - the files are stored in the database. This option provides worse performance, but it allows you to use full-text search in uploaded files. It also doesn't require the Modify permission on the disk and it allows you to easily backup the uploaded files as a part of your database backup.
- **Both - Database and file system** - this option combines the advantages of both options. It provides the same performance as the file system-only option since the files are stored in the file system. At the same time, you can use the full-text search because the database is also available.

Document attachments and metafiles location

Document attachments are stored in the file system under `~/<site code name>/files`, metafiles are stored under `~/<site code name>/metafiles`. Both of these folders can be located in a different location, which can be configured using the **Site Manager -> Settings -> System -> Files -> Custom files folder** settings option. Learn more in [File-related settings](#).

Form files location

Files uploaded by site users into [forms](#) are always stored in the file system. The default location is `~/<site code name>/BizFormFiles`. You can customize the location in **Site Manager -> Settings ->**

System -> Files -> Form files folder.

Media library files location

Files stored in [media libraries](#) are always stored in the file system. The default location is `~/<site code name>/media`, while the location of the folder can be customized in **Site Manager -> Settings -> Content -> Media -> Custom media libraries folder**, as described in [Modules -> Media libraries -> Media libraries settings](#).

4.8.4 File-related settings

You can configure file storage options in **Site Manager -> Settings -> System -> Files**.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The 'Settings' section is expanded to show 'Files'. The left sidebar lists various settings categories, with 'Files' selected. The main content area displays the following settings:

- Storage**
 - Store files in file system:
 - Store files in database:
 - Generate thumbnails:
 - Files folder:
 - Use site-specific subfolders for custom files folder:
 - Custom form files folder:
 - Use site-specific subfolders for custom form files folder:
 - File import folder:
- Security**
 - Upload extensions:
 - Check if files are published:
 - Check files permissions:
- Image resizing**
 - Automatic image resize on upload (width):
 - Automatic image resize on upload (height):
 - Automatic image resize on upload (max side size):

The following options can be set on the page:

Storage	
Store files in file system	Indicates if files should be stored in the file system.

Store files in database	Indicates if files should be stored in the database.
Generate thumbnails	Indicates if the CMS should generate image thumbnails on the disk when a resized version of the image is displayed. This option only applies if files are stored in the file system. It improves site performance .
Files folder	<p>The folder on the disk where document attachments and metafiles are stored. You can use:</p> <ul style="list-style-type: none"> • physical disk path: e.g. <code>c:\myfiles\</code> • virtual path: <code>~/UploadedFiles</code> • UNC path: <code>\\server\folder</code> <p>If you do not specify any value, the files are stored in folder <code>~/<site code name>/files</code>.</p>
Use site-specific subfolders for custom files folder	This setting is only applied when a Custom form files folder is configured. If enabled, attachment files will be stored in a sub-folder named according to the code name of the site where the form is placed, i.e. <code><custom form files folder>/<site code name></code> . It is useful for better orientation in files when multiple sites are running in the system.
Custom form files folder	<p>Folder where files uploaded via Forms are stored. You can use:</p> <ul style="list-style-type: none"> • physical disk path: e.g. <code>c:\myfiles\mysite</code> • virtual path: <code>~/UploadedFiles</code> • UNC path: <code>\\server\folder</code> <p>If no value is entered, the files are stored in <code>~/<site code name>/BizFormFiles</code>.</p>
Use site-specific subfolders for custom form files folder	This setting is only applied when a Custom form files folder is configured. If enabled, attachment files will be stored in a sub-folder named as the site code name under the custom files folder, i.e. <code><custom BizForm files folder>/<site code name></code> . It is useful for better orientation in files when multiple sites are running in the system.
File import folder	Path to the source folder where files to be imported by the File import should be uploaded before import. If no value is entered, <code>~/CMSImportFiles</code> is used by default.
Security	
Upload extensions	<p>Specifies which extensions are allowed for uploaded files. You can restrict the types of uploaded files by entering a limited list of extensions separated by semicolons, for example: <code>gif;jpg;doc;pdf</code></p> <p>This allows you to block users from uploading potentially dangerous files, such as ASPX scripts. If no value is specified, uploading will be allowed for all file types.</p>
Check if files are published	If checked, only files that are in the Published workflow step can be accessed from the live site when a workflow is applied to the document.
Check files permissions	If checked, document permissions are applied to the files.

Image resizing	
Automatic image resize on upload (width, height, max side size)	<p>Depending on which values you fill in, the functionality is the following when uploading images:</p> <ul style="list-style-type: none"> • No values are entered - images are not resized. • Only width or only height - images are resized so that their width or height matches the entered value. The other dimension is also resized so that aspect ratio is preserved. • Both width and height - images are resized so that the larger dimension matches the respective entered value. Aspect ratio is not preserved. • Max side size - if one of the image's sides is larger than this value, the image is resized so that its larger side's dimension matches the entered value. Aspect ratio is preserved and width and height settings are not applied. <p>More info can be found in the Resizing images chapter of Kentico CMS Developer's Guide.</p>
Watermark	
Watermark image	Image name or path that will be used for watermarking the images. User either a full path (~/. .) or just a file name from the <code>~/App_Themes/Default/Images/Watermarks</code> folder.
Watermark position	The position where the image watermark is placed on the watermarked images.
Minimum image width for watermark	Minimum width of an image to be watermarked.
Minimum image height for watermark	Minimum height of an image to be watermarked.
Use watermark for document images	If checked, the watermark is used for document attachments.
Use watermark for media files	If checked, the watermark is used for media files.
Use watermark for object attachments	If checked, the watermark is used for object attachments.

4.8.5 Using the Media selection control

The **Media selection** form control can be used to enable users to select files on the **Form** tab of a document. It allows to use any file from any source (from Document attachments, Content and Media libraries) in your documents. The following example demonstrates how you can achieve this:

1. Navigate to **Site Manager -> Development -> Document types** and create a custom document type with 3 fields, which will enable content editors to select images, videos and documents. Name the document type *Test document type* and the three fields *ItemPhoto*, *ItemVideo* and *ItemDocument*. Make sure that all three fields use the **Media selection Form control**:

The screenshot shows the 'Document type properties' interface for a 'Test document type'. The 'Fields' tab is active, and the 'ItemVideo' field is selected. The 'Form control' dropdown is set to 'Media selection'. The 'Database' section shows the column name 'ItemVideo' with a 'Text' attribute type and a size of 250. The 'Field appearance' section shows the field caption 'Video' and the form control 'Media selection'. The 'Editing control settings' section shows the automatic image resize on upload settings.

2. In the **Document type properties** user interface, switch to the **Transformations** tab and specify the new transformation as follows:

```
<%@ Register Src="~/CMSInlineControls/MediaControl.ascx" TagName="Media"
TagPrefix="cms" %>

Name: <%# Eval ("ItemName") %><br />
Photo: <cms:Media id="MediaElement1" runat="server" URL='<%# Eval<string>
("ItemPhoto") %>' /><br />
Video: <cms:Media id="MediaElement2" runat="server" URL='<%# Eval<string>
("ItemVideo") %>' AVControls="true" /><br />
Document: <a href="<%# Eval ("ItemDocument") %>" target="_blank">Show me</a><br />
Description: <%# Eval ("ItemDescription") %>
```

Document type properties

Document types > Test document type

General Fields Form **Transformations** Queries Child types Sites Alternative forms Search fields Documents

Transformations > TestDocumentTypeTransformation

General Theme

Save Check out to file

You can check out the transformation to the
 c:\inetpub\wwwroot\KenticoCMS4251.14830BETA\CMSTransformations\custom\testdocumenttype\testdocumenttypetransformation.ascx file to edit it externally.

Transformation name: TestDocumentTypeTransformation

Transformation type: ASCX

Code: Default [Generate default transformation](#)

```
<%@ Control Language="C#" AutoEventWireup="true" Inherits="CMS.Controls.CMSAbstractTransformation" %>
<%@ Register TagPrefix="cc1" Namespace="CMS.Controls" Assembly="CMS.Controls" %>
<%= Register Src="~/CMSInlineControls/MediaControl.ascx" TagName="Media" TagPrefix="cms" %>
Name: <%= Eval ("ItemName") %><br />
Photo: <cms:Media id="MediaElement1" runat="server" URL="<%= Eval<string>("ItemPhoto") %>" /><br />
Video: <cms:Media id="MediaElement2" runat="server" URL="<%= Eval<string>("ItemVideo") %>" AVControls="true" /><br />
Document: <a href="<%= Eval("ItemDocument") %>" target="_blank">Show me</a><br />
Description: <%= Eval ("ItemDescription") %>
```

3. Now go to **CMS Desk -> Content**, [create](#) a new document of the *Test document type* and specify its data on the **Form** tab:

Kentico CMS Desk Live Site Site Manager Corporate Site

Content My desk Tools Administration E-commerce On-line marketing

New Delete Copy Move Down Up Edit Preview Live site List Search

Content management View mode Other

TestDocumentTypeID: 1

Name: My media page

Photo:  /KenticoCMS4251.14830 [Select](#) [Clear](#)

Video:  /KenticoCMS4251.14830 [Select](#) [Clear](#)

Document:  /KenticoCMS4251.14830 [Select](#) [Clear](#)

Description: This is my media page.

Publish from: 8/22/2011 1:37:58 PM [Now](#)

Publish to: [Now](#)

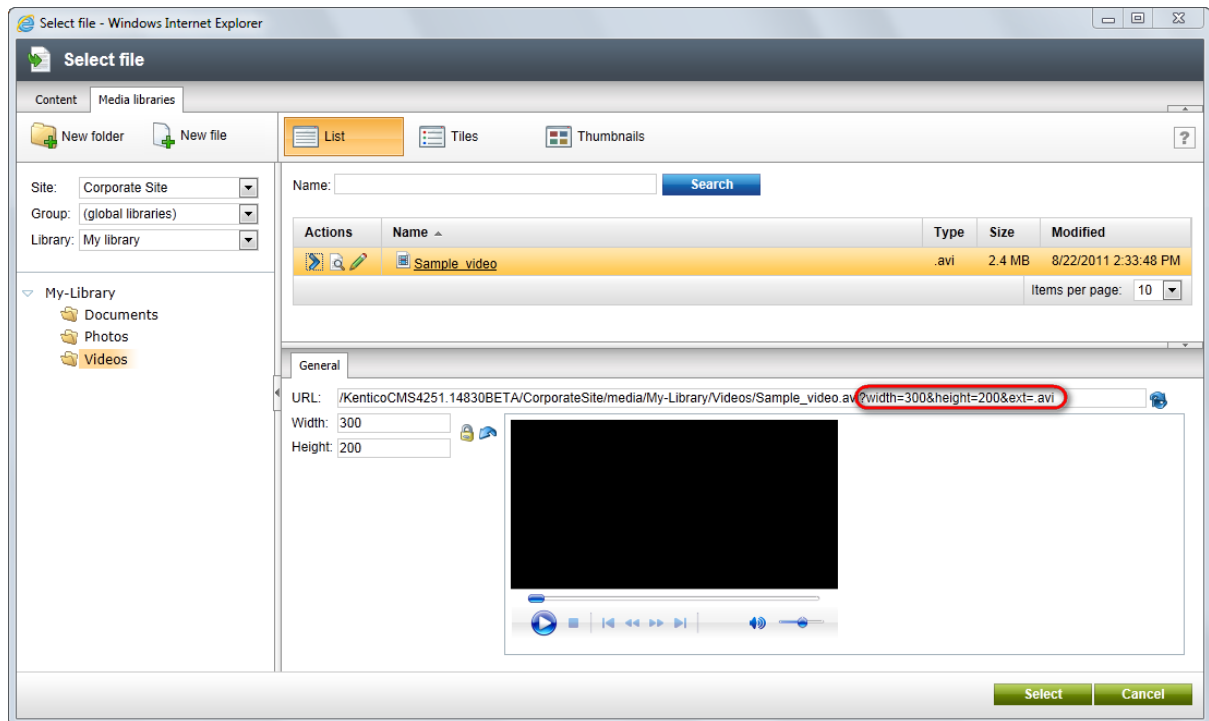

4. Finally, switch to the **Live site** mode to see the results. You will need to use some of the viewers (e.g. the **Repeater** web part) to display data of your new document using your defined transformation:

The screenshot shows the Kentico CMS 7.0 Developer's Guide interface. The top navigation bar includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The 'Live site' button is highlighted with a red box. The main content area displays a koala image, a video player, and various widgets like 'Newsletter', 'Featured product', 'Latest news', and 'Polls'.

As you can see, the **Media selection** control is able to identify the type of content from its URL property automatically. It is recognized according to the following URL parameters:

- **Width** - the width of the image or media player.
- **Height** - the height of the image or media player.
- **Ext** - the extension of the file (i.e. the type of media).

These parameters are automatically attached to the selected file URL when selecting the media using the **Media selection** field:

4.8.6 Image editor

4.8.6.1 Overview

Kentico CMS comes shipped with the integrated Image editor that enables you to edit images of four image formats: **.bmp**, **.gif**, **.png** and **.jpg**. The editor can be accessed throughout the whole system, everywhere the **Edit** (✏️) icon is available for a listed image, just like in:

- **Media libraries**
- **Document attachments**
- **CMS.File documents Form tab**
- **Product images**
- **Form files**
- **etc.**

After the **Edit** (✏️) icon is clicked, the following Image editor dialog is displayed:

- [Image editing tools](#) - enable you to perform actions such as **Resize**, **Rotation**, **Convert**, **Crop** and **Color** adjustment; you can view also the **Properties** of the image.
- **Image preview** - previews the current change to the image.
- **Undo & Redo changes** - you can undo and redo the changes made to the image.
- **Save changes & Close** - if you want to keep the changes you have made, you can save the image; or you can leave the editor and keep the original image.

For more information on how to perform the **Undo & Redo** changes and how to use the **Save changes & Close** buttons, please refer to the [Saving changes](#) topic.

4.8.6.2 Image editing

Here you will learn how to edit the selected image. Besides, you will learn how to view the image properties:

- [Resize](#)
- [Rotation](#)
- [Convert](#)
- [Crop](#)
- [Color](#)
- [Properties](#)

Each action is performed after clicking the **OK** button. Please refer to the [Saving changes](#) topic for more

details.

Resize

The **Resize** action lets you change the size of the image. The image is either enlarged or reduced to the size you specify. You may specify either a relative percentage to resize the image by, or an absolute pixel size. If the **Maintain aspect ratio** option is checked, then typing a new **Width** value will maintain a proportional **Height** value, and vice versa.

- **By percentage** - resizes the image to the entered percentage of side size.
- **By absolute size** - resizes the image to the size specified in the **Width** and **Height** fields.
 - **Width** - the width size of the image; in pixels.
 - **Height** - the height size of the image; in pixels.
 - **Maintain aspect ratio** - if checked, proportional values of the image dimensions will be maintained.

Rotation

The **Rotation** action commands enable you to rotate the image by 90 degrees (in either the clockwise or counter-clockwise directions) and to flip the image, both horizontally and vertically.

- **Rotate 90° left** - rotates the image to the left by 90 degrees.
- **Rotate 90° right** - rotates the image to the right by 90 degrees.
- **Flip horizontally** - flips the image horizontally.
- **Flip vertically** - flips the image vertically.

Convert

The **Convert** action enables you to transform the image file from one format to another. The **From** field of the action dialog tab is always filled in automatically according to the current format of the edited image. Please note that for the **.jpeg** image file type, you can also define image quality by entering the

image quality percentage into the **Quality** field.

Resize	
Rotation	
Convert	
From: <input type="text" value="jpg"/> To: <input type="text" value="jpg"/> <input type="button" value="v"/> Quality: <input type="text" value="10"/> % <input type="button" value="OK"/>	

- **From** - the source format of the image.
- **To** - the target format of the image; **.bmp**, **.gif**, **.png** and **.jpg** image formats are supported.
- **Quality** - the quality of compression; applicable only for **.jpg** conversion.

Crop

The **Crop** action enables you to remove portions of the image to create focus or strengthen the composition. Image size is reduced without changing image resolution, so that the edited image is not distorted. Using Kentico CMS Image editor, you can crop images either manually by entering the coordinates of the upper-left point of the crop area rectangle and its width and height or you can move the mouse over the area of focus. The crop area rectangle can be resized in any direction unless the **Lock aspect ratio** option is checked. If checked, proportions of the currently selected crop area rectangle are maintained while resizing.

Resize	
Rotation	
Convert	
Crop X: <input type="text" value="39"/> Y: <input type="text" value="22"/> Width: <input type="text" value="112"/> Height: <input type="text" value="106"/> Lock aspect ratio: <input type="checkbox"/> <input type="button" value="Reset"/> <input type="button" value="OK"/>	

- **X** - the X coordinate of the upper-left point of the crop area rectangle.
- **Y** - the Y coordinate of the upper-left point of the crop area rectangle.
- **Width** - the width of the crop area rectangle; in pixels.
- **Height** - the height of the crop area rectangle; in pixels.
- **Lock aspect ratio** - if checked, the crop area rectangle will keep its current proportions while resizing it in any direction.
 - The same functionality can be achieved by holding the SHIFT key while moving the mouse. If the **Lock aspect ratio** option is checked while performing this operation, the result is inverse.
 - Pressing the CTRL key will result in returning the square of the currently selected rectangle area.

Please note that the crop area rectangle can be moved within the crop area by moving the mouse inside the rectangle.

Click **OK** to confirm the immediate change or click **Reset** or anywhere within the edited image outside the crop area rectangle to clear all the **Crop** action input fields.

Color

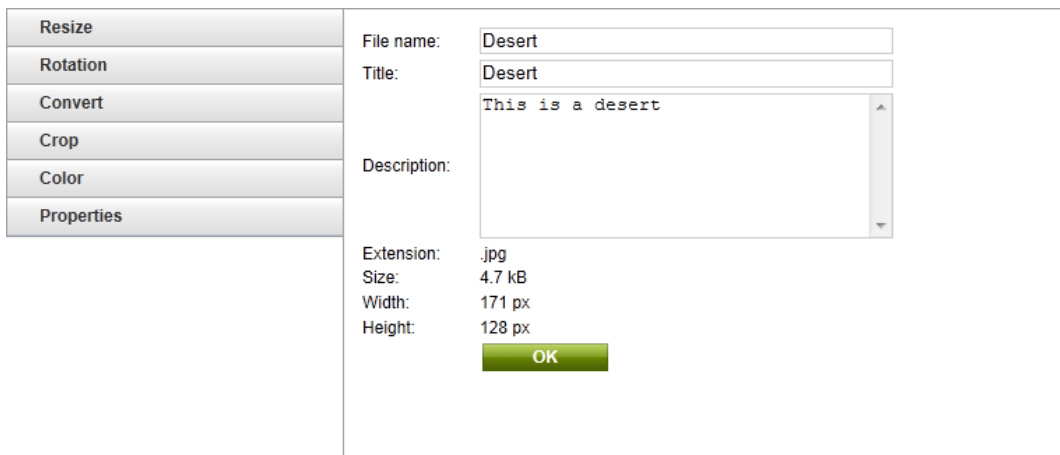

The **Color** action lets you easily convert the image from color to grayscale.

Convert to grayscale - clicking this link results in converting the image from color to grayscale.

Properties

The **Properties** tab displays important information about the image such as its file name, title, description, extension, size, width and height. The **File name**, **Title** and **Description** fields are editable, enabling you to change the respective properties of the image.

- **File name** - the file name of the image.
- **Title** - the title of the image; image metadata that can be used e.g. in transformations.
- **Description** - the description of the image; image metadata that can be used e.g. in transformations.
- **Extension** - the file type extension of the image.
- **Size** - the size of the image; in kB.
- **Width** - the width of the image; in pixels.
- **Height** - the height of the image; in pixels.

Please note

If you decide to leave the Image editor without saving the changes you have made (by clicking the **Close** button), a message window will pop up informing you that all changes will be lost.

4.8.6.3 Saving changes

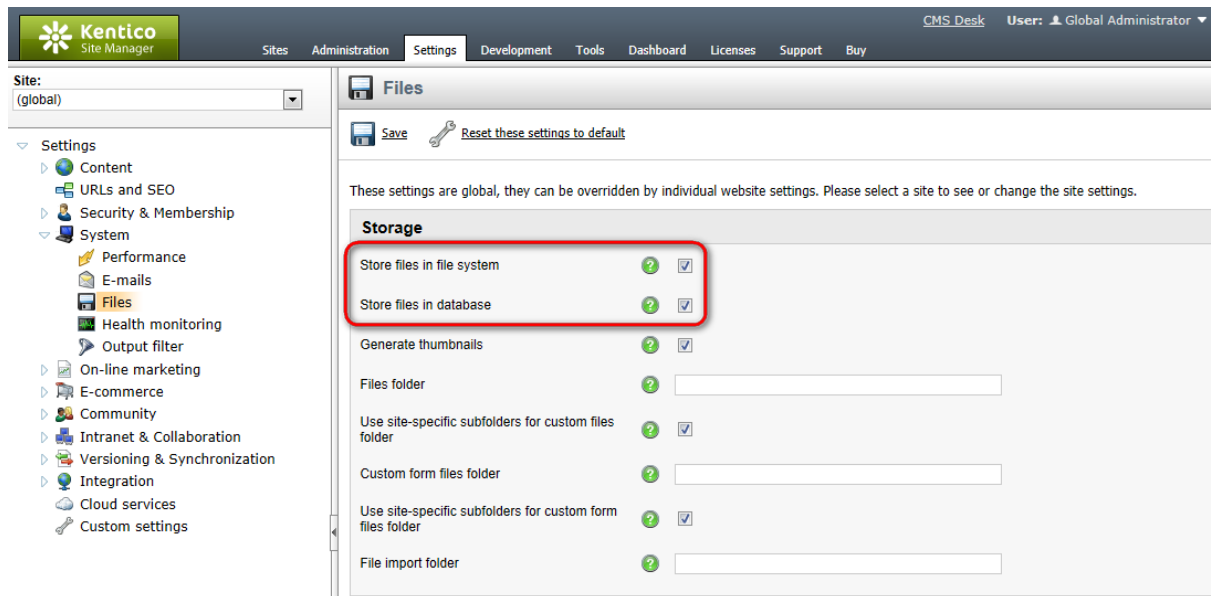

Undo and Redo

The **Undo** and **Redo** actions allow you to undo and redo up to 1000 changes made while editing the image. After each partial change, a temporary version of the image is created and stored in *Application URL/App_Data/CMSTemp/ImageEditor/First two letters of image editor instance GUID/Image editor instance GUID*, the database or in both; see [Storing image versions](#). By clicking the **Undo** and **Redo** buttons, you can view the stored separate versions of the image. By clicking the **Save changes** button, the original image is replaced by the currently edited version of the image.

Storing image versions

Separate image versions containing changes of the image are stored either in the database or on the disk, as set in **Site Manager -> Settings -> System -> Files**.

Please note that if only the storing of files in the file system is enabled and permission to write to the local disk is missing, the **Undo**, **Redo** and **Save changes** buttons are hidden and the changes are applied immediately to the original image.

Deleting image versions

If you decide to leave the Image editor by clicking the **Close** button, all image versions files from the current editing session will be deleted, regardless of their storing location. However, if you happen to finish editing in a non-standard way, e.g. by quitting the browser, the files will remain stored (both in the file system and in the database) until a global scheduled task performs their deletion.

You can change the settings of this global task in **Site Manager -> Administration -> Scheduled tasks**. Select **(global)** from the **Site** drop-down list and choose to **Edit** (✎) the **Delete image editor history** scheduled task. Change the settings of the schedule as required and click **OK**.

By default, this task deletes all image versions older than 24 hours. If you would like to change this, you need to alter the value in the settings key of the global task. This key is contained in the **web.config** file placed in your Kentico CMS installation folder.

- `<add key="CMSDeletelImageEditorHistoryOlderThan" value="24"/>` - the value is in hours, the default value is 24.

For more details on how to configure scheduled tasks, please refer to the [Scheduler](#) chapter in the **Development** section of this guide.

4.8.7 Metadata editor

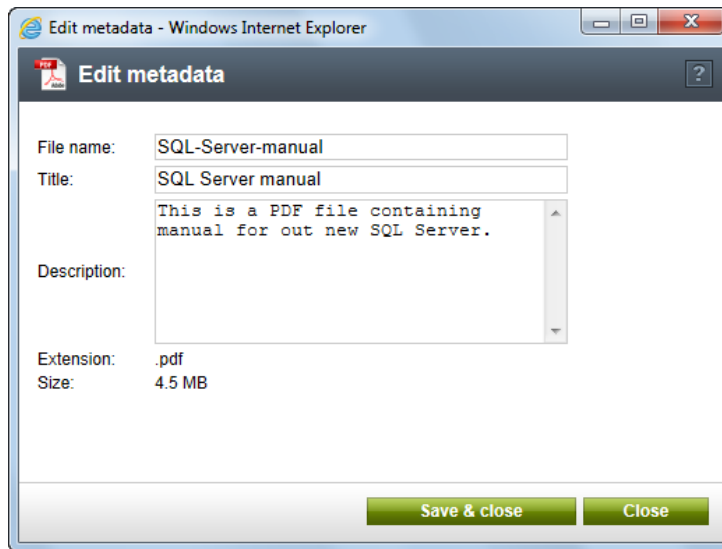

The Metadata editor can be used to edit metadata (i.e. descriptions) of non-image files stored in [Media libraries](#), as [document attachments](#) or as object metafiles. The dialog is always accessible by clicking the **Edit**  icon next to the file listed in the respective part of the UI.

The following metadata can be entered:

- **File name** - name of the file (without the trailing dot and extension). The current file name is always

pre-filled when the dialog is opened.

- **Title** - title of the file (may be different from the actual file name).
- **Description** - text describing the content of the file.

The screenshot shows a web browser window titled "Edit metadata - Windows Internet Explorer". Inside the browser, there is a dialog box titled "Edit metadata". The dialog contains the following fields and values:

- File name: SQL-Server-manual
- Title: SQL Server manual
- Description: This is a PDF file containing manual for out new SQL Server.
- Extension: .pdf
- Size: 4.5 MB

At the bottom of the dialog, there are two buttons: "Save & close" and "Close".

4.8.8 Resizing images on upload

You can set global image resizing parameters in **Site Manager -> Settings -> System -> Files -> Image resizing** by entering the following values:

- **Automatic image resize on upload (width, height, max side size)** - depending on which values you fill in, the functionality is the following when uploading images:
 - **No values are entered** - images are not resized.
 - **Only width or only height** - images are resized so that their width or height matches the entered value. The other dimension is also resized so that aspect ratio is preserved.
 - **Both width and height** - images are resized so that the larger dimension matches the respective entered value. Aspect ratio is preserved.
 - **Max side size** - if one of the image's sides is larger than this value, the image is resized so that its larger side's dimension matches the entered value. Aspect ratio is preserved and width and height settings are not applied.

The screenshot displays the Kentico CMS 7.0 Settings interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The 'Settings' section is active, and the 'Files' sub-section is selected. The left sidebar shows a tree view of settings categories, with 'Files' highlighted. The main content area is titled 'Files' and contains the following settings:

- Storage**
 - Store files in file system:
 - Store files in database:
 - Generate thumbnails:
 - Files folder:
 - Use site-specific subfolders for custom files folder:
 - Custom form files folder:
 - Use site-specific subfolders for custom form files folder:
 - File import folder:
- Security**
 - Upload extensions: pdf,doc,docx;ppt,pptx,xls,xlsx;htm,html+xml;bmp,g
 - Check if files are published:
 - Check files permissions:
- Image resizing** (highlighted with a red box)
 - Automatic image resize on upload (width):
 - Automatic image resize on upload (height):
 - Automatic image resize on upload (max side size):

These settings are applied by default when uploading images as:

- **media library files**
- **document attachments**
- **CMS.File documents**
- **Editable text web part** - uploading images using the WYSIWYG editor dialogs
- **Editable image web part** - uploading images using the **Select image** dialog
- **Field editor fields** - uploading images using the following field types (form controls), e.g. in forms, Document type field editor, etc.
 - **File** attribute type -> **Upload file** and **Direct uploader** form controls
 - **Text** attribute type -> **HTML Area (Formatted Fext)**, **BBcode editor**, **Image selection**, **Media selection** and **File selection** form controls

The default settings defined here can be overridden by local settings in the particular parts of the user interface (e.g. web part properties, field editor, WYSIWYG editor dialogs, etc.).

4.8.9 Uploading multiple files at once

Files in Kentico CMS can be uploaded either one by one or as multiple files. This can be useful if you need to upload a greater number of files at once or if you need to perform the task in the quickest possible way. Upload of multiple files at once is available for:

- **media files** - files in a [media library](#) (e.g. CMS Desk -> Tools -> Media -> Edit (✎) *media library* -> Files tab).
- **meta files** - files related to a specified object (e.g. [e-mail template](#) attachments in CMS Desk -> Administration -> E-mail templates -> Edit (✎) *e-mail template* -> Attachments).
- **document attachments** - files attached to a document (e.g. CMS Desk -> Content -> *document* -> Properties tab -> Attachments tab).

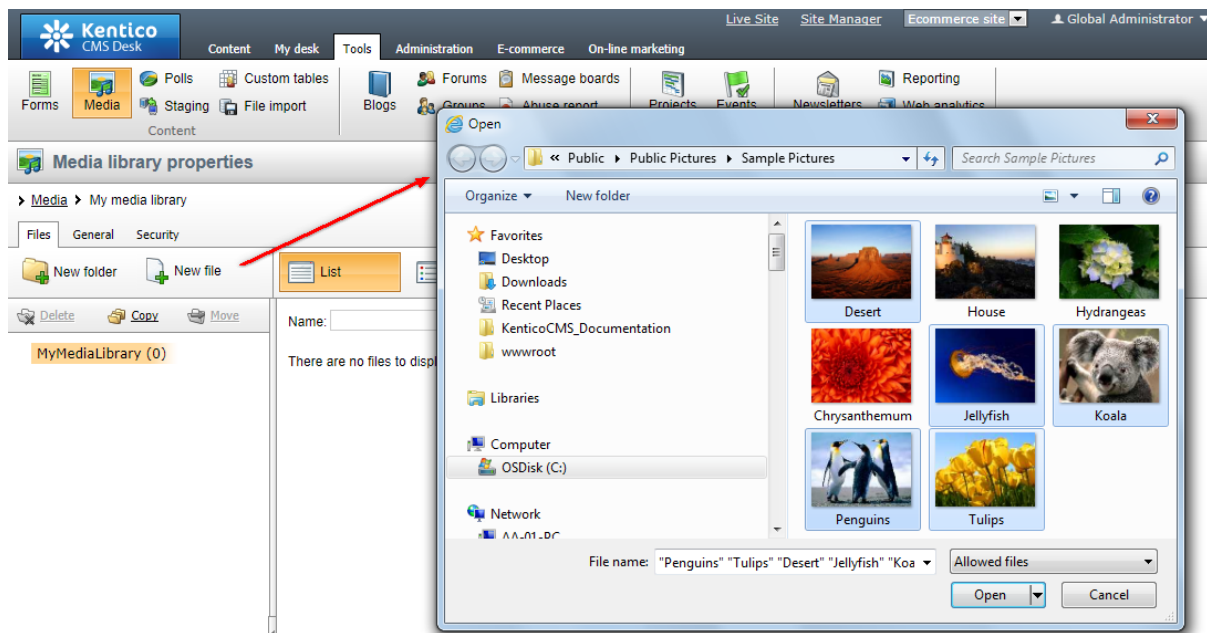

Enabling upload of multiple files

To enable upload of multiple files in the whole CMS the following conditions must be met concurrently:

1. The value of the ***CMSUseSilverlightUploader*** key is set to TRUE or the key is not added in the *appSettings* section of the *web.config* file (because the upload of multiple files is the default option).
2. The CMS application has the write-to-disk [permission](#) for the temporary files repository, i.e. for **web project\App_Data\CMSTemp\MultiFileUploader**.
3. [Microsoft Silverlight](#) is installed on your client computer.

How it works

1. First you need to select one or more files from a given location.

2. The files are downloaded as temporary files to a temporary repository (*App_Data\CMSTemp\MultiFileUploader*). However, to upload the files successfully, you need to avoid POST BACK on the current page during the upload.
3. When the upload is finished, the temporary files become the requested files:

The screenshot shows the Kentico CMS Media library interface. The top navigation bar includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The 'Media' tab is active, showing 'My media library'. The interface includes a search bar, a list of files, and a preview of the selected file.

Actions	Update	Name	Type	Size	Modified
		Desert	.jpg	826 kB	8/18/2011 12:40:52 PM
		Jellyfish	.jpg	758 kB	8/18/2011 12:40:52 PM
		Koala	.jpg	763 kB	8/18/2011 12:40:52 PM
		Penquins	.jpg	760 kB	8/18/2011 12:40:53 PM
		Tulips	.jpg	606 kB	8/18/2011 12:40:53 PM

Selected files: (select an action) OK

Direct path: /6.0.4246.16572/EcommerceSite/media/MyMediaLibrary/Tulips.jpg
 Permanent link: /6.0.4246.16572/getmedia/0cdd834b-746b-4653-b5ec-b6812f6b0bde/Tulips.aspx

Please note

If you don't avoid POST BACK during the upload of multiple files or some other error occurs, the temporary files remain in the temporary repository. That's why there is the **Delete old temporary upload files** [scheduled task](#) (configurable in Site Manager -> Administration -> Scheduled tasks), which deletes these temporary files, by default older than 24h. However, you can change this setting by changing the value of the **CMSTemporaryUploadFilesOlderThan** key (please note that you need to manually add the key into the *web.config* file in the current web project folder).

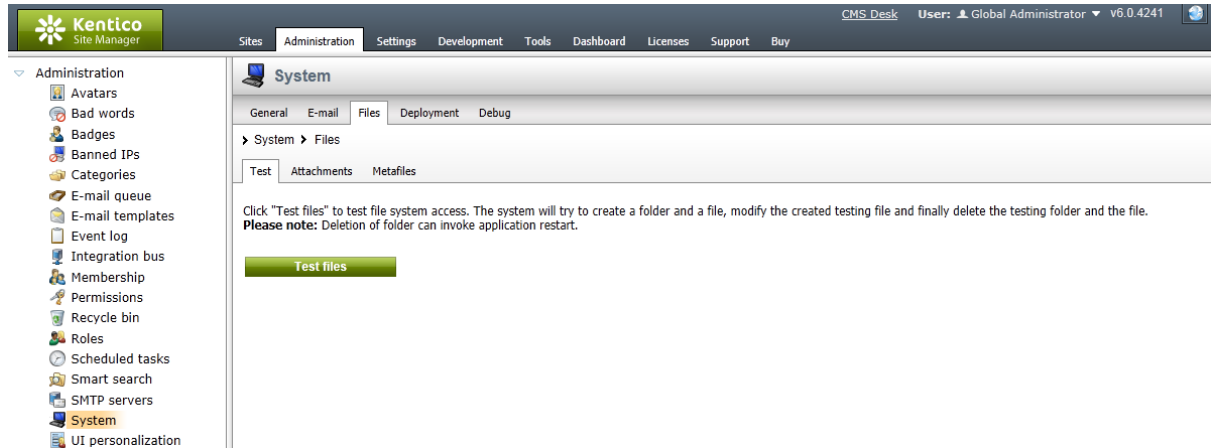

4.8.10 File administration UI

A user interface for global-level administration of files stored by the CMS is located on the **Files** tab in **Site Manager -> Administration -> System**. This part of the user interface is divided into three tabs described in the following text.

Test tab

On the **Test** tab, you can perform a test that verifies that Kentico CMS has access to the file system. The test consists of creation of a folder and a file, modification of the created file and deletion of the folder and the file. To perform the test, just click the **Test files** button.

If the test detects that Kentico CMS is not able to access the file system, you can find a solution to this problem in the [Installation and deployment -> Troubleshooting installation issues -> Disk permissions problems](#) chapter of this guide.

Attachments tab

On the **Attachments** tab, you can find a list of document attachments stored by the CMS. Based on selection in the **Site** drop-down list, you can either select a site and view all document attachments on the site, or choose **(all)** to view all document attachments on all websites in the system.

If there are more than 25 document attachments (or a different number set by means of the `CMSDefaultListingFilterLimit web.config` key), a filter is displayed above the grid. Using the filter, you can filter displayed attachments by their name, extension, size or depending on if they are stored in the database.

In the **Actions** column in the grid, action icons are displayed depending on the **Store files in file system** and **Store files in database** settings in **Site Manager -> Settings -> System -> Files**. The displayed actions are the following:

- **Copy to database** - copies the attachment to the database. This action is only displayed if the attachment is stored only in the file system while settings are configured for files to be stored both in the file system and in the database.
- **Delete from database** - deletes the attachment from the database. This action is only displayed if the attachment is stored both in the file system and in the database while settings are configured for files to be stored only in the file system or to be stored both in the file system and in the database.
- **Copy to file system** - copies the attachment to the file system. This action is only displayed if the attachment is stored only in the database while settings are configured for files to be stored only in the file system or both in the file system and in the database.
- **Delete from file system** - deletes the attachment from the file system. This action is only displayed if the attachment is stored both in the file system and in the database while settings are configured for files to be stored only in the database.

Using the two drop-down lists below the grid, you can perform the above listed actions for multiple attachments at once. In the first drop-down list, you can choose from the following:

- **Selected files** - performs the action for files selected using the check-boxes () in the grid.
- **All files** - performs the action for all listed files.

Then you can choose the required action from the second drop-down list and click **OK** to perform it. The same actions as listed above are offered in the drop-down list, while the conditions described above need to be met for the actions to be offered.

The screenshot shows the Kentico CMS 7.0 Administration interface. The main content area is titled "System" and has tabs for "General", "E-mail", "Files", "Deployment", and "Debug". The "Files" tab is active, and the "Metafiles" sub-tab is selected. A search filter is set to "Site: Corporate Site". Below the filter are input fields for "Name", "Extension", "Size", and "Stored in DB", with a "Show" button. A table of metafiles is displayed below, with columns for "Actions", "Name", "Extension", "Size", "Last modified", "Stored in DB", and "Stored in FS".

Actions	Name	Extension	Size	Last modified	Stored in DB	Stored in FS
<input type="checkbox"/>	arrow_apieexamples	.png	3 kB	6/27/2011 6:27:39 PM	Yes	Yes
<input type="checkbox"/>	arrow_devnet	.png	3.1 kB	6/27/2011 6:33:54 PM	Yes	Yes
<input type="checkbox"/>	arrow_documentation	.png	4.2 kB	6/27/2011 6:34:06 PM	Yes	No
<input type="checkbox"/>	arrow_examples	.png	2.6 kB	6/27/2011 6:34:13 PM	Yes	No
<input type="checkbox"/>	bb_torch_1	.jpg	24 kB	6/29/2011 4:11:40 PM	Yes	No
<input type="checkbox"/>	bb_torch_2	.jpg	31 kB	6/29/2011 4:11:56 PM	Yes	No
<input type="checkbox"/>	bb_torch_3	.jpg	57 kB	6/29/2011 4:12:07 PM	Yes	No
<input type="checkbox"/>	bb_torch_4	.jpg	48 kB	6/29/2011 4:12:20 PM	Yes	No
<input type="checkbox"/>	blogs_teaser	.jpg	16.8 kB	6/23/2011 5:13:38 PM	Yes	No
<input type="checkbox"/>	brads	.jpg	11.1 kB	7/20/2011 2:37:36 PM	Yes	No

At the bottom of the interface, there is a "Selected files" dropdown menu, a "(select an action)" dropdown menu, and an "OK" button.

Metafiles tab

On the **Metafiles** tab, you can find a list of metafiles stored by the CMS. Based on selection in the **Site** drop-down list, you can select:

- **(all)** - displays all metafiles stored by the system.
- **(global)** - displays metafiles of global, i.e. not site-related objects.
- **<website>** - displays metafiles of site-related objects belonging to the selected site.

Using the **Object type** drop-down list, you can further limit which metafiles will be displayed. By selecting **(all)**, you get all metafiles that match the selection in the drop-down list above. The other options in the drop-down are particular object types, while choosing one displays only metafiles of these objects that match the selection in the drop-down list above.

If there are more than 25 metafiles (or a different number set by means of the `CMSDefaultListingFilterLimit web.config` key), a filter is displayed above the grid. Using the filter, you can filter displayed metafiles by their name, extension, size or depending on if they are stored in the database.

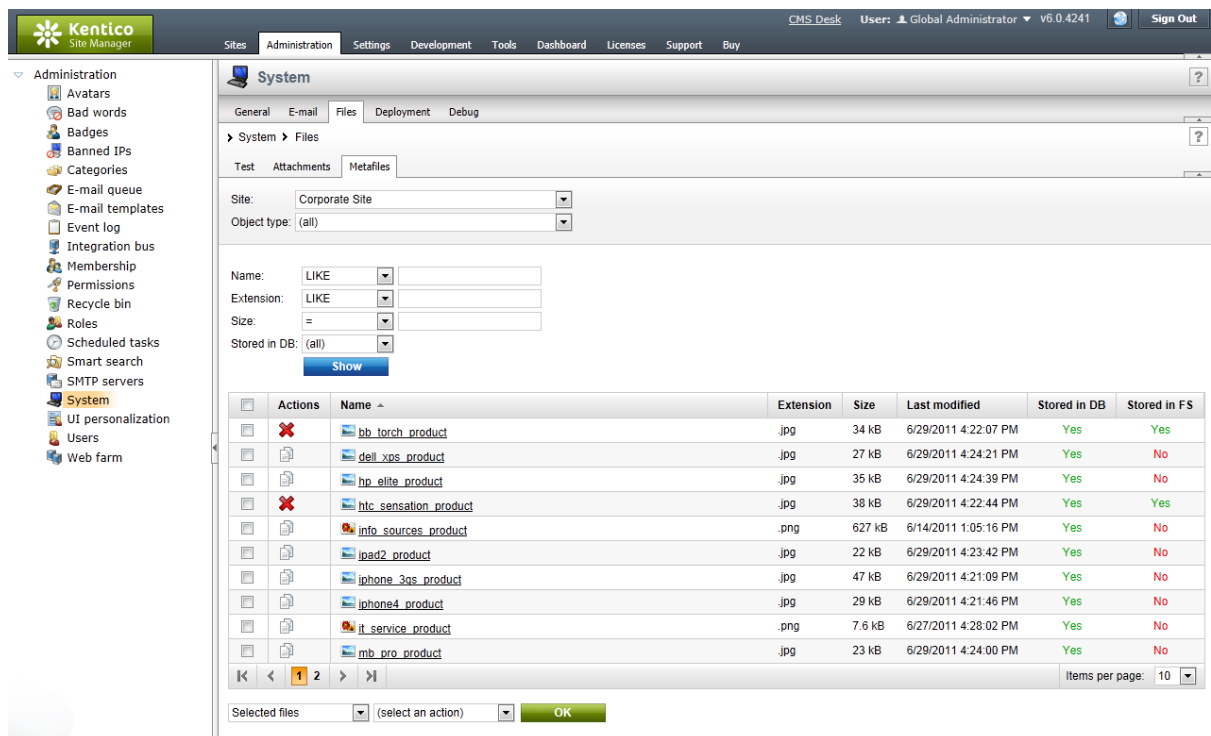

In the **Actions** column in the grid, action icons are displayed depending on the **Store files in file system** and **Store files in database** settings in **Site Manager -> Settings -> System -> Files**. The displayed actions are the following:

-  **Copy to database** - copies the metafile to the database. This action is only displayed if the metafile is stored only in the file system while settings are configured for files to be stored both in the file system and in the database.
-  **Delete from database** - deletes the metafile from the database. This action is only displayed if the metafile is stored both in the file system and in the database while settings are configured for files to be stored only in the file system or to be stored both in the file system and in the database.
-  **Copy to file system** - copies the metafile to the file system. This action is only displayed if the metafile is stored only in the database while settings are configured for files to be stored only in the file system or both in the file system and in the database.
-  **Delete from file system** - deletes the metafile from the file system. This action is only displayed if the metafile is stored both in the file system and in the database while settings are configured for files to be stored only in the database.

Using the two drop-down lists below the grid, you can perform the above listed actions for multiple metafiles at once. In the first drop-down list, you can choose from the following:

- **Selected files** - performs the action for files selected using the check-boxes () in the grid.
- **All files** - performs the action for all listed files.

Then you can choose the required action from the second drop-down list and click **OK** to perform it. The same actions as listed above are offered in the drop-down list, while the conditions described above need to be met for the actions to be offered.

The screenshot shows the Kentico Site Manager Administration interface. The main content area displays the 'System' management screen, specifically the 'Files' tab. The interface includes a search filter with the following fields:

- Site: Corporate Site
- Object type: (all)
- Name: LIKE
- Extension: LIKE
- Size: =
- Stored in DB: (all)

A 'Show' button is located below the search fields. Below the search fields is a table of files with the following columns: Actions, Name, Extension, Size, Last modified, Stored in DB, and Stored in FS.

Actions	Name	Extension	Size	Last modified	Stored in DB	Stored in FS
<input checked="" type="checkbox"/>	bb_torch_product	.jpg	34 kB	6/29/2011 4:22:07 PM	Yes	Yes
<input type="checkbox"/>	dell_xps_product	.jpg	27 kB	6/29/2011 4:24:21 PM	Yes	No
<input type="checkbox"/>	hp_elite_product	.jpg	35 kB	6/29/2011 4:24:39 PM	Yes	No
<input checked="" type="checkbox"/>	htc_sensation_product	.jpg	38 kB	6/29/2011 4:22:44 PM	Yes	Yes
<input type="checkbox"/>	info_sources_product	.png	627 kB	6/14/2011 1:05:16 PM	Yes	No
<input type="checkbox"/>	ipad2_product	.jpg	22 kB	6/29/2011 4:23:42 PM	Yes	No
<input type="checkbox"/>	iphone_3gs_product	.jpg	47 kB	6/29/2011 4:21:09 PM	Yes	No
<input type="checkbox"/>	iphone4_product	.jpg	29 kB	6/29/2011 4:21:46 PM	Yes	No
<input type="checkbox"/>	it_service_product	.png	7.6 kB	6/27/2011 4:28:02 PM	Yes	No
<input type="checkbox"/>	mb_pro_product	.jpg	23 kB	6/29/2011 4:24:00 PM	Yes	No

At the bottom of the interface, there is a 'Selected files' dropdown menu, a '(select an action)' dropdown menu, and an 'OK' button.

4.9 Multilingual content

4.9.1 Overview

Kentico CMS websites can host content in multiple languages (cultures). Multilingual websites have separate versions of documents for each language. The system allows you to automatically offer particular culture versions of the website to visitors based on various settings. Users may also switch between individual languages manually using a dedicated web part.

You can find a list of the available content cultures in **Site Manager -> Development -> Cultures**. All major cultures are provided by default. You can assign these cultures to websites and then translate the content to the respective languages.

The administration interface of Kentico CMS can also be multilingual. To learn more, refer to the [Development -> UI cultures and localization](#) chapter of this guide.

Topics:

- [Configuring multilingual content](#)
- [Using language-specific page templates](#)
- [Selecting default languages for visitors](#)
- [Languages and URLs](#)
- [Managing multilingual websites](#)
- [Translation services](#)

4.9.2 Configuring multilingual content

This topic explains how to configure a website to display content in multiple languages.

Setting the default content culture

When you create a new website, its default culture is the one specified in Step 2 of the [New site wizard](#). If you create a website based on a web template, it uses the culture of the given web template. All default Kentico CMS web templates use **English - United States** as their default culture.

Default culture settings can be modified in the following sections of the user interface:

- **Site Manager -> Settings -> Content -> Default content culture**
- **Site Manager -> Sites -> edit (✎) -> Default content culture**

The two settings are interlinked, i.e. values configured in one section are reflected in the other one.

Configuring multilingual content

The following example demonstrates how to add extra language versions to documents on the sample Corporate Site:

1. Go to **Site Manager -> Sites** and click the **Edit site (✎)** icon next to the **Corporate Site**. Then open the **Cultures** tab and click the **Add cultures** button. In the selection dialog, choose the **French - France** and **German - Germany** cultures and click **OK**.

2. Open CMS Desk. You can see there is a new section with language selection options in the main toolbar. Using this toolbar, you can switch between particular language versions of the currently selected document. You can also click the **Compare** (📄) button to switch to [Language version comparison](#) mode and edit language versions side-by-side.

3. Select the root document in the content tree and switch to the **French** culture. Since the French version of the document does not exist yet, you need to create it through one of the following ways:

- **Create empty document** - creates a new document of the same type, but without any content.
- **Copy content from another language** - creates a copy of the document with content loaded from the selected language version. If *Save the new document before editing* is checked, the system adds the new document version and immediately saves the copied content.
- **Translate using translation service** - with this option, the content of the document's new language version will be provided by an external translation service. See the [Translation services](#) sub-chapter to learn more.

Choose to copy content from the English version and click **Create document**.

New culture version (French - France)

The document does not exist in the current culture. You can create a new culture version of the document.

Create empty document
 Copy content from another language

Copy from language:

Save the new document before editing:

Translate using translation service

Create document

The French version of the root document has now been created.

4. Repeat the same for the **Home** page, but this time disable the **Save the new document before editing** option before creating the document. The editing form of the new document version opens. Here, change the **Document name** to *French Home* and click **Save**.

Page Design Form Properties Analytics

Save Spell check

Document name:

Teaser image:

Menu group:

Publish from:

Publish to:

5. Switch to the **Page** tab and change the text of the heading in the second editable region to *Welcome to the French version of the sample Corporate Site*. Click **Save**.

Welcome to the French version of the sample Corporate Site

If you are new to Kentico CMS, please read the following information before you start exploring the website:

Default user name and password

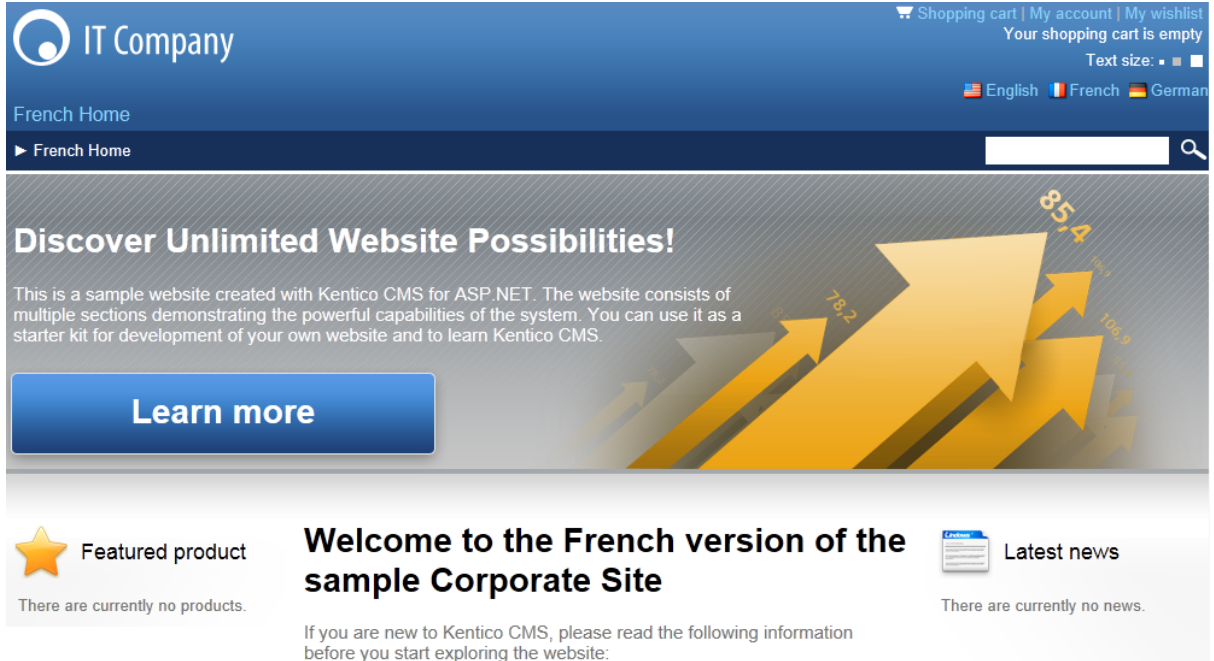

You can sign in to the system's administration interface using the links in the header of the page or by going to the following addresses:

CMS Desk: http://<your domain>/CMSDesk
Site Manager: http://<your domain>/CMSSiteManager

This step shows that you can modify the content of a page's editable regions to be different for each

specific language version. It is also possible to translate the content entered on a document's **Form** tab, and even assign culture specific values for many of its **Properties**.

6. Sign out of CMS Desk and you will be able to see the French version of the live site.

Welcome to the French version of the sample Corporate Site

If you are new to Kentico CMS, please read the following information before you start exploring the website:

Default user name and password

You can sign in to the system's administration interface using the links in the header of the page or by going to the following addresses:

Latest news

Apple iPad 2 In Stock
06/09/2011 Today, we have good news for all fans of the awesome Apple iPad. We are glad to announce that its new version, Apple iPad 2, is available in our web shop. Furthermore, we keep our reasonable pricin...

 **Creating content for another language**

When adding a new language to the website, please be sure to always create a language version for at least the **root** document and the default **home page**. Otherwise, the website will not be displayed correctly.

The system adds a cross (✖) icon next to documents in the content tree that do not exist in the currently selected culture. This allows you to see which parts of the site still need to be translated.

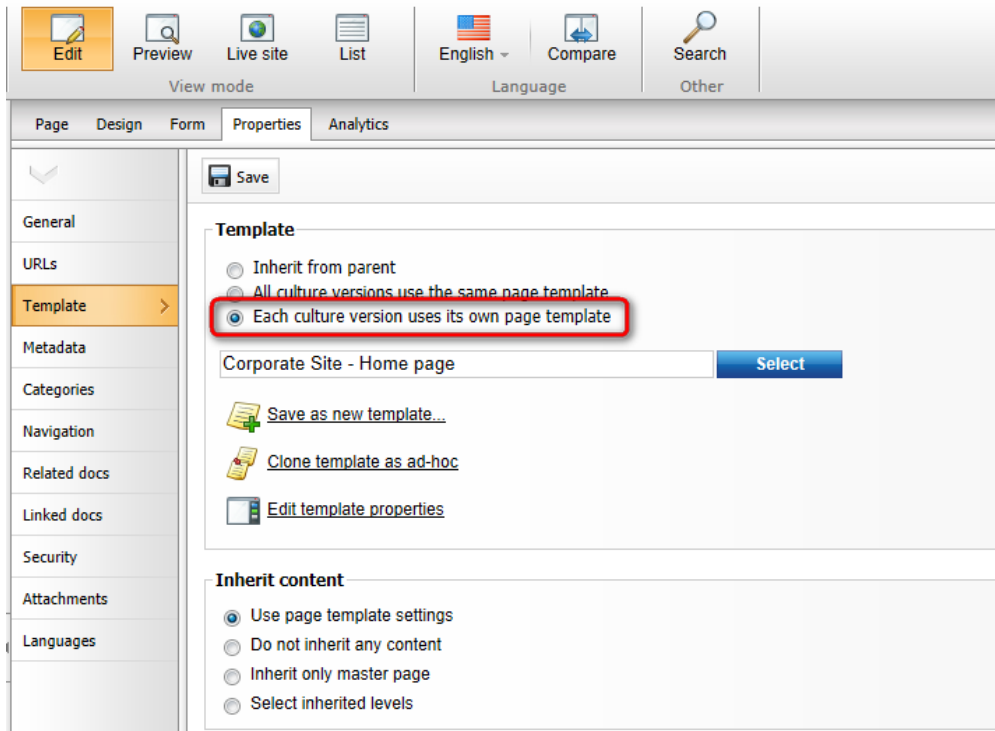

4.9.3 Using language-specific page templates

When creating a new language version of a document, it should usually be enough to edit the original document on the level of page content, i.e. translate the text on its **Page** or **Form** tabs. However, you can also make major changes to the basic layout and design of each culture version by using a different [page template](#). By default, documents share the same page template for all of their language versions.

The following steps demonstrate how to assign a unique page template to a specific language version of a document and then modify it as required. This continues the example from the [Configuring multilingual content](#) topic, so there should already be some additional cultures added to the website and a French version of the Home page.

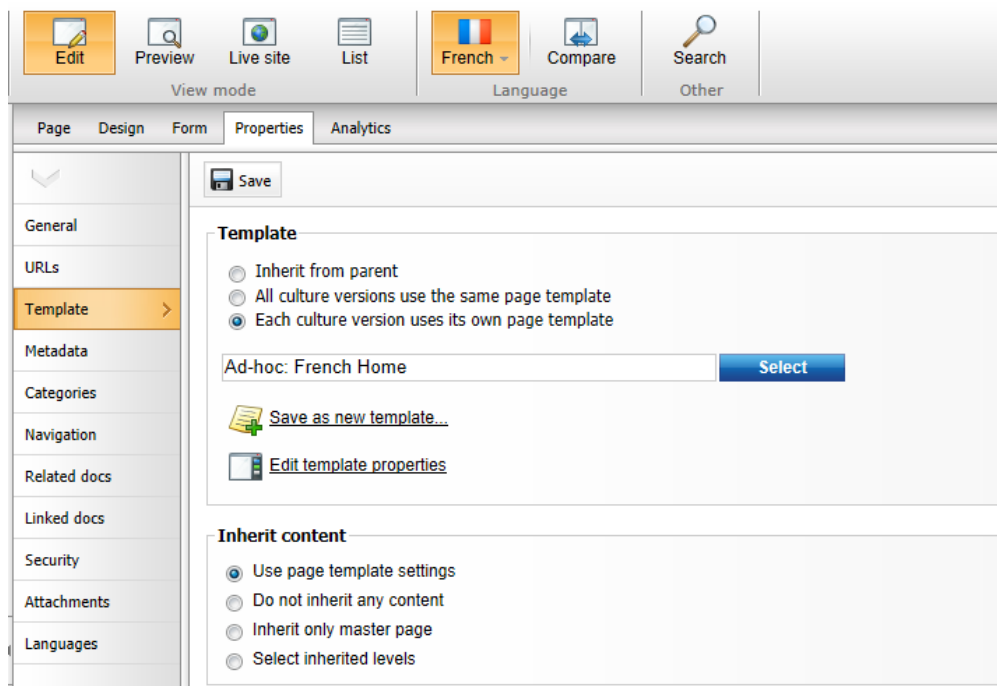

1. Open CMS Desk on the **Content** tab and select the **Home** page in the content tree. Make sure you are in **Edit** mode and switch to the **Properties -> Template** tab. Here, choose the **Each culture**

version uses its own page template option for the document and click  **Save**.

This setting is shared between all versions of the document, so it is not important which language is currently selected.

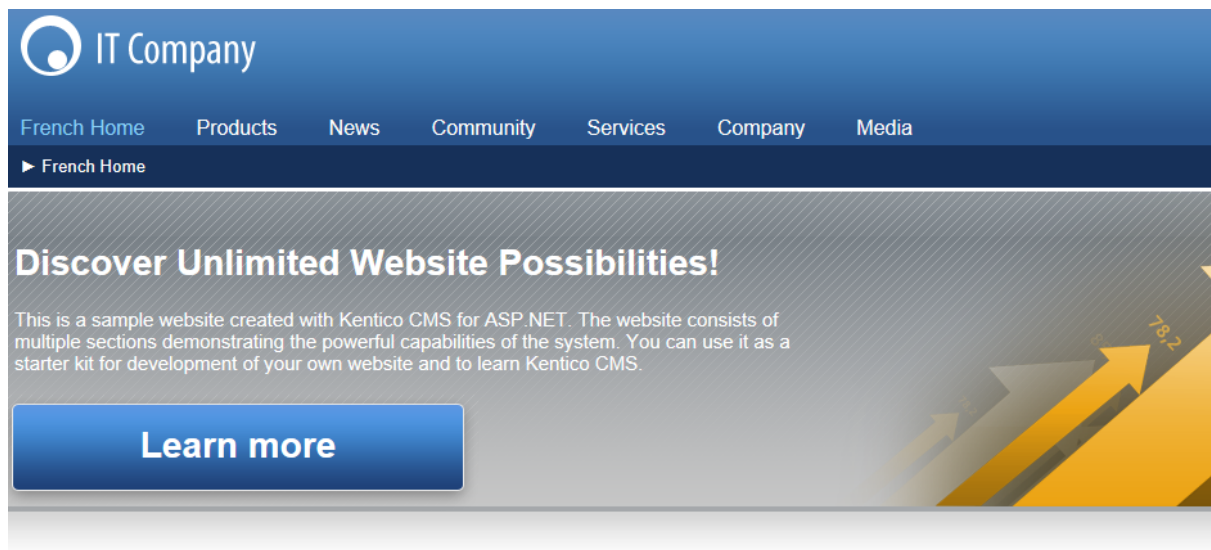

2. Switch to the French language and click the  **Clone template as ad-hoc** action. This creates a separate copy of the current Home page template and assigns it to the French version of the document. You can now change the design of the French page without affecting the other language versions.

Cloning the template used by the default culture version provides a convenient starting point from which you can quickly make modifications, but it is also possible to select a completely different template if necessary.

3. Open the page's **Design** tab and add (+) a new **Text & Images -> Editable text** web part into the **Actions zone**. Then switch to the **Page** tab and you can notice there is an additional editable region. Cut the header text from the bottom region and paste it into the empty region that was added. Click **Save** to confirm the change.

4. Sign out and view the Home page in the French language. The header text is now aligned on the left and placed above the remaining content.

Welcome to the French version of the sample Corporate Site

 **Featured product**

Price: **\$1596,99**

If you are new to Kentico CMS, please read the following information before you start exploring the website:

Default user name and password

You can sign in to the system's administration interface using the links in the header of the page or by going to the following addresses:

CMS Desk: <http://<your domain>/CMSDesk>
Site Manager: <http://<your domain>/CMSSiteManager>

If you switch to English, the page is unchanged, because it still uses the original template.

This is only a very simple example of a modification that can be done when the language version has a separate page template. There are many other possibilities, such as setting different properties for web parts or editing the overall layout of the page.

4.9.4 Selecting default languages for visitors

You can configure which language version the system displays to users when they arrive on the website.

Configuration for registered users

The website culture displayed to registered website users depends on each user's **Preferred content culture** setting. Users themselves can change this setting in **CMS Desk -> My desk -> My profile**, or on the live site by means of the [My account](#) web part. Website administrators can adjust these settings in **Site Manager -> Administration -> Users -> edit (✎) -> General**.

Depending on this configuration, the user will either see the content in their preferred culture (if available), or in the website's default content culture (if set to *(default)* or if the preferred culture is not available).

Please note that the act of logging in does not change the current culture, so this setting only has an

effect if users are already logged in when they first reach the website (e.g. when using [Windows authentication](#)).

Configuration for anonymous visitors

It is also possible to configure the default content culture displayed to anonymous visitors of the website. This can be done separately for the main website domain and for individual domain aliases:

- **Site Manager -> Sites -> edit (✎) site -> General -> Visitor culture** - used for visitors accessing the website through a URL containing the main domain name.
- **Site Manager -> Sites -> edit (✎) site -> Domain Aliases -> edit (✎) alias -> Visitor culture** - used for visitors accessing the website through a URL that contains the respective domain alias.

The values can either be set to one of the cultures available for the website, or to **(Automatic)**, in which case the **user's browser settings** are used (for example, in Internet Explorer, you can set the default language in Tools -> Internet options -> General -> Languages).

Setting the default language for specific domains

Using the **Visitor culture** settings of the site and its domain aliases (described in the section above), you can configure the system to use a different default language based on the current domain. For example, if you use the following domains:

- example.com (main domain)
- example.de (domain alias)
- example.fr (domain alias)

You can set English, German and French as the default cultures for the domain and domain aliases (respectively). Now, when a visitor arrives at *example.fr*, the website automatically displays its French content. Refer to the [Languages and URLs](#) topic for additional information about cultures, domains and URLs.

4.9.5 Languages and URLs

On multilingual websites, all language versions of a page use the same URL by default. This URL is based on the given document's [alias path](#). For example, the home page always has the following URL: */Home.aspx*

If you want to see the same page in French, you need to change the culture by entering the URL with an appropriate query string parameter: */Home.aspx?lang=fr-fr*

Once the language is selected this way, the system stores it in the visitor's browser using a cookie. This means that the given visitor automatically sees the French version when returning to */Home.aspx* or another translated page, even without any parameters in the URL.

Having to type a URL with a query string manually would be inconvenient for visitors, so you can provide a more user-friendly way to switch between cultures by placing one of the following language selection web parts onto the pages of your website:

- [Language selection](#)
- [Language selection drop-down](#)

- [Language selection with flags](#)

These web parts automatically generate appropriate links to the language versions of the current document.

Renaming the language selection parameter

The default name of the language selection parameter is *lang*.

To rename the parameter:

1. Add the **CMSLanguageParameterName** key into the */configuration/appSettings* section of your application's **web.config** file.
2. Enter the new name as the key's **value**.

```
<add key="CMSLanguageParameterName" value="sprache" />
```

Even though switching between languages using URL query string parameters is the default approach, it is generally not recommended for live production websites. Parameters make URLs more confusing and are not friendly toward search engines. Instead, you can configure the system to use one of the options described in the sections below.

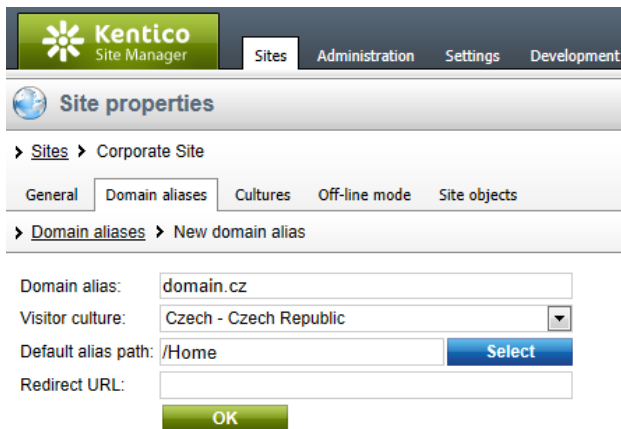

Enforcing separate domains for languages

Having a different domain name for each culture is a good way to let visitors know that the particular version of the site is intended for a certain language audience. It is also the best option for multilingual websites with regard to [Search engine optimization](#).

For example, if the English version of your site is available under *domain.com*, the French version could use *domain.fr* and so on. This scenario uses a different country-code top-level domain, but you can set any other domain name format, such as unique subdomains for each culture.

To implement domain separation based on languages:

1. Go to **Site Manager -> Sites** and edit (✎) your site.
2. On the **General** tab, select your website's primary language in the **Visitor culture** field.
 - This assigns the given language to the site's main domain name.
3. Set up additional domain names for other languages as domain aliases on the **Domain aliases** tab.
 - Just like with the main domain, you can assign a language to each alias by selecting the matching culture in the **Visitor culture** field.

Kentico Site Manager

Sites Administration Settings Development

Site properties

> Sites > Corporate Site

General Domain aliases Cultures Off-line mode Site objects

> Domain aliases > New domain alias

Domain alias:

Visitor culture:

Default alias path:

Redirect URL:

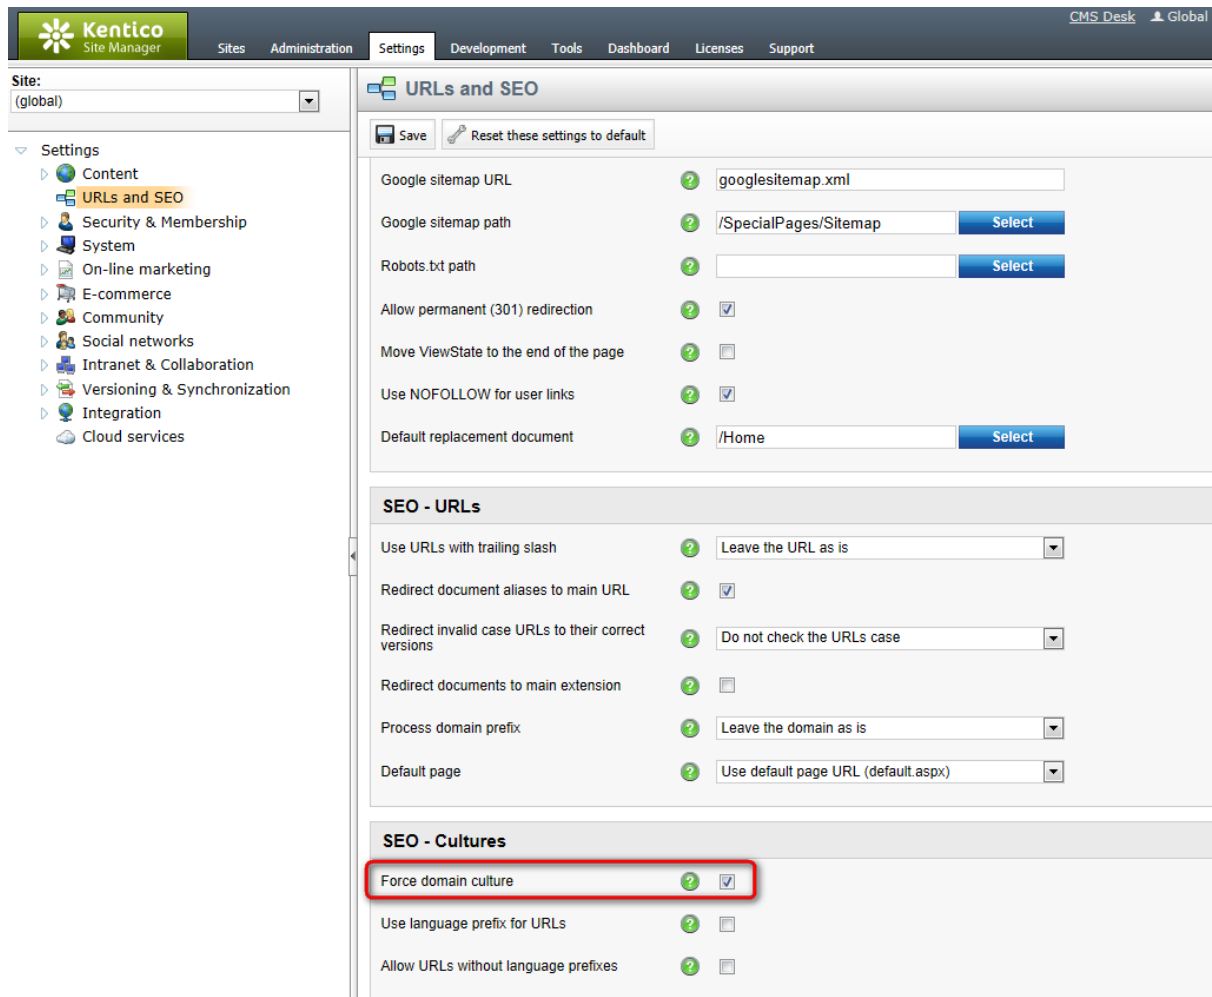

Configuration requirements

When setting up the **Visitor culture** of the site and its aliases, only assign each language to a single domain and do not use the (*Automatic*) value. Otherwise the system will not be able to determine with certainty which content culture to display.

Also make sure that your domain aliases do *not* use a **Redirect URL** leading to another domain name.

4. Go to **Site Manager -> Settings -> URLs and SEO** and enable the **Force domain culture** setting.

Note: You cannot use forced culture domains in combination with the language URL prefixes described in the next section.

The screenshot shows the Kentico Site Manager interface. The left sidebar contains a navigation menu with categories like Content, Security & Membership, System, On-line marketing, E-commerce, Community, Social networks, Intranet & Collaboration, Versioning & Synchronization, Integration, and Cloud services. The main area is titled 'URLs and SEO' and contains several sections of settings:

- General Settings:** Includes fields for Google sitemap URL (googlesitemap.xml), Google sitemap path (/SpecialPages/Sitemap), Robots.txt path, and a checkbox for 'Allow permanent (301) redirection' (checked). Other options include 'Move ViewState to the end of the page' (unchecked), 'Use NOFOLLOW for user links' (checked), and 'Default replacement document' (/Home).
- SEO - URLs:** Includes settings for 'Use URLs with trailing slash' (Leave the URL as is), 'Redirect document aliases to main URL' (checked), 'Redirect invalid case URLs to their correct versions' (Do not check the URLs case), 'Redirect documents to main extension' (unchecked), 'Process domain prefix' (Leave the domain as is), and 'Default page' (Use default page URL (default.aspx)).
- SEO - Cultures:** This section contains three settings:
 - Force domain culture:** This checkbox is checked and highlighted with a red box in the original image.
 - Use language prefix for URLs:** Unchecked.
 - Allow URLs without language prefixes:** Unchecked.

The system now ensures the following:

- The default content culture is selected based on the domain name through which the website is opened.
- All documents URLs (e.g. in navigation elements) are generated using the domain name to which the current content culture is assigned.
- When a user selects a different language through one of the language selection web parts, the system redirects the URL to the corresponding domain name.

Authentication with multiple domains

The user context is not carried over when switching between domains on the live site. If you are using standard Forms [authentication](#), registered users who change the content culture while browsing need to log in separately on each language version of the website.

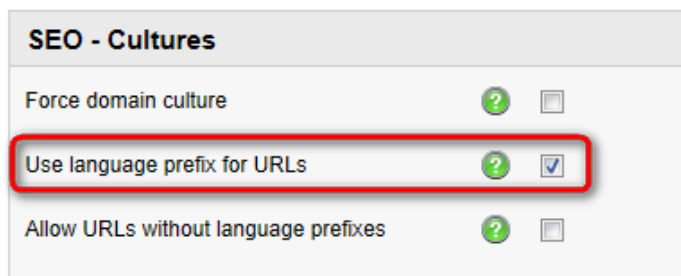

If this is a problem, you can work around it by implementing a single sign-on mechanism for all domains.

Using language prefixes for URLs

If you do not own a different domain name for each language version of the website, but still want to ensure unique URLs for each culture without adding query string parameters, you can use language prefixes. Language prefixes insert a subdirectory into the URL in format **<domain>/<language prefix>/<URL path>**, for example: `<domain>/fr-FR/Home.aspx`

To enable language prefixes, go to **Site Manager -> Settings -> URLs and SEO**, and check the **Use language prefix for URLs** field.

Note: You cannot use language prefixes if the **Force domain culture** setting is enabled.

Unless you check the **Allow URLs without language prefixes** setting, the system automatically redirects all URLs without a language prefix to a corresponding URL that includes a language prefix (according to the current content culture).

If language prefixes are enabled, the language selection web parts used on your site generate links containing the appropriate URL prefix by default. If you wish to configure a specific web part to use links with the standard query string parameter, disable its **Use culture specific URLs** property. Please keep in mind that all other settings still apply, so the resulting URLs may be redirected.

Changing the language prefix text:

By default, the language prefix matches the culture code of the requested language. If a *culture alias* is set for the language, it takes precedence and the system uses the alias instead of the culture code. If you want to change the language prefix for a certain language, the best way is to set a culture alias.

For example, to change the language prefix for the French language to *France*:

1. Go to **Site Manager -> Development -> Cultures**.
2. Type *fr-fr* into the **Culture code** field of the filter and click **Show**.
3. Edit (✎) the *French - France* culture.
4. Set the **Culture alias** property to *France*.
5. Click **Save**.

The system now displays the language prefix in URLs of French document as for example: `<domain>/France/Home.aspx`

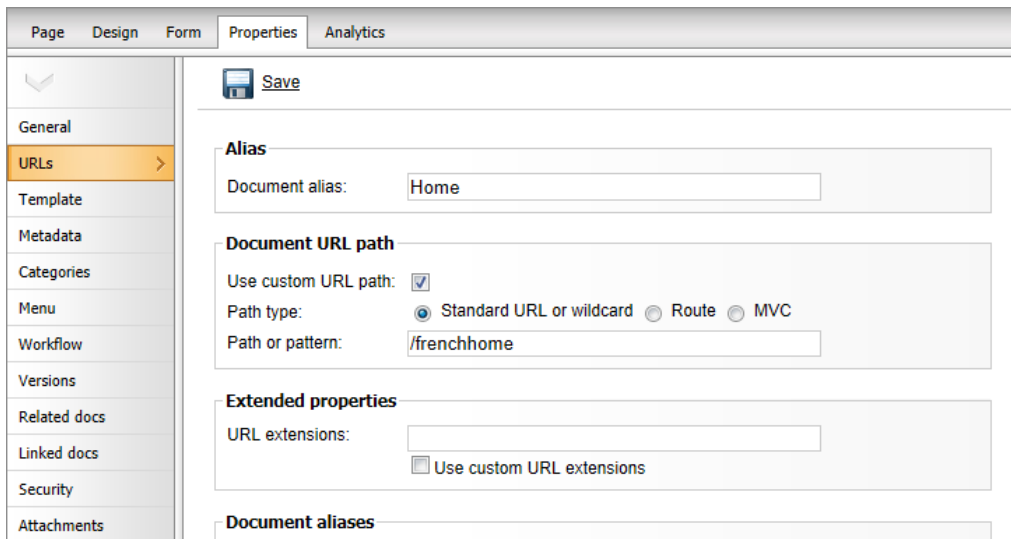

Using a custom document URL path for different culture versions

Forcing culture domains or using language prefixes for URLs ensures that you have a different URL for

every document culture version. You can use the following approach if the features described above are disabled or if you want different culture versions of documents to have different names in the URL path.

For example, if you want the French home page to have a different URL than the English version:

1. Go to **CMS Desk -> Content**, and select the Home page in the content tree.
2. Select the French language on the main toolbar.
3. Open the **Properties -> URLs** tab.
4. In the **Document URL path** section, check **Use custom URL path**.
5. Leave the **Standard URL or wildcard** option selected as the **Path type**.
6. Set the **Path or pattern** value to: `/frenchhome`
7. Click  **Save**.

The screenshot shows the 'Properties' tab in the CMS interface, specifically the 'URLs' section. The left sidebar contains a navigation menu with options: General, URLs (selected), Template, Metadata, Categories, Menu, Workflow, Versions, Related docs, Linked docs, Security, and Attachments. The main content area is titled 'Save' and contains the following configuration options:

- Alias**: Document alias: Home
- Document URL path**:
 - Use custom URL path:
 - Path type: Standard URL or wildcard Route MVC
 - Path or pattern: /frenchhome
- Extended properties**:
 - URL extensions:
 - Use custom URL extensions
- Document aliases**:

To try out how the custom URL works, sign out and view the English version of the website. If you open the URL `<domain>/frenchhome.aspx`, the website automatically switches the culture to French and displays the French version of the home page.

By default, language selection web parts reflect custom URL paths for documents when generating links to the corresponding culture version. If you wish to disable this behavior for a specific web part and have it use links with the standard document URL, disable its **Use culture specific URLs** property.

You can also set [Document aliases](#) for a pages dedicated to specific cultures. When the document is accessed through this type of alias, the system always opens it in the corresponding culture.

Note: that you may encounter problems when using wildcards in URLs on multilingual sites. You can find more details and a possible solution in the [Development -> Page processing and URLs -> Wildcard URLs](#) topic.

4.9.6 Managing multilingual websites

Kentico CMS provides several additional features that help localize websites and manage multilingual content:

- [Language status overview in List mode](#) - allows you to check which language versions of documents exist on the website.

- [Languages document tab](#) - displays information about all language versions of the current document.
- [Language version comparison](#) - allows content editors to work with two language versions of a document side-by-side.
- [Culture-dependent workflow scopes](#) - each language version of the website can have its own workflow definition.
- [Language-bound editors](#) - you can limit which users are allowed to edit particular language versions of the website.

4.9.6.1 Language status overview

The **List** mode of CMS Desk provides an overview of document language versions. You can select a node in the content tree and switch to List mode, which shows all child documents placed under the given node.

The **Languages** column displays flags with differently colored backgrounds for all languages available on the website. The flags represent particular language versions of documents and indicate the following statuses:

- **Green - Translated** - the document is available in the given language and up-to-date. The actual language of the document's content has no effect on the status, the system only checks whether the language version exists.
- **Orange - Outdated** - the language version exists for the document, but is outdated. The system considers language versions to be outdated if the default language version of the document has been modified (or published when using workflow) more recently.
- **Red - Not available** - the document does not exist in the given language. You can also see the **x** icon next to documents in this status, both in the listing and in the content tree.

Clicking a **Translated** or **Outdated** flag redirects you to the **Edit -> Page** tab of the appropriate language version of the document. If you click a **Not available** flag, the language versions's creation dialog opens.

The **Document name** column displays the names of the documents in the currently edited culture. If the document version **does not exist** in this language, the column displays the name from the **default culture** with the default culture code appended in brackets.

Document listing

Document name: LIKE
 Document type: LIKE
 Language: Translated to (any culture)

Actions	Document name	Document type	Modified	Published	Version	Languages
	Home	Page (menu item)	8/22/2011 5:25:37 PM	Yes	-	English, French, Italian
	Services	Page (menu item)	8/22/2011 5:33:15 PM	No	-	English, French, Italian
	Products	Page (menu item)	8/22/2011 5:26:39 PM	Yes	-	English, French, Italian
	News (en-US)	Page (menu item)	8/18/2011 9:06:58 PM	Yes	-	English, French, Italian
	Partners	Page (menu item)	8/22/2011 5:34:51 PM	No	-	English, French, Italian
	Community (en-US)	Page (menu item)	6/30/2011 9:54:16 AM	Yes	-	English, French, Italian

	Images (en-US)	Folder	6/27/2011 10:27:48 AM	Yes	-	English, French, Italian

Selected documents (select an action) OK

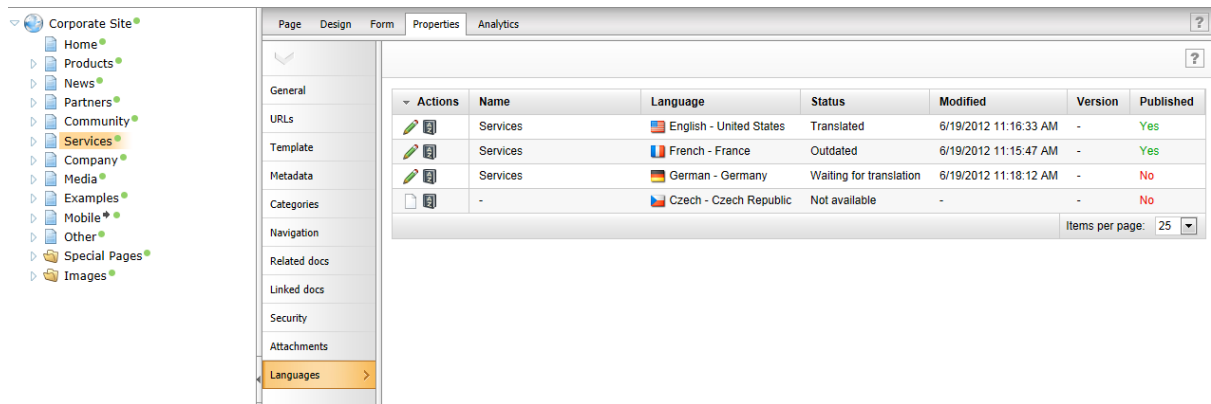

If you hover a flag with the mouse cursor, an info box is displayed, giving additional information about the language version.

The Languages tab

You may also view the language statuses separately for individual documents. To do so, select a document in the content tree and switch to the **Properties -> Languages** tab. Here you can also use the following actions for individual language versions:

- **Edit culture version** - allows you to edit the fields for the given language version of the document (i.e. opens the **Edit -> Form** tab in CMS Desk).
- **Create new culture version** - shown for languages in which the document is not available. Clicking the action creates a new version of the document in the given language.
- **Translate document** - opens a dialog where you can submit the document for translation to the given language, using a specified [Translation service](#).

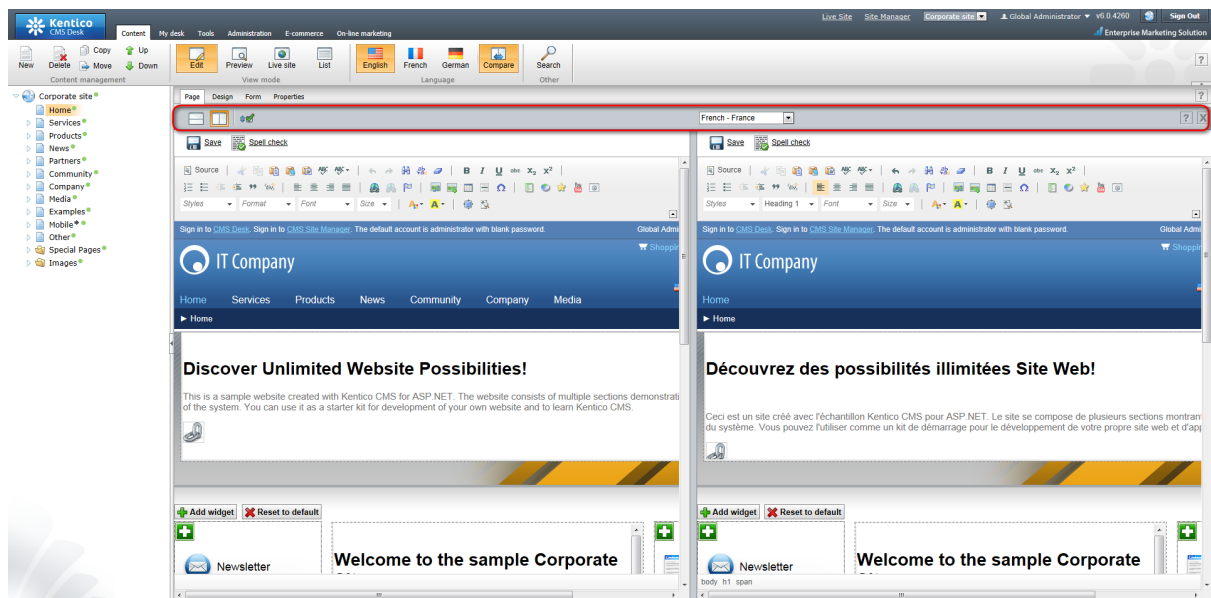

Hiding the Languages tab

The **Languages** tab can be displayed or hidden for members of particular roles. This can be set up using [UI personalization](#).

4.9.6.2 Language version comparison

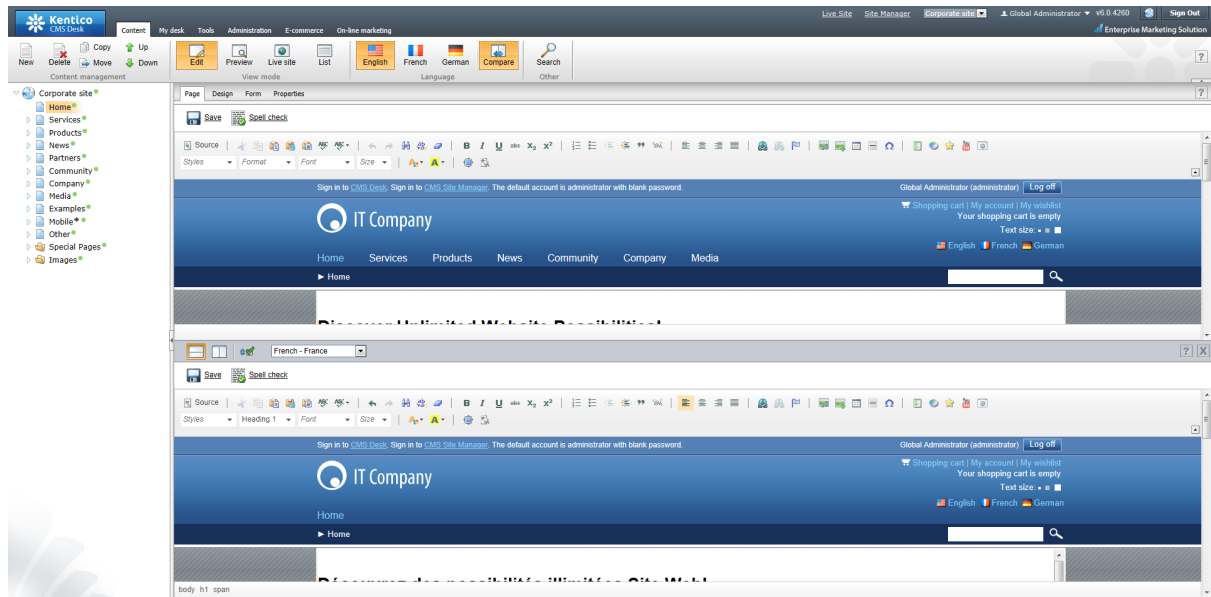

Language version comparison enables content editors to view and edit two different language versions of a document side-by-side. This is convenient when translating website content into multiple languages, as it eliminates the need to switch to the original language version to read source content and back to write its translation.

To switch to the language version comparison mode, select a document in the content tree and click the **Compare** () button in the **Language** toolbar. It results in the language version comparison toolbar being displayed (as highlighted in the following screenshot), while the document editing area below the toolbar gets split into two parts. The left part displays the document in the language selected in the **Language** toolbar, while the right part displays the language selected using the drop-down list in the language version comparison toolbar. Both displayed language versions can be edited independently at the same time.

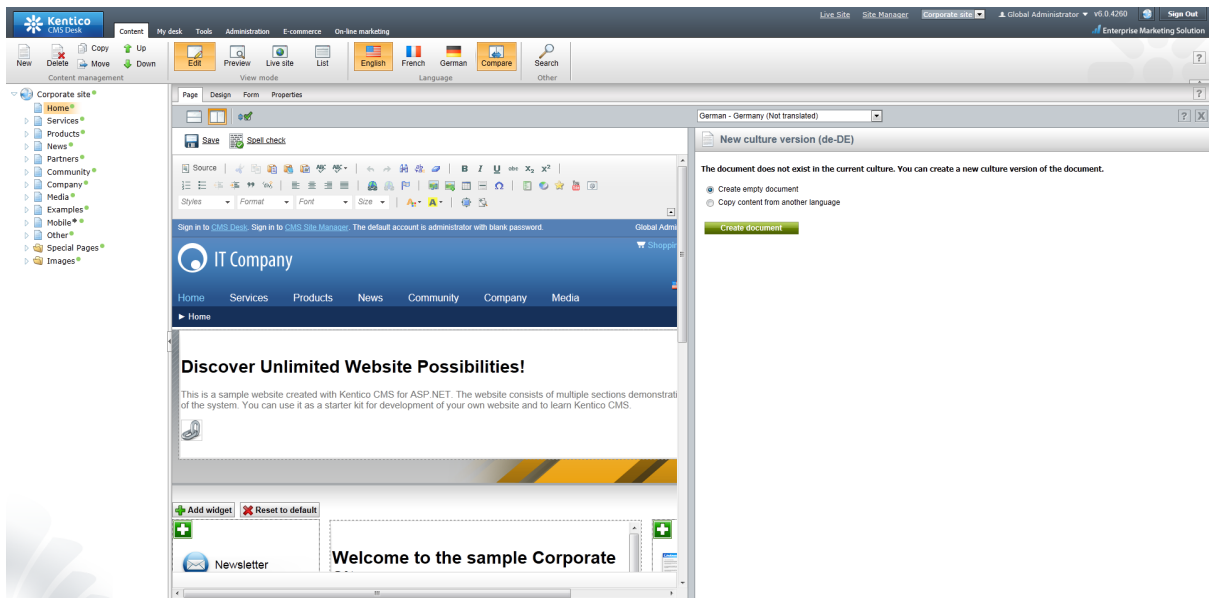

On the language version comparison toolbar, you can find the following controls:

 Horizontal layout	<p>Splits the editing area horizontally (as in the screenshot below). The top part displays the document in the language selected in the Language toolbar, while the bottom part displays the language selected using the drop-down list in the language version comparison toolbar.</p>
 Vertical layout	<p>Splits the editing area vertically (as in the screenshot above). The left part displays the document in the language selected in the Language toolbar, while the right part displays the language selected using the drop-down list in the language version comparison toolbar.</p>
 Synchronize scrollbars	<p>If enabled, scrollbars in both parts of the editing area will be synchronized, resulting in the same sections of both language versions being displayed while scrolling.</p>
Comparison language drop-down list	<p>Using this drop-down list, you choose which language version of the currently selected document will be compared with the language version selected in the Language toolbar.</p>
 Close comparison mode	<p>Closes the comparison mode and returns to the standard view of a single language version. The same can be achieved by clicking the Compare () button in the Language toolbar again.</p>

If you select a document whose version in the comparison language is not created yet, the standard **New culture version** dialog is displayed in the respective part of the editing area, letting you create a new empty document or copy content from another language.

Language version comparison mode is available in all three view modes: **Edit**, **Preview** and **Live site**. In **Edit** mode, you can use it on the **Page**, **Design**, **Form**, **Master page** and **Properties** tabs. On the **Properties** tab, it is available on all sub-tabs except for **Linked docs**, **Related docs**, **Security** and **Languages**, as document configuration performed on these tabs is shared by all language versions of the document.

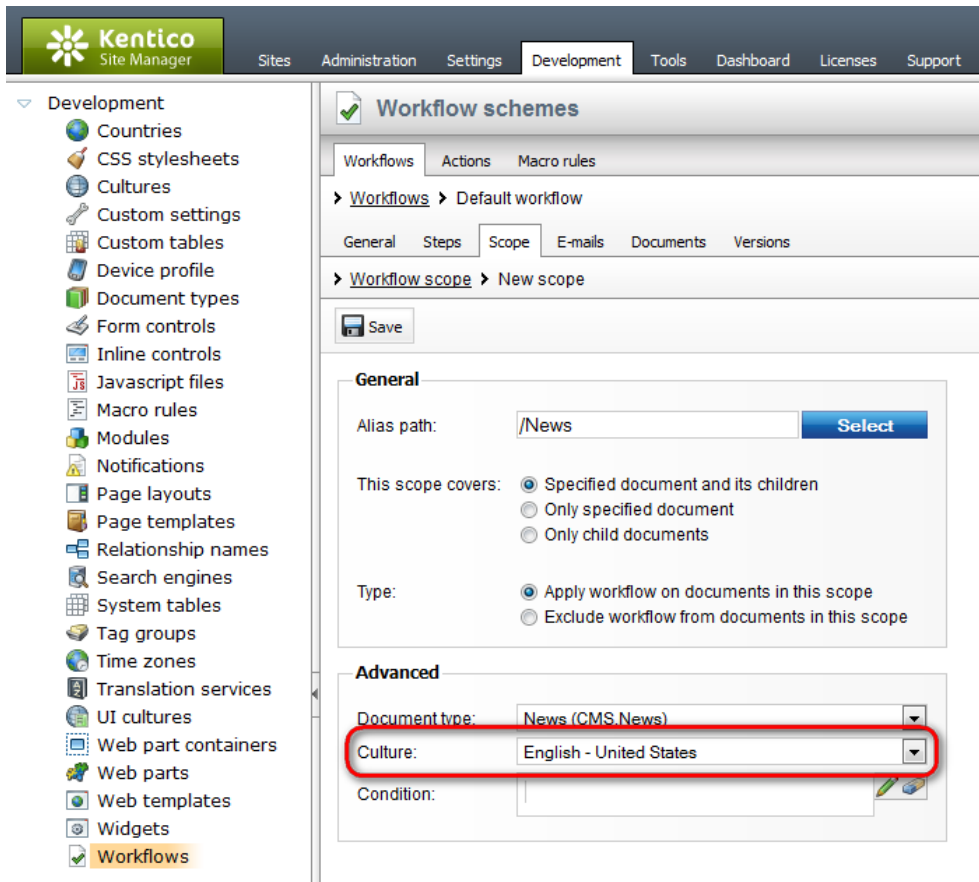

4.9.6.3 Culture-dependent workflow scopes

Workflows can be defined separately for each language version of your documents by using culture-dependent workflow scopes. A workflow scope determines which documents are affected by a particular workflow.

To learn how to create workflows and workflow scopes, refer to the [Workflow and versioning](#) chapter.

The system applies workflow scopes with the following priority (from highest to lowest):

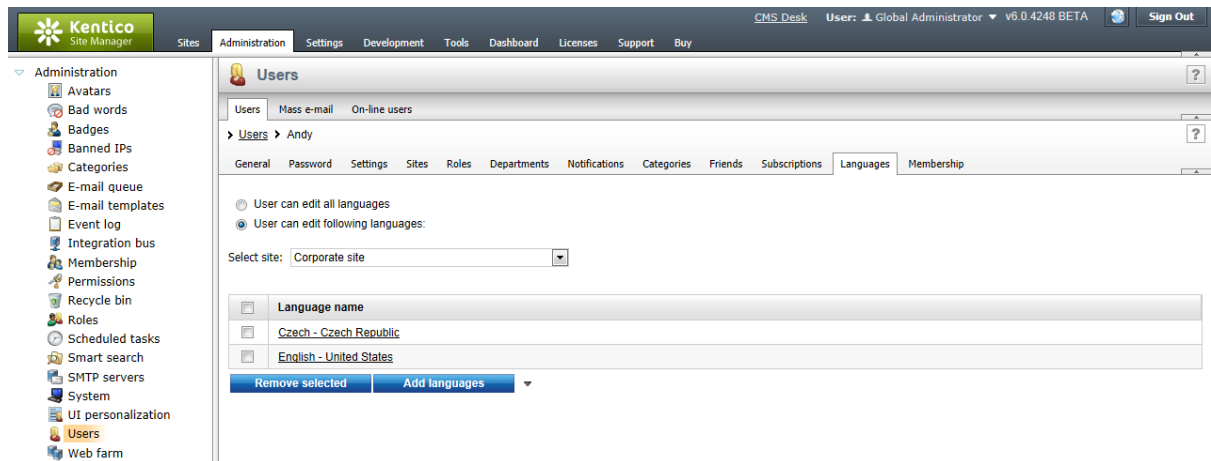

1. Scopes with a specified document type and culture
2. Scopes with a specified document type
3. Scopes with a specified culture
4. Scopes without a specified document type and culture

4.9.6.4 Language-bound editors

The system allows you to specify which language versions of documents users are allowed to edit.

1. Go to **CMS Desk / Site Manager -> Administration -> Users**.
2. **Edit** (✎) a particular user.
3. Switch to the **Languages** tab and select one of the following options:
 - **User can edit all languages** - the current user can edit documents in any language.
 - **User can edit following languages** - you can choose which language versions the user can edit.
The *Select site* list allows you to configure the language bindings for specific websites.

4.9.7 Translation services

4.9.7.1 Overview

Translation services provide a way to automate or outsource the translation of website content. By utilizing translation services, you can create multilingual sites without having to edit the text in the Kentico CMS administration interface. The system automatically ensures the transfer of data between the website's documents and translation providers. Translation data is exported and imported via files using the standard XML-based [XLIFF](#) format.

There are two general categories of translation services:

- **Machine services** - use translation software to programmatically convert source text from one language to another.
- **Standard services (human translation)** - provide an automated interface between the CMS and external human translators.

The system includes several default translation services of both types and also supports integration of custom services.

Topics:

- [Translating documents](#)
- [Configuring content for translation](#)
- [Machine translation services](#)
 - [Translating localization strings](#)
 - [Microsoft Translator](#)
 - [Google Translate](#)
- [Standard translation services](#)
 - [Managing translation submissions](#)
 - [Importing completed translations](#)
 - [Translations.com](#)
 - [Manual translation](#)
 - [E-mail translation](#)

- [Adding custom translation services](#)
- [Translating via the REST service](#)
- [Security](#)

4.9.7.2 Translating documents

The main purpose of translation services is to create language versions of the website's documents based on the content in another language. There are several different ways to submit documents for translation.

Requirements:

- The **Enable translation services** setting must be enabled in **Site Manager -> Settings -> Content -> Translation services**.
- Your website needs to be configured for [multiple content cultures](#), including all languages that you plan to use.

Translating documents to other languages

To create new language versions of documents using a translation service:

1. Select the document that you wish to translate in the content tree.
2. Switch to the target language using the selector on the main CMS Desk toolbar.
3. Select **Translate using translation service** in the *New culture version* dialog.
4. Choose one of the available translation services.
5. Fill in the following details for the translation (some of the options may not be supported by the selected service):

Translate from language	If the document already exists in more than one language, you can choose which one the service uses as the source for the translation.
Human translation parameters	
Translate attached files	Enable this option to submit the document's file attachments for translation along with the main content. The system adds file attachments directly into the XLIFF translation source as binary data encoded in Base64 format.
Priority	Sets the priority of the translation (low, normal or high).
Translation requested due	Specifies a deadline date for the translation.
Instructions for translators	Here you can enter additional instructions for human translators.

Submitting a new document language version for translation

6. Click **Submit for translation**.

The system adds the new language version of the document.

- [Machine services](#) immediately insert the translated content into the new document version.
- When using [standard \(human\) translation services](#), the system initially creates the new document version as a copy of the source language. The content tree shows the *Waiting for translation* status icon (●) next to documents in this state. You can manage the translation through a [submission ticket](#) in **CMS Desk -> Tools -> Translations**. Once the service completes the translation, you can process the submission to transfer the new content into the appropriate language version of the document.

Tip

You can integrate document translation via services into your [workflow](#) process. Advanced workflow offers action steps that allow you to automatically [manage document translations](#).

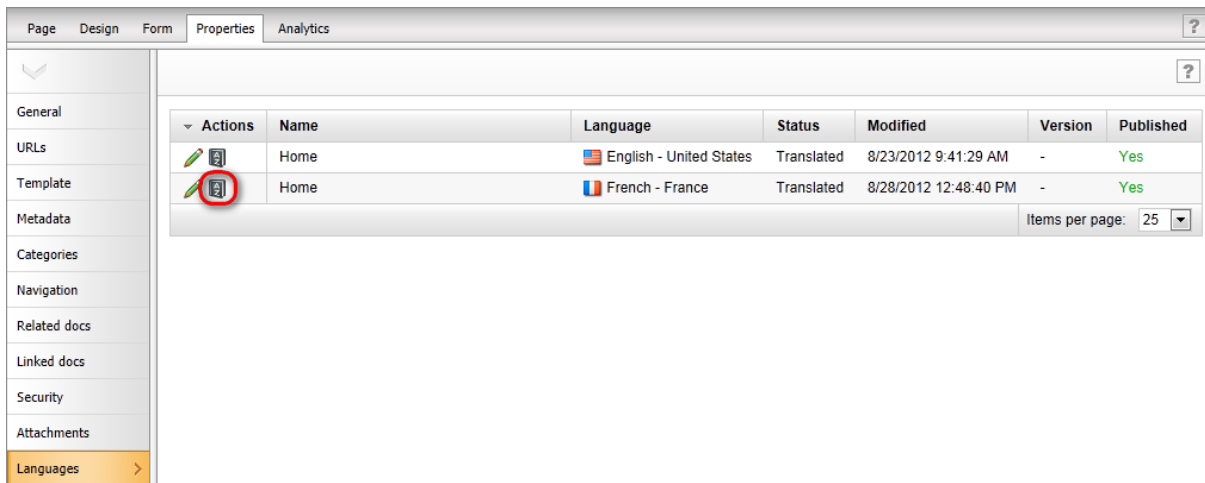

There are two predefined workflows (in **Site Manager -> Development -> Workflows**) that you can configure and apply to your website:

- **Translation - Default language version** - automatically sends documents for translation via a selected service when a user approves the default language version.
- **Translation - Import to other language versions** - periodically checks for translations completed by standard services and imports them into the appropriate documents when ready.

Re-translating existing document versions

You can submit documents for translation even if they already exist in the target language. This allows you to use translation services to update the language versions of a document after making changes to its main content.

1. Select the document in the content tree.
2. Open the **Properties -> Languages** tab.
3. Click the **Translate document** (📄) action for the language version that you wish to re-translate.

The screenshot shows the 'Properties -> Languages' tab in the Kentico interface. A table lists document versions with columns for Actions, Name, Language, Status, Modified, Version, and Published. The 'French - France' version is highlighted, and the 'Translate document' icon in the Actions column is circled in red.

Actions	Name	Language	Status	Modified	Version	Published
	Home	English - United States	Translated	8/23/2012 9:41:29 AM	-	Yes
	Home	French - France	Translated	8/28/2012 12:48:40 PM	-	Yes

Items per page: 25

A translation dialog opens.

4. Choose a service and specify the parameters of the translation.
5. Click **Translate**.

The system submits the document for translation just like when creating a new language version. The text returned by the translation service overwrites the original content of the document in the selected language.

Note

You may also use the **Properties -> Languages** tab to create new language versions of documents (even if the given document does not exist in the target language).

Translating multiple documents

To translate more than one document using a single action:

1. Open the **List** mode of CMS Desk.
2. Select the *parent* of the documents that you wish to translate in the content tree.
3. Select the target language of the translation on the main CMS Desk toolbar.
4. Mark documents for translation using the checkboxes next to the listed items.
5. Select the **Translate** action below the document list and click **OK**.
6. Choose a service and specify the parameters of the translation. When submitting multiple documents for translation, you can also enable or disable the following options:

Skip already translated documents	If checked, documents that already exist in the target language are not submitted for translation. Disable this option to overwrite the current content of the documents with the text returned by the translation service.
Send all documents within one submission	If enabled, the system includes all listed documents in a single translation submission . Otherwise, separate submissions are created for individual documents. Only applicable when using a human translation service.

Translating all documents under the News sections of a website

7. Click **Translate**.

The translation process works the same way as for single items, but the system performs it for all selected documents.

4.9.7.3 Configuring content for translation

Translation services can process the following types of document content:

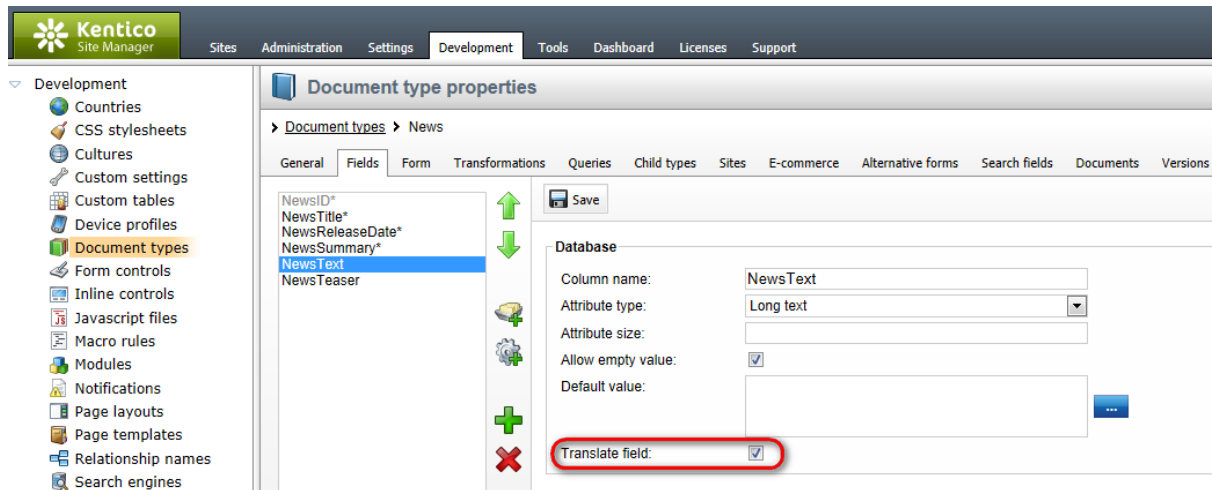

- Content of editable regions
- Values of document fields (entered on the **Form** tab)
- The properties of web parts placed on the given document
- Document file attachments

The system allows you to specify exactly which parts of the content are translated. These settings affect all types of translation services.

Configuring document fields

To choose which document fields are sent for translation, adjust the form definition of individual [document types](#):

1. Go to **Site Manager -> Development -> Document types**.
2. Edit (✎) a specific document type and open the **Fields** tab.
3. Select the field that you wish to configure and enable or disable the **Translate field** flag. Translation is only available for fields with the *Text*, *Long text* or *File* **Attribute type**.
4. Click  **Save** to confirm the changes to the field.

Enabling the Translate field flag in the field editor

When users submit documents of the given type for translation, only the content of fields that have the **Translate field** flag enabled is included in the translation.

Configuring web part content

Pages may also contain text added via [Web parts](#) and [Widgets](#). The only way to translate web part content is to localize the values of the corresponding web part properties. You can configure the system to automatically include specific web part properties in translations. This is only recommended for web parts that directly add text onto the page (such as [Static text](#)).

1. Go to **Site Manager -> Settings -> Content -> Translation services** and enable the **Translate web part properties** setting.
2. Open **Site Manager -> Development -> UI cultures**, select the **All cultures** tab, and add [UI cultures](#) for all content languages that you use on your website.
3. Navigate to **Site Manager -> Development -> Web parts**.
4. Select the appropriate web part and open the **Properties** tab.

5. Enable or disable the **Translate field** flag for individual properties. Translation is only available for properties that use the *Text*, *Long text* or *File Attribute type*.

6. Click  **Save** for every modified property.

If a document that contains the given web part is submitted for translation, the system includes the values of all properties that have the **Translate field** flag enabled. When importing the translation, the system creates a [resource string](#) for every translated property, containing the value in the target language. The original text values of the properties are replaced by [localization macros](#), which insert the appropriate resource strings.

Editable text regions

Translation submissions always include the page content entered by users into [Editable text](#) web parts, regardless of the web part translation settings.

Allowing translation of document attachments

Human translation services allow users to submit [file attachments](#) for translation along with the main content of documents. To configure attachment translation for your website:

1. Go to **Site Manager -> Settings -> Content -> Translation services**.
2. Enable the **Allow attachment translation** setting.
3. Specify which types of files should be translated using the **Translation attachments file types** setting. Enter a list of all allowed file extensions separated by semicolons (for example: *txt;docx;pdf*). Leave the setting empty to allow translation for all types of attached files.
4. Click  **Save**.

Users can check the **Translate attached files** option when submitting documents for translation, and the system adds all allowed file attachments into the translation source. When the completed translation is imported, the translated file is attached to the appropriate language version of the document.

File format

The system adds file attachments directly into the XLIFF translation source as binary data encoded in Base64 format.

4.9.7.4 Customizing XLIFF export

Note that by default, the exported XLIFF files use [CDATA](#) notation. You can turn CDATA off in exported XLIFF files by adding the `CMSTranslationServicesUseCDATAForTransUnit` key into your web.config file.

Example of an XLIFF file with the CDATA notation.

```
<xliff version="1.2">
  <file original="cms.document;25" source-language="en-US" target-language="fr-FR"
  datatype="htmlbody">
    <body>
      ...

      <trans-unit id="newstitle">
        <source><![CDATA[Apple iPad Mini In Stock]]></source>
      </trans-unit>
      <trans-unit id="newssummary">
        <source><![CDATA[Today, we have good news for all fans of the awesome
        Apple iPad. We are glad to announce that its new version, Apple iPad Mini, is
        available in our web shop. Furthermore, we keep our reasonable pricing policy,
        providing the lowest price currently available on the Web.]]></source>
      </trans-unit>

      ...
    </body>
  </file>
</xliff>
```

Disabling CDATA in exported XLIFF files

1. Open the web.config file located in the root of the website.
2. Add the *CMSTranslationServicesUseCDATAForTransUnit* key into the <app settings> section of the file.

```
<appSettings>
  ...

  <add key="CMSTranslationServicesUseCDATAForTransUnit" value="false" />

  ...
</appSettings>
```

3. Save the web.config file.

Now, whenever you [submit a document for translation](#), the system exports it without the CDATA notation.

Example of an XLIFF file with the CDATA notation turned off.

```
<xliff version="1.2">
  <file original="cms.document;25" source-language="en-US" target-language="fr-FR"
  datatype="htmlbody">
    <body>
```

```
...  
  
    <trans-unit id="newstitle">  
      <source>Apple iPad Mini In Stock</source>  
    </trans-unit>  
    <trans-unit id="newssummary">  
      <source>Today, we have good news for all fans of the awesome Apple iPad.  
We are glad to announce that its new version, Apple iPad Mini, is available in our  
web shop. Furthermore, we keep our reasonable pricing policy, providing the lowest  
price currently available on the Web.</source>  
    </trans-unit>  
  
    ...  
  </body>  
</file>  
</xliff>
```

4.9.7.5 Machine translation services

Machine services produce translations by submitting the source text to a dedicated translation application, typically a web service. There is no human involvement in the translation procedure, which allows the services to return the translated text immediately (after a short processing period). In most cases, the output text is not directly suitable for publishing without additional editing, but you can use machine translation to quickly create a foundation of the website's content in any language.

In addition to [translating documents](#), machine services also allow users to automatically [translate localization strings](#).

Default machine services:

- [Microsoft Translator](#)
- [Google Translate](#)

4.9.7.5.1 Translating localization strings

You can use machine services to assist in the translation of [localization strings](#). Multilingual resource strings allow you to dynamically display text in the language selected by the current user, both on the live website and inside the Kentico CMS administration interface.

Requirements:

- The system needs to be configured for [multiple UI cultures](#), including all languages that you wish to use in your translations.
- At least one machine translation service must be enabled and configured for the website.

The following example demonstrates how to insert and translate a string into the display name of a [category](#):

1. Open CMS Desk and navigate to **Administration -> Categories**.
2. Select a category in the tree menu and switch to the **General** tab.

3. Click the **Localize** icon (🌐) next to the **Display name** field.

The **Localize field** dialog opens.

4. Leave the default **Create new resource string** option and type in a name for the resource string. Click **OK**.

The **Localize string** dialog shows the content of the string in the default language, and you can fill in a translation for all other available UI cultures.

5. Click on the icon representing the preferred machine translation service under the editing area of a particular language.

The Google Translate and Microsoft Translator icons in the localization dialog

The service automatically translates the string's text from the default language.

6. Click **OK** to save the new content of the string.

7. Click **Save** on the category's **General** tab to insert the localization string into the **Display name** field.

Users now see the name of the category translated according to their currently selected language (or UI culture in the administration interface).

You can use the same approach when translating any type of localization string. Machine translation services are also available when editing resource strings directly in the **Site Manager -> Development -> UI cultures** interface.

4.9.7.5.2 Default machine services

4.9.7.5.2.1 Microsoft Translator

This service uses the [Microsoft \(Bing\) Translator](#) API to translate text. Microsoft Translator offers a free subscription for up to 2 million characters per month, higher editions must be purchased.

Character limit

This service has a 2000 character limit for every translation request. When translating documents, the service submits the content of every field and editable region as a separate unit, so the total number of characters per document is not restricted.

Configuring the Microsoft Translator service

To set up the Microsoft Translator service on your website:

1. Sign up for a subscription to the Microsoft Translator on the [Windows Azure Marketplace](#). You need to create a Windows Live ID account if you do not already have one.
2. Register your website as an application on the [Azure DataMarket](#).

Register your application

* Client ID	<input type="text" value="UniqueClientID"/>
* Name	<input type="text" value="John Doe"/>
* Client secret	<input type="text" value="c1jiskoxz47VKMF3Adsrzvlus2pDZTX/cikky"/>
* Redirect URI	<input type="text" value="https://www.mydomain.com"/>
	<input type="checkbox"/> Enable subdomain access
Description	<input type="text"/>
* Required fields	
← Cancel	<input type="button" value="CREATE"/>

3. Open Kentico CMS and go to **Site Manager -> Settings -> Content -> Translation services**.

4. Enter the **Client ID** and **Client secret** of your application into the corresponding settings in the **Microsoft Translator** section. Click  **Save**.

You can now [translate documents](#) and [localization strings](#) using the Microsoft Translator service.

4.9.7.5.2.2 Google Translate

This service uses the [Google Translate API](#) to translate text. Google Translate is a paid service.

Character limit

This service has a 2000 character limit for every translation request. When translating documents, the service submits the content of every field and editable region as a separate unit, so the total number of characters per document is not restricted.

Configuring the Google Translate service

To set up the Google Translate service on your website:

1. Sign in to the [Google APIs console](#) using a Google account.
2. Create a new project and activate the **Translate API** service.
3. Obtain your project's API key on **API Access** pane.
4. Open Kentico CMS and go to **Site Manager -> Settings -> Content -> Translation services**.
5. Copy the **API Key** into the corresponding setting in the **Google Translator** section. Click  **Save**.

You can now [translate documents](#) and [localization strings](#) using the Google Translate service.

4.9.7.6 Standard translation services

Standard services automatically deliver the translation source data to designated human translators. Human translation takes time, so the results are not available immediately, but it should provide significantly higher translation quality than [machine services](#). The services export and import data using the [XLIFF](#) format, which is generally supported by translation tools.

Document translation via standard services uses the following life cycle:

1. Users [submit documents for translation](#) in CMS Desk.
2. If the given documents do not exist in the target language, the system creates the new culture versions as direct copies of the source language. The content tree marks the documents with the *Waiting for translation* status icon (●).

Important!

When translating documents on live websites, apply [Workflow](#) to avoid publishing content before the translations are complete.

3. The system creates a submission ticket for every translation. You can [manage](#) the submissions in **CMS Desk -> Tools -> Translations**.

4. Once the service provider finishes the translation, you can [import](#) the data and process the corresponding submission. This inserts the translated content into the appropriate language version of the submitted documents.

Default human translation services:

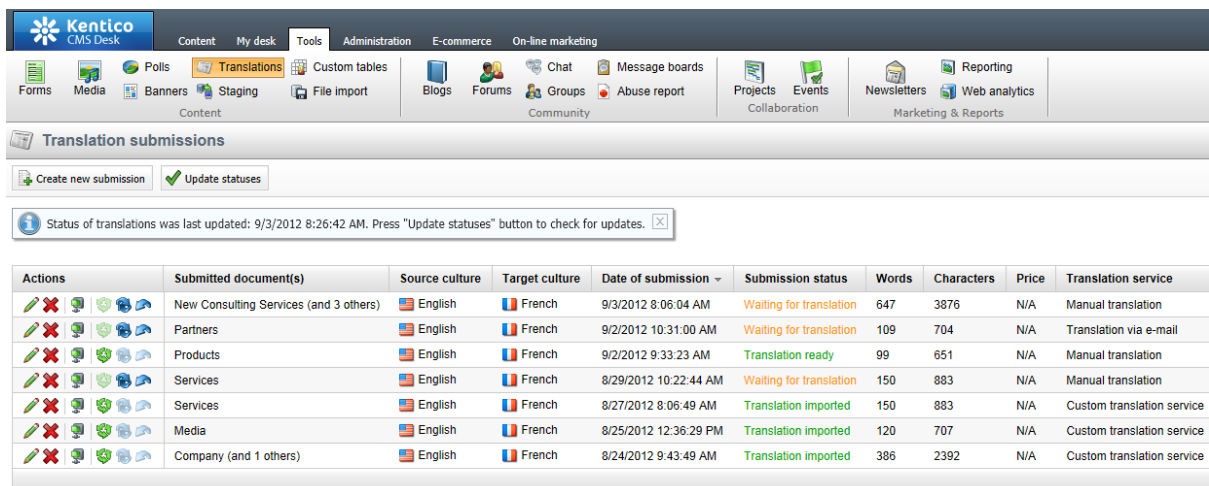

- [Translations.com](#)
- [Manual translation](#)
- [E-mail translation](#)

4.9.7.6.1 Managing translation submissions

Standard services use submission tickets to keep track of translation tasks. The system automatically creates a new submission whenever a user assigns a document (or batch of documents) for translation via a human service. To access a list of all translation submissions created on a specific website, go to **CMS Desk -> Tools -> Translations**.

You can manage the listed submissions through the following actions:

-  **Edit** - allows you to modify the details of the submission. For example, you can update the submission's deadline date and then resubmit it to the service.
-  **Delete** - removes the translation submission. When deleting submissions that have the *Waiting for translation* status, the system also performs the *Cancel submission* action.
-  **Export all to zip** - allows you to download a zip package containing the translation source data for all documents in the submission. The data is stored in *.xlf* files using the [XLIFF](#) format.
-  **Process translations** - inserts the translated content into the corresponding language versions of the documents included in the submission. Only available for submissions that have a completed translation (i.e. those in the *Translation ready* status). See more in [Importing completed translations](#).
-  **Resubmit to translation service** - resends the translation assignment to the service according to the current settings of the submission and the latest content of the source documents.
-  **Cancel submission** - switches the submission to the canceled status. This also informs the translators that they no longer need to finish the translation. The exact functionality performed when canceling a submission depends on the implementation of the used service.

Actions	Submitted document(s)	Source culture	Target culture	Date of submission	Submission status	Words	Characters	Price	Translation service
    	New Consulting Services (and 3 others)	English	French	9/3/2012 8:06:04 AM	Waiting for translation	647	3876	N/A	Manual translation
    	Partners	English	French	9/2/2012 10:31:00 AM	Waiting for translation	109	704	N/A	Translation via e-mail
    	Products	English	French	9/2/2012 9:33:23 AM	Translation ready	99	651	N/A	Manual translation
    	Services	English	French	8/29/2012 10:22:44 AM	Waiting for translation	150	883	N/A	Manual translation
    	Services	English	French	8/27/2012 8:06:49 AM	Translation imported	150	883	N/A	Custom translation service
    	Media	English	French	8/25/2012 12:36:29 PM	Translation imported	120	707	N/A	Custom translation service
    	Company (and 1 others)	English	French	8/24/2012 9:43:49 AM	Translation imported	386	2392	N/A	Custom translation service

4.9.7.6.2 Importing completed translations

Because of the waiting period involved in human translation, the system provides an import mechanism that checks the status of translations and retrieves the required data when it is ready. Most human translation services support automatic loading of completed translations.

The translation retrieval process consists of two steps:

- 1. Importing the translation data** - loads the XLIFF data of the finished translation from the service and transfers it into the matching submission. This does not affect the website's content.
- 2. Processing the submission** - inserts the translated content into the actual documents. This overwrites the appropriate language version of the documents that were submitted for translation.

Note

You can combine both steps of the translation retrieval process by enabling the **Automatically import translated submissions** setting in **Site Manager -> Settings -> Content -> Translation services**. In this case, the system automatically inserts translated content into documents when the data is imported into submissions.

Warning: This overwrites documents immediately when a service finishes the translations, without the approval of the content administrators.

To import the content of translated submissions:

1. Go to **CMS Desk -> Tools -> Translations**. All untranslated submissions are in the *Waiting for translation* status.
2. Click  **Update statuses** above the list of submissions. This imports all completed translations and switches the corresponding submissions to the *Translation ready* status.

You can automate the translation status updates by enabling and configuring the **Translation retrieval scheduled task** for your site. With this task running, the system regularly updates all translation submissions according to a predefined time interval.

3. Click the  **Process translations** action for submissions that are in the *Translation ready* status.

The system transfers the translated content into the corresponding document(s) and changes the submission status to *Translation imported*.

Manually uploading translation data

The system allows you to directly upload the XLIFF translation data into submissions. You can use this approach if you encounter any problems with the translation retrieval, or if your service does not support automatic loading of finished translations.

1. Edit () the given translation submission in **CMS Desk -> Tools -> Translations**.

2. Load the translated data into the submission. You have two options:

- To upload an `.xlf` file containing the translated data of a specific document, use the  **Upload translated XLIFF file** action next to the matching item in the list.
- If you have the completed translation for the entire submission in a zip archive, upload it by clicking the **Import all from ZIP** button.

 **Translation submission properties**

 Target culture: French - France
 Date of submission: 9/3/2012 8:06:04 AM
 Translation submitted by: Global Administrator (administrato) [Select](#) [Clear](#)
 Submission status: Waiting for translation

Settings

Priority: Normal

Submission deadline: 9/10/2012 9:00:00 AM  [Now](#)

Include binary files:

Instructions for translators:

Content

	Actions	Document name ^	File type	Words	Characters
Submitted document(s):		Apple iPad 2 In Stock	XLIFF	158	884
		Community Website Section	XLIFF	170	1064
		Company Growth Exceeds Expectations	XLIFF	176	1018
		New Consulting Services	XLIFF	143	910

Items per page: 25

Export all to ZIP
Import all from ZIP

If the upload is successful, the submission switches to the *Translation ready* status. You can then process the submission to transfer the translated content into the website's documents.

4.9.7.6.3 Default standard services

4.9.7.6.3.1 Translations.com

Translations.com is a worldwide translation provider that offers website localization in over 170 languages. Kentico CMS includes a default service that automatically ensures the transfer of translation data between the system and Translations.com.

To set up the Translation.com service:

1. [Contact](#) a Translations.com representative and arrange a translation project for your website.
2. Open Kentico CMS and go to **Site Manager -> Settings -> Content -> Translation services**.
3. Fill in the information of your Translation.com project into the settings under the **Translations.com** section:
 - Client user name
 - Client user password
 - Project short code

Click  **Save**.

4. Add the following endpoints into the `<system.serviceModel><client>` section of your application's web.config file:

```
<endpoint address="" binding="basicHttpBinding"
contract="TranslationsComSessionService.SessionService2PortType" />

<endpoint address="" binding="basicHttpBinding"
contract="TranslationsComProjectService.ProjectService2PortType" />

<endpoint address="" binding="basicHttpBinding"
contract="TranslationsComDocumentService.DocumentService2PortType" />

<endpoint address="" binding="basicHttpBinding"
contract="TranslationsComSubmissionService.SubmissionService2PortType" />

<endpoint address="" binding="basicHttpBinding"
contract="TranslationsComTargetService.TargetService2PortType" />

<endpoint address="" binding="basicHttpBinding"
contract="TranslationsComUserProfileService.UserProfileService2PortType" />
```

Valid endpoint addresses for your application will be provided by Translations.com.

You can now [submit documents for translation](#) using the Translations.com service.

Translation submission logs

Whenever a user submits a translation to Translations.com, the system creates a record in the event log (**Administration -> Event log**). The service also logs any errors that may occur while sending or receiving translation data.

4.9.7.6.3.2 Manual translation

The manual service exports the translation data onto the file system. Every translation submission is converted to a zip archive containing *.xlf* files (the source data in XLIFF format) and instructions. This allows you to deliver the translation assignment by sharing the export folder or by manually sending the submission package to the translators.

The service checks for finished translations in a designated import folder. The translators can also manually upload the completed zip package through a specific system page (the default instructions provide a link).

Important!

The package containing the completed translation must have the same names as the original source package for all *.xlf* files and the parent zip archive. The system uses the names as identifiers when importing the translated data.

Configuring the manual translation service

To set up the manual translation service, go to **Site Manager -> Settings -> Content -> Translation services** and configure the settings in the **Manual translation** section:

Translation submission export folder	Specifies the path of the folder where the service creates the zip packages with the translation source data (XLIFF files and instructions). If empty, the <code>~/App_Data/Translations/Export/</code> folder is used.
Translations import folder	Sets the path of the folder from which the system imports zip packages containing completed translations. If empty, the <code>~/App_Data/Translations/Import/</code> folder is used.
Delete ZIP after successful download	If enabled, the system deletes the zip packages containing finished translations after importing the XLIFF data.

Customizing the instruction files

In addition to the *.xlf* files that store the translation source data, the manual translation service places instruction files into the exported zip packages. The instruction files are created as copies of template files found in the `~/App_Data/CMSModules/Translations/Template/` folder under your web project.

By default, the folder contains the **Instructions.html** file. You can modify the content of this file according to your own requirements and even add additional instruction files that the service will include in the zip packages.

You can use context [macro expressions](#) in the text of instruction files to dynamically insert the values of the given submission. For example:

- `{% Submission.SubmissionSourceCulture %}` - returns the culture code of the translation source language.

- `{% Submission.SubmissionTargetCulture %}` - returns the culture code of the target language.
- `{% GetTranslationPriority(Submission.SubmissionPriority) %}` - returns the priority set for the submission (low, normal or high).
- `{% Submission.SubmissionDeadline %}` - returns the date and time of the submission's deadline.
- `{% Submission.SubmissionInstructions %}` - returns the additional instructions entered for the submission.
- `{% Submission.SubmissionWordCount %}` - returns the total number of words in the translation source text.
- `{%SubmissionLink%}` - returns the URL of a system page where users can upload finished translation packages.

4.9.7.6.3.3 E-mail translation

This service delivers the translation data via e-mail. When a user submits a document for translation, the service creates a zip package containing the XLIFF source file(s) and sends it to the specified translators as an attachment of an e-mail message. The e-mail service allows you to exchange data with translators or agencies that do not have their own API for managing submissions.

The system cannot cancel e-mail translation submissions once they have been sent. In these cases, you need to contact the translators directly.

The e-mail translation service does not support automatic retrieval of completed translations. The translators can submit the files by:

- Uploading the zip archive containing the finished translation via a link included in the original assignment e-mail
- Sending the translation (in XLIFF format) to a member of the website's staff, who can then [import](#) it manually through the **CMS Desk -> Tools -> Translations** interface

Once the translation is imported into the corresponding submission, you can process it to transfer the new content into the documents.

Configuring the e-mail translation service

To set up the e-mail translation service:

1. Ensure that your application is configured to send e-mails through an appropriate [SMTP server](#).
2. Go to **Site Manager -> Settings -> Content -> Translation services** and fill in the following settings in the **Translation via e-mail** section:

Translation submission recipients	Sets the addresses to which the system sends translation assignments through the e-mail service. You can enter multiple e-mail addresses separated by semicolons.
E-mail sender	When sending translation assignment e-mails, the system automatically sets the sender to the address of the user who submitted the translation. The value of this setting is used if no user address is available, for example in the case of translations submitted automatically or via the API.

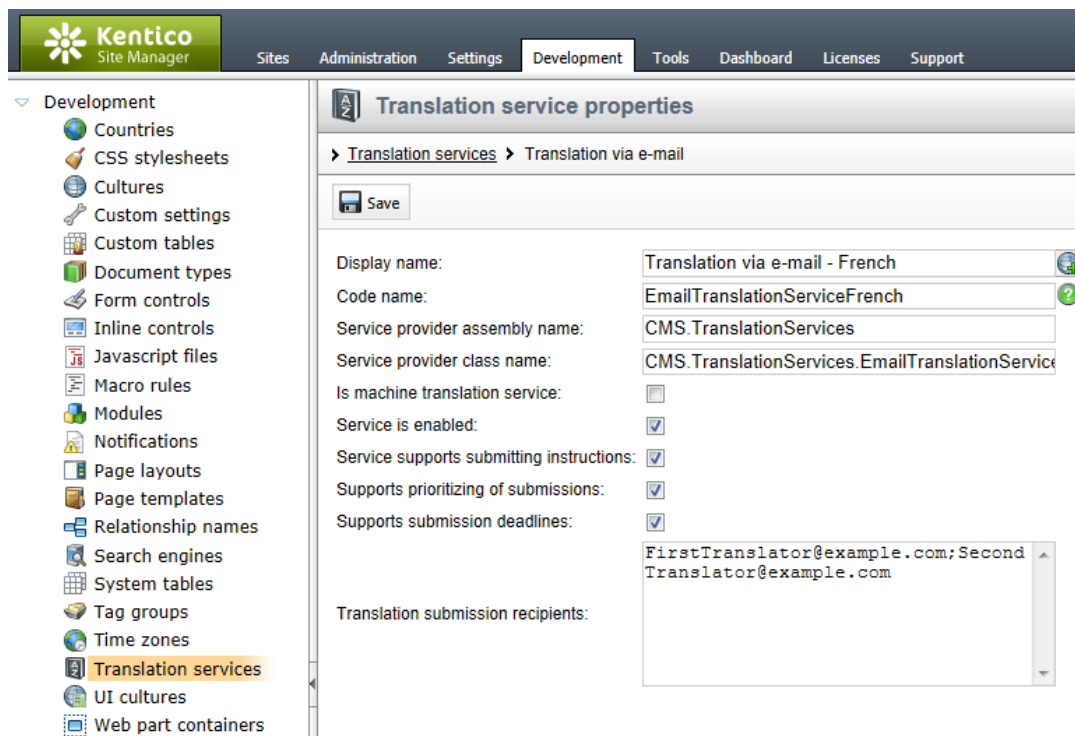

Click  **Save**.

The service sends the translation e-mails using the specified addresses.

Setting language-specific recipients

If you need to assign different translator addresses for individual languages:

1. Go to **Site Manager -> Development -> Translation services**.
2. Create a **Clone** () of the *Translation via e-mail* service for each additional language.
3. Edit the services and enter the appropriate translator addresses into the **Translation submission recipients** property. This property overrides the **E-mail sender** setting.

The screenshot shows the Kentico Site Manager interface. The left sidebar contains a navigation tree with 'Development' expanded, and 'Translation services' selected. The main content area displays the 'Translation service properties' for a service named 'Translation via e-mail - French'. The properties are as follows:

Display name:	Translation via e-mail - French
Code name:	EmailTranslationServiceFrench
Service provider assembly name:	CMS.TranslationServices
Service provider class name:	CMS.TranslationServices.EmailTranslationService
Is machine translation service:	<input type="checkbox"/>
Service is enabled:	<input checked="" type="checkbox"/>
Service supports submitting instructions:	<input checked="" type="checkbox"/>
Supports prioritizing of submissions:	<input checked="" type="checkbox"/>
Supports submission deadlines:	<input checked="" type="checkbox"/>
Translation submission recipients:	FirstTranslator@example.com;SecondTranslator@example.com

Cloned e-mail translation service for the French language

When submitting documents for translation, users need to select the clone of the e-mail translation service that matches the target language.

Customizing the translation e-mails

To change the content of the e-mail messages that the service sends to translators, you need to modify the appropriate [e-mail template](#):

1. Go to **Site Manager -> Administration -> E-mail templates**.
2. Edit the **Translation services - Submit translation** template.

3. Alter the template according to your specific requirements and click  **Save**.

You can use context [macro expressions](#) to dynamically insert the values of the given translation submission. For example:

- **{% Submission.SubmissionSourceCulture %}** - returns the culture code of the translation source language.
- **{% Submission.SubmissionTargetCulture %}** - returns the culture code of the target language.
- **{% GetTranslationPriority(Submission.SubmissionPriority) %}** - returns the priority set for the submission (low, normal or high).
- **{% Submission.SubmissionDeadline %}** - returns the date and time of the submission's deadline.
- **{% Submission.SubmissionInstructions %}** - returns the additional instructions entered for the submission.
- **{% Submission.SubmissionWordCount %}** - returns the total number of words in the translation source text.

- **{%SubmissionLink%}** - returns the URL of a system page where users can upload finished translation packages.

4. (Optional) Follow the steps described for the manual translation service if you wish to [customize the instruction files](#) included in the zip package attached to the e-mails.

The service sends all translation assignment e-mails based on the current e-mail and instruction file templates.

4.9.7.7 Adding custom translation services

In addition to the translation providers available by default, you can also integrate any other services or your own translation mechanisms.

To add a custom service:

1. Create a class that defines the translation functionality or the communication logic between Kentico CMS and an external service. The implementation rules for the class are different for machine and human translation services. You can find detailed information and custom development examples for the two types of services in the dedicated topics:

- [Creating machine services](#)
- [Creating human translation services](#)

2. Connect the class to the CMS application. There are two options:

- Create a new assembly (Class library) in your web project and include the service class there. In this case, you must add the appropriate references to both the assembly and the main CMS project.
- Define the service in **App_Code** and [load the class](#) via the API. This ensures that the system automatically compiles the service class and you do not need to use a separate assembly.

3. Register the service in the system via the **Site Manager -> Development -> Translation services** interface and specify its [properties](#).

4. Create [Custom settings](#) for any additional parameters required by the service, such as connection credentials or API keys. This allows administrators to configure the service for specific websites or translation projects.

When translating documents or resource strings, users can choose custom services among the translation options offered by the system.

4.9.7.7.1 Creating machine services

To develop a custom machine translation service, you need to define a class that inherits from **AbstractMachineTranslationService** (found in the **CMS.TranslationServices** namespace).

The service class must override and implement the following abstract methods:

Method	Description
Translate	<p>The main translation method which calls the appropriate web service (Google, Bing etc.) or otherwise translates the specified text from the source language into a target language.</p> <p>When a user submits a translation to the service, the system calls the Translate method for every translation unit (<trans-unit> element) in the XLIFF source data. The method's <i>text</i> parameter contains the source text of the unit.</p>
Detect	<p>You can use this method to call the logic of the translation service to automatically determine the language of the source text.</p> <p>Kentico CMS does not use the <i>Detect</i> method by default, but you can implement it if you need language detection functionality in your custom API.</p>
Speak	<p>Converts text to a stream of sound using the given service's text-to-speech engine.</p> <p>Kentico CMS does not use the <i>Speak</i> method by default, but you can implement it if you need text-to-speech functionality in your custom API. If your service does not support such an option, throw a not implemented exception.</p>
IsAvailable	<p>Checks whether the service is appropriately configured and ready to be used. For example, you can confirm that the target service is currently online, or load any credentials and API keys required by the service from the website settings and confirm their validity.</p> <p>The system only offers the service when translating documents and resource strings if the <i>IsAvailable</i> method returns a <i>true</i> value.</p>

Defining machine service classes

This example demonstrates how to write a class providing functionality for a machine translation service. The sample class does not use a real translation service, it only converts the source text to upper case. When creating your own classes, replace the code of the methods with your own translation logic or call the API of the appropriate web service.

1. Open your web project in Visual Studio and add a new class into the **App_Code** folder (or

Old_App_Code if the project is installed as a web application). For example, name the class **SampleMachineTS.cs**.

2. Edit the class and change its code to the following:

[C#]

```
using System;

using CMS.TranslationServices;
using CMS.IO;

/// <summary>
/// Sample machine translation service.
/// </summary>
public class SampleMachineTS : AbstractMachineTranslationService
{
    /// <summary>
    /// Translates the specified text from the source language to the target
    language.
    /// Must return the translated text as a string.
    /// </summary>
    /// <param name="text">Text to translate</param>
    /// <param name="sourceLang">Source language culture code</param>
    /// <param name="targetLang">Target language culture code</param>
    public override string Translate(string text, string sourceLang, string
targetLang)
    {
        // "Translates" the text to upper case.
        return text.ToUpper();
    }

    /// <summary>
    /// Automatically attempts to detect the language of the source text.
    /// Returns the culture code of the detected language.
    /// </summary>
    /// <param name="text">Text to be processed</param>
    public override string Detect(string text)
    {
        // Use your service to detect the language. This example always returns
English.
        return "en-US";
    }

    /// <summary>
    /// Returns a stream of sound generated by text-to-speech services (if
supported).
    /// </summary>
    /// <param name="text">Text to be processed</param>
    /// <param name="lang">Culture code of the text's language</param>
    public override Stream Speak(string text, string lang)
    {
        // This service provider does not support Text-to-speech.
        throw new NotImplementedException();
    }

    /// <summary>
```

```
/// Checks the necessary prerequisites needed for the service to work,
/// e.g. availability of credentials for connecting to the service etc.
/// </summary>
public override bool IsAvailable()
{
    // This sample provider does not require any settings and does not depend
on
    // any other services, therefore is always available.
    return true;
}
}
```

The system calls the methods of the class as needed when the given translation service is used.

3. Follow the instructions in the [Loading service classes from App_Code](#) topic to ensure that the application can access the custom class.

Registering machine services in the system

Once you have implemented the class with the required functionality, you need to register the translation service as an object in Kentico CMS:

1. Go to **Site Manager -> Development -> Translation services** and click  **New translation service**.

2. Enter the following values into the service's [properties](#):

- **Display name:** Sample machine service
- **Code name:** Leave the *(automatic)* option. The system will generate the code name as *Sample_machine_service* (based on the display name).
- **Service provider assembly name:** App_Code
- **Service provider class name:** SampleMachineTS
- **Is machine translation service:** Yes (checked)
- **Service is enabled:** yes (checked)

Click  **Save**.

The service is now ready to be used.

Assigning icons to machine services

When editing [resource strings](#) for specific user interface cultures, users can translate the text from the default language by clicking on icons representing the available machine translation services. To set an icon for your custom service:

1. Open the `\App_Themes\Default\Images\` folder in your web project.
2. Extract the **CMSModules** folder from the **Images.zip** archive and place it into the `\App_Themes\Default\Images\` directory.
3. Add the icon image file into the `CMSModules\CMS_TranslationServices` folder. The name of the file must match the code name of the given translation service, so use *Sample_machine_service.png* for this example. The recommended size for the icon is 16 x 16 px.

The system automatically loads the service icon images from this folder.

Result

When submitting documents for translation, the dialog offers the *Sample machine service* as one of the translation service options. Using this option creates the new language version of the document as a copy of the original content, with all characters converted to upper case.

The document does not exist in the current culture. You can create a new culture version of the document.

Create empty document
 Copy content from another language
 Translate using translation service

Save | New string

Key: administration-system.restartsuccess

Text: THE APPLICATION WAS SUCCESSFULLY RESTARTED.

Default text (en-us): The application was successfully restarted.

Custom string:

"Translating" a resource string using the sample service

4.9.7.7.2 Creating human translation services

To develop a custom human translation service, you need to define a class that inherits from **AbstractHumanTranslationService** (found in the **CMS.TranslationServices** namespace).

The service class must override and implement the following abstract methods:

Method	Description
--------	-------------

IsAvailable	<p>Checks whether the service is appropriately configured and ready to be used. For example, you can confirm that valid connection credentials are specified for the service in the website settings or check whether there is sufficient credit to perform translations.</p> <p>When translating documents, users can only choose the service if the <i>IsAvailable</i> method returns a <i>true</i> value.</p>
IsLanguageSupported	<p>Checks whether the service supports translation to a specific language.</p> <p>The system calls this method before creating new translation submissions for the service. Users can only create submissions if the <i>IsLanguageSupported</i> method of the selected service returns a true value for the target language.</p>
CreateSubmission	<p>Delivers the translation assignment to the translators. Called when creating new translation submissions for the service or resubmitting existing ones.</p>
CancelSubmission	<p>Executed when a user cancels a translation submission in CMS Desk -> Tools -> Translations.</p> <p>Depending on the type of the service, you can delete the submission's physical file, call the appropriate service API or otherwise inform the translators that the submission has been canceled.</p>
DownloadCompletedTranslations	<p>Retrieves translated content from the service and imports it into the submission tickets.</p> <p>The system automatically calls this method when updating the status of translation submissions, which can be triggered by:</p> <ul style="list-style-type: none"> • Users clicking Update statuses in CMS Desk -> Tools -> Translations • Execution of the Translation retrieval scheduled task

Defining human service classes

This example shows the implementation of a translation service that saves translation submissions into zip packages and exports them into a designated folder. It also provides a way to automatically load completed translations from an import folder. This sample service is a simplified version of the default [Manual translation service](#).

1. Open your web project in Visual Studio and add a new class into the **App_Code** folder (or **Old_App_Code** if the project is installed as a web application). For example, name the class **SampleTS.cs**.
2. Change the class declaration and add references according to the following code:

[C#]

```
using System;
using System.Text;
using System.Data;
using System.Collections.Generic;
using System.Collections;
using System.Web;

using CMS.IO;
using CMS.SettingsProvider;
using CMS.GlobalHelper;
using CMS.TranslationServices;

/// <summary>
/// Sample human translation service.
/// </summary>
public class SampleTS : AbstractHumanTranslationService
{
}
```

3. Add the following properties into the class:

[C#]

```
/// <summary>
/// Gets the path of the folder to which the service exports translation
submissions.
/// </summary>
public string ExportFolder
{
    get
    {
        string folder = SettingsKeyProvider.GetStringValue(SiteName +
".SampleTranslationExportFolder");
        if (string.IsNullOrEmpty(folder))
        {
            // Sets a default export folder if the path can't be loaded from the
site settings.
            folder = "~/App_Data/Translations/Export/";
        }
        return URLHelper.GetPhysicalPath(folder);
    }
}

/// <summary>
/// Gets the path of the folder that the service checks for files containing
completed translations.
/// </summary>
public string ImportFolder
{
    get
    {
        string folder = SettingsKeyProvider.GetStringValue(SiteName +
".SampleTranslationImportFolder");
        if (string.IsNullOrEmpty(folder))
        {
```

```
        // Sets a default import folder if the path can't be loaded from the
        site settings.
        folder = "~/App_Data/Translations/Import/";
    }
    return URLHelper.GetPhysicalPath(folder);
}
}
```

The **ExportFolder** and **ImportFolder** properties load the translation folder paths from the website settings. If the setting values are not available, the properties return default folder paths. The **SiteName** property used to build the setting key names is inherited from the parent class. It gets the code name of the site from which the translation was submitted.

4. Define the required methods inside the class:

IsAvailable

[C#]

```
/// <summary>
/// Checks if all conditions required to run the service are fulfilled.
/// </summary>
public override bool IsAvailable()
{
    // This service is always available.
    return true;
}
```

The sample service only needs to know the paths for its import and export folders, but it uses default paths if the values are not specified through the settings. The method returns a *true* value to indicate that the service is always ready.

IsLanguageSupported

[C#]

```
/// <summary>
/// Checks if the service supports a specific language.
/// </summary>
/// <param name="langCode">Culture code of the language to be checked</param>
public override bool IsLanguageSupported(string langCode)
{
    // All languages are supported.
    return true;
}
```

CreateSubmission

[C#]

```

/// <summary>
/// Creates a new submission or resubmits it if the submission ticket already
exists.
/// Returns an empty string if all operations are successful or the details of the
encountered error.
/// </summary>
/// <param name="submission">Info object representing the translation submission</
param>
public override string CreateSubmission(TranslationSubmissionInfo submission)
{
    try
    {
        if (submission != null)
        {
            // Gets the path of the zip file containing the submission.
            string path = null;
            if (string.IsNullOrEmpty(submission.SubmissionTicket))
            {
                path = Path.Combine(this.ExportFolder,
ValidationHelper.GetSafeFileName(submission.SubmissionName) + ".zip");
                path = FileHelper.GetUniqueFileName(path);

                // Assigns the zip file name as the ticket ID of the new
submission.
                submission.SubmissionTicket = Path.GetFileName(path);
            }
            else
            {
                // The resubmit action uses the existing file path stored in the
ticket ID.
                path = Path.Combine(this.ExportFolder,
submission.SubmissionTicket);
            }

            // Writes the zip file under the specified path. Overwrites the file
if it exists.
            DirectoryHelper.EnsureDiskPath(path, null);
            using (FileStream stream = File.Create(path))
            {
                TranslationServiceHelper.WriteSubmissionInZIP(submission, stream);
            }
        }
    }
    catch (Exception ex)
    {
        TranslationServiceHelper.LogEvent(ex);
        return ex.Message;
    }
    return null;
}

```

The **TranslationServiceHelper.WriteSubmissionInZip** method creates the zip archive with the translation assignment. The archive contains the source text of the submitted documents in XLIFF format and an HTML instructions file with the details entered for the translation.

CancelSubmission

[C#]

```
/// <summary>
/// Cancels the specified submission.
/// Returns an empty string if all operations are successful or the details of the
/// encountered error.
/// </summary>
/// <param name="submission">Info object representing the canceled submission</
param>
public override string CancelSubmission(TranslationSubmissionInfo submission)
{
    try
    {
        if (submission != null)
        {
            // Tries to delete the assignment zip file (loads the file name from
            the submission ticket ID).
            string path = Path.Combine(this.ExportFolder,
            submission.SubmissionTicket);
            if (File.Exists(path))
            {
                File.Delete(path);
            }
        }
    }
    catch (Exception ex)
    {
        TranslationServiceHelper.LogEvent(ex);
        return ex.Message;
    }
    return null;
}
```

DownloadCompletedTranslations

[C#]

```
/// <summary>
/// Retrieves completed XLIFF translation files from the service and imports them
/// into the system.
/// Returns an empty string if all operations are successful or the details of the
/// encountered error.
/// </summary>
public override string DownloadCompletedTranslations()
{
    try
    {
        if (Directory.Exists(this.ImportFolder))
        {
            // Gets all zip files from the import folder.
            string[] files = Directory.GetFiles(this.ImportFolder, "*.zip");
            foreach (string filePath in files)
            {
                string file = Path.GetFileName(filePath);

                // Gets all translation submissions matching the zip file name.
            }
        }
    }
}
```

```

        DataSet ds = TranslationSubmissionInfoProvider.GetSubmissions
("SubmissionTicket = '" + SqlHelperClass.GetSafeQueryString(file, false) + "'",
null);

        if (!DataHelper.DataSourceIsEmpty(ds))
        {
            foreach (DataRow dr in ds.Tables[0].Rows)
            {
                TranslationSubmissionInfo submission = new
TranslationSubmissionInfo(dr);

                // Only imports content for submissions in the 'Waiting
for translation' status.
                if (submission.SubmissionStatus ==
TranslationStatusEnum.WaitingForTranslation)
                {
                    // Gets the zip name from the submission ticket.
                    string fileName = submission.SubmissionTicket;
                    string path = Path.Combine(this.ImportFolder,
fileName);

                    if (File.Exists(path))
                    {
                        // Imports XLIFF file content from the zip
package.
                        string err =
TranslationServiceHelper.ImportXLIFFfromZIP(submission, FileStream.New(path,
FileStream.Open));

                        if (string.IsNullOrEmpty(err))
                        {
                            // Changes the status to 'Translation ready'
and saves the submission.
                            submission.SubmissionStatus =
TranslationStatusEnum.TranslationReady;
                            TranslationSubmissionInfoProvider.SetTranslati
onSubmissionInfo(submission);
                        }
                        else
                        {
                            return err;
                        }
                    }
                }
            }
        }
        return null;
    }
    catch (Exception ex)
    {
        TranslationServiceHelper.LogEvent(ex);
        return ex.Message;
    }
}

```

The **TranslationServiceHelper.ImportXLIFFfromZIP** method loads the translated content from all XLIFF files in the zip package and saves it into the submission ticket.

5. Follow the instructions in the [Loading service classes from App Code](#) topic to ensure that the

application can access the custom class.

Registering human translation services

Once you have implemented the class with the required functionality, you need to register the translation service as an object in Kentico CMS:

1. Go to **Site Manager -> Development -> Translation services** and click  **New translation service**.

2. Enter the following values into the service's [properties](#):

- **Display name:** Sample translation service
- **Service provider assembly name:** App_Code
- **Service provider class name:** SampleTS
- **Service is enabled:** yes (checked)

- **Service supports submitting instructions** - yes
- **Supports prioritizing of submissions** - yes
- **Supports submission deadlines** - yes

Click  **Save**.

The service is now ready to be used.

Adding custom settings for translation services

To allow administrators to configure the import and export folder paths of the service, you need to create [custom settings](#):

1. Go to **Site Manager -> Development -> Custom settings** and click  **New settings group**.

2. Enter the following names for the group:

- **Display name:** Sample translation paths
- **Code name:** SampleTranslationPaths

Click  **Save**.

3. Click  **New settings key** under the new *Sample translation paths* section and define two setting keys:

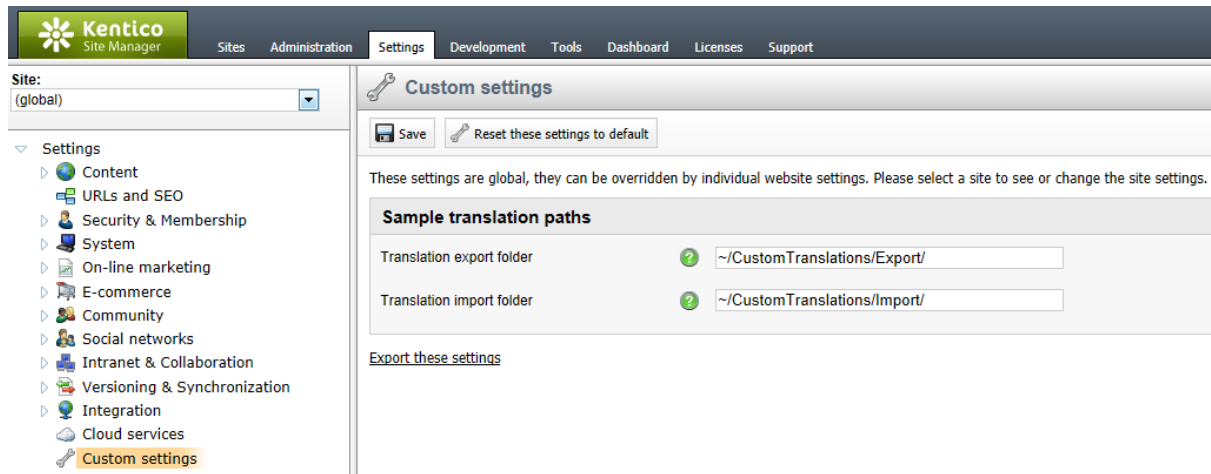

- **Display name:** Translation export folder
- **Code name:** SampleTranslationExportFolder (matches the name of the key loaded by the *ExportFolder* property in the code of the sample service class)
- **Description:** Sets the path of the folder where the system creates translation submissions. If empty, the `~/App_Data/Translations/Export/` folder is used.
- **Type:** String

- **Display name:** Translation import folder
- **Code name:** SampleTranslationImportFolder (matches the name of the key loaded by the *ImportFolder* property in the code of the sample service class)

- **Description:** Sets the path of the folder from which the system loads completed translation packages. If empty, the ~/App_Data/Translations/Import/ folder is used.
- **Type:** String

Click  **Save** for each key.

You can now set the service's folder paths for specific websites in **Site Manager -> Settings -> Custom settings**.

The screenshot displays the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The left sidebar shows a tree view of settings categories, with 'Custom settings' highlighted. The main content area is titled 'Custom settings' and features a 'Save' button and a 'Reset these settings to default' button. Below this, a message states: 'These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.' A section titled 'Sample translation paths' contains two rows: 'Translation export folder' with a value of '~/CustomTranslations/Export/' and 'Translation import folder' with a value of '~/CustomTranslations/Import/'. A link 'Export these settings' is located below the paths.

Result

When submitting documents for translation, the dialog offers the *Sample translation service* as one of the translation options.

 **New culture version (French - France)**

The document does not exist in the current culture. You can create a new culture version of the document.

Create empty document

Copy content from another language

Translate using translation service

Google Translator (machine translation)

Manual translation

Sample translation service

Translation via e-mail

Translate from language:

Translate attached files:

Priority:

Translation requested due:  N/A

Instructions for translators:

Submitting a document for translation using the sample service

Try translating a document using the custom service:

1. Click **Submit for translation** in the *New culture version* dialog. The system creates a new submission and adds the translation zip package into the specified export folder.
2. Translate the content and add the modified *.xlf* file into a new zip package (with the same name as the export zip file). Place the zip package into the import folder.
3. Go to **CMS Desk -> Tools -> Translations** and click  **Update statuses**. The service imports the translated content and switches the matching submission to the *Translation ready* status.
4. Click the  **Process submission** action of the submission. The system transfers the translated content into the corresponding document and changes the submission status to *Translation imported*.

The document is now available in the target language.

4.9.7.7.3 Loading service classes from App_Code

For translation services defined in the *App_Code* folder, you need to ensure that the system loads the appropriate class when calling the given service. You can find additional information related to this topic in [Registering custom classes in App_Code](#).

1. Create a dedicated class in the **App_Code** folder (or **Old_App_Code** if the project is installed as a web application). For example, name the class **ClassLoader.cs**.
2. Edit the class and add the following reference:

[C#]

```
using CMS.SettingsProvider;
```

3. Delete the default class declaration and its content. Instead, extend the **CMSModuleLoader** partial class and define a new attribute inheriting from *CMS.SettingsProvider.CMSLoaderAttribute*:

[C#]

```
[ClassLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Attribute class for loading custom classes.
    /// </summary>
    private class ClassLoader : CMSLoaderAttribute
    {
    }
}
```

4. Add the following code into the **ClassLoader** attribute class:

Warning!

This loads the sample [machine](#) and [human](#) translation providers created according to the instructions in this chapter.

You need to adjust the code to match the names of your own custom service classes. If you do not have the sample classes in your web project, delete or comment out the corresponding cases in the switch statement.

[C#]

```
/// <summary>
/// Called automatically when the application starts.
/// </summary>
public override void Init()
{
    // Assigns a handler for the OnGetCustomClass event.
    ClassHelper.OnGetCustomClass += ClassHelper_OnGetCustomClass;
}

/// <summary>
/// Gets a custom class object based on the given parameters.
/// </summary>
private void ClassHelper_OnGetCustomClass(object sender, ClassEventArgs e)
{
    if (e.Object == null)
```

```

{
    // Checks the name of the requested class.
    switch (e.ClassName)
    {
        // Gets an instance of the SampleMachineTS class.
        case "SampleMachineTS":
            e.Object = new SampleMachineTS();
            break;

        // Gets an instance of the SampleTS class.
        case "SampleTS":
            e.Object = new SampleTS();
            break;
    }
}

```

The value of the **ClassName** property of the **ClassHelper_OnGetCustomClass** handler's **ClassEventArgs** parameter matches the **Service provider class name** specified for the service in the system. The handler checks the class name to identify which translation service is being requested and then passes on an instance of the appropriate class.

4.9.7.7.4 Translation service properties

You can configure the following properties when creating or editing translation services in **Site Manager -> Development -> Translation services**:

Display name	Sets the name of the service displayed to users in the administration interface, e.g. in the list of possible options when submitting a document for translation.
Code name	Sets a name that serves as a unique identifier for the service, for example in the API. You can leave the default (<i>automatic</i>) option to have the system generate an appropriate code name based on the display name.
Service provider assembly name	Must contain the name of the assembly where the service is implemented. Enter <i>App_Code</i> for classes defined in the application's <i>App_Code</i> (or <i>Old_App_Code</i>) folder.
Service provider class name	Specifies the exact class (including any namespaces) that defines the functionality of the translation service.
Is machine translation service	Indicates whether the service is based on machine translation. If disabled, it is considered as a human translation service. <ul style="list-style-type: none"> • When translating documents using a machine service, the system creates the new document versions in the target language immediately. • With human translation services, there is a waiting period and the system tracks translations through submission tickets.
Service is enabled	Can be used to manually enable or disable the service. Users can only choose enabled services when submitting documents for translation.

Service supports submitting instructions	If enabled, users can include additional instructions (for human translators) when creating submissions for this service.
Supports prioritizing of submissions	If checked, users are able to set a priority (low, normal or high) for individual translation submissions that use the service.
Supports submission deadlines	Indicates if users are allowed to specify deadline dates for translation submissions that use this service.
Service parameter	<p>The text data entered into this field may be accessed from within the code implementing the service. It serves as a string parameter through which you can modify the functionality of the service without having to edit its code.</p> <p>You can load the value in the code of your service classes through the CustomParameter property, which is inherited from the parent class (<i>AbstractMachineTranslationService</i> or <i>AbstractHumanTranslationService</i>).</p> <p>C# example:</p> <pre>CMS.GlobalHelper.ValidationHelper.GetString(CustomParameter</pre>

4.9.7.8 Translating via the REST service

Kentico CMS provides a way to retrieve and submit translation data through [REST](#). This service allows you to manage document translations using HTTP request methods. You can utilize the REST service in the code of your [Custom translation services](#) to transfer data in and out of the system.

Use the following root URL to access the REST translation service:

~/rest/translate/

Replace the ~ character with the domain name and virtual directory of your website, for example: *http://localhost/KenticoCMS/rest/translate/*

Enabling the REST translation service

To set up your website for handling translation operations via the REST service:

1. Ensure that all REST [prerequisites](#) are fulfilled on the machine hosting your website.
2. Configure your application's *web.config* according to the instructions in the [Configuration for REST](#) topic. The settings in **Site Manager -> Settings -> Integration -> REST** do *not* affect the translation service. You can leave the general Kentico CMS REST service disabled.
3. Go to **Site Manager -> Settings -> Content -> Translation services** and enable the **Enable REST translation service** setting.

Retrieving translation data from the system

To retrieve document translation data, send an HTTP GET request to a URL in one of the following formats:

- `~/rest/translate/content/currentsite/<culture code>/document/<alias path>`
- `~/rest/translate/content/site/<site code name>/<culture code>/document/<alias path>`

Set the target language of the translation by adding the corresponding culture code into the **targetlanguage** URL parameter. The system automatically fills in the source language based on the language version of the specified document.

The request returns a response containing XLIFF data that you can use as the translation source. The REST service only supports retrieval of a single object per request.

Examples:

```
~/rest/translate/content/site/CorporateSite/en-us/document/Services?targetlanguage=fr-fr  
~/rest/translate/content/currentsite/fr-fr/document/Company/Careers?targetlanguage=cs-cz
```

You can also use the following boolean parameters in the URL:

- **TranslateDocCoupledData** (true by default)
If true, the returned translation source data includes the content of the document's coupled data fields (i.e. the fields of the specific document type). The service only exports fields that have the *Translate field* flag enabled in the document type's form definition.
- **TranslateEditableItems** (true by default)
If true, the translation data includes the content of the document's editable regions.
- **TranslateWebpartProperties** (false by default)
If true, the translation data includes the properties of web parts placed on the document. The service only exports the values of properties that have the *Translate field* flag enabled in the web part definition.
- **TranslateAttachments** (false by default)
If true, the translation data includes the document's file attachments. Attachment translation must also be allowed in the website's settings.

See also: [Configuring content for translation](#)

Submitting completed translations

To import a translation into the system, send a POST request to the root URL of the REST translation service:

```
~/rest/translate/
```

Add the XLIFF content of the completed translation into the body of the request.

The root URL of the service is the only access point used for submitting translations. The system automatically identifies the target document based on the XLIFF data. When the system processes the

request, it creates the appropriate language version of the document (if necessary) and inserts the translation data.

Sample POST request:

```
POST http://localhost/KenticoCMS/rest/translate/
User-Agent: REST client
Authorization: Basic <enter <username>:<password> encoded in Base64>
Host: localhost
Content-Type: text/xml

<xliff version="1.2">
  <file original="cms.document;9" source-language="en-US" target-language="fr-FR"
  datatype="htmlbody">
    <body>
      <trans-unit id="menuitemname">
        <source><![CDATA[Company]]></source>
        <target><![CDATA[Entreprise]]></target>
      </trans-unit>
      <trans-unit id="documentname">
        <source><![CDATA[Company]]></source>
        <target><![CDATA[Entreprise]]></target>
      </trans-unit>
      <trans-unit id="editable;we">
        <source><![CDATA[<p>Source text.</p>]]></source>
        <target><![CDATA[<p>Translated text.</p>]]></target>
      </trans-unit>
      <trans-unit id="editable;wh">
        <source><![CDATA[Company]]></source>
        <target><![CDATA[Entreprise]]></target>
      </trans-unit>
    </body>
  </file>
</xliff>
```

4.9.7.9 Security

There are several module [permissions](#) that determine how users are allowed to work with translation services. To configure these permissions for specific roles, go to **Site Manager / CMS Desk -> Administration -> Permissions**.

Module	Permission	Description
Content	Submit for translation	Allows users to translate documents using the available services.
	Create	Required to create documents, including specific language versions. Users need this permission to translate documents into new languages. Alternatively, you can assign the <i>Create</i> permission only for specific document types .
Translations	Read	Allows users to view translation submissions and their data in CMS

		Desk -> Tools -> Translations.
	Modify	Allows users to create, edit, and delete translation submissions in CMS Desk -> Tools -> Translations . Also required to perform all submission-related actions (re-submitting, canceling, updating status, processing).

4.10 Workflow and versioning

4.10.1 Overview

Kentico CMS allows you to organize and control the process of creating, updating and publishing documents on your website by applying a workflow on them.

In this chapter, you will learn how to define and apply workflow processes for your documents. You will also learn how to manage the workflow process of a particular document in CMS Desk.

What is a workflow?

Workflow is a sequence of steps that define the life cycle of a document. This allows for setting up a reviewing and approval process to ensure quality of content and design. In such a process, you can specify the roles that different people will play and the places in the flow where the individual people will have influence on a particular document.

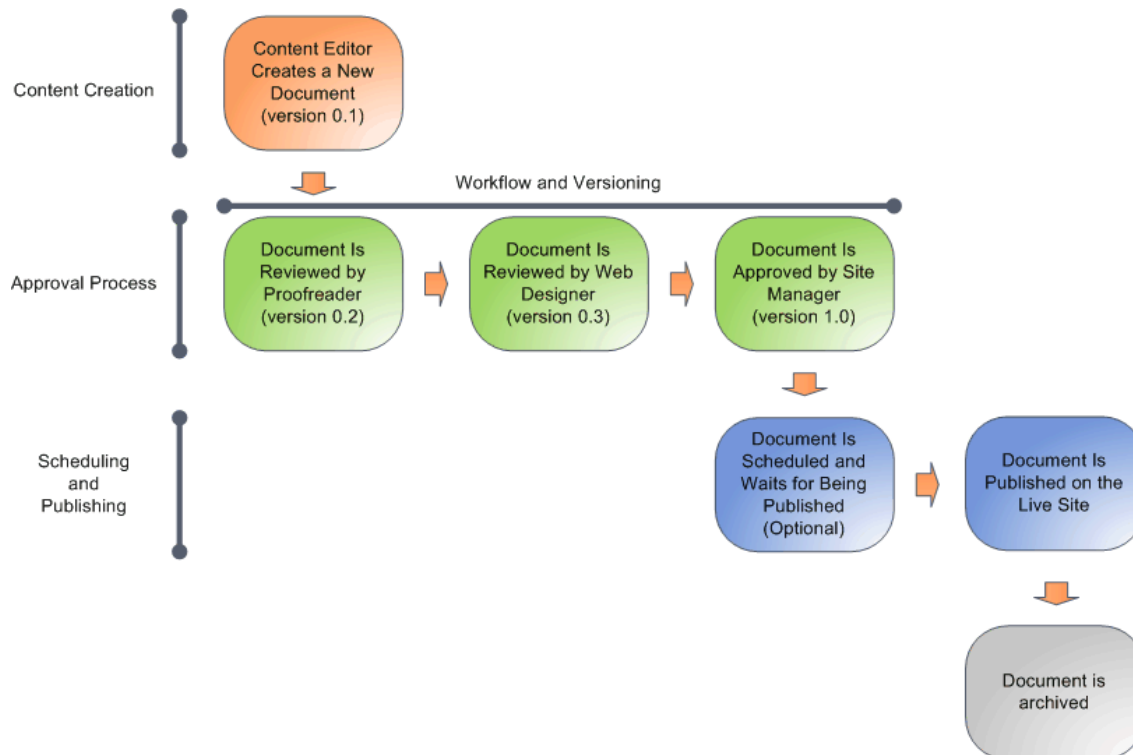

An example of a simple workflow process could be a hypothetical website that publishes scientific articles. An author can write an article and send it for approval to an editor, who will make corrections and submit the article to the head of the respective department. The head will then publish the document, thus making it publicly available to read on the website.

What features are available?

Kentico CMS allows you to use workflow for all documents in the content tree, including uploaded files. It consists of the following features:

- The **workflow** support allows you to organize the process of content creation, updates and publishing on your website.
- **Advanced workflow** adds support of branching the workflow process based on macro conditions and user decisions. It also allows for automatic manipulation of the documents as they go through the workflow process.
- The **versioning** support is tightly bound with workflow and allows you to store, view and roll back previous versions of the content.
- **Versioning without workflow** creates a new version whenever a document is modified, while the whole editing process remains as if the document was using no workflow at all.
- The **content locking (check-in/check-out)** support allows you to avoid concurrent modifications of the same document by multiple users.
- The **preview** support allows you to see the content in the context of the site before it's published. This feature is only available for documents that use workflow - you can preview the documents before switching them to the following step.
- The **archiving** support allows you to archive a document. Such a document is no longer displayed on the website, but it's kept in the content tree and can be re-published at any time later.

The following figure shows an example of document life cycle with a workflow:

The workflow process consists of any number of custom steps. Only authorized users or roles are allowed to modify and approve/reject a document in a particular step. Any authorized user can switch a document to the following or the preceding step. The current workflow step of a document can be found on its **Properties -> Workflow** tab. It is also indicated by the [document status icons](#) displayed next to documents in the content tree.

What type of workflow should I use?

Kentico CMS offers two types of workflows - basic and advanced.

Basic workflow

In a basic workflow, one step is followed by another in a direct sequence. A basic workflow cycle of a document starts in the **Edit** step, which means the document is newly created or that there are yet unapproved changes in the document. After going through the defined approval steps, the document gets into the **Published** step. At that point the system makes the last version of the document visible on the live site.

Advanced workflow

Advanced workflow significantly differs from basic workflow in the way how you can design the flow of steps. You can let a document go through different steps based on various conditions, you can allow editors to choose which step they want the document to be moved to, or you can set timeouts for automatically moving documents from one step to another.

4.10.2 Defining a workflow

This chapter explains how to define a workflow from scratch. You will learn how to:

- [create a workflow](#)
- [apply the workflow on documents](#) by creating workflow scopes
- [define workflow steps](#) for basic and advanced workflow

4.10.2.1 Creating a workflow

Workflow is a sequence of steps that define the life cycle of a document. This allows for setting up a reviewing and approval process to ensure quality of content and design. In such a process, you can specify the roles that different people will play and the places in the flow where the individual people will have influence on a particular document.

You can create and manage workflows in **Site Manager -> Development -> Workflows**.

Creating a basic workflow

In a basic workflow, one step is followed by another in a direct sequence. A basic workflow cycle of a document starts in the **Edit** step, which means the document is newly created or that there are yet unapproved changes in the document. After going through the defined approval steps, the document gets into the **Published** step. At that point the system makes the last version of the document visible on the live site.

1. Log in to **Site Manager** and navigate to **Development -> Workflows**.
2. Click  **New workflow**.
3. Choose a name for the new workflow and type it in the **Display name** text box.
4. Click  **Save**.

The workflow appears in the list on the **Workflows** page. Now you can proceed with [applying the workflow on documents](#) and [creating workflow steps](#).

Creating an advanced workflow

Advanced workflow significantly differs from basic workflow in the way how you design the flow of steps. You can let a document go through different steps based on various conditions, you can allow editors to choose which step they want the document to be moved to, or you can set timeouts for automatically moving documents from one step to another.

1. Log in to **Site Manager** and navigate to **Development -> Workflows**.
2. Click  **New advanced workflow**.
3. Choose a name for the new workflow and type it in the **Display name** text box.
4. Click  **Save**.

The workflow appears in the list on the **Workflows** page. Now you can proceed with [applying the](#)

[workflow on documents](#) and [designing the workflow process](#).

Converting a basic workflow to advanced workflow

The Workflow page allows you to convert a basic workflow to an advanced workflow.

1. Log in to **Site Manager** and navigate to **Development -> Workflows**.
2. Edit (✎) a basic workflow.
3. If the workflow has the **Automatically publish changes** property turned on, turn the property off and save the workflow.
4. Click **Convert to advanced workflow**. A message will appear asking if you really want to convert the workflow to advanced workflow.
5. Click **OK** to finish the conversion or click **Cancel** to return to the workflow editing page.

The system converted the basic workflow to an advanced workflow. Also, all the defined steps have been converted into advanced workflow steps.

4.10.2.2 Applying workflow on documents

A workflow scope defines the conditions based on which a workflow will be applied to documents. When creating a workflow scope, you have to specify a document's alias path and whether you want to include child documents under this path. Then you can narrow down the set of covered documents by specifying some of the following parameters:

- document type
- culture
- macro condition

The system offers two types of scopes - **allowed** and **excluded**. This way you can apply a workflow on a large section of a site and then exclude sections, which you don't want the workflow to be applied on.

Workflow priority

If a document matches scopes of multiple workflows, the workflow with the most specific parameters is applied on the document. Scopes are applied with the following priorities, from highest to lowest:

1. Scope with specified **document type and culture**
2. Scope with specified **document type**
3. Scope with specified **culture**
4. Scope **without** specified document type and culture.
5. Scope with the longest **path**.
6. Scope that covers only the specified **document without children**.
7. Scope that has its type set to **Excluded**.
8. Scope with specified **macro condition**.

Workflow priority examples

The following table presents most common scenarios, where scopes from two different workflows (**Scope 1** and **Scope 2** columns in the table) conflict with each other. The **Result** column explains which scope takes priority.

Scope 1 setup	Scope 2 setup	Result
Alias path: /News	Alias path: /News Document type: Press releases	Press releases under the News document will use Scope 2, the News document itself and its other children will use Scope 1.
Alias path: /Products	Alias path: /Products/ Smartphones	All documents under the Products document will use Scope 1, except for the Smartphones document and its child documents, which will use Scope 2.
Alias path: /Products	Alias path: /Products/ Smartphones Coverage: Only specified document	All documents under the Products document will use Scope 1, except for the Smartphones document, which will use Scope 2. However, children under the Smartphones document will use Scope 1.

Creating a workflow scope

1. Edit an existing workflow and select the **Scope** tab.
2. Choose a site you want the scope to be effective on using the **Site** drop-down list and click  **New workflow scope**.
3. Define the part of the content tree that you want to be covered by the scope.
 - a. Click **Select** next to the **Alias path** property and in the dialog that opens, choose the document you want covered by the scope.
 - b. Specify whether you want to cover the document and its child documents, only the document or only its children.
 - c. Select if you want the scope to be allowed or excluded. Keep the [following behavior](#) in mind when working with exclusions.

General

Alias path: Select **a.**

This scope covers: Specified document and its children
 Only specified document
 Only child documents **b.**

Type: Apply workflow on documents in this scope
 Exclude workflow from documents in this scope **c.**

**Tip**

If you want the scope to cover the whole site, or you want to specify only the parameters in the Advanced section, enter "/" (i.e. the path of the root document) in the **Alias path** property. Make sure that the scope covers the specified document including its children.

4. (Optional) Choose a document type. The workflow will be applied only on documents of this type.
 - a. Make sure the desired document type is assigned to the site you selected in step 2.
 - b. If you had to assign the document type to the site, click  **Save** to refresh the page and load the newly assigned document type.
 - c. Select the document type from the **Document type** drop-down list.
5. (Optional) Specify a culture. The workflow will be applied only on documents in this culture.
 - a. Make sure the culture is assigned to the site you selected in step 2.
 - b. If you had to assign the culture to the site, click  **Save** to refresh the page and load the newly assigned culture.
 - c. Select the culture from the **Culture** drop-down list.
6. (Optional) Enter a macro condition. If the condition is met when starting a workflow cycle on a document within the scope, the workflow will be applied to the document.
7. Click  **Save**.
8. If you want to apply the workflow to an existing document within the scope, make changes to the document.
 - If you're using basic workflow, navigate to the document in CMS Desk and click  **Save**.
 - If you're using advanced workflow, navigate to the document in CMS Desk and click  **New version**.

**Please note**

Exclude workflow from documents in this option applies only to the workflow under which it has been specified and does not override scopes in different workflows.

For example, under *Workflow 1*, you have *"/Products" and its children* allowed and *"/Products/Smartphones"* excluded. Under *Workflow 2*, however, you have *"/Products" and its children* allowed and no exclusion specified. The exclusion specified under *Workflow 1* will have no effect on the scope of *Workflow 2*.

4.10.2.3 Defining workflow steps

This chapter explains how to design a workflow process. Here you can find instructions how to accomplish the following tasks:

- [creating basic workflow steps](#)
- [designing an advanced workflow process](#)
- [configuring workflow operators](#), i.e., users and roles allowed for approving or rejecting in different steps
- [configuring e-mail notifications](#)

4.10.2.3.1 Creating and managing basic workflow steps

A workflow consists of a series of steps. Each step in a workflow defines a part of the document approval process. Each workflow process in Kentico CMS has three default steps, whose order cannot be changed. However, you can add any number of custom steps between the Edit and Published step.

Edit step

The Edit step is the first step in every workflow process. When you create a document, it starts in the Edit step. When you make changes to a published document, it gets moved to the Edit step. Live site visitors will not see changes made to a document while in the Edit step until it gets moved to the Published step.

Published step

When a document reaches the Published step, the system makes it visible to live site visitors. After a document is published, you can make changes to it, while live site visitors see the published version of the document.

Archived step

When you move a document to the Archived step, it gets pulled off from the live site. Documents in the Archived step will not be accessible by live site visitors. Making changes to an archived document moves it back to the Edit step.

Creating a workflow step

1. Edit a basic workflow and switch to the **Steps** tab.
2. Click  **New workflow step**.
3. Enter a name into the **Display name** field. This is the name that will be displayed to editors when viewing documents that are in the step.
4. Click  **Save**.

The system inserts the step immediately before the Published step. You can view the step on the Steps page under the workflow you're editing.

You can proceed with [configuring operators](#) and [e-mail notifications](#) for this step.

Rearranging workflow steps

You can move steps up and down using the **↑ Move up** and **↓ Move down** buttons in the list of steps. However, you cannot move the default steps, nor can you move any custom step before the Edit step or past the Published step. If you wish to design a flexible workflow process where the cycle doesn't begin and end with the default steps, consider using an advanced workflow.

Allowing or denying users to manage documents in the step

Refer to the [Configuring workflow operators](#) topic to learn how to set up security rules of a step.

4.10.2.3.2 Designing advanced workflow

In this chapter, you will learn how to design an advanced workflow process. The topics in this chapter explain the different types of workflow steps, their configuration, and usage.

This chapter contains the following topics and sub-chapters:

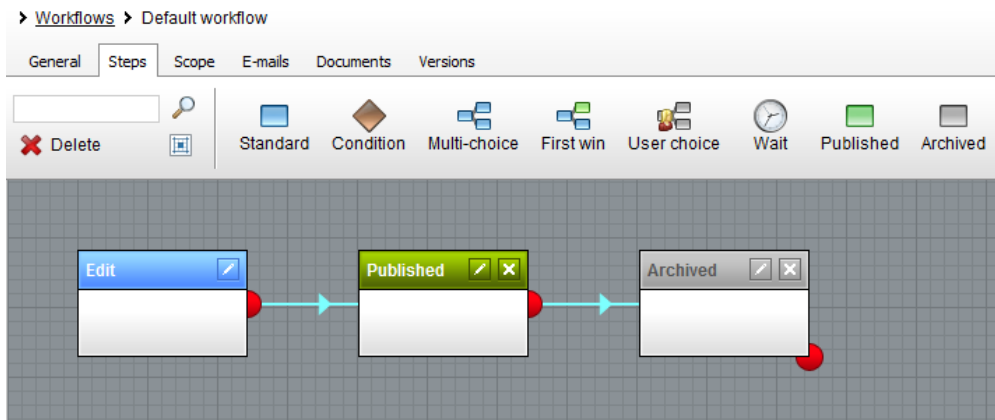

- [Introduction to workflow designer](#)
- [Connecting steps](#)
- [Adding and configuring steps](#)
- [Defining if/else conditions](#)
- [Defining user decisions](#)
- [Defining automatic decisions](#)
- [Setting timeouts for automatic approving](#)
- [Adding action steps](#)

4.10.2.3.2.1 Introduction to workflow designer

This topic describes the workflow designer, which is a tool for creating complex workflow processes.

You can find the workflow designer on the **Steps** tab when editing an advanced workflow. It consists of a toolbar and a grid. By placing workflow steps from the toolbar on the grid and connecting them, you form a graph that represents the workflow process.

The following image shows a basic workflow process consisting of the Edit, Published and Archived steps, as it appears in the workflow designer. The steps are connected with transition lines. The direction in which the arrows point is the direction in which a document will be moved through the steps.

If your graph doesn't fit into the designer area, you can click and drag an unoccupied area of the grid to move it and expose additional free space.

Step types

In advanced workflow, you can use the following types of steps:

- **Standard** step allows approving or rejecting a document.
- **Condition** allows splitting the workflow process into two branches, according to whether the condition is met or not.
- **Multi-choice** step allows splitting the workflow process into multiple branches. You can define a number of conditions, one of which will determine the branch the process will automatically continue in. If more than one condition is met, users will be able to choose.
- **First-win** step allows defining a number of conditions, where the first condition that is met determines the branch the process will automatically continue in.
- **User choice** allows defining branches of the process, where the user will choose the branch the process will continue in.
- **Wait** allows to define a time period after which a document will be automatically moved to the next step.
- **Published** step puts a document's latest version up to the live site.
- **Archived** step makes a document inaccessible from the live site.

You can also embed actions that will be automatically performed when a document reaches an action step:

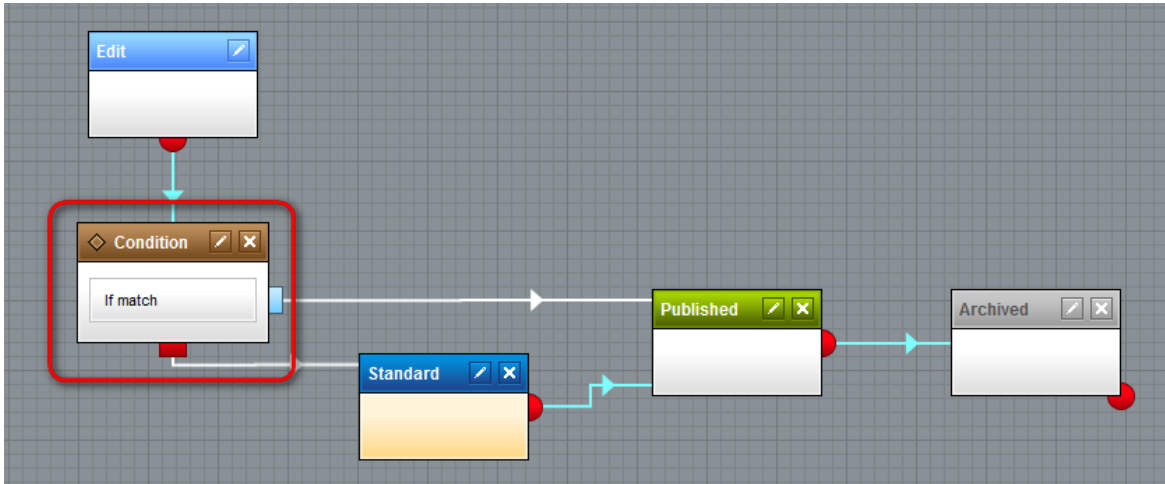

- **Copy document** - copies a specified document to another location.
- **Delete document** - deletes a specified document.
- **Import translation** - imports translations of the document that are ready.
- **Link document** - creates a linked document.
- **Move document** - moves a specified document to another location.
- **Publish to Facebook** - automatically sends a predefined post on Facebook.
- **Publish to Twitter** - automatically sends a predefined post on Twitter.
- **Send for translation** - submits a document for translation using the specified translation service.
- **Send e-mails** - sends e-mails based on a specified e-mail template.
- **Send notification e-mails** - sends e-mails according to the e-mail settings defined for the step that immediately follows.
- **Set document property** - assigns a specified value to a document's property.
- **Synchronize document** - synchronizes a specified document to all enabled staging servers.

You can also script your own actions.

Source points

The red points are **source points**. You can drag a source point with your mouse and drop it on another step to create a connection between the two steps.

Some steps can have more than a single source point, as you can see in the following image.

The highlighted step is an *if/else* condition, which allows you to create branches of the process. Therefore, it has two source points. The blue point is used when the specified condition is met. The red point indicates where the process should continue if the condition is not met. Steps that offer multiple conditions have multiple blue source points, one for each condition.

To learn how to connect steps together, refer to the [Connecting steps](#) topic.

4.10.2.3.2.2 Adding and configuring steps

An advanced workflow consists of a set of interconnected steps. The steps represent state of documents under the workflow, allow you to define automatic or user-made decisions and perform scripted actions.

To design an advanced workflow process, use the [workflow designer](#).

Adding steps

1. Click a step button on the toolbar and hold the mouse button.
2. Drag the step onto the grid.
3. Release the mouse button.

The step appears in the grid as in the following image.

Placing steps onto an existing connection

1. Click a step button on the toolbar and hold the mouse button.
2. Drag the step onto an existing connection between two steps.

The connection increases in thickness once it is in the correct position under your mouse pointer.

3. Release the mouse button.

The step automatically splits the connection and connects to the steps.

Note that you can only place steps directly from the toolbar to be able to split a connection.

Renaming steps

1. Double-click the step name in the graph.
2. Type in a new name.
3. Press **Enter** to save the new name.

Changing the action button text

You can change how buttons that enable users to move a document to different steps look. The default text is determined by the type of step that the button sends the document to.

The following image shows the action buttons available when editing a document that is in a **User choice** step, that has two choices. The first choice sends the document to the Published step, the second sends the document to a standard approval step named "PR Approval".

You can change the text for all steps that require user interaction and for choices, if they are available in the particular step.

1. Edit the step where you want the button to appear differently.
2. If the step you're editing allows defining cases, edit the case that you want to appear differently.
3. Fill one or both the following fields:
 - User action text
 - User action tooltip
4. Click  **Save**.

4.10.2.3.2.3 Connecting steps

To enable documents to be moved from one step to another, you must connect the steps first. Each step has one or more source points, which you can drag to another step to create a connection.

Creating a connection between steps

1. Click a source point and hold the mouse button.
2. Drag the source point to the step you want to connect to.

The step will be highlighted with a yellow glow around it, as shown in the following image.

3. Release the mouse button.

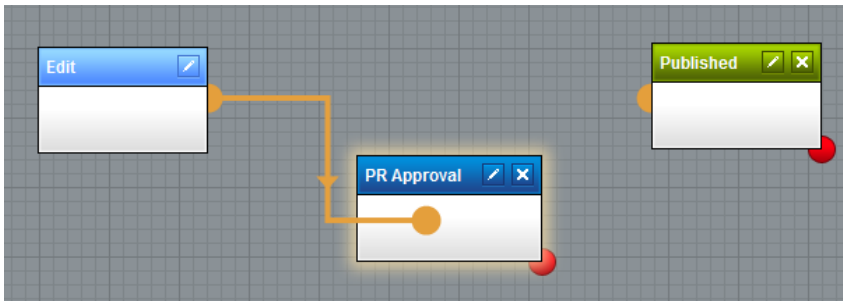

The resulting connection will look like the following image. After you create the connection, it stays selected, so you can immediately change it or delete it.

Changing a connection to a different step

1. Make sure you place the step that you want to change the connection to onto the grid.
2. Click the connection that you want to change and hold the mouse button.
3. Drag the connection to the step you want to change the connection to.

The target step highlights with a yellow glow around it.

4. Release the mouse button.

Deleting a connection

1. Click a connection to select it. The connection will change its color and increase thickness.
2. Click **✖ Delete** in the toolbar or press Delete on the keyboard. A confirmation message appears.
3. Click **OK** to confirm that you want to delete the connection.

4.10.2.3.2.4 Defining if/else conditions

Advanced workflow allows you to define conditions based on which the workflow process can be split into branches.

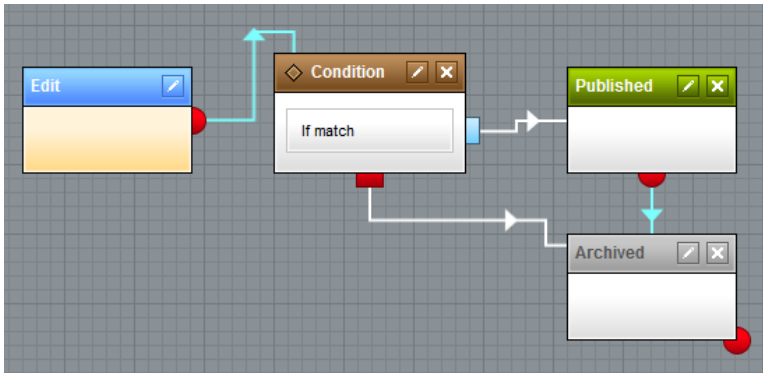

Adding a condition

1. Drag and drop the **Condition** step onto the grid.
2. Edit the step.

The **Workflow step properties** dialog opens.

3. Enter a [macro condition](#) into the **Condition** field. The condition must evaluate as true or false.
4. Click  **Save** and close the dialog.
5. [Connect](#) a step that will precede this step and connect both source points with other steps.

The following image shows an example result.

4.10.2.3.2.5 Defining user decisions

The **User choice** step type allow editors to make decisions.

Adding a user choice

1. Drag and drop the **User choice** step from the toolbar onto the grid.
2. Connect a step that will precede this step.
3. [Define choices](#).
4. [Connect](#) the choices with other steps.

Defining choices

1. Set the number of choices that you want users to have.
 - Click **Add choice** (plus sign) to add a new choice.
 - Click **Delete choice** (a cross next to the particular choice) to delete unneeded choices.
2. (Optional) Give names to the choices.
 - a. Double-click the choice name.
 - b. Type in a new name.
 - c. Press **Enter** to save the name.
3. (Optional) Configure additional parameters:
 - [User action button parameters](#)

- [Macro condition](#) based on which particular choices will be offered to users
- [Roles and users who can make particular choices](#)

4.10.2.3.2.6 Defining automatic decisions

Advanced workflow provides two types of steps that split a workflow process based on multiple conditions - **multi-choice** and **first win**.

Adding a multi-choice step

The multi-choice step allows you to define a set of cases that will be automatically evaluated when a document reaches the step. If a matching case is found, the workflow process continues to the step connected with the matching case's source point. If more than one matching case is found, the system lets the editor choose from the matching cases. If no matching case is found, the process continues through the *else* branch.

1. Drag and drop the Multi-choice step from the toolbar onto the grid.
2. [Connect](#) a step to the entry point (green).
3. Connect the *else* source point (red) with another step.
4. [Define cases](#).
5. Connect the cases' source points with other steps.

Adding a first win step

The first win step allows you to define a set of cases that will be automatically evaluated when a document reaches the step. If a matching case is found, the workflow process continues to the step connected with the matching case's source point. After the system finds the first matching case, it doesn't evaluate the other cases.

1. Drag and drop the First win step from the toolbar onto the grid.
2. [Connect](#) a step to the entry point (green).
3. Connect the *else* source point (red) with another step.
4. [Define cases](#).
5. Connect the cases' source points with other steps.

Defining cases

1. Set the number of cases that you want to evaluate.
 - Click **Add new case** (plus sign) to add a new case.
 - Click **Delete case** (a cross next to the particular case) to delete an unneeded case.
2. Give names to the cases.

- a. Double-click a case name.
 - b. Type in a new name.
 - c. Press **Enter** to save the name.
3. Define conditions that will be evaluated.
- a. Click **Edit case properties** (pencil icon).
 - b. Enter the condition into the **Condition** field.
4. (Optional) Configure additional parameters:
- [User action button parameters](#)
 - [Roles and users who will be able to move a document through particular cases](#)

4.10.2.3.2.7 Setting timeouts for automatic approving

Advanced workflow allows you to define a timeout, after which the system automatically moves a document in a certain step to the next step in the workflow process.

You have two options how to define a timeout:

- Setting a timeout in a step's properties
- Adding a Wait step into the process

When you set a timeout for a specific step, you can ensure that documents won't stay in the particular step longer than what is necessary. If nobody moves a document to another step before the time expires, the system moves it automatically. If you set a timeout for a step that creates multiple branches, you can choose the branch to continue in after the timeout expires. For all steps, you can also use a special timeout branch.

The Wait step acts as a stand-alone approval step, with one incoming and one outgoing connection. During the time a document is in this step, users can approve or reject it as they're used to. After the specified timeout expires, the workflow process automatically continues in the next step.

Setting a timeout in a step's properties

1. Edit (pencil icon) the step you want to set a timeout for.
2. Specify when you want to move to the next step on the **Timeout settings** panel. You have two options:
 - Select **Specific interval** and specify a time interval. The time starts running when documents get approved to the step.
 - Select **Specific day** and choose the date and optionally the time when you want documents to move to next step.
3. Select the step that you want the process to continue in after the timeout expires in the **Leave through** drop-down list. Note that besides the standard source points of the step you're editing, the drop-down list offers an extra timeout source point.
4. Click  **Save** and close the properties dialog.

5. If you selected the timeout source point in the **Leave through** drop-down list, [connect](#) another step to the source point.

Adding a wait step

1. Drag and drop the Wait step from the toolbar onto the grid.
2. [Connect](#) the step with a step that will precede it and with a step that will follow.
3. Open the step's properties by clicking the Edit (pencil icon) button.
4. Specify when you want to move to the next step. You have two options:
 - Select **Specific interval** and specify a time interval. The time starts running when documents get approved to the step.
 - Select **Specific day** and choose the date and optionally the time when you want documents to move to next step.
5. Click  **Save**.

4.10.2.3.2.8 Adding action steps

This chapter describes how to enhance a workflow process with configurable automatic actions.

Using **action steps**, you can automate tasks that editors would have normally had to do manually after a document reached a certain step. For example, you might want to move a document to another section of the site the moment it reaches the Archived step. Advanced workflow makes this possible with the **Move document** action step.

The following is a list of all available action steps:

- **Copy document** - copies a specified document to another location.
- **Delete document** - deletes a specified document.
- **Import translation** - imports translations of the document that are ready.
- **Link document** - creates a linked document.
- **Move document** - moves a specified document to another location.
- **Publish to Facebook** - automatically sends a predefined post on Facebook.
- **Publish to Twitter** - automatically sends a predefined post on Twitter.
- **Send for translation** - submits a document for translation using the specified translation service.
- **Send e-mails** - sends e-mails based on a specified e-mail template.
- **Send notification e-mails** - sends e-mails according to the e-mail settings defined for the step that immediately follows.
- **Set document property** - assigns a specified value to a document's property.
- **Synchronize document** - synchronizes a specified document to all enabled staging servers on the site the document is on.

For information how to add and configure a particular action step, refer to its respective section of this topic.

Manipulating documents within a workflow process

Copying a document

1. Drag and drop the **Copy document** step onto the grid.
2. Connect the step with a preceding step and optionally with a following step.
3. Edit the step (click the pencil icon).
4. (Optional) Specify the document that you want to copy using the following properties:
 - **Source site** - site that the document should be copied from. If you don't specify a site, the current site will be used.
 - **Source path** - path to the document that should be copied. If you don't specify a document, the current document (i.e., the one that reaches the step) will be used.
5. (Optional) Adjust the following properties:
 - **Include child documents** - copies also all child documents of the copied document.
 - **Copy permissions** - prevents resetting permissions for the document.
6. Specify the document under which you want to make the copy using the following properties:
 - (Optional) **Target site** - site that contains the parent document for the copy. If you don't specify a site, the current site will be used.
 - **Target path** - path to the parent document for the copy.
7. Click  **Save**.

Moving a document

1. Drag and drop the **Move document** step onto the grid.
2. Connect the step with a preceding step and optionally with a following step.
3. Edit the step (click the pencil icon).
4. (Optional) Specify the document that you want to move using the following properties:
 - **Source site** - site that the document should be moved from. If you don't specify a site, the current site will be used.
 - **Source path** - path to the document that should be moved. If you don't specify a document, the current document (i.e., the one that reaches the step) will be used.
5. (Optional) Adjust the following properties:
 - **Only child documents** - makes the action step move only the child documents of the specified document and not the document itself.
 - **Preserve permissions** - moves the document without resetting its permissions.
6. Specify the document under which you want to move the document:
 - (Optional) **Target site** - site that contains the parent document for the move. If you don't specify a

site, the current site will be used.

- **Target path** - path to the parent document for the move.

7. Click  **Save**.

Creating a linked document

1. Drag and drop the **Link document** step onto the grid.

2. Connect the step with a preceding step and optionally with a following step.

3. Edit the step (click the pencil icon).

4. (Optional) Specify the document that you want to link using the following properties:

- **Source site** - site that the document should be linked from. If you don't specify a site, the current site will be used.
- **Source path** - path to the document that you want to link. If you don't specify a document, the current document (i.e., the one that reaches the step) will be used.

5. (Optional) Adjust the following properties:

- **Include child documents** - creates also links to the child documents of the document.
- **Copy permissions** - copies the permissions for the document to the linked document.

6. Specify the document under which you want to create the link:

- (Optional) **Target site** - site that contains the parent document for the link. If you don't specify a site, the current site will be used.
- **Target path** - path to the parent document for the link.

7. Click  **Save**.

Deleting a document

1. Drag and drop the **Delete document** step onto the grid.

2. Connect the step with a preceding step and optionally with a following step.

3. Edit the step (click the pencil icon).

4. Specify the document that you want to delete using the following properties:

- **Source site** - site that the document should be copied from. If you don't specify a site, the current site will be used.
- **Source path** - path to the document that should be copied. If you don't specify a document, the current document (i.e., the one that reaches the step) will be used.

5. (Optional) Adjust the following deletion properties:

- **Destroy document** - deletes the document without a chance to restore it from the Recycle bin.
- **Delete all culture versions** - if the document is translated to more than one culture, the property

makes sure that all the culture versions will be deleted.

6. (Optional) Specify what to do with SKUs (stock keeping units, also known as products) assigned to the deleted documents in the **Assigned SKUs** section.

7. (Optional) Define a replacement document for the deleted document. The replacement document will be served when visitors request the deleted document's URL. You can also adjust the following related settings:

- **Copy all paths** - the replacement document will be accessible via all the deleted document's URLs instead of only the default one.
- **Include child documents** - the replacement document will be applied also to child documents of the deleted documents.

8. Click  **Save**.

Adjusting document properties

You can use the **Set document property** action step to modify properties of a document, including document type specific fields.

1. Drag and drop the **Set document property** step onto the grid.

2. Connect the step with a preceding step and optionally with a following step.

3. Edit the step (click the pencil icon).

4. Specify the document that you want to modify using the following attributes:

- **Source site** - site that the document is on. If you don't specify a site, the current site will be used.
- **Source path** - path to the document that you want modified. If you don't specify a document, the current document (i.e., the one that reaches the step) will be used.

5. Enter the name of the property that you want to modify. To learn what properties documents have, consult the **Kentico CMS API reference**. The properties are listed in tables *CMS_Tree* and *CMS_Document*.

6. Enter a new value for the property. Make sure the type of the data you entered matches the data type of the respective database column.

7. Click  **Save**.

Synchronizing a document to staging servers

You can use the **Synchronize document** action step to synchronize changes in a specified document to other servers using the [Staging](#) module.

1. Drag and drop the **Synchronize document** step onto the grid.

2. Connect the step with a preceding step and optionally with a following step.

3. Edit the step (click the pencil icon).

4. Specify the document that you want to synchronize using the following properties:
 - **Source site** - site that the document should be synchronized from. If you don't specify a site, the current site will be used.
 - **Source path** - path to the document that should be synchronized. If you don't specify a document, the current document (i.e., the one that reaches the step) will be used.
5. (Optional) Adjust the following properties:
 - **Include child documents** - synchronizes also all child documents of the synchronized document.
 - **Log update tasks** - forces synchronization of documents that don't have any tasks generated for them. If you turn this setting off, the system will check whether there are any staging tasks generated for the document and synchronize them.
6. Click  **Save**.

Configuring workflow to automatically post on Facebook and Twitter

1. Configure the settings in **Site Manager -> Settings -> Social networks -> Facebook/Twitter**. Please use the corresponding context help for details about how to acquire the required keys (all fields in the **General** section of the settings must be filled in).
2. Drag and drop the **Publish to Facebook** or **Publish to Twitter** step onto the grid.
3. Connect the step with a preceding and following step (the best position is before the Publish step).
4. Edit the workflow step (click the pencil icon).
5. Enter the **Text** of the message which will be automatically posted on Facebook/Twitter when going to the next step. You can click the provided button to open an editor with a macro selection control to define a message using macros.
 - For example, *Check out our new blog post at `www.mydomain.com{% GetDocumentURL() %}`.*
6. Click  **Save**.
7. Edit the previous step and set a **User action text** field to a suitable button text, for example, *Publish to Facebook*. The default button text, which will be visible to content editors, is **Submit for approval**.
8. Click  **Save**.

Configuring workflow to automatically send e-mails

Advanced workflow offers two ways of incorporating sending of e-mails into a workflow process:

- **Send e-mails action step** - sends an e-mail to specified recipients. You can choose an e-mail template or write the text of the e-mail from scratch.
- **Send notification e-mails action step** - sends e-mails associated with the next step to the next step's [workflow operators](#). You can use this step in combination with the [Wait step](#) or [timeout settings](#) to notify users that a document is waiting for their approval for a long time.

Adding a Send e-mails step

1. Drag and drop the **Send e-mails** step onto the grid.
2. Connect the step with a preceding and a following step.
3. Edit the step (click the pencil icon).
4. (Optional) Enter the sender's e-mail address. If you don't enter any address, the value from *Settings -> Content -> Content management -> Send workflow e-mails from* will be used.
5. Enter the recipients of the e-mail into the **To** field. Separate multiple recipients by semicolons.
6. Specify the text of the e-mail. You have two options:
 - **Select an e-mail template** or create a new one.
 - Select **HTML formatted text** in the **Based on** field and write the text into the text area that appears.
7. Click  **Save**.

Adding a Send notification e-mails step

1. Drag and drop the **Send notification e-mails** step onto the grid.
2. Connect the step with a step that will precede. This should typically be a Wait step or a step with a defined timeout.
3. Connect the step with a step that will follow. This is the step that the notification steps will be sent for.

Managing document translations within workflow

You can leverage the following two action steps to facilitate translation of documents within a workflow process:

- **Send for translation** - submits the current document for translation using the specified [translation service](#).
- **Import translation** - if the current document's translation is ready, imports the translated data into the respective culture version of the document.

You can find more information about translation services in the [Translation services](#) chapter.

Sending a document for translation

1. Drag and drop the **Send for translation** step onto the grid.
2. Connect the step with a preceding and optionally a following step.
3. Edit the step (click the pencil icon).
4. Set the following attributes:

- Translation service to use
- Target language
- Translate document attributes
- Priority
- Translation deadline
- Instructions for translators

5. Click  **Save**.

Importing translation

1. Drag and drop the **Import translation** step onto the grid.
2. Connect the step with a preceding and optionally a following step.

4.10.2.3.2.9 Creating custom action steps

Kentico CMS enables you to write your own actions that you will be able to incorporate into a workflow process. The procedure consists of two steps - writing the code of the action and registering the action into the system.

Writing actions

1. Create a new class and make it inherit from *CMS.DocumentEngine.DocumentWorkflowAction*.
2. Override the *Execute()* method from the base class.
3. Write the code that you want to be executed with the action into the *Execute* method's body.

Action steps can have parameters (settings) specified that you can use to modify their behavior. You can then enter the parameter's values when configuring an action step in the workflow designer. If you want your custom action step to rely on parameters, you can specify them on the **Actions** tab in **Site Manager -> Development -> Workflows**. To access the parameter's values in the code of an action, use the *GetResolvedParameter* method.

To access the data of the document that will go through the action step, use the *Node* object and its properties.

```
using System;
using CMS.DocumentEngine;
using CMS.CMSHelper;

public class CustomAction : DocumentWorkflowAction
{
    public override void Execute()
    {
        // Get the parameter value or assign a default value - an empty string
        string appendText = GetResolvedParameter("MyParameter", "");

        // Append the parameter value to the name of the document
    }
}
```

```
Node.DocumentName += appendText;

// Save the changes into the database
TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);
DocumentHelper.UpdateDocument(Node, tree);

    }
}
```

Registering actions in the system

1. Navigate to **Site Manager -> Workflows -> Actions** and click  **New action**.
2. Fill in the following mandatory fields:
 - **Display name** - name of the action step.
 - **Assembly name** - name of the library that contains the action's code.
 - **Class name** - full name of the class that contains the action's code.
3. (Optional) Select the module that the action will belong to.
4. (Optional) Define the action's parameters on the **Parameters** tab.
5. If you created the class in the App_Code folder (or Old_App_Code if you're using web application), you must [register it in code](#) to make sure the system loads it.

4.10.3 Defining macro rules

To speed up and simplify the process of defining conditions in workflows, you can prepare a set of macro rules. For information on how to create and manage Macro rules, refer to the [Macro conditions](#) chapter.

4.10.4 Configuring workflow operators

This topic shows how to allow or deny site editors to approve and reject documents in certain steps, or make certain choices.

Allowing users to approve or reject documents

Kentico CMS allows you to assign different users and roles to different steps, which in turn allows the specified users and roles to approve or reject documents in a particular step.

The only steps to which you cannot assign different users and roles are the default:

- **Edit step** - any user who is editing the document can move the document to the next step.
- **Published and Archived steps** - only users with the Manage workflow permission under the Content module, and Global administrators can move the document from these steps.

This procedure applies to both basic and advanced workflow.

To allow users to approve or reject a document in a certain step, follow these instructions:

1. Edit a step.

- If you're using basic workflow, click **Edit**  next to the step.
- If you're using advanced workflow, click **Edit** (pencil icon) in the step's header.

2. Switch to the **Security** tab.

3. Select which roles you want to be allowed to approve or reject the step. You have the following options:

- **None**
- **Only listed** - if you select this option, click **Add roles** to choose roles you want to add. If you don't add any roles, the result will be the same as if you select the **None** option.
- **All except listed** - if you select this option, click **Add roles** to choose roles you want to exclude. All other roles will be allowed to approve or reject the step.

4. Choose if you want to include or exclude individual users from the list of allowed operators.

- **No extra users**
- **Include the following users** - if you select this option, click **Add users** to choose users you want to add to the list of allowed users. If you don't add any users, the result will be the same as if you select the **No extra users** option.
- **Exclude the following users** - if you select this option, click **Add users** to choose users you don't want to be allowed to approve or reject documents in this step.

Allowing users to make a choice

When using workflow steps that allow multiple choices, you can allow or deny roles and users to send a document through certain branches of the workflow process. This feature is only available in advanced workflows, as basic workflows don't support multi-choice steps.

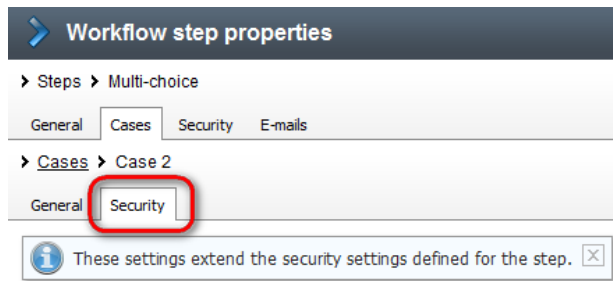

You can allow or deny making choices in the properties of the individual choices. By default, choices inherit security settings from the step they belong to. If you adjust security settings for a choice, these settings will be added to the settings defined for the step.

When determining whether the current user can make a choice, the system first checks security settings for the step. If the user is allowed to approve documents in the step, the system checks whether the user is allowed to make choices. If a user is not allowed to approve documents in the step, the user will not be able to make any choices that belong to the step, regardless of the choices' settings.

To allow or deny users to make choices, follow these steps:

1. Edit the choice by clicking the **Edit** (pencil icon) button next to it.

2. Switch to the Security tab.

3. Define roles, which can approve (select) the choice. You have the following options:

- **Use step settings**
- **Only listed** - when selected, you can add roles that you want the choice to be allowed for using the **Add roles** button.
- **All except listed** - when selected, all users in roles on all sites will be allowed the choice, except for users in those roles, which you select using the **Add roles** button.

4. Define additional users, who can approve (select) the choice. You have the following options:

- **Use step settings**
- **Include the following users** - if you select this option, click **Add users** to choose users you want to add to the list of allowed users. If you don't add any users, the result will be the same as if you select the **No extra users** option.
- **Exclude the following users** - if you select this option, click **Add users** to choose users you don't want to be allowed to approve or reject documents in this step.

4.10.5 Configuring e-mail notifications

When a document reaches a workflow step, the system can send out notification e-mail messages to those involved in the workflow process. This topic describes how to enable e-mail notifications [globally](#), [for a workflow](#) or for a [workflow step](#). The topic applies to both basic and advanced workflow.

The e-mails are based on e-mail templates. Kentico CMS comes with several default templates, which you can use without any additional configuration. If you want to create your own e-mail templates for workflow notifications, follow the instructions in the [Writing workflow e-mail templates](#) section.

The system sends notification e-mails according to the following rules:

- When a document reaches a step (except Edit, Published and Archived), the **Waiting for approval** e-mail is sent to users allowed to approve or reject the current (new) step.
- When someone approves a document, i.e., moves it from an approval step to the next step, the **Approved** e-mail is sent to the user who submitted the document for approval.
- When someone rejects a document, i.e., moves it to the previous step, the **Rejected** e-mail is sent to the user who submitted the document for approval.
- E-mails are never sent to users who performed the action that invoked the sending.

Enabling workflow e-mail notifications globally

1. Open **Site Manager** and navigate to **Settings -> Content -> Content management**.
2. Turn the **Send workflow e-mails** setting on.

4. Type an address into the **Send workflow e-mails from** setting. This address will appear to recipients as the sender of the e-mails.

5. Click  **Save**.

Configuring e-mail notifications for a workflow

1. Edit () the workflow and switch to the **E-mails** tab.

2. Set the **Send notification e-mails** setting to **Yes**. Alternatively, you can **Use site settings**. See [Enabling workflow e-mail notifications globally](#).

3. Check the box next to events that you want users to be notified about:

- **Send waiting for approval** - sends an e-mail when a document reaches an approval step (i.e. all steps except Edit, Published and Archived).
- **Send approved** - sends an e-mail when a document leaves an approval step in the direction towards the end of the workflow process.
- **Send rejected** - sends an e-mail when a document leaves a step in the direction towards the beginning of the workflow process.
- **Send published** - sends an e-mail when a document reaches a Published step.
- **Send archived** - sends an e-mail when a document reaches an Archived step.

4. (Optional) Select an e-mail template for events for which you don't want to use the default template.

- To bring up the list of available templates, click **Select**.
- To edit the currently selected template, click **Edit**.
- To create a new template, click **New**.
- To clear your template selection and revert back to the default template, click **Clear**.

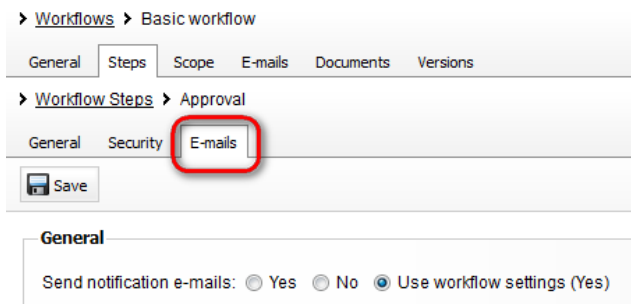

5. (Optional) Specify whether you want to notify users who are not involved in the process. This notification will be sent every time a document reaches a step that needs to be manually approved.

- a. Select users using the **Add users** button.
- b. (Optional) Select an e-mail template. Otherwise, the default template will be used.

6. Click  **Save**.

Configuring e-mail notifications for a particular workflow step

1. Edit the step and switch to the **E-mails** tab.

The screenshot shows the configuration interface for a workflow step. The breadcrumb path is "Workflows > Basic workflow". The "E-mails" tab is selected and highlighted with a red circle. Below the tabs, there is a "Save" button. The "General" section is visible, showing the "Send notification e-mails" setting with radio buttons for "Yes", "No", and "Use workflow settings (Yes)".

2. Set the **Send notification e-mails** setting to **Yes**. Alternatively, you can **Use workflow settings**. See [Configuring e-mail notifications for a workflow](#).
3. Choose events you want users to be notified about.
 - **Send waiting for approval** - sends an e-mail when a document reaches the step.
 - **Send approved** - sends an e-mail when a document leaves the step in the direction towards the end of the workflow process.
 - **Send rejected** - sends an e-mail when a document leaves the step in the direction towards the beginning of the workflow process.
4. (Optional) Select an e-mail template for events for which you don't want to use the default template.
 - To bring up the list of available templates, click **Select**.
 - To edit the currently selected template, click **Edit**.
 - To create a new template, click **New**.
 - To clear your template selection and revert back to the default template, click **Clear**.
5. Click  **Save**.

Writing workflow e-mail templates

1. Navigate to **Site Manager -> Administration -> E-mail templates**.
2. Select a site you want the template to be available on and click  **New template**.
3. Enter a name for the new template into the **Display name** field.
4. Choose **Workflow** from the **E-mail type** drop-down list. This ensures that you will have relevant macros available to insert into the template's text.
5. (Optional) Specify a sender, a recipient, copy and blind copy recipients and a subject (**From**, **Cc**, **Bcc** and **Subject** fields).
6. Write the text of the template. An e-mail template can have two formats - HTML and plain text. You should write the template text at least in the format that you use on your websites. By default, the system sends HTML e-mails. You can find out what your settings are in **Site Manager -> Settings -> System -> E-mails -> E-mail format**.

You can insert context-specific information into the template's text, such as the current step name, the link to edit the document, etc., by using macros. See the [Macros in workflow e-mail templates](#) section for a list of available macros.

7. Click  **Save**.

Macros in workflow e-mail templates

In e-mail templates of the **Workflow** type, you can use macros that hold information about the workflow and about the document that invoked sending the e-mail. The following list presents workflow-related macros that you can use:

- **ActionDefinition** - object that holds the parameters of the current step, if the current step is an action step.
- **ApplicationURL** - URL address of the application.
- **Comment** - comment that users can add when approving or rejecting documents.
- **CurrentStep** - object that holds data of the step the document is currently in.
- **CurrentUser** - object that holds data of the currently logged in user.
- **Document** - object that holds data of the document.
- **DocumentPreviewUrl** - address where anyone can view the latest version of the document as it would appear on the live site.
- **DocumentEditUrl** - address pointing to the page in CMS Desk, where editors can modify the document.
- **DocumentActionName** - name of the action that was performed with the document. The macro has four possible values.
 - Approve
 - Archive
 - Publish
 - Reject
- **OriginalStep** - object that holds data of the step the document was in before it was moved to the current step.
- **Workflow** - object that holds data of the workflow process.

Besides the listed macros, you can also use any other macro expression, as described in the [Macro expressions](#) chapter.

4.10.6 Using workflows

This topic describes how you can manage documents under a workflow.

Please note

The following tasks refer to buttons in CMS Desk by their default captions, i.e., Submit for approval, Approve, Reject. However, the caption texts are customizable, so you may not always see the same buttons in the user interface.

Submitting a document for approval

When a document is in the Edit step, you can submit it for approval to move it to the next step.

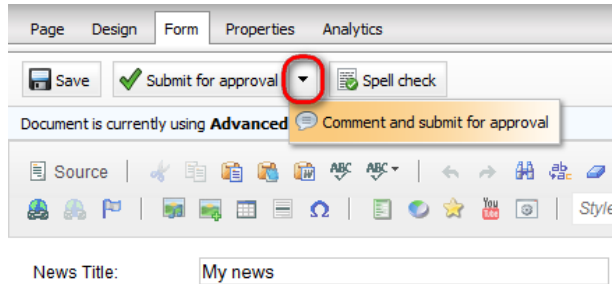

1. In **CMS Desk -> Content**, navigate to the document that you want to submit for approval.
2. Click **Submit for approval**. The document will be moved to the next step in the workflow process.

Submitting a document for approval with a comment.

To submit a document for approval and add a comment for the person who will be approving it, follow these steps:

1. In **CMS Desk -> Content**, navigate to the document that you want to submit for approval.

2. Click the arrow icon next to the **Submit for approval** button and then click **Comment and submit for approval**. A dialog box will pop up.

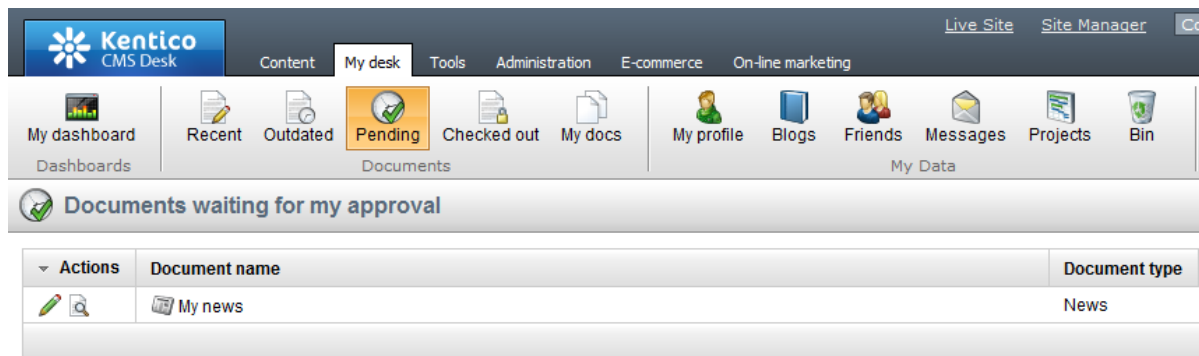

3. Enter your comment and click **Approve**. The document will be moved to the next step in the workflow process.

Viewing documents waiting for your approval

To view documents that are in an approval step, which you're an [operator](#) of, you can use the **Pending** page in **My desk**.

1. In **CMS Desk**, switch to **My desk**.
2. Switch to the **Pending** page.

3. (Optional) Click  **Navigate to document** to view the current version of the document on the live site.
4. (Optional) Click  **Edit** to make changes to the document and approve or reject it.

Approving and rejecting a document

When a document reaches a step that requires user interaction, you can approve the document, or, if settings of the step permit, reject it.

1. Navigate to the document you want to approve or reject.
2. (Optional) Make changes to the document.

- (Optional) Disable the **Send notification e-mails** checkbox to prevent the system from sending e-mails to users involved in the next step.
- Approve or reject the document. Note that if the step that follows is the **Published** step, the default text of the **Approve** button changes to **Publish**.
 - To approve the document without commenting on the approval, click **Approve**.
 - To reject the document without commenting on the rejection, click **Reject**.
 - To approve the document and make a comment, click the arrow icon next to the **Approve** button, then click **Comment and approve**. Enter your comment into the dialog box and click **Approve**.
 - To reject the document and make a comment, click the arrow icon next to the **Reject** button, then click **Comment and reject**. Enter your comment into the dialog box and click **Reject**.

Publishing a document

When a document is published, its most recent version will be made available to visitors on the live site. You can publish documents in one of the following ways:

- Manually moving through the whole workflow process
- Directly publishing if the current step allows it
- Publishing multiple document at once

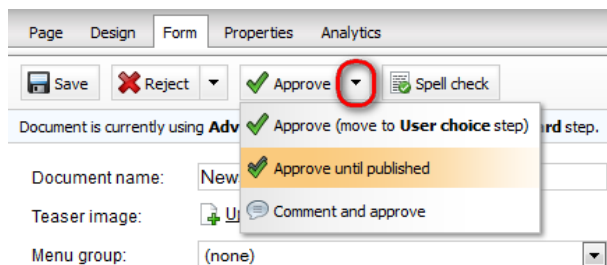

Manually moving through the whole workflow process

- Navigate to the document that you want to publish.
- Repeatedly **approve** the document until it is in the **Published** step.

Directly publishing a document

When a document is in a standard approval step and the settings of the step allow it, you can publish the document immediately. To do this, a direct approval path must exist in the workflow process. Direct publishing won't work if your workflow process contains user decisions.

- Navigate to the document that you want to publish.
- Click the arrow icon next to the **Approve** button, then click **Approve until published**.

Publishing multiple documents at once

You can publish entire sections of your website using the **List** mode.

1. Click **List** in the **View mode** section of the toolbar in **CMS Desk**.
2. Navigate to the document, which is a parent of the documents that you want to publish.
3. Select the documents you want to publish. You have two options:
 - Check the boxes next to documents you want to publish.
 - Select All documents in the drop-down list below the document list.
4. Select **Publish** in the drop-down list marked (*select an action*) and click **OK** to confirm. You will be redirected to a page with the list of documents to be published.
5. (Optional) Adjust the following settings:
 - **Publish also all child documents**
 - **Perform Undo check-out for checked out documents** - if checked, all documents that are checked out will be checked in and the changes made during the last check-out will be discarded.
6. Click **Yes** to start publishing the documents.

Archiving a document

When you archive a document, it stays in its location in the content tree, but disappears from the live site. You can archive documents in one of the following ways:

- Manually archiving
- Archiving multiple documents at once

Manually archiving a document

When a document reaches a step that is immediately followed by the Archived step, you can click the **Archive** button to archive the document.

Archiving multiple documents at once

You can archive entire sections of your website using the **List** mode.

1. Click **List** in the **View mode** section of the toolbar in **CMS Desk**.
2. Navigate to the document, which is a parent of the documents that you want to archive.
3. Select the documents you want to archive. You have two options:
 - Check the boxes next to documents you want to archive.
 - Select All documents in the drop-down list below the document list.
4. Select **Archive** in the drop-down list marked (*select an action*) and click **OK** to confirm. You will be redirected to a page with the list of documents to be archived.
5. (Optional) Adjust the following settings:

- **Archive also all child documents**
- **Perform Undo check-out for checked out documents** - if checked, all documents that are checked out will be checked in and the changes made during the last check-out will be discarded.

6. Click **Yes** to start archiving the documents.

Viewing a document's workflow history

For all documents under a workflow, the system records every move from one step to another. That means that you can review all the workflow actions that were performed on the document, the users who performed them and comments.

To view the workflow history of a document, select it in the content tree and navigate to **Properties -> Workflow**.

Restarting a workflow cycle

When a document reaches the Published or Archived step (whichever comes first), it completes its workflow cycle. That means that the document has gone all the way from the Edit step through the whole process to the final step. To start a new cycle and put the document back to the edit step, do the following:

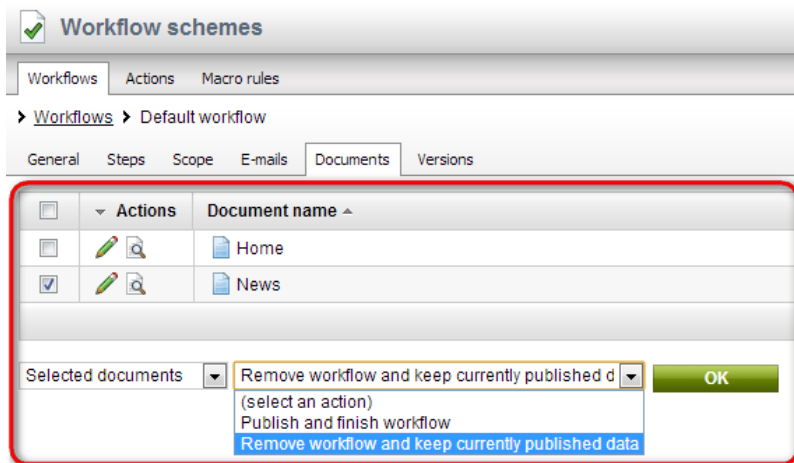

- If you're using basic workflow, open the document in CMS Desk, make changes to it and click  **Save**. This will create a new version of the document.
- If you're using advanced workflow, click  **New version**.

When you start a new cycle, the system re-evaluates workflow scopes that cover this document and chooses the workflow with the [highest priority](#).

Removing documents from a workflow

If you want to remove documents from an existing workflow. That is, documents that are under a workflow scope, and that are in any of the steps belonging to the workflow, then proceed as follows:

1. Navigate to **Site manager -> Development -> Workflows**.
2. **Edit**  the workflow from which you want to remove the documents.
3. Switch to the **Documents** tab.
4. Select the documents that you want to remove from the workflow.
5. Choose the **Remove workflow and keep currently published data** option in the second drop-down list under the list of documents.

6. Click **OK**.

Note that this action does not remove the document from under the workflow scope. It may become part of the workflow again when modified.

4.10.7 Versioning

The versioning functionality in workflows stores document versions as documents are edited. Versioning enables viewing and comparing document versions and rolling documents back to previous versions.

Versioning is closely tied to the workflow module. To use versioning on documents, you need to apply a workflow on them. If you don't want documents to go through any workflow process and use versioning at the same time, refer to the [Versioning without workflow](#) topic.

Version numbering

Every document version is identified by a version number. By default, the system assigns numbers to versions automatically according to the following rules:

- When you create a document, it gets version number **0.1**.
- When you save a document, a minor version is created and the number after the period increases. Example: **0.2**, **0.3**, etc.
- When you publish a document, the latest minor version gets promoted to a major version. The number before the period increases and the number after the period resets to zero. Example: **1.0**, **2.0**, etc.

If you [use content locking](#), you can disable the automatic numbering in **Settings -> Content -> Content management**, by turning off the **Use automatic version numbering** setting.

Viewing and comparing document versions

1. Navigate to the document that you want to view versions of.
2. Switch to **Properties -> Versions**.
3. Click  **View** next to the version you want to view. The **Document version** window opens.

4. Select a version for comparison using the **Compare to** drop-down list. When comparing document versions, the older version appears on the left.

Rolling back versions

1. Navigate to the document that you want to view versions of and switch to **Properties -> Versions**.
2. Click  **Roll back** next to a version. The system will make a copy of the version and mark the copy as the latest version.

4.10.7.1 Content locking

Content locking allows content editors to lock a document for editing, so that other editors cannot modify the document at the same time.

Content locking is based on the check-in/check-out principle. The following is an example of operations in the document life cycle when content locking is used:

1. A user creates a new document and saves it. The system automatically checks it out (locks it), so that other users cannot edit it.
2. The user finishes the changes, checks in the document and submits it for approval.
3. A reviewer checks out the document and makes changes, then checks it in and approves it.

Enabling content locking

You can enable content locking for versioned documents at two levels:

- Globally
- For a particular workflow

To enable content locking **globally** for all sites or a particular site, navigate to **Site Manager -> Settings -> Content -> Content management** and turn on the **Use check-in/check-out** setting.

To enable content locking **for a particular workflow**, edit it and configure the **Use check-in/check-out** property.

Checking documents in and out

To check out documents when editing them, use the  **Check out** button. When you check out a document, you can then check it in with the  **Check in** button.

To discard the changes you made while the document was checked out, click  **Undo check-out**. The document will revert back to the latest version before the check-out.

Changing version numbers and commenting on versions

You can use the **Check in/Check out/Undo check-out** buttons on the **Properties -> Versions** page. This page enables you to specify custom version numbers and comments for each version when you check in the document.

You need to **check in** the document before submitting for approval.
Document is currently using **Default workflow** workflow and is in **Edit** step.

The document is currently checked out.

Checking in any document

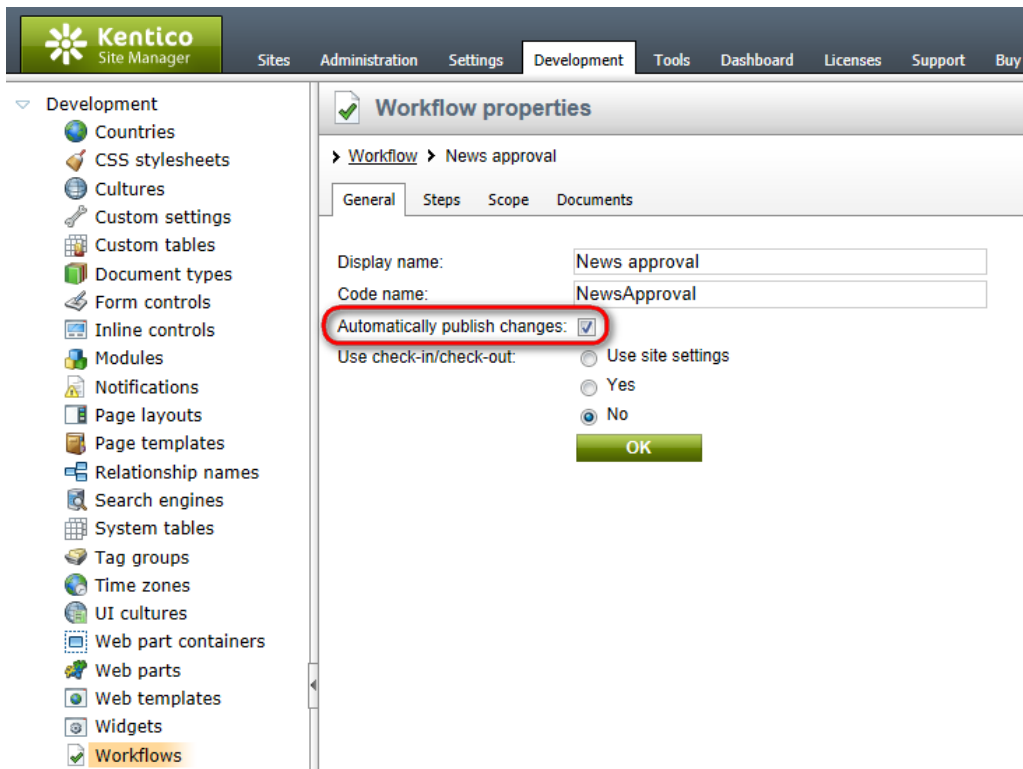

Users to whom the **Check in any document** permission was granted can check in any document, even if they haven't checked out the document. This permission can be set in **Site Manager -> Administration -> Permissions**, in the permission matrix under **Modules -> CMS Content**.

However, this check-in can only be performed from the **Properties -> Versions** tab of the selected document, by clicking either the **Check in** or the **Undo check-out** button.

4.10.7.2 Versioning without workflow

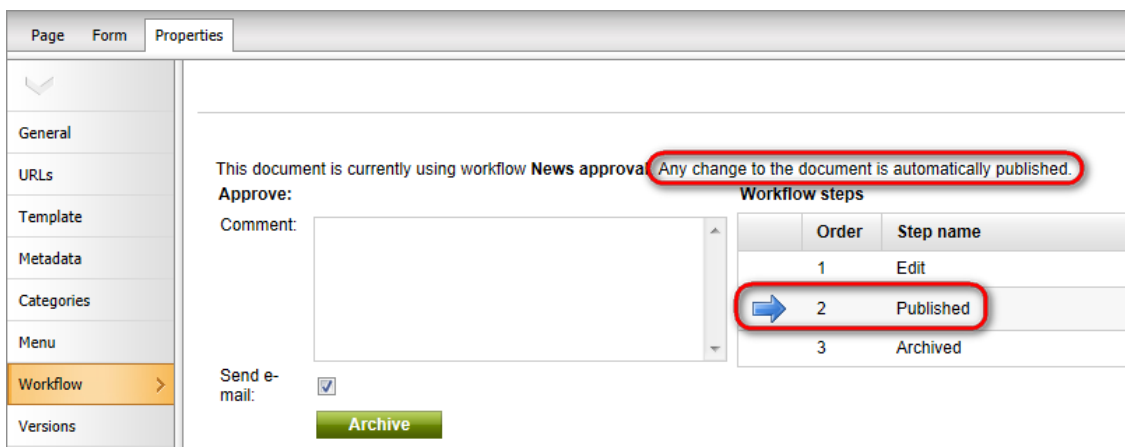

It is possible to use versioning without actually using any workflow steps. In other words, it is possible to have a new document version created whenever a document is modified and saved.

To enable versioning without workflow, you only need to enable the **Automatically publish changes** option either when creating a new workflow, or when editing (✎) a workflow on its **General** tab. With this option enabled, custom steps can't be created on the **Steps** tab. You only need to define appropriate scope(s) so that the workflow affects the required documents.

From the end-user point of view, editing a document using versioning without workflow is the same as if the document was using no workflow at all. The **Submit to approval**, **Approve** and **Reject** buttons are not displayed on the document editing form - there is just the standard **Save** button present.

On the **Properties -> Workflow** tab, you can recognize a document using versioning without workflow by the "Any change to the document is automatically published." sentence, as highlighted below. You may also notice that the document remains in the **Published** step all the time until it gets archived.

4.10.8 Workflows internals and API

4.10.8.1 Overview

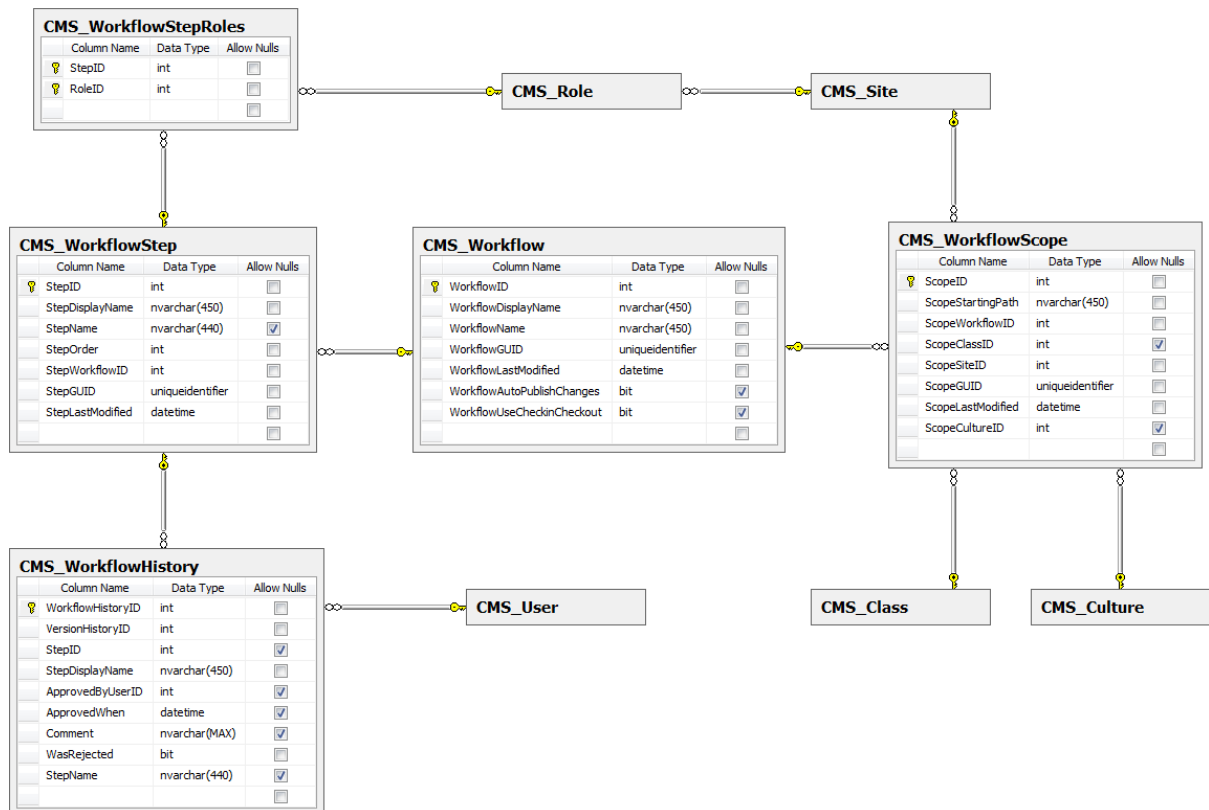

In this chapter, you will learn which [database tables](#) and [API classes](#) are used by workflow and versioning. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

4.10.8.2 Database tables

The following database tables are used by workflows:

- **CMS_Workflow** - contains records representing defined workflows.
- **CMS_WorkflowStep** - contains records representing defined workflow steps of all defined workflows.
- **CMS_WorkflowScope** - contains records representing defined workflow scopes.
- **CMS_WorkflowStepRoles** - contains relationships between defined workflow steps and roles whose members can approve documents in these steps.
- **CMS_WorkflowHistory** - contains workflow history records, i.e. the information stored when a document is moved to a different workflow step.

4.10.8.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes used by workflows can be found in the **CMS.WorkflowEngine** namespace.

CMS_Workflow table API:

- **WorkflowInfo** - represents one workflow object.
- **WorkflowInfoProvider** - provides management functionality for workflows.

CMS_WorkflowStep table API:

- **WorkflowStepInfo** - represents one workflow step object.
- **WorkflowStepInfoProvider** - provides management functionality for workflow steps.

CMS_WorkflowScope table API:

- **WorkflowScopeInfo** - represents one workflow scope object.
- **WorkflowScopeInfoProvider** - provides management functionality for workflow scopes.

4.10.8.4 API examples

4.10.8.4.1 Overview

These topics show examples of how the API for workflows can be used:

- [Managing workflows](#)
- [Managing workflow steps](#)
- [Managing workflow scopes](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Development\Workflows\Default.aspx.cs**.

The workflows API examples use the following namespaces:

```
using System;
```

```
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.WorkflowEngine;
using CMS.SettingsProvider;
```

4.10.8.4.2 Managing workflows

The following example creates a workflow.

```
private bool CreateWorkflow()
{
    // Create new workflow object
    WorkflowInfo newWorkflow = new WorkflowInfo();

    // Set the properties
    newWorkflow.WorkflowDisplayName = "My new workflow";
    newWorkflow.WorkflowName = "MyNewWorkflow";

    // Save the workflow
    WorkflowInfoProvider.SetWorkflowInfo(newWorkflow);

    // Create the three default workflow steps
    WorkflowStepInfoProvider.CreateDefaultWorkflowSteps(newWorkflow.WorkflowID);

    return true;
}
```

The following example gets and updates the workflow created by the code example above.

```
private bool GetAndUpdateWorkflow()
{
    // Get the workflow
    WorkflowInfo updateWorkflow = WorkflowInfoProvider.GetWorkflowInfo(
        "MyNewWorkflow");
    if (updateWorkflow != null)
    {
        // Update the properties
        updateWorkflow.WorkflowDisplayName =
            updateWorkflow.WorkflowDisplayName.ToLower();

        // Save the changes
        WorkflowInfoProvider.SetWorkflowInfo(updateWorkflow);

        return true;
    }
}
```

```
    return false;
}
```

The following example gets and bulk updates workflows matching the specified WHERE condition.

```
private bool GetAndBulkUpdateWorkflows()
{
    // Prepare the parameters
    string where = "WorkflowName LIKE N'MyNewWorkflow%'";

    // Get the data
    DataSet workflows = WorkflowInfoProvider.GetWorkflows(where, null, 0, null);
    if (!DataHelper.DataSourceIsEmpty(workflows))
    {
        // Loop through the individual items
        foreach (DataRow workflowDr in workflows.Tables[0].Rows)
        {
            // Create object from DataRow
            WorkflowInfo modifyWorkflow = new WorkflowInfo(workflowDr);

            // Update the properties
            modifyWorkflow.WorkflowDisplayName =
            modifyWorkflow.WorkflowDisplayName.ToUpper();

            // Save the changes
            WorkflowInfoProvider.SetWorkflowInfo(modifyWorkflow);
        }

        return true;
    }

    return false;
}
```

The following example deletes the workflow created by the first example on this page.

```
private bool DeleteWorkflow()
{
    // Get the workflow
    WorkflowInfo deleteWorkflow = WorkflowInfoProvider.GetWorkflowInfo
    ("MyNewWorkflow");

    // Delete the workflow
    WorkflowInfoProvider.DeleteWorkflowInfo(deleteWorkflow);

    return (deleteWorkflow != null);
}
```

4.10.8.4.3 Managing workflow steps

The following example creates a workflow step.

```
private bool CreateWorkflowStep()
{
    // Get the workflow
    WorkflowInfo myWorkflow = WorkflowInfoProvider.GetWorkflowInfo
("MyNewWorkflow");
    if (myWorkflow != null)
    {
        // Create new workflow step object
        WorkflowStepInfo newStep = new WorkflowStepInfo();

        // Set the properties
        newStep.StepWorkflowID = myWorkflow.WorkflowID;
        newStep.StepName = "MyNewWorkflowStep";
        newStep.StepDisplayName = "My new workflow step";
        newStep.StepOrder = 1;

        // Save the step into database
        WorkflowStepInfoProvider.SetWorkflowStepInfo(newStep);

        // Ensure correct step order
        WorkflowStepInfoProvider.InitStepOrders(newStep.StepWorkflowID);

        return true;
    }

    return false;
}
```

The following example adds a role to the workflow step created by the code example above. Members of the added role will be able to approve documents in the step.

```
private bool AddRoleToStep()
{
    // Get the workflow
    WorkflowInfo workflow = WorkflowInfoProvider.GetWorkflowInfo("MyNewWorkflow");

    if (workflow != null)
    {
        // Get the custom step
        WorkflowStepInfo step = WorkflowStepInfoProvider.GetWorkflowStepInfo
("MyNewWorkflowStep", workflow.WorkflowID);

        if (step != null)
        {
            // Get the role to be assigned to the step
            RoleInfo role = RoleInfoProvider.GetRoleInfo("CMSEditor",
CMSContext.CurrentSiteID);

```

```
        if (role != null)
        {
            // Make the assignment
            WorkflowStepRoleInfoProvider.AddRoleToWorkflowStep(step.StepID,
role.RoleID);

            return true;
        }
        else
        {
            // Role was not found
            apiAddRoleToStep.ErrorMessage = "Role 'CMS Editors' was not
found.";
        }
    }
    else
    {
        // Step was not found
        apiAddRoleToStep.ErrorMessage = "Step 'My new workflow step' was not
found.";
    }
}

return false;
}
```

The following example removes the role added by the above code example from the workflow step.

```
bool RemoveRoleFromStep()
{
    // Get the workflow
    WorkflowInfo workflow = WorkflowInfoProvider.GetWorkflowInfo("MyNewWorkflow");

    if (workflow != null)
    {
        // Get the custom step
        WorkflowStepInfo step = WorkflowStepInfoProvider.GetWorkflowStepInfo
("MyNewWorkflowStep", workflow.WorkflowID);

        if (step != null)
        {
            // Get the role to be assigned to the step
            RoleInfo role = RoleInfoProvider.GetRoleInfo("CMSEditor",
CMSContext.CurrentSiteID);

            if (role != null)
            {
                // Get the step - role relationship
                WorkflowStepRoleInfo stepRoleInfo =
WorkflowStepRoleInfoProvider.GetWorkflowStepRoleInfo(step.StepID, role.RoleID);

                if (stepRoleInfo != null)
```

```
        {
            // Remove the assignment
            WorkflowStepRoleInfoProvider.RemoveRoleFromWorkflowStep
(step.StepID, role.RoleID);

            return true;
        }
        else
        {
            // The role is not assigned to the step
            apiRemoveRoleFromStep.ErrorMessage = "The 'CMS Editors' role
is not assigned to the step.";
        }
    }
    else
    {
        // The role was not found
        apiRemoveRoleFromStep.ErrorMessage = "The role 'CMS Editors' was
not found.";
    }
}
else
{
    // The step was not found
    apiRemoveRoleFromStep.ErrorMessage = "The step 'My new workflow step'
was not found.";
}
}

return false;
}
```

The following example deletes the workflow step created by the first example on this page.

```
private bool DeleteWorkflowStep()
{
    // Get the workflow
    WorkflowInfo workflow = WorkflowInfoProvider.GetWorkflowInfo("MyNewWorkflow");

    if (workflow != null)
    {
        // Get the custom step
        WorkflowStepInfo deleteStep = WorkflowStepInfoProvider.GetWorkflowStepInfo
("MyNewWorkflowStep", workflow.WorkflowID);

        if (deleteStep != null)
        {
            // Remove the step
            WorkflowStepInfoProvider.DeleteWorkflowStepInfo(deleteStep);
            return true;
        }
    }
}
```

```
    return false;
}
```

4.10.8.4.4 Managing workflow scopes

The following example creates a workflow scope.

```
private bool CreateWorkflowScope()
{
    // Get the workflow
    WorkflowInfo workflow = WorkflowInfoProvider.GetWorkflowInfo("MyNewWorkflow");

    if (workflow != null)
    {
        // Create new workflow scope object
        WorkflowScopeInfo newScope = new WorkflowScopeInfo();

        // Get the site default culture from settings
        string cultureCode = SettingsKeyProvider.GetStringValue
(CMSContext.CurrentSiteName + ".CMSDefaultCultureCode");
        CultureInfo culture = CultureInfoProvider.GetCultureInfo(cultureCode);

        // Get root document type class ID
        int classID = DataClassInfoProvider.GetDataClass("CMS.Root").ClassID;

        // Set the properties
        newScope.ScopeStartingPath = "/";
        newScope.ScopeCultureID = culture.CultureID;
        newScope.ScopeClassID = classID;

        newScope.ScopeWorkflowID = workflow.WorkflowID;
        newScope.ScopeSiteID = CMSContext.CurrentSiteID;

        // Save the workflow scope
        WorkflowScopeInfoProvider.SetWorkflowScopeInfo(newScope);

        return true;
    }

    return false;
}
```

The following example gets and updates the workflow scope created by the code example above.

```
private bool GetAndUpdateWorkflowScope()
{
    // Get the workflow
    WorkflowInfo workflow = WorkflowInfoProvider.GetWorkflowInfo("MyNewWorkflow");
```

```
if (workflow != null)
{
    // Get the workflow's scopes
    DataSet scopes = WorkflowScopeInfoProvider.GetWorkflowScopes
(workflow.WorkflowID);

    if (!DataHelper.DataSourceIsEmpty(scopes))
    {
        // Create the scope info object
        WorkflowScopeInfo updateScope = new WorkflowScopeInfo(scopes.Tables[0]
.Rows[0]);

        // Update the properties - the scope will include all cultures and
document types
        updateScope.ScopeCultureID = 0;
        updateScope.ScopeClassID = 0;

        // Save the changes
        WorkflowScopeInfoProvider.SetWorkflowScopeInfo(updateScope);

        return true;
    }
    else
    {
        // No scope was found
        apiGetAndUpdateWorkflowScope.ErrorMessage = "The scope was not
found.";
    }
}

return false;
}
```

The following example deletes the workflow scope created by the first example on this page.

```
private bool DeleteWorkflowScope()
{
    // Get the workflow
    WorkflowInfo workflow = WorkflowInfoProvider.GetWorkflowInfo("MyNewWorkflow");

    if (workflow != null)
    {
        // Get the workflow's scopes
        DataSet scopes = WorkflowScopeInfoProvider.GetWorkflowScopes
(workflow.WorkflowID);

        if (!DataHelper.DataSourceIsEmpty(scopes))
        {
            // Create the scope info object
            WorkflowScopeInfo deleteScope = new WorkflowScopeInfo(scopes.Tables[0]
.Rows[0]);
        }
    }
}
```

```
// Delete the workflow scope
WorkflowScopeInfoProvider.DeleteWorkflowScopeInfo(deleteScope);

return true;
}
else
{
    // No scope was found
    apiDeleteWorkflowScope.ErrorMessage = "The scope was not found.";
}
}

return false;
}
```

4.11 Validators

4.11.1 Overview

Kentico CMS comes with built-in page validation features. The main advantage of these built-in validators over standard web based validation services is that your pages needn't be live to get validated. All that is required is to have an Internet connection. This way, you can validate pages before you publish them and ensure that they are valid before making them available to the general public.

Validation can be performed on the **Validate** tab in **CMS Desk -> Content**, which is only available in **Live site** and **Preview** modes. The validators always validate the version of the document that is displayed in the currently selected view mode. Three types of validators are currently available on the tab:

- [HTML validator](#) - checks page output code validity against the (X)HTML standard version declared in page code.
- [CSS validator](#) - checks validity of CSS styles used by the page against the CSS 2.1 standard.
- [Link checker](#) - checks availability of links on a page.
- [Accessibility validator](#) - checks accessibility of the page.

There are situations when the validators may not be available: the **Validate** tab is not accessible in **Live site** mode if the document is not published and in **Preview** mode on multilingual websites if the document does not have its version in the currently selected language.

The **Validate** tab and its sub-tabs can also be hidden to members of certain roles by means of [UI personalization](#). The **Content** module has the **Validation**, **HTML**, **CSS**, **Link checker** and **Accessibility validator** UI elements. These elements represent the respective tabs, while access to the tabs can be restricted by allowing access to the UI elements only to members of specified roles. See [Development -> Membership -> UI personalization -> UI profile configuration](#) for more details.

4.11.2 HTML validator

On the **Validate -> HTML** tab, you can perform validation of output HTML code of the page currently selected in the content tree, specifically of its version displayed in the currently selected view mode (**Preview** or **Live site**). Please note that even if you navigate to some other page in the preview or live

site mode using links on displayed pages and then switch to the **Validate** tab, actions performed on this tab will still be related to the page selected in the content tree.

Validation is always performed against the version of HTML declared in the validated code.

**Important!**

Your data is sent to an external 3rd party validation service. If you have sensitive, non-public content, we recommend that you use some other way to validate your website.

The following actions are available in the top row:

-  **Validate** - performs HTML validation of the page currently selected in the content tree and displays validation results below.
-  **View source** - opens a new pop-up window where source code of the page selected in the content tree will be displayed.

The following actions are only available after performing validation which showed that the document is not valid:

- **Show results in new window** - displays validation results in a new window.
- **Export to various formats** - After clicking the  icon in the header of the **Actions** column, a context menu is displayed, offering options for [export of listed data](#) to various types of files.

When validity issues are found in the page's output HTML code, they are listed in a grid in the main area. You can see the following information about each issue:

- **Line** - line of the HTML code on which the issue appears.
- **Column** - column of the HTML code (i.e. number of characters from the beginning of the respective line) where the issue appears.
- **Error message** - message describing the validity issue.
- **Error explanation** - detailed explanation of the validity issue.
- **Source** - extract of the part of the code where the validity issue appears.

Line	Column	Error message	Error explanation	Source
10	24	there is no attribute "ID"	<p>You have used the attribute named above in your document, but the document type you are using does not support that attribute for this element. This error is often caused by incorrect use of the "Strict" document type with a document that uses frames (e.g. you must use the "Transitional" document type to get the "target" attribute), or by using vendor proprietary extensions such as "marginheight" (this is usually fixed by using CSS to achieve the desired effect instead).</p> <p>This error may also result if the element itself is not supported in the document type you are using, as an undefined element will have no supported attributes; in this case, see the element-undefined error message for further information.</p> <p>How to fix: check the spelling and case of the element and attribute, (Remember XHTML is all lower-case) and/or check that they are both allowed in the chosen document type, and/or use CSS instead of this attribute. If you received this error when using the <embed> element to incorporate flash media in a Web page, see the FAQ item on valid flash.</p>	<cc1:CMSWebPartZone ID="zoneTop" runat="server" />

4.11.3 CSS validator

The system allows you to validate the CSS style definitions used on pages against the [CSS 2.1 standard](#). The validator checks styles from:

- Linked [CSS stylesheets](#)
- Styles declared in the head section of the page code

Inline styles declared as attributes of individual HTML elements are not validated.

To validate a page's CSS:

Warning: During validation, your data is sent to an external 3rd party validation service. If you have sensitive, non-public content, we recommend using other types of validation.

1. Go to **CMS Desk -> Content**.
2. Select the page in the content tree.
3. Switch to **Preview** or **Live site** mode.
4. Open the **Validate -> CSS** tab.
5. Click **Validate**.

If the validator finds invalid style definitions, the page displays a list of all detected issues. You can see the following information for each issue:

- **Line** - the line number in the CSS stylesheet (or approximate line of the HTML source code) where the issue was found.
- **Context** - name of the CSS class that contains the issue.
- **Error message** - message explaining the issue.
- **Source** - if the issue was found in a stylesheet, the column displays a link to the stylesheet. If you have permissions to edit the stylesheet, the link opens an editing dialog.

Notes:

- We recommend waiting at least 30 seconds between validation requests. If you submit a page for validation multiple times within a short interval, the validation service may temporarily block your page's URL.
- If you navigate to another page in preview mode using links on the displayed pages, and then switch to the **Validate** tab, the system still validates the page selected in the content tree.

The screenshot shows the Kentico CMS interface with the 'Validate' tab active. The main content area displays a warning: 'Document contains invalid CSS definitions.' Below this, a table lists the validation results:

Line	Context	Error message	Source
14	.ui-helper-hidden-accessible	Value Error : clip (http://www.w3.org/TR/CSS21/visufx.html#propdef-clip) Invalid separator in shape definition. It must be a comma. .	/KenticoCMS4497-16444/CMSPages/GetResource.ashx?stylesheet=/KenticoCMS4497-16444/CMSScripts/jquery/jquery-ui.css
22	.ui-helper-zfix	Property opacity doesn't exist in CSS level 2.1 but exists in [css3] :	/KenticoCMS4497-16444/CMSPages/GetResource.ashx?stylesheet=/KenticoCMS4497-16444/CMSScripts/jquery/jquery-ui.css
22	.ui-helper-zfix	Parse Error	/KenticoCMS4497-16444/CMSPages/GetResource.ashx?stylesheet=/KenticoCMS4497-16444/CMSScripts/jquery/jquery-ui.css
30	.OnSiteSlider	Property box-shadow doesn't exist in CSS level 2.1 but exists in [css3] :	/KenticoCMS4497-16444/CMSPages/GetResource.ashx?stylesheet=/KenticoCMS4497-16444/App_Themes/Design/OnSiteEdit.css

80	.ui-priority-secondary, .ui-widget-content, .ui-priority-secondary, .ui-widget-header, .ui-priority-secondary	Parse Error	/KenticoCMS4497-16444/CMSPages/GetResource.ashx?stylesheet=/KenticoCMS4497-16444/CMSScripts/jquery/jquery-ui.css

4.11.4 Link checker

On the **Validate** -> **Link checker** tab, you can perform a check for broken links on the page selected in the content tree, specifically of its version displayed in the currently selected view mode (**Preview** or

Live site). Please note that even if you navigate to some other page in the preview or live site mode using links on displayed pages and then switch to the **Validate** tab, actions performed on this tab will still be related to the page selected in the content tree.

Only links within **<a>**, ****, **<script>** and **<link>** elements are checked by the link checker.

The following actions are available in the top row:

-  **Validate** - performs validation of links on the page currently selected in the content tree and displays validation results below.
-  **View source** - opens a new pop-up window where source code of the page selected in the content tree will be displayed.

The following actions are only available after performing validation which showed that the document contains broken links:

- **Show results in new window** - displays validation results in a new window.
- **Export to various formats** - After clicking the  icon in the header of the **Actions** column, a context menu is displayed, offering options for [export of listed data](#) to various types of files.

If some broken links are found on the page, a grid with these links is displayed in the main area. You can see the following information about each broken link:

- **Status code** - HTML status code returned when the link is accessed. Statuses of redirected links are shown for each page within the redirection (e.g. 301 -> 200, 301 -> 301 -> 404, etc.).
- **Type** - W is shown when the link is redirected to a different location (301 status code), E is shown when the link is broken (404 status code).
- **Error message** - message providing details about the link issue.
- **URL** - URL to which the link is pointing.
- **Request time** - time elapsed between sending a request to the link and receiving a response.

The screenshot displays the Kentico CMS 7.0 interface. The top navigation bar includes 'Live Site', 'Site Manager', and 'Corporate Site' tabs. Below the navigation bar is a toolbar with 'New', 'Delete', 'Copy', 'Move', 'Up', 'Down', 'Edit', 'Preview', 'Live site', 'List', and 'Search' buttons. The main content area shows a content tree on the left and a validation results table on the right. The table has columns for Status code, Type, Error message, URL, and Request time. Three rows of results are shown, all with a status of 'Temporary Redirection -> OK' and a type of 'W'.

Status code	Type	Error message	URL	Request time
Temporary Redirection -> OK	W	/KenticoCMS4497-16444/cmsdesk/default.aspx?username=administrator&nodeid=4 redirects to http://localhost/KenticoCMS4497-16444/CMSPages/logon.aspx?ReturnUrl=%2fKenticoCMS4497-16444%2fcmsdesk%2fdefault.aspx%3fusername%3dadministrator%26nodeid%3d4&username=administrator&nodeid=4 OK	http://localhost/KenticoCMS4497-16444/CMSPages/logon.aspx?ReturnUrl=%2fKenticoCMS4497-16444%2fcmsdesk%2fdefault.aspx%3fusername%3dadministrator%26nodeid%3d4&username=administrator&nodeid=4	141 ms
Temporary Redirection -> OK	W	/KenticoCMS4497-16444/cmsitemanager/default.aspx?username=administrator redirects to http://localhost/KenticoCMS4497-16444/CMSPages/logon.aspx?ReturnUrl=%2fKenticoCMS4497-16444%2fcmsitemanager%2fdefault.aspx%3fusername%3dadministrator&username=administrator OK	http://localhost/KenticoCMS4497-16444/CMSPages/logon.aspx?ReturnUrl=%2fKenticoCMS4497-16444%2fcmsitemanager%2fdefault.aspx%3fusername%3dadministrator&username=administrator	8 ms
Temporary Redirection -> OK	W	/KenticoCMS4497-16444/SpecialPages/User/My-account.aspx redirects to http://localhost/KenticoCMS4497-16444/SpecialPages/Logon-page.aspx?ReturnUrl=%2fKenticoCMS4497-16444%2fSpecialPages%2fUser%2fMy-account.aspx OK	http://localhost/KenticoCMS4497-16444/SpecialPages/Logon-page.aspx?ReturnUrl=%2fKenticoCMS4497-16444%2fSpecialPages%2fUser%2fMy-account.aspx	739 ms

4.11.5 Accessibility validator

On the **Validate -> Accessibility** tab, you can perform accessibility validation of the page currently selected in the content tree, specifically of its version displayed in the currently selected view mode (**Preview** or **Live site**). Please note that even if you navigate to some other page in the preview or live site mode using links on displayed pages and switch to the **Validate** tab, actions performed on this tab will still be related to the page selected in the content tree.

Important!

Your data is sent to an external 3rd party validation service. If you have sensitive, non-public content, we recommend that you use some other way to validate your website.

You can perform the validation against several standards:

- BITV 1.0 (Level 2)
- [U.S. Section 508](#)
- Stanca Act
- [WCAG 1.0 \(Level A\)](#)
- WCAG 1.0 (Level AA)
- WCAG 1.0 (Level AAA)
- [WCAG 2.0 \(Level A\)](#)
- WCAG 2.0 (Level AA)
- WCAG 2.0 (Level AAA)

You can choose the standard using the **Standard** drop-down list.

Make sure to use the HTML validator, CSS validator and Link checker before you use the accessibility validator to ensure valid markup.

The following actions are available in the top row:

-  **Validate** - performs accessibility validation on the page currently selected in the content tree and displays validation results below.
-  **View source** - opens a new pop-up window displaying the source code of the page selected in the content tree.

The following actions are only available after performing validation which showed that the document contains accessibility issues:

- **Show results in new window** - displays validation results in a new window.
- **Export to various formats** - after clicking the  icon in the first column of the results grid, a context menu is displayed, offering options for [export of listed data](#) to various types of files.

If the document contains accessibility issues, a grid is displayed in the main area, listing all issues detected by the validation. You can see the following information about each issue:

- **Line** - line of the HTML code on which the issue appears.
- **Column** - column of the HTML code (i.e. number of characters from the beginning of the respective line) where the issue appears.
- **Accessibility rule** - the standard's accessibility rule based on which the error was generated.
- **Error** - message describing the validity issue.
- **Fix suggestion** - description of steps to be taken to address the accessibility issue.
- **Source** - extract of the part of the code where the accessibility issue appears.

The screenshot shows the Kentico CMS interface with the 'Validate' tool active. The tool displays a warning icon and the message 'Document contains accessibility issues.' Below this, a table shows the validation results:

Line	Column	Accessibility rule	Error	Fix suggestion	Source
2	1	3.1 Readable: Make text content readable and understandable. Success Criteria 3.1.1 Language of Page (A)	Document language not identified.	Repair: For HTML documents add the lang attribute and a valid ISO-639-1 two letter language code to the opening HTML element. For XHTML documents add both the lang and xml:lang attributes with a valid ISO-639-1 two letter language code to the opening HTML element.	<html xmlns="http://www.w3.org/1999/xhtml" > <head id="head"><title> Corporate site - Home </title> ...
2	1	3.1 Readable: Make text content readable and understandable. Success Criteria 3.1.1 Language of Page (A)	Document has invalid language code.	Repair: Add a valid 2 letter or 3 letter language code as defined in the ISO 639 specification to the HTML 'lang' attribute. For XHTML, both 'lang' and 'xml:lang' must be set.	<html xmlns="http://www.w3.org/1999/xhtml" > <head id="head"><title> Corporate site - Home </title> ...

4.12 Document listing

On the **CMS Desk -> Content -> List** tab, you can see an **overview of documents placed under the currently selected document** in the content tree. You can filter the displayed pages using the filter above the list.

The **Document name** column displays the names of the documents in the currently edited culture. If the document's version in this culture **does not exist**, the column displays the name from the **default culture** with the default culture code appended in brackets. Document status icons are displayed next to document names in this column, the same as in the content tree. To learn more about these icons, please refer to [Content management -> Editing content -> Document status icons](#).

The **Languages** column displays the status of the document's particular language versions. More information about language statuses can be found in [Development -> Multilingual content -> Managing multilingual websites -> Language status overview](#).

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The main content area is titled 'Document listing' and features search filters for 'Document name', 'Document type', and 'Language'. Below the filters is a table of documents with columns for 'Actions', 'Document name', 'Document type', 'Modified', 'Published', 'Version', and 'Languages'. The table lists various documents such as 'Home', 'Services', 'Products', 'News (en-US)', 'Partners', 'Community (en-US)', 'Company (en-US)', 'Media (en-US)', 'Examples (en-US)', 'Mobile (en-US)', 'Other (en-US)', 'Special Pages (en-US)', and 'Images (en-US)'. At the bottom of the table, there are two drop-down menus for 'Selected documents' and '(select an action)', followed by an 'OK' button.

Single document actions on the List tab

The following operations can be performed for individual documents:

- **Edit** - by clicking the icon, you get redirected to the document's **Edit -> Page** tab in the currently selected culture.
- **Delete** - deletes the document.
- The action opens a context menu with further options that may be used to change the position of the document on the given level of the content tree:
 - **Top**
 - **Up**
 - **Down**
 - **Bottom**
- Clicking a document's name selects it in the content tree, which causes the list to display the documents found under it.

Bulk actions on the List tab

You can also perform **bulk actions** with the listed documents using the two drop-down lists at the bottom. First, you need to select from the following two options in the first drop-down list:

- **Selected documents** - performs the action only with the documents selected by the check-boxes ().
- **All documents** - performs the action with all listed documents.

Then you need to choose the action:

- **Move** - moves the documents to the location specified in a raised pop-up dialog.
- **Copy** - copies the documents to the location specified in a raised pop-up dialog.
- **Link** - creates a linked document in the location specified in a raised pop-up dialog.
- **Delete** - deletes the documents.
 - **Delete documents and their history (documents can't be restored)** - deletes the documents permanently without storing them in the recycle bin, which can be accessed in *CMS Desk -> My Desk -> Bin*.
 - **Delete all culture version of the specified documents** - if the documents have multiple language versions, all of them will be removed. If disabled, only the versions belonging to the currently selected culture will be deleted.
- **Translate** - submits the documents for translation into the language currently selected on the main toolbar (via an external service).
- **Publish/Archive** - this option publishes or archives the selected documents. Before the operation is performed, a dialog is displayed, listing the selected documents and offering the following extra options:
 - **Publish/Archive all culture versions of specified documents** - if enabled, all culture versions of the documents will be published/archived.
 - **Publish/Archive also all child documents** - if enabled, all documents located under the selected documents will be published/archived too.
 - **Perform Undo check-out for checked out documents** - this option is displayed only if you want to perform the operation for a document which is checked out (currently edited by some user). If you enable this options, such documents will be published/archived too.

and click **OK** to perform the action.

4.13 Content search

The interface for searching the documents in the content tree can be accessed by clicking the **Search** () icon in **CMS Desk -> Content**.

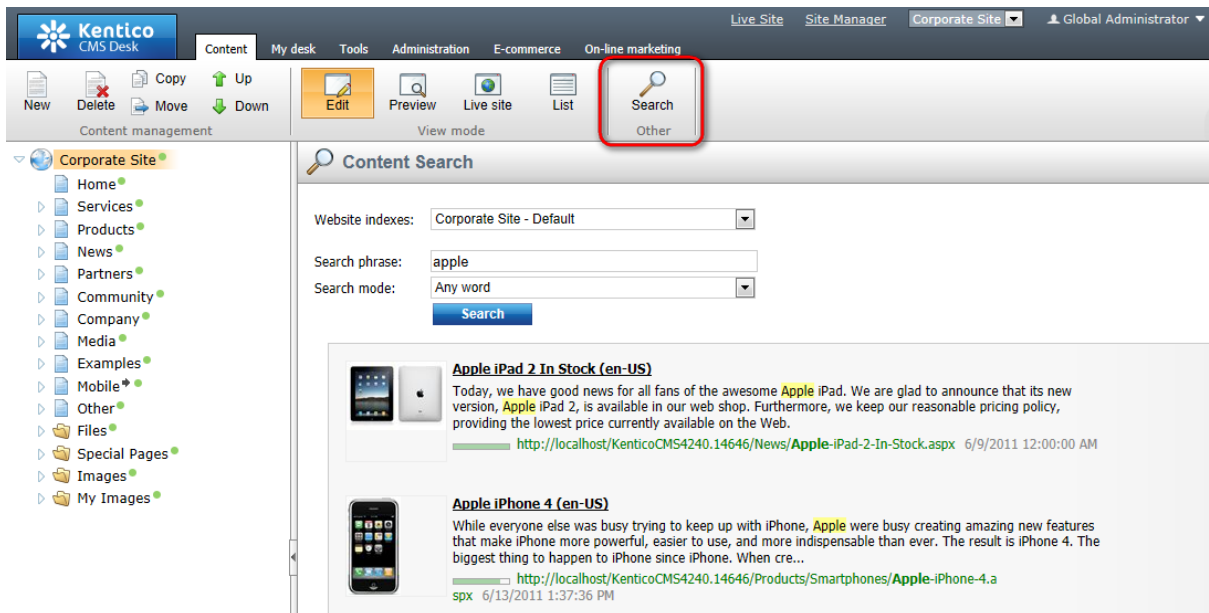

1. First, you need to decide if you want to perform the search using [Smart search](#) or [SQL search](#). This depends on the selection made in the **website indexes** drop-down:

- **SQL search** - you need to select (*SQL Search - default*); slower, but supports search in both published and unpublished documents
- **Smart search** - you need to select a particular smart search index; fast, but does not support search in unpublished documents

2. Then you need to specify the following criteria:

- **Search phrase**: the text that you are looking for; if you are searching using a Smart search index, you can use the syntax described [here](#); if you are searching using SQL search, standard SQL syntax can be used
- **Search mode**: specifies how the search phrase will be used:
 - *Exact phrase* - returns documents where the search phrase is found exactly as entered
 - *Any word* - returns documents where at least one word of the search phrase is found
 - *All words* - returns documents where all words of the search phrase are found, regardless of their position or order in the text

Click **Search**. Found documents will be listed as in the screenshot below.

4.14 Content scheduling

Kentico CMS allows you to specify when the document will be published. When you edit a document on their **Form** tab, you can typically find the **Publish from/Publish to** fields at the bottom of the form:

When you set these values, the document will be displayed on the website only in the given time period.

If you do not set the **Publish from** value, the document will be displayed on the live site immediately. If you do not set the **Publish to** value, the document will never expire.

Content scheduling and workflow/versioning

If you set publish from/to values to documents that use workflow, they will not be published before they

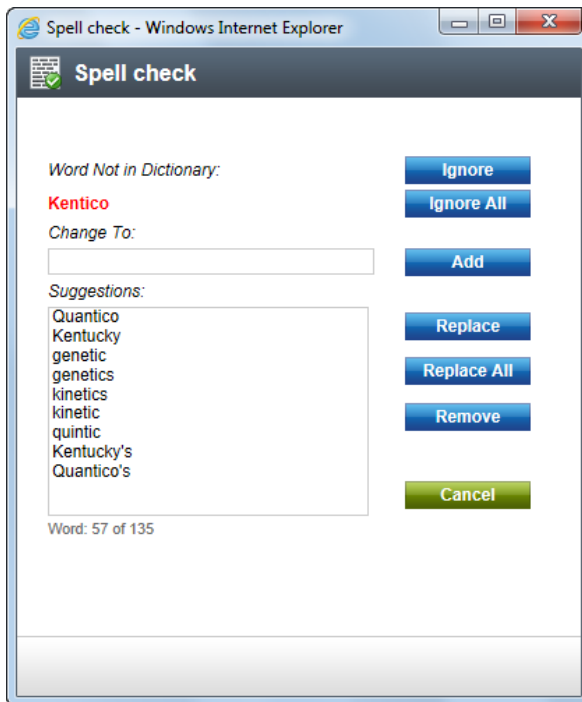

are approved. However, the publishing time may not be exact since the publishing is ensured by a scheduled process that is executed every minute by default. You can check the status of this process in **CMS Desk -> Administration -> Scheduled tasks** -> choose the website and search for the **Content publishing** task.

4.15 Using the built-in spell-checker

You can spell-check all the content on the **Page** and **Form** tabs using the built-in spell-checker:

When you click the **Spell check** button, the spell-checker reads all text fields and checks their content. If it finds any typo, it shows the dialog like this:

You can then ignore the word, add it to the dictionary or replace it with suggested word.

Please note: If you add a new word to dictionary it's only saved in the current session. The next time you sign in to Kentico CMS, the added words will be lost.

Dictionaries

The dictionary is used based on the currently chosen content culture. If no dictionary is available for the current content culture, the default dictionary is used. The default dictionary is specified in the **CMSDefaultSpellCheckerCulture** configuration key in the **appSettings** section of the **web.config** file. By default, it's set to en-US.

Adding additional dictionaries

The dictionaries are stored in folder **<web project>\App_Data\Dictionaries**. If you need some additional dictionaries, you can download them from the following URLs:

- AR-ae: <http://www.kentico.com/Downloads/SpellChecker/ar-AE.zip>
- CS-cz: <http://www.kentico.com/Downloads/SpellChecker/cs-cz.zip>
- DE-de: <http://www.kentico.com/Downloads/SpellChecker/de-de.zip>
- EL-gr: <http://www.kentico.com/Downloads/SpellChecker/el-gr.zip>
- EN-au: <http://www.kentico.com/Downloads/SpellChecker/en-au.zip>
- EN-ca: <http://www.kentico.com/Downloads/SpellChecker/en-ca.zip>
- EN-gb: <http://www.kentico.com/Downloads/SpellChecker/en-gb.zip>
- EN-us: <http://www.kentico.com/Downloads/SpellChecker/en-us.zip>
- ES-es: <http://www.kentico.com/Downloads/SpellChecker/es-es.zip>
- ES-mx: <http://www.kentico.com/Downloads/SpellChecker/es-mx.zip>
- FR-fr: <http://www.kentico.com/Downloads/SpellChecker/fr-fr.zip>
- HE-il: <http://www.kentico.com/Downloads/SpellChecker/he-il.zip>
- IT-it: <http://www.kentico.com/Downloads/SpellChecker/it-it.zip>
- NB-no: <http://www.kentico.com/Downloads/SpellChecker/nb-no.zip>
- NL-nl: <http://www.kentico.com/Downloads/SpellChecker/nl-nl.zip>
- NN-no: <http://www.kentico.com/Downloads/SpellChecker/nn-no.zip>
- PL-pl: <http://www.kentico.com/Downloads/SpellChecker/pl-pl.zip>
- PT-pt: <http://www.kentico.com/Downloads/SpellChecker/pt-pt.zip>
- RO-ro: <http://www.kentico.com/Downloads/SpellChecker/ro-ro.zip>
- RU-ru: <http://www.kentico.com/Downloads/SpellChecker/ru-ru.zip>
- TH-th: <http://www.kentico.com/Downloads/SpellChecker/th-th.zip>

and unpack them to the dic folder. Then, you should restart the website using **Site Manager -> Administration -> System dialog -> click Restart application**. The file name of the dictionary must match the culture code of the currently edited content - e.g. fr-fr.

4.16 Permissions and security

Kentico CMS allows you to configure permissions for particular site sections or even particular documents. You can find more details in the [Development -> Membership, permissions and security](#) chapter.

4.17 FAQ

This topic provides information about the most common issues and their solutions. If you do not find the answer here, please contact our technical support.

Q: The CMS Desk doesn't display the content tree or the WYSIWYG editor doesn't open.

A: Please check that you use one of the [supported browsers](#) and that you have JavaScript enabled. You should also unblock the pop-up blocker or any similar blocker for the website with Kentico CMS.

Q: I have modified a document, but the changes are not displayed on the live site.

A: This may be caused by several reasons:

1. **Caching** - if caching is used, the changes may not be displayed on the website immediately.
2. **Workflow** - if you use workflow, the changes are published on the live website only after the

document has been approved in all workflow steps.

Q: I have defined related documents, but they are not displayed anywhere on the page.

A: You (your developer) need to add some web part/control that will display the related documents - e.g. the **Listings and viewers/Related documents** web part or **Repeater** web part.

Q: I need to add a custom field to the document. Is it possible?

A: Yes, every structured document type can be customized with your own fields. See [Document types](#) for details.

4.18 Content management internals and API

4.18.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are to handle documents. Examples of how the documents API can be used are divided into separate sub-chapters:

- [Basics](#)
- [Advanced](#)
- [Document attachments](#)
- [Document relationships](#)
- [Workflow basics](#)
- [Workflow advanced](#)

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

4.18.2 Database tables

Document data is stored in several joined tables that are used for the tree structure, multilingual support and custom document fields. The document record consists of the following tables:

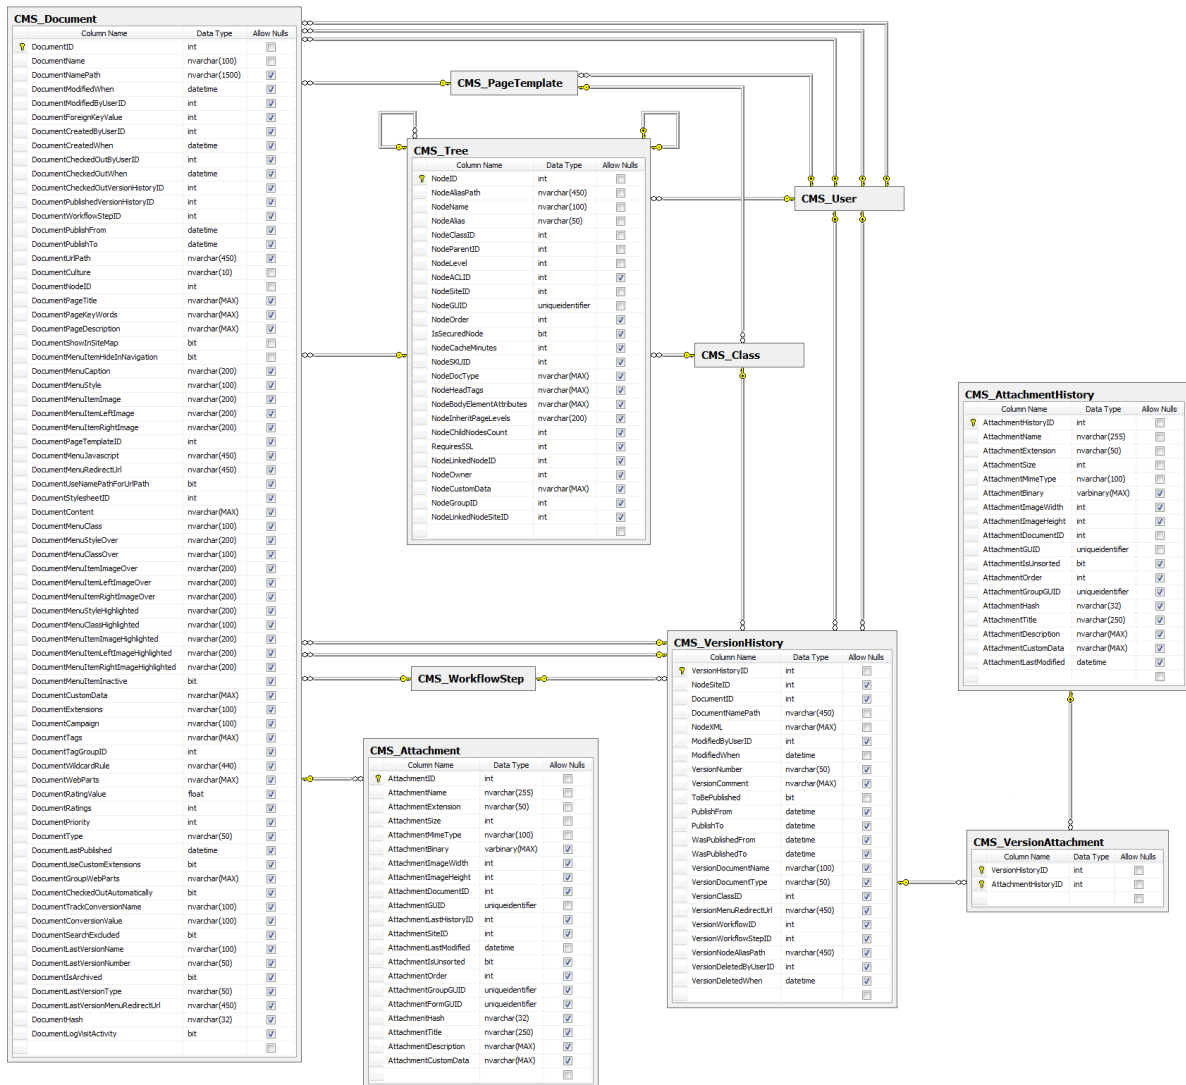

- **CMS_Tree** - a table with basic document data shared between different language versions of same document. This table determines the tree structure of the website document content. It contains **one record for all culture versions** of the document. The table does not contain any versioned data.
- **CMS_Document** - a table with document data of a specific language version of the document. It contains **several records** for every document, each one representing one language version of the document. Some of the document columns are versioned columns.
- **Coupled table** - a table that contains document-type specific fields defined by the developer. For example the News document type has a Content_News coupled table that contains NewsTitle, NewsSummary, NewsText and other fields specific for news. Coupled table primary key is referenced by the value of **DocumentForeignKeyValue** column and the table is determined by type of the document. Container document types, such as folder, do not have any coupled table. All columns from coupled tables are versioned. Each culture version of the coupled document contains one record in the coupled table.

The following figure shows how the three tables are connected:

Document – All culture versions

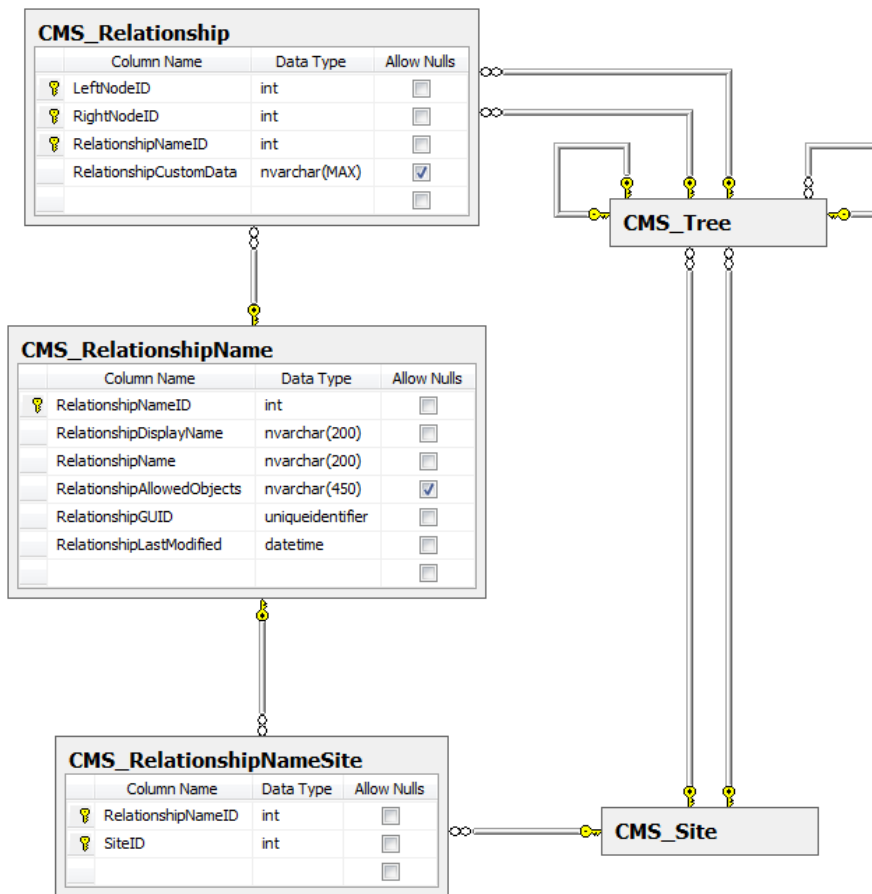

- **CMS_Attachment** - contains records representing document attachments.
- **CMS_VersionHistory** - contains records representing document versions. When a new document version is being created, it is only stored in this table. When it is published, respective records in the *CMS_Tree* and *CMS_Document* tables are updated with data from the new version record in this table.
- **CMS_AttachmentHistory** - contains records representing attachments of document versions. The main purpose of this table is to avoid redundancy when a new document version with the same attachments is created. When a new document version is published, respective records in the *CMS_Attachment* table are updated with data from the new version record in this table.
- **CMS_VersionAttachment** - contains records representing relationships between document versions and their document attachments.

Document relationships use the following database tables:

- **CMS_Relationship** - contains records representing relationships between two documents.
- **CMS_RelationshipName** - contains records representing relationship names.
- **CMS_RelationshipNameSite** - contains records representing assignments of relationship names to websites.

4.18.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

CMS_Tree table API:

- **CMS.DocumentEngine.TreeNode** - encapsulates data from the CMS_Tree and CMS_Document tables and the respective coupled tables.
- **CMS.DocumentEngine.TreeProvider** - provides functionality for manipulation with tree nodes.

CMS_Relationship table API:

- **CMS.DocumentEngine.RelationshipInfo** - represents a relationship between two documents.
- **CMS.DocumentEngine.RelationshipProvider** - provides functionality for management of document relationships.

CMS_RelationshipName table API:

- **CMS.SiteProvider.RelationshipNameInfo** - represents one relationship name object.
- **CMS.SiteProvider.RelationshipNameInfoProvider** - provides functionality for management of relationship names.

CMS_RelationshipSiteName table API:

- **CMS.SiteProvider.RelationshipNameSiteInfo** - represents assignment of one relationship name to one website.
- **CMS.SiteProvider.RelationshipNameSiteInfoProvider** - provides functionality for management of relationship name assignments to websites.

4.18.4 API examples

4.18.4.1 Basics

4.18.4.1.1 Overview

These topics show examples of how the documents API can be used:

- [Creating documents](#)
- [Managing documents](#)
- [Deleting documents](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Documents\Basics\Default.aspx.cs**.

The documents API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.CMSHelper;
using CMS.GlobalHelper;
using CMS.SiteProvider;
using CMS.DocumentEngine;
using CMS.UIControls;
```

4.18.4.1.2 Creating documents

The following example creates a document structure used by all the following code examples in this chapter.

```
private bool CreateDocumentStructure()
{
    // Add a new culture to the current site
    CultureInfo culture = CultureInfoProvider.GetCultureInfo("de-de");
    CultureInfoProvider.AddCultureToSite(culture.CultureID,
```

```
CMSContext.CurrentSiteID);

    // Create new instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get parent node
    TreeNode parentNode = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/",
"en-us");

    if (parentNode != null)
    {
        // Create the API Example folder
        TreeNode newNode = TreeNode.New("CMS.Folder", tree);

        newNode.DocumentName = "API Example";
        newNode.DocumentCulture = "en-us";

        newNode.Insert(parentNode);

        parentNode = newNode;

        // Create the Source folder - the document to be moved will be stored here
        newNode = TreeNode.New("CMS.Folder", tree);

        newNode.DocumentName = "Source";
        newNode.DocumentCulture = "en-us";

        newNode.Insert(parentNode);

        // Create the Target folder - a document will be moved here
        newNode = TreeNode.New("CMS.Folder", tree);

        newNode.DocumentName = "Target";
        newNode.DocumentCulture = "en-us";

        newNode.Insert(parentNode);

        return true;
    }

    return false;
}
```

The following example creates a document.

```
private bool CreateDocument()
{
    // Create an instance of the Tree provider first
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the parent node - the API Example folder
    TreeNode parentNode = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
```

```
Example", "en-us");

    if (parentNode != null)
    {
        // Create a new instance of the Tree node
        TreeNode newNode = TreeNode.New("CMS.MenuItem", tree);

        // Set the document's properties
        newNode.DocumentName = "My new document";
        newNode.DocumentCulture = "en-us";

        // Insert the document into the content tree
        newNode.Insert(parentNode);

        return true;
    }

    return false;
}
```

The following example creates a new culture version of the document created by the example above.

```
private bool CreateNewCultureVersion()
{
    // Create an instance of the Tree provider first
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the document in the english culture
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-Example/My-new-document", "en-us");

    if (node != null)
    {
        // Translate its name
        node.DocumentName = "My new translation";
        node.SetValue("MenuItemName", "My new translation");

        // Insert into database
        node.InsertAsNewCultureVersion("de-de");

        return true;
    }

    return false;
}
```

The following example creates a linked document based on the document created by the first code example on this page.

```
private bool CreateLinkedDocument()
```

```
{
    // Create an instance of the Tree provider first
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the parent document
    TreeNode parentNode = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", "en-us");

    if (parentNode != null)
    {
        // Get the original document
        TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example/My-new-document", "en-us");

        if (node != null )
        {
            // Insert the link
            node.InsertAsLink(parentNode);

            return true;
        }
        else
        {
            apiCreateLinkedDocument.ErrorMessage = "Document 'My new document' was
not found.";
        }
    }

    return false;
}
```

4.18.4.1.3 Managing documents

Please note

For these examples to produce meaningful results, it is expected to run the API examples on the [Creating documents](#) page first.

The following example gets all documents located under a folder in the content tree and updates them.

```
private bool GetAndUpdateDocuments()
{
    // Create an instance of the Tree provider first
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Fill dataset with documents
    DataSet documents = tree.SelectNodes(CMSContext.CurrentSiteName, "/API-
Example/%", "en-us", false, "CMS.MenuItem");
}
```

```
if (!DataHelper.DataSourceIsEmpty(documents))
{
    // Loop through all documents
    foreach (DataRow documentRow in documents.Tables[0].Rows)
    {
        // Create a new Tree node from the data row
        TreeNode editDocument = TreeNode.New(documentRow, "CMS.MenuItem",
tree);

        string newName = editDocument.DocumentName.ToLower();

        // Change coupled data
        editDocument.SetValue("MenuItemName", newName);
        // Change document data
        editDocument.DocumentName = newName;

        // Save to database
        editDocument.Update();

    }

    return true;
}

return false;
}
```

The following example creates a copy of a document.

```
private bool CopyDocument()
{
    // Create an instance of the Tree provider first
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example/My-new-document", "en-us");

    // Get the new parent document
    TreeNode parentNode = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example/Source", "en-us");

    if ((node != null) && (parentNode != null))
    {
        // Copy the document
        tree.CopyNode(node, parentNode.NodeID);

        return true;
    }

    return false;
}
```

```
}
```

The following example moves a document.

```
private bool MoveDocument()
{
    // Create an instance of the Tree provider first
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example/Source/My-new-document", "en-us");

    // Get the new parent document
    TreeNode parentNode = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example/Target", "en-us");

    if ((node != null) && (parentNode != null))
    {
        // Move the document
        tree.MoveNode(node, parentNode.NodeID);

        return true;
    }

    return false;
}
```

4.18.4.1.4 Deleting documents

Please note

For these examples to produce meaningful results, it is expected to run the API examples on the [Creating documents](#) page first.

The following example deletes a linked document.

```
private bool DeleteLinkedDocuments()
{
    // Create an instance of the Tree provider first
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    string siteName = CMSContext.CurrentSiteName;

    // Get the document
    TreeNode node = tree.SelectSingleNode(siteName, "/API-Example/My-new-
```

```
document", "en-us");

    if (node != null)
    {
        // Prepare the where condition
        string where = "NodeLinkedNodeID = " + node.NodeID;

        // Get linked documents' IDs
        DataSet documents = tree.SelectNodes(siteName, "/API-Example/%", "en-us",
false, null, where, null, -1, false, -1, "NodeID");

        if (!DataHelper.DataSourceIsEmpty(documents))
        {
            // Loop through the documents and delete them. Alternatively, the
DeleteLinks method from the TreeProvider can be used to delete all document's
links.

            foreach (DataRow documentRow in documents.Tables[0].Rows)
            {
                // Get additional document data
                TreeNode document = tree.SelectSingleNode
(ValidationHelper.GetInteger(documentRow["NodeID"], 0));

                // Delete the document
                document.Delete();
            }

            return true;
        }
        else
        {
            apiDeleteLinkedDocuments.ErrorMessage = "No linked documents were
found.";
        }
    }

    return false;
}
```

The following example deletes a document's culture version.

```
private bool DeleteCultureVersion()
{
    // Create an instance of the Tree provider first
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the german culture version of the document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example/My-new-document", "de-de");

    if (node != null)
    {
        // Delete the document
    }
}
```

```
        node.Delete();

        return true;
    }

    return false;
}
```

The following example deletes a document.

```
private bool DeleteDocument()
{
    // Create an instance of the Tree provider first
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example/My-new-document", "en-us");

    if (node != null)
    {
        // Delete the document and all its culture versions
        node.DeleteAllCultures();

        return true;
    }

    return false;
}
```

The following example deletes the example document structure.

```
private bool DeleteDocumentStructure()
{
    // Create an instance of the Tree provider first
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the API Example folder
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", "en-us");

    if (node != null)
    {
        // Delete the folder and all child documents
        node.DeleteAllCultures();
    }

    CultureInfo culture = CultureInfoProvider.GetCultureInfo("de-de");

    // Remove the example culture from the site
}
```

```
CultureSiteInfoProvider.RemoveCultureFromSite(culture.CultureID,
CMSContext.CurrentSiteID);

return true;
}
```

4.18.4.2 Advanced

4.18.4.2.1 Overview

These topics show examples of how the documents API can be used for advanced tasks:

- [Sample document structure](#)
- [Organizing documents](#)
- [Recycle bin](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Documents\Advanced\Default.aspx.cs**.

The documents API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.CMSHelper;
using CMS.GlobalHelper;
using CMS.DocumentEngine;
using CMS.UIControls;
using CMS.WorkflowEngine;
```

4.18.4.2.2 Sample document structure

The following example creates a sample document structure that will be used by the API examples in the following topics.

```
private bool CreateDocumentStructure()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // First get the root node
```

```
TreeNode parentNode = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/",
"en-us");

if (parentNode != null)
{
    // First create a folder
    TreeNode node = TreeNode.New("CMS.Folder", tree);

    node.DocumentName = "API Example";
    node.DocumentCulture = "en-us";

    node.Insert(parentNode);

    parentNode = node;

    // Create a few documents
    for (int i = 1; i <= 3; i++)
    {
        node = TreeNode.New("CMS.MenuItem", tree);

        node.DocumentName = "Document " + i;
        node.DocumentCulture = "en-us";

        node.Insert(parentNode);
    }

    return true;
}

return false;
}
```

The following example deletes the sample document structure created by the code example above.

```
private bool DeleteDocumentStructure()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the API Example folder
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", "en-us");

    // Delete the folder including all dependencies and child documents
    node.Delete();

    return true;
}
```

4.18.4.2.3 Organizing documents

The following example moves **Document 2** created by the code example in the [Sample document structure](#) topic up in the content tree.

```
private bool MoveDocumentUp()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Select a node
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example/Document-2", "en-us");

    if (node != null)
    {
        // Move the node up
        tree.MoveNodeUp(node.NodeID);

        return true;
    }

    return false;
}
```

The following example moves **Document 1** created by the code example in the [Sample document structure](#) topic down in the content tree.

```
private bool MoveDocumentDown()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Select a node
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example/Document-1", "en-us");

    if (node != null)
    {
        // Move the node up
        tree.MoveNodeDown(node.NodeID);

        return true;
    }

    return false;
}
```

The following example sorts documents created by the code example in the [Sample document structure](#) topic alphabetically.

```
private bool SortDocumentsAlphabetically()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Select a node
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", "en-us");

    if (node != null)
    {
        // Sort its child nodes alphabetically - ascending
        tree.OrderNodesAlphabetically(node.NodeID, true);

        return true;
    }

    return false;
}
```

The following example sorts documents created by the code example in the [Sample document structure](#) topic by date and time of creation from the oldest to the newest.

```
private bool SortDocumentsByDate()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Select a node
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", "en-us");

    if (node != null)
    {
        // Sort its child nodes by date - descending
        tree.OrderNodesByDate(node.NodeID, false);

        return true;
    }

    return false;
}
```

4.18.4.2.4 Recycle bin

The following example moves **Document 1** created by the code example in the [Sample document structure](#) topic the recycle bin.

```
private bool MoveToRecycleBin()
{
```

```
// Create an instance of the Tree provider
TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

// Get the document
TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example/Document-1", "en-us");

if (node != null)
{
    // Delete the document without destroying its history
    DocumentHelper.DeleteDocument(node, tree, true, false, true);

    return true;
}

return false;
}
```

The following example restores the document moved to the recycle bin by the example above back to the content tree.

```
private bool RestoreFromRecycleBin()
{
    // Prepare the where condition
    string where = "VersionNodeAliasPath LIKE N'/API-Example/Document-1'";

    // Get the recycled document
    DataSet recycleBin = VersionHistoryInfoProvider.GetRecycleBin
(CMSContext.CurrentSiteID, where, null, 0, "VersionHistoryID");

    if (!DataHelper.DataSourceIsEmpty(recycleBin))
    {
        // Create a new version history info object from the data row
        VersionHistoryInfo version = new VersionHistoryInfo(recycleBin.Tables[0]
.Rows[0]);

        // Create a new version manager instance and restore the document
        VersionManager manager = VersionManager.GetInstance(new TreeProvider
(CMSContext.CurrentUser));
        manager.RestoreDocument(version.VersionHistoryID);

        return true;
    }

    return false;
}
```

4.18.4.3 Document attachments

4.18.4.3.1 Overview

These topics show examples of how the document attachments API can be used:

- [Sample document structure](#)
- [Managing attachments](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Documents\Attachments\Default.aspx.cs**.

The document attachments API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.DocumentEngine;
using CMS.WorkflowEngine;
```

4.18.4.3.2 Sample document structure

The following example is not directly related to document attachments. It only creates a sample document to which attachments will be added and managed by the code examples in the [following topic](#).

```
private bool CreateExampleDocument()
{
    // Create a new instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get site root node
    TreeNode parentNode = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/",
"en-us");

    if (parentNode != null)
    {
        // Create the document
        TreeNode node = TreeNode.New("CMS.MenuItem", tree);

        node.DocumentName = "API Example";
        node.DocumentCulture = "en-us";
    }
}
```

```
        node.Insert(parentNode);

        return true;
    }

    return false;
}
```

The following example deletes the sample document created by the code example above.

```
private bool DeleteExampleDocument()
{
    // Create a new instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the example document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", "en-us");

    if (node != null)
    {
        // Delete the document
        node.Delete();

        return true;
    }

    return false;
}
```

4.18.4.3.3 Managing attachments

The following example adds an unsorted attachment to the document created by the example in the [previous topic](#).

```
private bool InsertUnsortedAttachment()
{
    // Create a new instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", "en-us");

    // Path to the file to be inserted. This example uses an explicitly defined
    file path. However, you can use an object of the HttpPostedFile type (uploaded via
    an upload control).
    string postedFile = Server.MapPath("Files/file.png");
}
```

```
    if (node != null)
    {
        // Insert the attachment
        return (DocumentHelper.AddUnsortedAttachment(node, Guid.NewGuid(),
postedFile, tree, ImageHelper.AUTOSIZE, ImageHelper.AUTOSIZE,
ImageHelper.AUTOSIZE) != null);
    }

    return false;
}
```

The following example inserts a field attachment to the document created by the example in the [previous topic](#).

```
private bool InsertFieldAttachment()
{
    // Create a new instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the example document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", "en-us");

    if (node != null)
    {
        AttachmentInfo newAttachment = null;

        // Path to the file to be inserted. This example uses an explicitly
        defined file path. However, you can use an object of the HttpPostedFile type
        (uploaded via an upload control).
        string postedFile = Server.MapPath("Files/file.png");

        // Insert the attachment and update the document with its GUID
        newAttachment = DocumentHelper.AddAttachment(node, "MenuItemTeaserImage",
postedFile, tree);
        node.Update();

        if (newAttachment != null)
        {
            return true;
        }

        apiInsertFieldAttachment.ErrorMessage = "Couldn't insert the attachment.";
    }

    return false;
}
```

The following example moves the unsorted attachment created by the first example on this page down in the order of the document's unsorted attachments.

```
private bool MoveAttachmentDown()
{
    // Create a new instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the example document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", "en-us");

    if (node != null)
    {
        string where = "AttachmentIsUnsorted = 1";
        string orderBy = "AttachmentLastModified DESC";

        // Get the document's unsorted attachments with the latest on top
        DataSet attachments = DocumentHelper.GetAttachments(node, where, orderBy,
false, tree);

        if (!DataHelper.DataSourceIsEmpty(attachments))
        {
            // Create attachment info object from the first DataRow
            AttachmentInfo attachment = new AttachmentInfo(attachments.Tables[0]
.Rows[0]);

            // Move the attachment
            DocumentHelper.MoveAttachmentDown(attachment.AttachmentGUID, node);

            return true;
        }
        else
        {
            apiMoveAttachmentDown.ErrorMessage = "No attachments were found.";
        }
    }

    return false;
}
```

The following example moves the unsorted attachment created by the first example on this page up in the order of the document's unsorted attachments.

```
private bool MoveAttachmentUp()
{
    // Create a new instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the example document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", "en-us");

    if (node != null)
    {
```

```
string where = "AttachmentIsUnsorted = 1";
string orderBy = "AttachmentLastModified DESC";

// Get the document's unsorted attachments with the latest on top
DataSet attachments = DocumentHelper.GetAttachments(node, where, orderBy,
false, tree);

if (!DataHelper.DataSourceIsEmpty(attachments))
{
    // Create attachment info object from the first DataRow
    AttachmentInfo attachment = new AttachmentInfo(attachments.Tables[0]
.Rows[0]);

    // Move the attachment
    DocumentHelper.MoveAttachmentUp(attachment.AttachmentGUID, node);

    return true;
}
else
{
    apiMoveAttachmentDown.ErrorMessage = "No attachments were found.";
}

return false;
}
```

The following example edits metadata of the unsorted attachment created by the first example on this page. It modifies its name, title and description.

```
private bool EditMetadata()
{
    // Create a new instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the example document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", "en-us");

    if (node != null)
    {
        string where = "AttachmentIsUnsorted = 1";
        string orderBy = "AttachmentLastModified DESC";

        // Get the document's unsorted attachments with the latest on top
        DataSet attachments = DocumentHelper.GetAttachments(node, where, orderBy,
false, tree);

        if (!DataHelper.DataSourceIsEmpty(attachments))
        {
            // Create attachment info object from the first DataRow
            AttachmentInfo attachment = new AttachmentInfo(attachments.Tables[0]
```

```
.Rows[0]);

    // Edit its metadata
    attachment.AttachmentName += " - modified";
    attachment.AttachmentTitle += "Example title";
    attachment.AttachmentDescription += "This is an example of an unsorted
attachment.";

    // Ensure that the attachment can be updated without supplying its
binary data.
    attachment.AllowPartialUpdate = true;

    // Save the object into database
    AttachmentInfoProvider.SetAttachmentInfo(attachment);

    return true;
}
else
{
    apiEditMetadata.ErrorMessage = "No attachments were found.";
}
}

return false;
}
```

The following example deletes the two document attachments created by the first and second example on this page.

```
private bool DeleteAttachments()
{
    // Create a new instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the example document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", "en-us");

    if (node != null)
    {
        // Get the document's unsorted attachments with the latest on top
        DataSet attachments = DocumentHelper.GetAttachments(node, null, null,
false, tree);

        if (!DataHelper.DataSourceIsEmpty(attachments))
        {
            foreach (DataRow attachmentRow in attachments.Tables[0].Rows)
            {
                // Create attachment info object from the first DataRow
                AttachmentInfo attachment = new AttachmentInfo(attachmentRow);

                // Delete the attachment
                DocumentHelper.DeleteAttachment(node, attachment.AttachmentGUID,
```

```
tree);
    }

    return true;
}
else
{
    apiDeleteAttachments.ErrorMessage = "No attachments found.";
}
}

return false;
}
```

4.18.4.4 Document relationships

4.18.4.4.1 Overview

These topics show examples of how the document relationships API can be used:

- [Managing relationship names](#)
- [Managing relationships](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Documents\Relationships\Default.aspx.cs**.

The document relationships API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.DocumentEngine;
```

4.18.4.4.2 Managing relationship names

The following example creates a relationship name.

```
private bool CreateRelationshipName()
```

```
{
    // Create new relationship name object
    RelationshipNameInfo newName = new RelationshipNameInfo();

    // Set the properties
    newName.RelationshipDisplayName = "My new relationship name";
    newName.RelationshipName = "MyNewRelationshipName";

    // Save the relationship name
    RelationshipNameInfoProvider.SetRelationshipNameInfo(newName);

    return true;
}
```

The following example gets and updates the relationship name created by the code example above.

```
private bool GetAndUpdateRelationshipName()
{
    // Get the relationship name
    RelationshipNameInfo updateName =
    RelationshipNameInfoProvider.GetRelationshipNameInfo("MyNewRelationshipName");
    if (updateName != null)
    {
        // Update the properties
        updateName.RelationshipDisplayName =
        updateName.RelationshipDisplayName.ToLower();

        // Save the changes
        RelationshipNameInfoProvider.SetRelationshipNameInfo(updateName);

        return true;
    }

    return false;
}
```

The following example gets multiple relationship names based on a WHERE condition and bulk updates them.

```
private bool GetAndBulkUpdateRelationshipNames()
{
    // Prepare the parameters
    string where = "RelationshipName LIKE N'MyNewRelationshipName%'";

    // Get the data
    DataSet names = RelationshipNameInfoProvider.GetRelationshipNames(where,
    null);
    if (!DataHelper.DataSourceIsEmpty(names))
    {
        // Loop through the individual items
        foreach (DataRow nameDr in names.Tables[0].Rows)
```

```
{
    // Create object from DataRow
    RelationshipNameInfo modifyName = new RelationshipNameInfo(nameDr);

    // Update the properties
    modifyName.RelationshipDisplayName =
modifyName.RelationshipDisplayName.ToUpper();

    // Save the changes
    RelationshipNameInfoProvider.SetRelationshipNameInfo(modifyName);
}

return true;
}

return false;
}
```

The following example adds the relationship name created by the first code example on this page to the current website.

```
private bool AddRelationshipNameToSite()
{
    // Get the relationship name
    RelationshipNameInfo name =
RelationshipNameInfoProvider.GetRelationshipNameInfo("MyNewRelationshipName");
    if (name != null)
    {
        int nameId = name.RelationshipNameId;
        int siteId = CMSContext.CurrentSiteID;

        // Save the binding
        RelationshipNameSiteInfoProvider.AddRelationshipNameToSite(nameId,
siteId);

        return true;
    }

    return false;
}
```

The following example removes the relationship name added to the current website by the code example above from the

```
private bool RemoveRelationshipNameFromSite()
{
    // Get the relationship name
    RelationshipNameInfo removeName =
RelationshipNameInfoProvider.GetRelationshipNameInfo("MyNewRelationshipName");
    if (removeName != null)
    {
        int siteId = CMSContext.CurrentSiteID;
```

```
        // Get the binding
        RelationshipNameSiteInfo nameSite =
RelationshipNameSiteInfoProvider.GetRelationshipNameSiteInfo
(removeName.RelationshipNameId, siteId);

        // Delete the binding
        RelationshipNameSiteInfoProvider.DeleteRelationshipNameSiteInfo(nameSite);

        return true;
    }

    return false;
}
```

The following example deletes the relationship name created by the first code example on this page.

```
private bool DeleteRelationshipName()
{
    // Get the relationship name
    RelationshipNameInfo deleteName =
RelationshipNameInfoProvider.GetRelationshipNameInfo("MyNewRelationshipName");

    // Delete the relationship name
    RelationshipNameInfoProvider.DeleteRelationshipName(deleteName);

    return (deleteName != null);
}
```

4.18.4.4.3 Managing relationships

The following example creates a relationship between two documents using the relationship name created by the first code example on the [previous page](#).

```
private bool CreateRelationship()
{
    // Get the relationship name
    RelationshipNameInfo relationshipName =
RelationshipNameInfoProvider.GetRelationshipNameInfo("MyNewRelationshipName");
    if (relationshipName != null)
    {
        // Get the tree structure
        TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

        // Get documents for relationship (the Root document is used for both in
this example)
        TreeNode root = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/",
null, true);

        // Create the relationship between documents
    }
}
```

```
        RelationshipProvider.AddRelationship(root.NodeID, root.NodeID,
relationshipName.RelationshipNameId);

        return true;
    }

    return false;
}
```

The following example deletes the relationship created by the code example above.

```
private bool DeleteRelationship()
{
    // Get the relationship name
    RelationshipNameInfo relationshipName =
RelationshipNameInfoProvider.GetRelationshipNameInfo("MyNewRelationshipName");
    if (relationshipName != null)
    {
        // Get the tree structure
        TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

        // Get documents which are in relationship (the Root document is used for
both in this example)
        TreeNode root = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/",
null, true);

        // Delete the relationship between documents
        RelationshipProvider.RemoveRelationship(root.NodeID, root.NodeID,
relationshipName.RelationshipNameId);

        return true;
    }

    return false;
}
```

4.18.4.5 Workflow basics

4.18.4.5.1 Overview

These topics show examples of how the workflow API can be used:

- [Sample document structure](#)
- [Creating documents](#)
- [Managing documents](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API

examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Documents\Workflow\Basics\Default.aspx.cs**.

The workflow basics API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.CMSHelper;
using CMS.GlobalHelper;
using CMS.SiteProvider;
using CMS.DocumentEngine;
using CMS.UIControls;
using CMS.WorkflowEngine;
```

4.18.4.5.2 Sample documents and objects

The following example creates a sample documents structure and workflow objects required for the API examples on the following pages to be executed.

```
private bool CreateExampleObjects()
{
    // Add a new culture to the current site
    CultureInfo culture = CultureInfoProvider.GetCultureInfo("de-de");
    CultureInfoProvider.AddCultureToSite(culture.CultureID,
    CMSContext.CurrentSiteID);

    // Create a new tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the root node
    TreeNode parent = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/", "en-
us");

    if (parent != null)
    {
        // Create the API example folder
        TreeNode node = TreeNode.New("CMS.Folder", tree);

        node.DocumentName = "API Example";
        node.DocumentCulture = "en-us";

        // Insert it to database
        DocumentHelper.InsertDocument(node, parent, tree);

        parent = node;

        // Create the Source folder for moving
```

```
node = TreeNode.New("CMS.Folder", tree);

node.DocumentName = "Source";
node.DocumentCulture = "en-us";

DocumentHelper.InsertDocument(node, parent, tree);

// Create the Target folder for moving
node = TreeNode.New("CMS.Folder", tree);

node.DocumentName = "Target";
node.DocumentCulture = "en-us";

DocumentHelper.InsertDocument(node, parent, tree);

// Get the default workflow
WorkflowInfo workflow = WorkflowInfoProvider.GetWorkflowInfo("default");

if (workflow != null)
{
    // Get the example folder data
    node = DocumentHelper.GetDocument(parent, tree);

    // Create new workflow scope
    WorkflowScopeInfo scope = new WorkflowScopeInfo();

    // Assign to the default workflow and current site and set starting
alias path to the example document
    scope.ScopeWorkflowID = workflow.WorkflowID;
    scope.ScopeStartingPath = node.NodeAliasPath;
    scope.ScopeSiteID = CMSContext.CurrentSiteID;

    // Save the scope into the database
    WorkflowScopeInfoProvider.SetWorkflowScopeInfo(scope);

    return true;
}
else
{
    apiCreateExampleObjects.ErrorMessage = "The default workflow was not
found.";
}

return false;
}
```

The following example deletes the sample document structure created by the example above, including the linked and copied documents created by executing the examples on the following pages.

```
private bool DeleteDocuments()
{
```

```
// Create new tree provider
TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

// Prepare parameters
string siteName = CMSContext.CurrentSiteName;
string aliasPath = "/API-Example";
string culture = "en-us";
bool combineWithDefaultCulture = false;
string classNames = TreeProvider.ALL_CLASSNAMES;
string where = null;
string orderBy = null;
int maxRelativeLevel = -1;
bool selectOnlyPublished = false;
string columns = null;

// Get the example folder
TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);

if (node != null)
{
    // Prepare delete parameters
    bool deleteAllCultures = true;
    bool destroyHistory = true;
    bool deleteProduct = false;

    // Delete all culture versions of the document and destroy its version
    history. This method also destroys all child documents.
    DocumentHelper.DeleteDocument(node, tree, deleteAllCultures,
destroyHistory, deleteProduct);

    return true;
}

return false;
}
```

The following example deletes the sample workflow objects created by the first example on this page.

```
private bool DeleteObjects()
{
    CultureInfo culture = CultureInfoProvider.GetCultureInfo("de-de");

    // Remove the example culture from the site
    CultureSiteInfoProvider.RemoveCultureFromSite(culture.CultureID,
CMSContext.CurrentSiteID);

    // Prepare parameters
    string where = "ScopeStartingPath LIKE '/API-Example%'";
    string orderBy = null;
    int topN = 0;
}
```

```
string columns = null;

DataSet scopes = WorkflowScopeInfoProvider.GetWorkflowScopes(where, orderBy,
topN, columns);

if (!DataHelper.DataSourceIsEmpty(scopes))
{
    // Loop through all the scopes in case more identical scopes were
    // accidentally created
    foreach (DataRow scopeRow in scopes.Tables[0].Rows)
    {
        // Create scope info object
        WorkflowScopeInfo scope = new WorkflowScopeInfo(scopeRow);

        // Delete the scope
        scope.Delete();
    }

    return true;
}

return false;
}
```

4.18.4.5.3 Creating documents

The following example creates a new document under workflow.

```
private bool CreateDocument()
{
    // Create new tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the example folder
    TreeNode parentNode = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);

    if (parentNode != null)
    {

```

```
// Create a new node
TreeNode node = TreeNode.New("CMS.MenuItem", tree);

// Set the required document properties
node.DocumentName = "My new document";
node.DocumentCulture = "en-us";

// Insert the document
DocumentHelper.InsertDocument(node, parentNode, tree);

return true;
}

return false;
}
```

The following example creates a new culture version of the document under workflow created by the example above.

```
private bool CreateNewCultureVersion()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example/My-new-document";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the document in the English culture
    TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
        combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
        selectOnlyPublished, columns, tree);

    if (node != null)
    {
        // Translate the name of the document
        node.DocumentName = "My new translation";
        node.SetValue("MenuItemName", "My new translation");

        // Insert into database
        DocumentHelper.InsertNewCultureVersion(node, tree, "de-de");

        return true;
    }
}
```

```
    return false;
}
```

The following example creates a new linked document based on the document under workflow created by the first code example on this page.

```
private bool CreateLinkedDocument()
{
    // Create new tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the example folder
    TreeNode parentNode = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);

    if (parentNode != null)
    {
        // Change the alias path
        aliasPath += "/My-new-document";

        // Get the original document
        TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);

        if (node != null)
        {
            // Insert the link
            DocumentHelper.InsertDocumentAsLink(node, parentNode.NodeID, tree);

            return true;
        }
        else
        {
            apiCreateLinkedDocument.ErrorMessage = "Document 'My new document' was
not found.";
        }
    }
}
```

```
    return false;
}
```

4.18.4.5.4 Managing documents

The following example gets and updates the document under workflow created by the first example in the [Creating documents](#)

```
private bool GetAndUpdateDocuments()
{
    // Create an instance of the Tree provider first
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example/%";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = "CMS.MenuItem";
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;

    // Fill dataset with documents
    DataSet documents = DocumentHelper.GetDocuments(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, tree);

    if (!DataHelper.DataSourceIsEmpty(documents))
    {
        // Create a new Version manager instance
        VersionManager manager = VersionManager.GetInstance(tree);

        // Loop through all documents
        foreach (DataRow documentRow in documents.Tables[0].Rows)
        {
            // Create a new Tree node from the data row
            TreeNode editDocument = TreeNode.New(documentRow, "CMS.MenuItem",
tree);

            // Check out the document
            manager.CheckOut(editDocument);

            string newName = editDocument.DocumentName.ToLower();

            // Change document data
            editDocument.DocumentName = newName;

            // Change coupled data
            editDocument.SetValue("MenuItemName", newName);
        }
    }
}
```

```
        // Save the changes
        DocumentHelper.UpdateDocument(editDocument, tree);

        // Check in the document
        manager.CheckIn(editDocument, null, null);
    }

    return true;
}

return false;
}
```

The following example creates a copy of the document under workflow created by the first example in the [Creating doc](#)

```
private bool CopyDocument()
{
    // Create an instance of the Tree provider first
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example/My-new-document";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the example folder
    TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
        combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
        selectOnlyPublished, columns, tree);

    aliasPath = "/API-Example/Source";

    // Get the new parent document
    TreeNode parentNode = DocumentHelper.GetDocument(siteName, aliasPath, culture,
        combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
        selectOnlyPublished, columns, tree);

    if ((node != null) && (parentNode != null))
    {
        // Copy the document
        DocumentHelper.CopyDocument(node, parentNode.NodeID, false, tree);
    }

    return true;
}
```

```
    return false;
}
```

The following example moves the document under workflow created by the first example in the [Creating documents](#) topic to a different location.

```
private bool MoveDocument()
{
    // Create an instance of the Tree provider first
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example/My-new-document";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the example folder
    TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
        combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
        selectOnlyPublished, columns, tree);

    aliasPath = "/API-Example/Target";

    // Get the new parent document
    TreeNode parentNode = DocumentHelper.GetDocument(siteName, aliasPath, culture,
        combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
        selectOnlyPublished, columns, tree);

    if ((node != null) && (parentNode != null))
    {
        // Move the document
        DocumentHelper.MoveDocument(node, parentNode.NodeID, tree);

        return true;
    }

    return false;
}
```

4.18.4.6 Workflow advanced

4.18.4.6.1 Overview

These topics show advanced examples of how the workflow API can be used:

- [Sample document structure](#)
- [Managing documents](#)
- [Workflow process](#)
- [Versioning](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Documents\Workflow\Advanced\Default.aspx.cs**.

The advanced workflow API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.CMSHelper;
using CMS.GlobalHelper;
using CMS.DocumentEngine;
using CMS.UIControls;
using CMS.WorkflowEngine;
```

4.18.4.6.2 Sample documents and objects

The following example creates a sample documents structure and workflow objects required for the API examples on the following pages to be executed.

```
private bool CreateExampleObjects()
{
    // Create a new tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the root node
    TreeNode parent = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/", "en-us");

    if (parent != null)
    {
        // Create the API document
        TreeNode node = TreeNode.New("CMS.MenuItem", tree);

        node.DocumentName = "API Example";
        node.DocumentCulture = "en-us";

        // Insert it to database
        DocumentHelper.InsertDocument(node, parent, tree);
    }
}
```

```
// Get the default workflow
WorkflowInfo workflow = WorkflowInfoProvider.GetWorkflowInfo("default");

if (workflow != null)
{
    // Get the document data
    node = DocumentHelper.GetDocument(node, tree);

    // Create new workflow scope
    WorkflowScopeInfo scope = new WorkflowScopeInfo();

    // Assign to the default workflow and current site and set starting
    // alias path to the example document
    scope.ScopeWorkflowID = workflow.WorkflowID;
    scope.ScopeStartingPath = node.NodeAliasPath;
    scope.ScopeSiteID = CMSContext.CurrentSiteID;

    // Save the scope into the database
    WorkflowScopeInfoProvider.SetWorkflowScopeInfo(scope);

    // Create a new workflow step
    WorkflowStepInfo step = new WorkflowStepInfo();

    // Set its properties
    step.StepWorkflowID = workflow.WorkflowID;
    step.StepName = "MyNewWorkflowStep";
    step.StepDisplayName = "My new workflow step";
    step.StepOrder = 1;

    // Save the workflow step
    WorkflowStepInfoProvider.SetWorkflowStepInfo(step);

    // Ensure correct step order
    WorkflowStepInfoProvider.InitStepOrders(workflow);

    return true;
}
else
{
    apiCreateExampleObjects.ErrorMessage = "The default workflow was not
found.";
}

return false;
}
```

The following example deletes the sample document structure and objects created by the example above.

```
private bool DeleteExampleObjects()
```

```
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get the example document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", "en-us");

    if (node != null)
    {
        // Delete the document
        DocumentHelper.DeleteDocument(node, tree, true, true, true);
    }

    string where = "ScopeStartingPath LIKE '/API-Example%'";

    // Get example workflow scopes
    DataSet scopes = WorkflowScopeInfoProvider.GetWorkflowScopes(where, null, 0,
null);

    if (!DataHelper.DataSourceIsEmpty(scopes))
    {
        // Loop through all the scopes in case more identical scopes were
accidentally created
        foreach (DataRow scopeRow in scopes.Tables[0].Rows)
        {
            // Create scope info object
            WorkflowScopeInfo scope = new WorkflowScopeInfo(scopeRow);

            // Delete the scope
            WorkflowScopeInfoProvider.DeleteWorkflowScopeInfo(scope);
        }
    }

    // Get the default workflow
    WorkflowInfo workflow = WorkflowInfoProvider.GetWorkflowInfo("default");

    if (workflow != null)
    {
        // Get the example step
        WorkflowStepInfo step = WorkflowStepInfoProvider.GetWorkflowStepInfo
("MyNewWorkflowStep", workflow.WorkflowID);

        if (step != null)
        {
            // Delete the step
            WorkflowStepInfoProvider.DeleteWorkflowStepInfo(step);
        }
    }

    return true;
}
```

4.18.4.6.3 Managing documents

The following example performs checkout of the sample document created by the example in the [Sample documents and objects](#) topic. Please note that check-in/check-out must be enabled for the respective workflow for this example to be functional.

```
private bool CheckOut()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the document
    TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);

    if (node != null)
    {
        // Create a new Workflow manager instance
        WorkflowManager workflowmanager = WorkflowManager.GetInstance(tree);

        // Make sure the document uses workflow
        WorkflowInfo workflow = workflowmanager.GetNodeWorkflow(node);

        if (workflow != null)
        {
            // Check if the workflow uses check-in/check-out functionality
            if (workflow.UseCheckInCheckOut(CMSContext.CurrentSiteName))
            {
                // The document has to be checked in
                if (!node.IsCheckedOut)
                {
                    // Create a new version manager instance
                    VersionManager versionmanager = VersionManager.GetInstance
(tree);

                    // Check out the document to create a new document version
                    versionmanager.CheckOut(node);

                    return true;
                }
            }
            else
            {

```

```
        apiCheckOut.ErrorMessage = "The document has already been
checked out.";
    }
    }
    else
    {
        apiCheckOut.ErrorMessage = "The workflow does not use check-in/
check-out. See the \"Edit document\" example, which checks the document out and in
automatically.";
    }
    }
    else
    {
        apiCheckOut.ErrorMessage = "The document doesn't use workflow.";
    }
}

return false;
}
```

The following example edits the document checked out by the previous example. If the document hasn't been checked out, it creates a new modified version of the document.

```
private bool EditDocument()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the document
    TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);

    if (node != null)
    {
        WorkflowManager workflowmanager = WorkflowManager.GetInstance(tree);

        // Make sure the document uses workflow
        WorkflowInfo workflow = workflowmanager.GetNodeWorkflow(node);

        if (workflow != null)
```

```
    {
        // Check if the workflow uses check-in/check-out
        bool autoCheck = !workflow.UseCheckInCheckOut
(CMSContext.CurrentSiteName);

        // Create a new version manager instance
        VersionManager versionmanager = VersionManager.GetInstance(tree);

        // If it does not use check-in/check-out, check out the document
        automatically
        if (autoCheck)
        {
            versionmanager.CheckOut(node);
        }

        if (node.IsCheckedOut)
        {
            // Edit the last version of the document
            string newName = node.DocumentName.ToLower();

            node.DocumentName = newName;
            node.SetValue("MenuItemName", newName);

            // Save the document version
            DocumentHelper.UpdateDocument(node, tree);

            // Automatically check in
            if (autoCheck)
            {
                versionmanager.CheckIn(node, null, null);
            }

            return true;
        }
        else
        {
            apiEditDocument.ErrorMessage = "The document hasn't been checked
out.";
        }
        else
        {
            apiEditDocument.ErrorMessage = "The document doesn't use workflow.";
        }
    }

    return false;
}
```

Use the following example to check the document in. Please note that check-in/check-out must be enabled for the respective workflow for this example to be functional.

```
private bool CheckIn()
```

```
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the document
    TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
        combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
        selectOnlyPublished, columns, tree);

    if (node != null)
    {
        WorkflowManager workflowmanager = WorkflowManager.GetInstance(tree);

        // Make sure the document uses workflow
        WorkflowInfo workflow = workflowmanager.GetNodeWorkflow(node);

        if (workflow != null)
        {
            if (node.IsCheckedOut)
            {
                VersionManager versionmanager = VersionManager.GetInstance(tree);

                // Check in the document
                versionmanager.CheckIn(node, null, null);

                return true;
            }
            else
            {
                apiCheckIn.ErrorMessage = "The document hasn't been checked out.";
            }
        }
        else
        {
            apiCheckIn.ErrorMessage = "The document doesn't use workflow.";
        }
    }

    return false;
}
```

You can also check the document back in by reverting the check-out used above.

```
private bool UndoCheckout()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the document
    TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);

    if (node != null)
    {
        WorkflowManager workflowmanager = WorkflowManager.GetInstance(tree);

        // Make sure the document uses workflow
        WorkflowInfo workflow = workflowmanager.GetNodeWorkflow(node);

        if (workflow != null)
        {
            if (node.IsCheckedOut)
            {
                VersionManager versionmanager = VersionManager.GetInstance(tree);

                // Undo the checkout
                versionmanager.UndoCheckOut(node);

                return true;
            }
            else
            {
                apiUndoCheckout.ErrorMessage = "The document hasn't been checked
out.";
            }
        }
        else
        {
            apiUndoCheckout.ErrorMessage = "The document doesn't use workflow.";
        }
    }

    return false;
}
```

4.18.4.6.4 Workflow process

The following example moves the document under workflow created in the [Sample documents and objects](#) topic to the subsequent workflow step.

```
private bool MoveToNextStep()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the document
    TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);

    if (node != null)
    {
        WorkflowManager workflowManager = WorkflowManager.GetInstance(tree);

        WorkflowInfo workflow = workflowManager.GetNodeWorkflow(node);

        // Check if the document uses workflow
        if (workflow != null)
        {
            // Check if the workflow doesn't use automatic publishing, otherwise,
documents can't change workflow steps.
            if (!workflow.WorkflowAutoPublishChanges)
            {
                // Check if the current user can move the document to the next
step
                if (workflowManager.CheckStepPermissions(node,
WorkflowActionEnum.Approve))
                {
                    // Move the document to the next step
                    workflowManager.MoveToNextStep(node, null);

                    return true;
                }
                else
                {
                    apiMoveToNextStep.ErrorMessage = "You are not authorized to
approve the document.";
                }
            }
        }
    }
}
```

```
        }
        else
        {
            apiMoveToNextStep.ErrorMessage = "The document uses versioning
without workflow, changes are published automatically.";
        }
    }
    else
    {
        apiMoveToNextStep.ErrorMessage = "The document doesn't use workflow.";
    }
}

return false;
}
```

The following example moves the document under workflow created in the [Sample documents and objects](#) topic to the previous workflow step.

```
private bool MoveToPreviousStep()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the document
    TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);

    if (node != null)
    {
        WorkflowManager workflowManager = WorkflowManager.GetInstance(tree);

        WorkflowInfo workflow = workflowManager.GetNodeWorkflow(node);

        // Check if the document uses workflow
        if (workflow != null)
        {
            // Check if the workflow doesn't use automatic publishing, otherwise,
documents can't change workflow steps.
            if (!workflow.WorkflowAutoPublishChanges)
```

```
        {
            // Check if the current user can move the document to the next
step
            if (workflowManager.CheckStepPermissions(node,
WorkflowActionEnum.Reject))
            {
                // Move the document to the previous step
                workflowManager.MoveToPreviousStep(node, null);

                return true;
            }
            else
            {
                apiMoveToPreviousStep.ErrorMessage = "You are not authorized
to reject the document.";
            }
        }
        else
        {
            apiMoveToPreviousStep.ErrorMessage = "The document uses versioning
without workflow, changes are published automatically.";
        }
    }
    else
    {
        apiMoveToPreviousStep.ErrorMessage = "The document doesn't use
workflow.";
    }
}

return false;
}
```

The following example publishes the document under workflow created in the [Sample documents and objects](#) topic.

```
private bool PublishDocument()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the document
```

```
TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);

if (node != null)
{
    WorkflowManager workflowManager = WorkflowManager.GetInstance(tree);

    WorkflowInfo workflow = workflowManager.GetNodeWorkflow(node);

    // Check if the document uses workflow
    if (workflow != null)
    {
        // Publish the document
        workflowManager.PublishDocument(node, null);

        return true;
    }
    else
    {
        apiArchiveDocument.ErrorMessage = "The document doesn't use
workflow.";
    }
}

return false;
}
```

The following example archives the document under workflow created in the [Sample documents and objects](#) topic.

```
private bool ArchiveDocument()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the document
    TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);
}
```

```
if (node != null)
{
    WorkflowManager workflowManager = WorkflowManager.GetInstance(tree);

    WorkflowInfo workflow = workflowManager.GetNodeWorkflow(node);

    // Check if the document uses workflow
    if (workflow != null)
    {
        // Archive the document
        workflowManager.ArchiveDocument(node, null);

        return true;
    }
    else
    {
        apiArchiveDocument.ErrorMessage = "The document doesn't use
workflow.";
    }
}

return false;
}
```

4.18.4.6.5 Versioning

The following example roll back the document created in the [Sample documents and objects](#) topic back a specified version. Please note that the document needs to have at least one previous version for this example to be functional.

```
private bool RollbackVersion()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

    // Get the document
    TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);

    if (node != null)
```

```

{
    // Prepare the WHERE condition for the oldest document version
    where = "DocumentID = " + node.DocumentID;
    orderBy = "ModifiedWhen ASC";
    int topN = 1;

    // Get the version ID
    DataSet versionHistory = VersionHistoryInfoProvider.GetVersionHistories
    (where, orderBy, topN, columns);

    if (!DataHelper.DataSourceIsEmpty(versionHistory))
    {
        // Create the Version history info object
        VersionHistoryInfo version = new VersionHistoryInfo
    (versionHistory.Tables[0].Rows[0]);

        VersionManager versionManager = VersionManager.GetInstance(tree);

        // Roll back version
        versionManager.RollbackVersion(version.VersionHistoryID);

        return true;
    }
    else
    {
        apiRollbackVersion.ErrorMessage = "The document's version history is
    empty.";
    }
}

return false;
}

```

The following example deletes the latest version of the document created in the [Sample documents and objects](#) topic. Please note that the document needs to have at least one version for the example to be functional.

```

private bool DeleteVersion()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
    string classNames = TreeProvider.ALL_CLASSNAMES;
    string where = null;
    string orderBy = null;
    int maxRelativeLevel = -1;
    bool selectOnlyPublished = false;
    string columns = null;

```

```
// Get the document
TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);

if (node != null)
{
    // Prepare the WHERE condition for the latest document version
    where = "DocumentID = " + node.DocumentID;
    orderBy = "ModifiedWhen DESC";
    int topN = 1;

    // Get the version ID
    DataSet versionHistory = VersionHistoryInfoProvider.GetVersionHistories
    (where, orderBy, topN, columns);

    if (!DataHelper.DataSourceIsEmpty(versionHistory))
    {
        // Create the Version history info object
        VersionHistoryInfo version = new VersionHistoryInfo
    (versionHistory.Tables[0].Rows[0]);

        VersionManager versionManager = VersionManager.GetInstance(tree);

        // Delete the version
        versionManager.DestroyDocumentVersion(version.VersionHistoryID);

        return true;
    }
    else
    {
        apiDeleteVersion.ErrorMessage = "The document's version history is
empty.";
    }
}

return false;
}
```

The following example deletes the entire version history of the document created in the [Sample documents and objects](#) topic.

```
private bool DestroyHistory()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Prepare parameters
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/API-Example";
    string culture = "en-us";
    bool combineWithDefaultCulture = false;
}
```

```
string classNames = TreeProvider.ALL_CLASSNAMES;
string where = null;
string orderBy = null;
int maxRelativeLevel = -1;
bool selectOnlyPublished = false;
string columns = null;

// Get the document
TreeNode node = DocumentHelper.GetDocument(siteName, aliasPath, culture,
combineWithDefaultCulture, classNames, where, orderBy, maxRelativeLevel,
selectOnlyPublished, columns, tree);

if (node != null)
{
    VersionManager versionManager = VersionManager.GetInstance(tree);

    // Destroy the version history
    versionManager.DestroyDocumentHistory(node.DocumentID);

    return true;
}

return false;
}
```

Part

Managing sites

5 Managing sites

5.1 Site Management Overview

Kentico CMS allows you to manage multiple sites in a single installation. The database contains data for all websites and the websites are managed using a single administration interface (single copy of code). The following figure shows the multi-site configuration where one database and one copy of CMS code are used for multiple websites.

When you use a multi-site configuration, you can share:

- documents
- users
- global settings and system tables
- document types
- page templates
- web parts

This feature is useful if you need to create multiple websites for a single company and share users/documents/settings between them.

When to choose separate installations

There are situations in which we recommend running separate instances of Kentico CMS for every website:

- You build websites with **many documents** and performance is critical for you.
- Your customers have very **different requirements** and you need to customize some common parts of the system, such as the administration interface or the structure of shared tables.
- Your customers are very sensitive to **security** and you do not want to risk that some other client will get access to other websites because of an administrator's mistake.

5.2 Managing sites

You can manage websites through the **Site Manager -> Sites** dialog. Please see [New site wizard](#) for more details on creating a new website. If you **Edit** (✎) a specific site, you can configure its details on the following tabs:

General tab

Site display name	The name of the site displayed in the administration interface and in site selectors.
Site code name	The name of the site used in the code.
Site domain name	<p>The main domain of the website. Enter the domain name without the <i>http://</i> protocol and <i>www</i> prefix. If you wish to use a different port than <i>80</i>, specify it as well.</p> <p>Correct: mycompany.com partners.mycompany.com mycompany.com:8080</p> <p>Incorrect: http://mycompany.com www.mycompany.com</p>
Default content culture	Default culture of the site's content. It can be changed using the Change button.
Visitor culture	<p>Sets the content culture that should be displayed by default to visitors who do not have a preferred culture selected (the value of a browser cookie is checked). The (<i>Automatic</i>) option means that the culture will be decided based on the preferences configured in the visitor's browser.</p> <p>If the Site Manager -> Settings -> URLs and SEO -> Force domain culture setting is enabled, the culture specified here will always be selected and displayed when the site is accessed through its main domain name. All URLs of documents in the given culture will also be generated with the main domain name.</p>

Site CSS stylesheet	Default CSS stylesheet used for all pages on the site unless they override the value with their own CSS stylesheet.
Editor CSS stylesheet	CSS stylesheet used for the WYSIWYG editor content.
Site description	Optional text description of the website for internal use.

Domain aliases tab

Here you can manage the website's domain aliases. Each alias represents a different domain name under which the site will be available. For example, if your website uses *mycompany.com* as its main domain and you also wish to assign the *my-company.co.uk* domain to the same website, you need to add this domain name to the list of domain aliases. This can be particularly useful for multilingual websites.

The following fields can be set when creating a new alias or editing (✎) an existing one:

Domain alias	Specifies the domain name used for the alias. Like with the site's main domain name, include the port number if it is not <i>80</i> , but do not enter the <i>http://</i> protocol or <i>www</i> prefix.
Visitor culture	Sets the content culture that should be displayed by default to visitors who arrive on the website through a URL containing this domain alias. If the Force domain culture setting is enabled for the website, the culture specified here will always be selected and displayed when the site is accessed through the alias's domain name. All URLs of documents in the given culture will also be generated with the this domain name.
Default alias path	Used to select the default page (document) that should be displayed when the website is accessed through the alias. This overrides the Site Manager -> Settings -> Content -> Default alias path setting.
Redirect URL	Users will be redirected to the entered URL when they access the website through this domain alias. Both absolute and relative URLs are accepted. This field supports macro expressions . If the only purpose of your aliases is to make the site available under multiple domain names, it is recommended to redirect them to the website's main domain. This is a common Search engine optimization practice that prevents duplicate web content (i.e. having several URLs leading to the same content). Example: Imagine that the main domain of your website is <i>domain.com</i> and you have <i>domain.co.uk</i> defined as a domain alias with the Redirect URL field set to: <code>{%protocol%}://domain.com{%relativepath%}</code> These macros can be used to dynamically redirect users to the correct

	<p>page under a different domain.</p> <p>{%relativepath%} - is resolved into the current relative URL path when the redirection takes place</p> <p>{%protocol%} - is resolved into the current URL scheme name (protocol) when the redirection takes place</p> <p>Now if a user accesses for example <i>http://domain.co.uk/example.aspx</i>, they will be redirected to <i>http://domain.com/example.aspx</i>.</p>
--	---

Cultures tab

Here you can assign content cultures to the site, which can then be used to create translated versions of the website's documents. You will use this tab to configure websites that provide content in multiple languages. To learn more, please see the [Content management -> Multilingual content](#) chapter.

Off-line mode tab

Here you can make the currently edited site unavailable for regular users.

When in off-line mode, the live version of the website will not be accessible by visitors, but the site will still remain running and can be worked with normally through the **CMS Desk** or **Site Manager** interface by editors and administrators. This can be useful if you need to make major modifications to the site and wish to hide it while the update is in progress. To enable this mode, click the **Take the site off-line** button.

You can choose between two ways of handling users who attempt to access the site while it is off-line:

1. Select the **Display following message** option and add some content using the WYSIWYG editor:

Kentico Site Manager Sites Administration Settings Development Tools Dashboard Licenses Support Buy

Site properties

> Sites > Corporate Site

General Domain aliases Cultures **Off-line mode**

The site is currently **off-line**. To enable site visitors to access the site, bring the site on-line.

Bring the site on-line

When the site is off-line:

Display following message

This site is currently under construction. Please try again at a later time.

Redirect visitor to following URL

OK

Click **OK** to save the message and its content will be displayed to all visitors. The HTTP response status code of the page will be set to 503, so applications and crawlers who access the site should be able to correctly recognize the situation.

This site is currently under construction. Please try again at a later time.

2. Choose **Redirect visitor to following URL** and enter the address of an alternate website or page to which users will automatically be redirected until the site is returned back on-line.

At any time, you can allow visitors to access the site again by clicking the **Bring the site on-line** button.

5.3 Starting and stopping sites

You can run and stop websites using the **Start site** and **Stop site** buttons in the **Sites** dialog.

Switching between Sites on a Single Domain

If you try to run a site that uses the **same domain name (or alias)** as another site that is already running, you will get an error message and the site will not be started.

If you need to test **several websites on a single domain**, such as `http://localhost`, you need to specify the domain (localhost) for multiple websites and start only one of them.

If you cannot use your own domain names, you can use several alternatives that point to the same computer with different host name `http://localhost`, `http://127.0.0.1` or `http://mycomputer`.

You can find more details on how to configure the websites in chapter [Configuring multiple websites](#).

5.4 Creating a new site

Please see [New site wizard](#).

5.5 Export and import

5.5.1 Overview

You can export and import website content and settings from one Kentico CMS instance to another. You can use this feature to move website or chosen objects between development, testing (QA) and production (live) server as illustrated in the figure below:

5.5.2 Folder structure and import/export

Kentico CMS uses a single folder structure, even if you manage multiple websites in a single installation. The following list describes the main folders and how they are affected during the import and export:

- **App_Browsers**
- **App_Code** (or **Old_App_Code** if you installed Kentico CMS as a web application)
- - CMSModules**<module_name>** (folders of custom modules)
- - **Global** (exports with any site, needs to be created manually; the folder is exported if the 'Export global folders' option is checked in Step 2 of the export process)
- - **<site code name>** (exports with given site, needs to be created manually; the folder is exported if the 'Export site folders' option is checked in Step 2 of the export process)
- **App_Data**
- - CMSModules**<module_name>** (folders of custom modules)
- **App_Themes**
- - **<stylesheet name>** (all folders related to stylesheets assigned to or used on the website)
- **App_WebReferences**
- **aspnet_client**
- **bin**
- **ClientBin**
- **CMSAdminControls**
- **CMSControlsExamples**
- **CMSDesk**
- **CMSFormControls** (all form controls selected in Step 2 of the export process are exported with any site)
- **CMSGlobalFiles** (exports with any website, needs to be created manually; folder is exported if the

'Export global folders' option is checked in Step 2 of the export process)

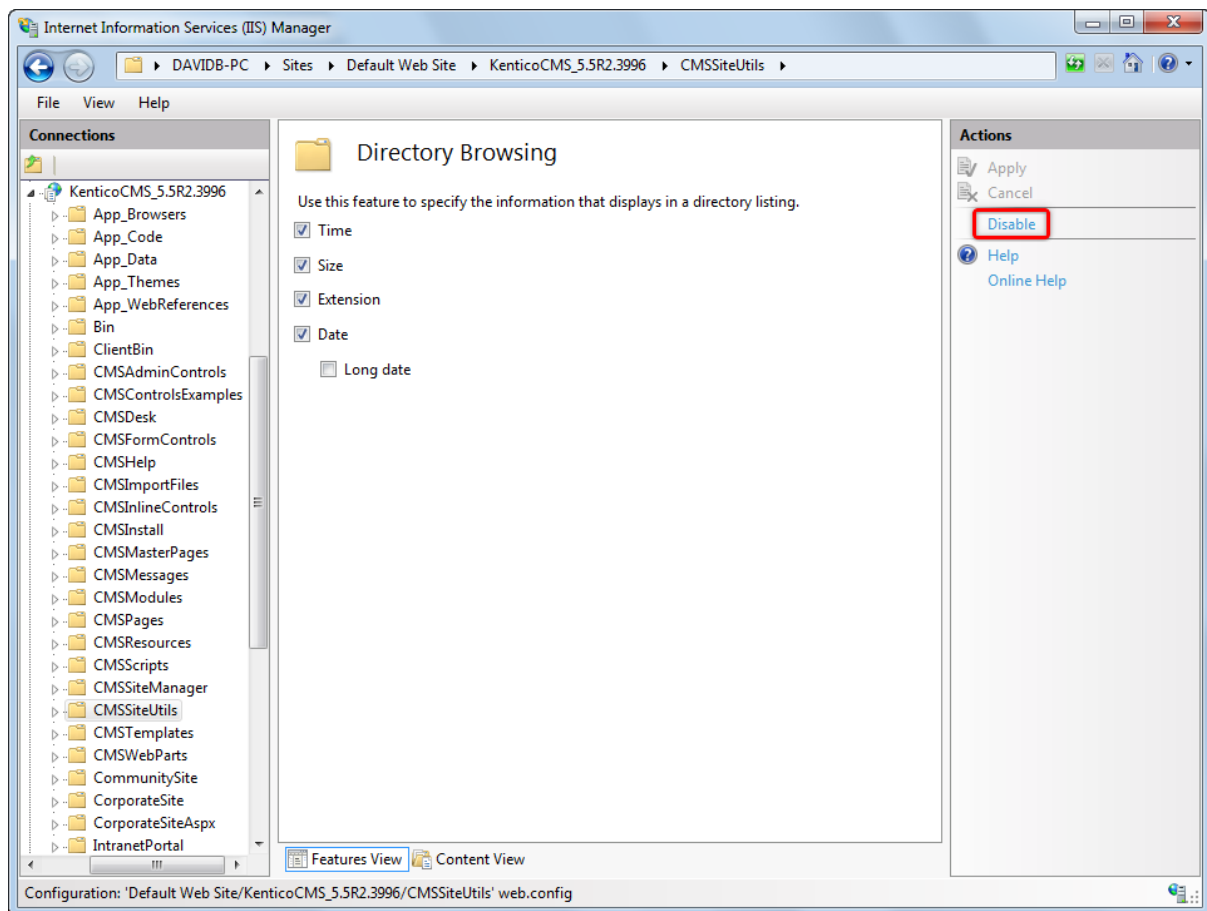

- **CMSImportFiles**
- **CMSInlineControls** (all inline controls selected in Step 2 of the export process are exported with any site)
- **CMSInstall**
- **CMSMasterPages**
- **CMessages**
- **CMSModules**
- - Forums\Controls\Layouts\Custom (forum custom layouts; exported with any website, needs to be created manually; folder is exported only if the 'Copy forum custom layouts folder' option is checked in Step 2 of the export process)
- - **<module name>** (folders of custom modules)
- **CMSPages**
- **CMSResources**
- **CMSScripts** (**CMSScripts\Custom** is a custom file folder and is part of the export package—the folder contains JavaScript files)
- **CMSSiteManager**
- **CMSSiteUtils**
- **CMSTemplates** (all files for selected ASPX page templates are exported with any site, page templates in other folders are exported as well if they are assigned/used in the given site; whole folder is exported if the 'Export ASPX templates folder' option is checked in Step 2 of the export process)
- **CMSWebParts** (all web parts selected in Step 2 of the export process are exported with any site; if the web part uses some additional files, they must be placed in a folder in format **<webpartCodeName>_files**; files that are not registered as web parts are not included in the export package)
- **<site code name>** (exports with given site, needs to be created manually or may be created automatically when storing files on the disk; the folder is exported if the 'Export site folders' option is checked in Step 2 of the export process)
 - Files (default folder for storing files if the system is configured for saving files on the disk)

Here's the explanation of colors:

- **red** - system folder, do not make changes or place your files here unless you want to modify the administration interface
- **blue** - folders for custom files, part of the export package
- **green** - folders for custom files, part of the export package, may need to be created manually
- **black** - service folders (import files, import/export)

Export/import package security

It is highly recommended to disable **Directory Browsing** in IIS for websites on live servers, at least for the **CMSSiteUtils** directory. If enabled, sensitive data from site export/import packages, such as user credentials, could be accessed directly from the browser.

5.5.3 Excluding files and folders from export

Files and folders that are exported into the **Files** folder of the export package can be filtered in order to be excluded from export. This is achieved by adding the following keys into the *AppSettings* section of your site's *web.config* file:

- **Excluding folders from export:** `<add key="CMSExportExcludedFolders" value="test*; cms*" />`
- **Excluding files from export:** `<add key="CMSExportExcludedFiles" value="test*; cms*" />`

Values of the keys define names of files/folders which will be excluded from export, i.e. will not be exported. Multiple values can be entered separated by semicolons.

You can also use the standard file system mask using the * wildcard, which substitutes any number of characters in the name. No other file system mask wildcards are supported.

If the keys are not entered in the *web.config* file, files with the **.scc** extension and folders with the **.svn** extension are excluded by default. However, if the keys are used, only the files and folders specified in their values are excluded.

5.5.4 Export

5.5.4.1 Exporting a site

Kentico CMS allows you to export entire websites including their settings and related objects (such as document types, workflows, web parts, page templates, etc.) into a single file archive that can be imported on the same or different Kentico CMS instance.

Exporting a site

1. Go to **Site Manager** -> **Sites** and click the **Export site** icon next to the site you want to export. This starts the export wizard.

2. In the first step of the wizard, fill in the name of the export package and choose the object pre-selection type:

File name	Sets the name of the export package. The wizard creates the zip file containing the export data in the <code>~/CMSiteUtils/Export</code> folder.
Preselect all objects	If chosen, all site objects will be preselected in the next step.
Preselect objects changed after specific date	If chosen, only objects changed after the specified date will be selected in the next step.
Use previous export settings	If chosen, settings used in a previous export selected from the list below will be used.

Select the option that suits your purposes and click **Next**.

Step 1

Export type

Please enter export details and select type of the export.

File name:

Site:

Preselect all objects
 Preselect objects changed after specific date

 Use previous export settings (preselect the same objects)

3. In **Step 2**, you can select which objects will be exported. The tree on the left represents object categories. These reflect the sections of the administration interface under which the objects can be found. The **Site** category contains objects related to the selected website. The **Global objects** category contains global objects that can be used by all sites. Selecting a category opens a set of check boxes in the right part of the screen, allowing you to select which objects will be exported.

Select the root of the tree (*All objects*) to access the following general export settings:

Global selection	
Load default selection	Preselects all objects based on your choices in Step 1 of the import wizard.
Select all objects	Selects all available objects.
Deselect all objects	Unselects all objects.
Export settings	
Export tasks	If enabled, delete tasks (incremental deployment) will be included in the package.
Export files	Some database objects are linked with physical files stored on the file system inside the web project. If you check this option, such files will be exported along with the corresponding database objects.
Export global folders	If enabled, all files under the following folders will be added to the export package:

	<ul style="list-style-type: none"> ~/App_Code/Global/ ~/CMSGlobalFiles/ ~/CMSScripts/Custom/ ~/App_Code/Controllers/ ~/Controllers/Global/ ~/Views/Global/
Export custom assembly files	If enabled, bound custom assembly files will be exported together with notification gateways, payment options, integration connectors, scheduled tasks and smart search indexes. Custom assemblies are those whose names do not begin with the <i>CMS.</i> prefix.
Export site folders	This option is only available when exporting websites, not just separate objects. If enabled, all files under the following site-related folders will be added to the export package: <ul style="list-style-type: none"> ~/App_Code/<site code name>/ ~/App_Data/<site code name>/ ~/<site code name>/ ~/Controllers/<site code name>/ ~/Views/<site code name>/
Export ASPX templates folder	If enabled, the folder with ASPX page templates will be exported: <ul style="list-style-type: none"> ~/CMSTemplates/
Export forum custom layouts folder	If enabled, folder with custom forum layouts will be exported: <ul style="list-style-type: none"> ~/CMSModules/Forums/Controls/Layouts/Custom/

Step 2 | **Objects selection**
Please select objects which should be exported.

▼ All objects

- ▼ Website
 - Documents

4. The following categories contain extra options to be set:

Custom tables	
Export custom table data	If checked, custom table records (the actual data stored in the tables) will be exported along with the selected custom tables.
Documents	
Export documents	If checked, documents will be exported
Export document histories	If checked, histories of all exported documents will be exported.
Export document relationships	If checked, relationships of all exported documents will be exported.
Export document level permissions	If checked, document security settings made in CMS Desk will be exported.
Export blog comments	If checked, blog comments will be exported.
Export event attendees	If checked, event attendees will be exported for all exported events.
Forms	
Export forms data	If checked, stored forms' data will be exported together with the exported forms.
Export physical files	If checked, physical files saved within form records (if there are some) will also be imported.
Forums	
Export forum posts	If checked, forum posts will be exported together with the exported forums.
Message boards	
Export board messages	If checked, board messages will be exported together with particular message boards.
Media libraries	
Export media files	If checked, media files stored in the database will be exported.
Export physical files	If checked, physical media files stored in the file system will be exported. This option is not selected by default as it may cause the package size grow extremely large; instead, it is recommended to export these files manually.

5. If you have the **Log export tasks** option enabled in **Site Manager -> Settings -> Versioning & synchronization -> Staging**, a list of object deletion tasks may also be displayed at the bottom of the list. This happens when some objects have been deleted (just as the two web part containers in the screenshot below). If you leave the check-boxes checked, the objects will be deleted after importing the package on the target server.

Step 2 | **Objects selection**
Please select objects which should be exported.

- Cultures
- Custom tables
- Document types

< Previous Next >

6. After making all required selections, click **Next** to proceed to the next step. A log appears, showing you the progress of exporting. You can abort exporting by clicking **Cancel** at any time. When exporting finishes, a message appears at the top of the log, telling you the full path to the exported file.

Click **Finish**. You will be redirected back to **Site manager** -> **Sites**.

Now you can copy the exported package into the `~/CMSSiteUtils/Import` folder of the target installation of Kentico CMS, and use the **Import site or objects** wizard described in the [Importing a site or objects](#) topic.

5.5.4.2 Exporting objects

Besides exporting the whole website, you can also choose to export only selected objects (web parts, document types, page templates, etc.). This is useful when you update some object on the development machine and want to copy the updated object to the staging or production server.

Exporting selected objects

1. Go to **Site Manager -> Sites** and click **Export objects**. The Export objects wizard starts.

2. In the first step of the wizard, fill in the name of the export package and choose the object pre-selection type:

File name	Sets the name of the export package. The wizard creates the zip file containing the export data in the <code>~/CMSSiteUtils/Export</code> folder.
-----------	---

Do not preselect any objects	If chosen, no objects will be preselected in the next step.
Preselect all objects	If chosen, all objects will be preselected in the next step.
Preselect objects changed after specific date	If chosen, only objects changed after the specified date will be selected in the next step.
Use previous export settings	If chosen, settings used in a previous export selected from the list below will be used.

Select the option that suits your purposes and click **Next**.

Step 1

Export type
Please enter export details and select type of the export.

File name:

Site:

Do not preselect any objects
 Preselect all objects
 Preselect objects changed after specific date

Use previous export settings (preselect the same objects)

3. In **Step 2**, you can select which objects will be exported. The tree on the left represents object categories. These reflect the sections of the administration interface under which the objects can be found. Selecting a category opens a set of check boxes in the right part of the screen, allowing you to select which objects will be exported.

Select the root of the tree (*All objects*) to access the following general export settings:

Global selection	
Load default selection	Preselects all objects based on your choices in Step 1 of the import wizard.
Select all objects	Selects all available objects.
Deselect all objects	Unselects all objects.

Export settings	
Export tasks	If enabled, delete tasks (incremental deployment) will be included in the package.
Export files	Some database objects are linked with physical files stored on the file system inside the web project. If you check this option, such files will be exported along with the corresponding database objects.
Export global folders	If enabled, all files under the following folders will be added to the export package: <ul style="list-style-type: none"> ~/App_Code/Global/ ~/CMSGlobalFiles/ ~/CMSScripts/Custom/ ~/App_Code/Controllers/ ~/Controllers/Global/ ~/Views/Global/
Export custom assembly files	If enabled, bound custom assembly files will be exported together with notification gateways, payment options, integration connectors, scheduled tasks and smart search indexes. Custom assemblies are those whose names do not begin with the <i>CMS.</i> prefix.
Export ASPX templates folder	If enabled, the folder with ASPX page templates will be exported: <ul style="list-style-type: none"> ~/CMSTemplates/
Export forum custom layouts folder	If enabled, folder with custom forum layouts will be exported: <ul style="list-style-type: none"> ~/CMSModules/Forums/Controls/Layouts/Custom/

6. After making all required selections, click **Next** to proceed to the next step. A log appears, showing you the progress of exporting. You can abort exporting by clicking **Cancel** at any time. When exporting finishes, a message appears at the top of the log, telling you the full path to the exported file.

Click **Finish**. You will be redirected back to **Site manager** -> **Sites**.

Now you can copy the exported file into the `~/CMSSiteUtils/Import` folder of the target installation of Kentico CMS, and use the **Import site or objects** wizard described in the [Importing a site or objects](#) topic.

5.5.4.3 Exporting single objects

Some objects can also be exported separately as single object packages. This is useful when you want to quickly export only one or few objects apart from the rest of all other objects.

Single object export is supported for: CSS stylesheets, Document types, E-mail templates, Form controls, Inline controls, Page layouts, Page templates, Web part containers, Web parts, Workflow schemas.

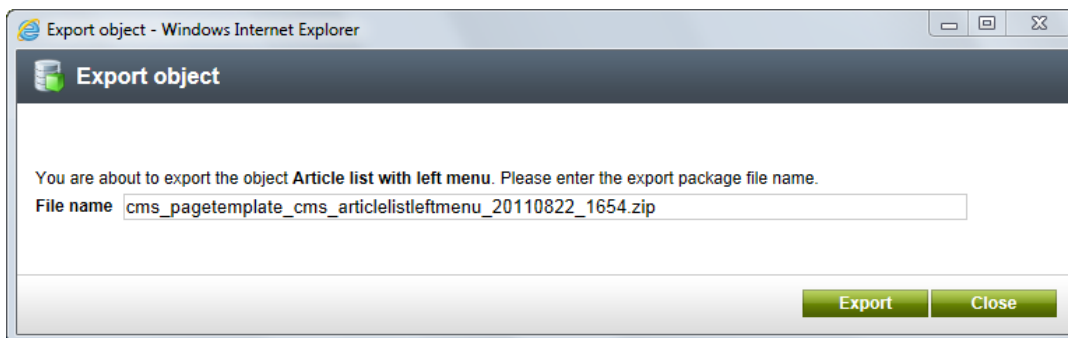

These objects can be found in the corresponding sections in **Site manager** -> **Development** or **Administration**. You can export an object by clicking the **Export object** (📁) icon.

Or **📁 Export selected** in case of Page templates and Web parts.

The following window will appear. Enter the name of the export file (default name will be pre-entered) and click **OK**.

Now wait while the object is being exported.

When the exporting is successfully finished, the following message with path to the exported file will be displayed. The **Download object** link below can be used for storing the file into a different location. Click it to open the typical file download dialog of your web browser.

Close the window by clicking **Close**.

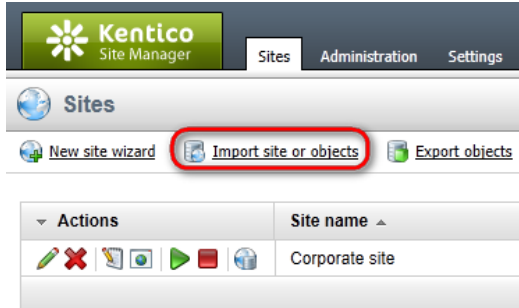

5.5.5 Import

5.5.5.1 Importing a site or objects

After you export a site or objects using the **Export site wizard** or **Export objects wizard**, you can import the content using the **Import site or objects wizard**. Before you start the wizard, you need to copy your export packages into the application's `~/CMSSiteUtils/Import` folder.

Importing a site

1. Go to **Site Manager -> Sites** and click **Import site or objects**.

2. In the first step of the wizard, you need to choose the import package that you want to import. Packages that are already stored in the in `~/CMSSiteUtils/Import` folder are listed in the **Import packages** listbox.

You can upload additional packages to the folder (and hence add them to the list) by clicking **Upload package**. You can also add the package to the folder manually and then click **Refresh** (🔄). Packages can be deleted (both from the list and from the file system) by clicking **Delete package** (✖).

With a package selected, you can choose from the following options:

Preselect all items	If selected, all items in the package will be preselected in the next step.
Preselect only new items	If selected, only items that are not already in the database will be preselected.

Make the desired selection and proceed to the next step by clicking **Next**.

Step 1

Import type
Please select package to be imported and type of the import.

Import packages:

Upload package
 Delete package
 Refresh

export_20110822_1658.zip

Preselect all items
 Preselect only new items

Next >

3. **Step 2** appears only when importing a site package. If you are importing a package containing only global objects, Step 3 is displayed instead.

You have the following two options in Step 2:

Import a new site	A new site will be created based on the contents of the package. You need to enter the site's display name, code name and domain name.
Import objects into an existing site	The wizard imports the content of the package into the selected site.

Click **Next**.

Step 2

Site details
Please enter the site code name, display name and domain or select existing site.

Import a new site

Site display name:

Site code name:

Domain name:

Import objects into an existing site

Select site:

< Previous
Next >

4. In **Step 3**, select which of the objects from the package will be imported.

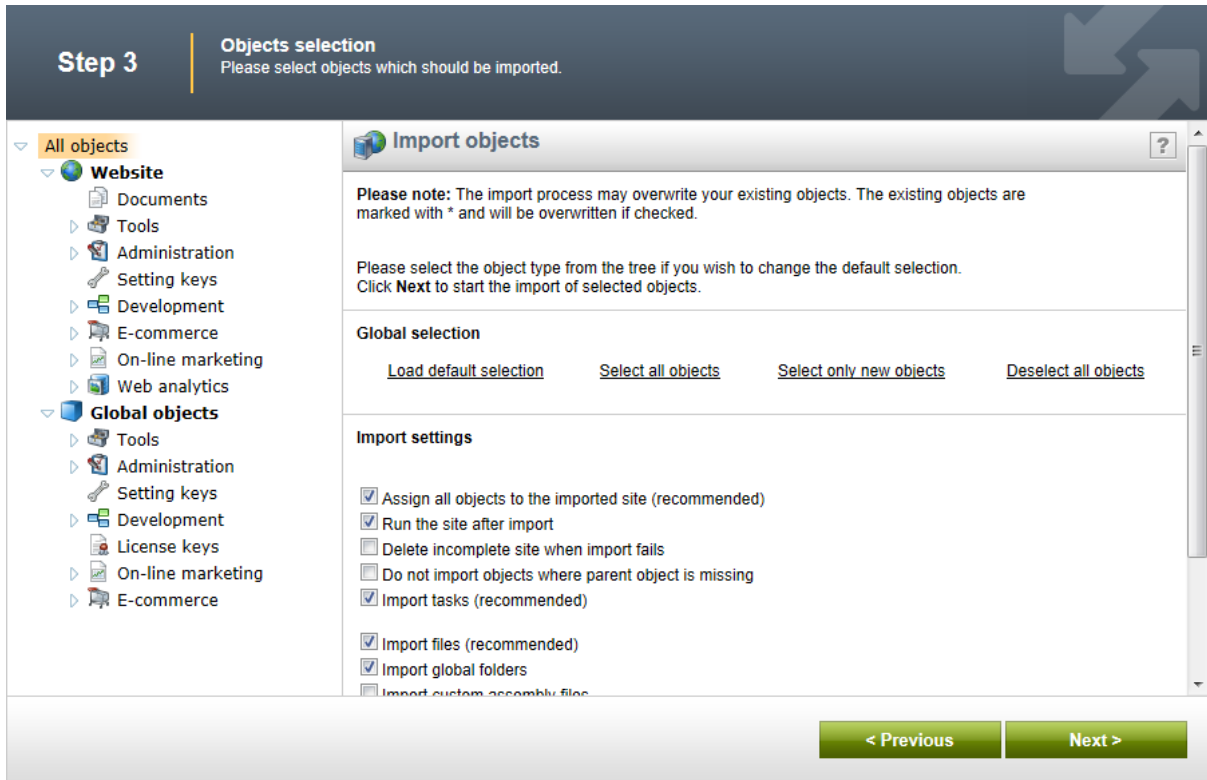

The tree on the left represents object categories. These reflect the sections of the administration interface under which the objects can be found. Selecting a category opens a set of check boxes in the right part of the screen, allowing you to choose which objects will be imported. Objects that already exist on the target server are marked with an asterisk (*). If you import an existing object, the new version overwrites the current one.

Select the root of the tree (*All objects*) to access the following import settings:

Global selection	
Load default selection	Preselects all objects based on your choices in Step 1 of the import wizard.
Select all objects	Selects all objects in the import package.
Select only new objects	Selects only those objects that do not exist in the target database (existing objects are unselected).
Deselect all objects	Unselects all objects in the import package.
Import settings	
Update site definition	Displayed only when importing to an existing site. If enabled, all settings stored as part of the site object will be updated with those contained in the package. These settings are stored in the <code>Site\cms_site.xml</code> file inside the export package.

Assign all objects to the imported site (recommended)	If enabled, all imported site-related objects will be assigned to the imported site.
Run the site after import	If enabled, the imported site automatically starts once the import process is complete.
Delete incomplete site when import fails	If enabled, partially imported sites are automatically deleted if the import process fails.
Do not import objects where parent object is missing	If enabled, the import process skips any child objects whose parent objects are not found in the import package.
Import tasks (recommend)	If enabled, delete tasks (incremental deployment) included in the package will be performed.
Import files (recommended)	Some database objects are linked with physical files stored on the file system inside the web project. If you check this option, the import process creates all files that are included in the import package.
Import global folders	If checked, the import process includes global files originally exported from the following folders: <ul style="list-style-type: none"> • ~/App_Code/Global/ • ~/CMSGlobalFiles/ • ~/CMSScripts/Custom/ • ~/App_Code/Controllers/ • ~/Controllers/Global/ • ~/Views/Global/
Import custom assembly files	If enabled, the import process includes custom assembly files bound to notification gateways, payment options, integration connectors, scheduled tasks and smart search indexes included in the import package. Custom assemblies are those whose names do not begin with the <i>CMS.</i> prefix.
Import site folders	If checked, the import process includes site-related files originally exported from the following folders: <ul style="list-style-type: none"> • ~/App_Code/<site code name>/ • ~/App_Data/<site code name>/ • ~/<site code name>/ • ~/Controllers/<site code name>/ • ~/Views/<site code name>/
Log staging synchronization tasks	If enabled, the system logs staging tasks reflecting all changes made by the import. Check this option to synchronize the imported data to other servers connected through Content staging .
Log integration tasks	If enabled, the system logs outgoing integration tasks for all changes made by the import. Check this option if you want to transfer the imported data to a system connected via the System integration bus).
Overwrite system queries	Available only when importing from an older version of Kentico CMS. If checked, the system imports all queries from the package and overwrites the current ones.

Important: If the **package contains custom queries** that you added to the system, it is necessary to have this option enabled.

5. The following object categories contain extra options that you can set:

Automation processes	
Import all site specific triggers	If checked, all site specific triggers will be imported, even if the respective processes are not selected. This check-box is only displayed when the import package contains an exported website, not only separate objects. If you are importing to an existing site, this option is deselected by default.
Custom tables	
Import custom table data	If checked, custom table records (the actual data stored in the tables) included in the package will be imported together with the respective custom tables. If you are importing to an existing site, this option is disabled by default.
Documents	
Import new documents	If enabled, documents included in the import package will be imported. Please note: when importing into an existing site, only new documents can be imported. Modified documents that are already

	present on the target server will not be overwritten.
Import document histories	If enabled, document histories (i.e. previous versions of documents) will be imported.
Import document relationships	If enabled, document relationships will be imported.
Import document-level permissions	If enabled, document security settings made in CMSDesk -> Content -> Edit -> Properties -> Security will be imported.
Import blog comments	If enabled, blog comments will be imported together with blog post documents.
Import event attendees	If checked, event attendees will be imported together with all imported events.
Import all user personalization	If checked, user personalization of all users will be imported, even for users who are not selected to be imported. If you are importing to an existing site, this option is de-selected by default.
Forms	
Import form data	If enabled, forms data included in the package will be imported together with the forms.
Import physical files data	If checked, physical files saved within form records (if there are some) will also be imported.
Forums	
Import forum posts	If enabled, forum posts included in the package will be imported together with the forums.
Groups	
Import all group memberships	If enabled, user memberships will be imported together with the selected groups.
Message boards	
Import board messages	If enabled, board messages included in the package will be imported together with the message boards.
Media libraries	
Import media files	If enabled, media files (stored in database) included in the package will be imported together with the media libraries.
Import physical files	If enabled, physical files (stored in the file system) included in the package will be imported together with the media libraries.
Page templates	
Import all site specific page template scopes	If checked, site-specific page template scopes will be imported for all page templates, even if a page template itself is not selected to be imported. This check-box is only displayed with page templates in the Global section of the tree and only when the import package contains an exported website, not only separate objects. If you are importing to an existing site, this option is de-selected by default.

Import web part and zone variants with the selected page templates	If checked, web part and zone variants (from MVT testing or Content personalization) included in the package will be imported together with the selected page templates.
Users	
Import user dashboards	Indicates if user dashboards should be imported together with the imported users. If you are importing to an existing site, this option is de-selected by default so that existing dashboards are not overwritten.
Import all user site specific dashboards	If checked, all user dashboards will be imported, even if the respective users are not selected to be imported. This check-box is only displayed when the import package contains an exported website, not only separate objects. If you are importing to an existing site, this option is de-selected by default so that existing dashboards are not overwritten.
Workflows	
Import all workflow scopes	If checked, all workflow scopes will be imported, even if the respective workflows are not selected. Import web part and zone variants with the selected page templates. This check-box is only displayed when the import package contains an exported website, not only separate objects. If you are importing to an existing site, this option is deselected by default.

6. If you have the **Log export tasks** option enabled in **Site Manager -> Settings -> Versioning & Synchronization -> Staging**, a list of tasks may also be displayed under the objects list. This happens when some global objects were deleted (like the two Web part containers in the screenshot below). If you leave the boxes checked, these objects will also be deleted on the target server.

Step 3

7. Click **Next** to execute the import process. An import log appears, showing the progress of the import (you can abort the import process at any time by clicking **Cancel**).

Click **Finish**. You will be redirected back to **Site manager** -> **Sites**.

Step 4 | **Import progress**
Objects are being imported.

Import has finished with minor problems. Please see warning messages below.

- Starting site 'Corporate site2'
- Copying objects files
- Rebuilding site indexes
- Ensuring missing site settings
- Processing additional actions
- Importing 'Smart search indexes' objects
- Importing 'Task status' objects
- Importing 'Task priority' objects
- Importing 'Project status' objects
- Importing 'Notification templates' objects
- Importing 'Notification gateways' objects
- Importing 'Membership' objects
- Importing 'Bad words' objects
- Importing media library 'Video gallery' file objects
- Importing 'Media libraries' objects
- Importing forum 'Website forums' posts
- Importing 'Forums' objects
- Importing 'Forum groups' objects
- Importing 'Reports' objects
- Importing 'Report categories' objects
- Importing 'Polls' objects
- Importing 'Newsletter issues' objects
- Importing 'Newsletters' objects
- Importing 'Newsletter templates' objects
- Importing form 'Contact Us' data
- Importing 'Forms' objects
- Importing 'Dashboard' objects
- Importing additional document properties

Objects are being imported

Cancel Finish

Please note

Packages from different versions of Kentico CMS have a different structure. When importing packages from an older version of Kentico CMS to a newer one, the system automatically converts the package to the newer format.

Please pay special attention when importing **Form control**, **Inline control** and **Web part** objects from older packages. If possible, avoid overwriting your current objects of these types, as it may cause incompatibility problems.

Conflicts of running sites

If the imported site uses the same domain name or alias as one of the websites already running in your system, the import displays a warning at the end and the imported site does not start.

Step 4

Import progress
 Objects are being imported.

Import has finished with minor problems. Please see warning messages below.

- Starting site 'Corporate site2'
- Copying objects files
- Rebuilding site indexes
- Ensuring missing site settings
- Processing additional actions
- Importing 'Smart search indexes' objects
- Importing 'Task status' objects
- Importing 'Task priority' objects
- Importing 'Project status' objects

- Importing 'Report categories' objects
- Importing 'Polls' objects
- Importing 'Newsletter issues' objects
- Importing 'Newsletters' objects
- Importing 'Newsletter templates' objects
- Importing form 'Contact Us' data
- Importing 'Forms' objects
- Importing 'Dashboard' objects
- Importing additional document properties

Objects are being imported

Cancel
Finish

WARNING: Failed to start site 'Corporate site2', there is already a site running under this domain alias. You first need to stop the existing site and then start the new site manually.

In such cases, you need to:

1. Go to **Site Manager -> Sites**.
2. Edit (✎) the imported site and change the conflicting **Site domain name** or **Domain alias**.
3. Return to the list of sites and click **Start site** (▶) next to the imported site.

Application restart

If you get the following error message at the end of the import process:

"Application has been restarted and the logging of the import process has been terminated. Please see context help in this section for more details and how to solve this issue."

you need to finish the import process manually:

1. Open the import package and extract all content of the `<package>\Data\Files` folder.
2. Remove the `.export` extension from the names of all files in all extracted sub-folders.
3. Rename all folders named `##SITENAME##` to the code name of the target website

and copy them to the root of the web project.

4. Copy all contents of the *cms_attachments* folder (if it is present among the extracted folders) to the location in the target project where document attachments are stored (as configured in [Site Manager -> Settings -> System -> Files](#)). Please note that this is applicable only when the system is configured to store document attachments in the file system (not in the database).

5. Copy the content of all folders named as an object type (e.g. *cms_avatar*, *cms_documenttype*, *forums_forum*, etc.) to the root of your web project.

Re-signing imported macro expressions [*requires [hotfix 7.0.9](#) or newer*]

The system uses signatures to ensure the security of [macro expressions](#). The signatures are only valid in the environment of the application where the macros were originally saved.

To ensure that macros inside the data of imported sites or objects work correctly, you need to re-sign the macros using the **Site Manager -> Administration -> System -> Macros** interface. See [Macro security](#) for additional information.

5.5.5.2 Importing from web site to web application projects

Due to the [differences between website and web application](#) projects, the system cannot import from one to another automatically. After completing the standard import procedure, manually perform the following steps to ensure that your web application runs correctly:

1. The import places all physical files from the imported package into the *~/App_Data/CMSTemp/ImportExport/Files* folder. Copy the content of the folder into the root of your web application project.

Important!

We strongly recommend creating a backup of your project before overwriting any files.

2. Open the solution file (*WebApp.sln*) in Visual Studio from the web project directory.

3. Include the files that did not exist in the project before the import:

- a. Click **Show all files** at the top of the Solution Explorer.
- b. Locate the newly added files.
- c. Select the files you wish to include one-by-one while holding the **Ctrl** key.
- d. Right-click one of the files and select **Include in Project**.

4. Right-click the project node (CMSApp) in the Solution Explorer, and select **Convert To Web Application**.

5. Rebuild the solution.

5.5.6 Export and import internals and API

5.5.6.1 Overview

In this chapter, you will learn which [API classes](#) are used by export and import and see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

5.5.6.2 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes used by export and import can be found in the **CMS.CMSImportExport** namespace.

Import API classes:

- **ImportProvider** - provides functionality for import of sites and objects.
- **SiteImportSettings** - object representing settings of website import.
- **ImportTypeEnum** - enumeration used to determine object pre-selection in import settings.

Export API classes:

- **ExportProvider** - provides functionality for export of sites and objects.
- **SiteExportSettings** - object representing settings of website export.
- **ExportTypeEnum** - enumeration used to determine object pre-selection in export settings.

Other classes:

- **ImportExportHelper** - provides helper methods for export and import.

5.5.6.3 API examples

5.5.6.3.1 Overview

These topics show examples of how the export and import API can be used:

- [Import](#)
- [Export](#)

**Please note**

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Tools\ImportExport\Default.aspx.cs**.

The API examples of export and import use the following namespaces:

```
using System;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.CMSImportExport;
using CMS.IO;
using CMS.DocumentEngine;
using CMS.WorkflowEngine;
```

5.5.6.3.2 Import

The following example imports a single user object included in a sample *APIExample_User.zip* import package stored in `~\CMSAPIExamples\Code\Tools\ImportExport\Packages\`.

```
private bool ImportObject()
{
    // Create site import settings
    SiteImportSettings settings = new SiteImportSettings(CMSContext.CurrentUser);

    // Initialize the settings
    settings.WebsitePath = Server.MapPath("~/");
    settings.SourceFilePath = settings.WebsitePath + "\\CMSAPIExamples\\Code\\
\\Tools\\ImportExport\\Packages\\APIExample_User.zip";
    settings.ImportType = ImportTypeEnum.All;
    settings.LoadDefaultSelection();

    // Import
    ImportProvider.ImportObjectsData(settings);

    // Delete temporary data
    ImportProvider.DeleteTemporaryFiles(settings, false);

    return true;
}
```

The following example imports a complete website included in a sample *APIExample_Site.zip* import package stored in `~\CMSAPIExamples\Code\Tools\ImportExport\Packages\`.

```

private bool ImportSite()
{
    // Prepare the properties
    string websitePath = Server.MapPath("~/");
    string sourceFilePath = websitePath + "\\CMSAPIExamples\\Code\\Tools\\
ImportExport\\Packages\\APIExample_Site.zip";
    string siteDisplayName = "My new imported site";
    string siteName = "MyNewImportedSite";
    string siteDomain = "127.0.0.1";

    // Ensure there is no site with the set name
    if (SiteInfoProvider.GetSiteInfo(siteName) == null)
    {
        // Import
        ImportProvider.ImportSite(siteName, siteDisplayName, siteDomain,
sourceFilePath, websitePath, CMSContext.CurrentUser);

        return true;
    }

    return false;
}

```

5.5.6.3.3 Export

The following example exports the user object imported by the first example on the [previous page](#) into a new export package.

```

private bool ExportObject()
{
    // Delete temporary data
    try
    {
        ExportProvider.DeleteTemporaryFiles();
    }
    catch
    {
    }

    // Get user
    UserInfo exportedUser = UserInfoProvider.GetUserInfo("MyNewImportedUser");

    // Ensure that user exists
    if (exportedUser != null)
    {
        // Prepare the properties
        string websitePath = Server.MapPath("~/");
        string exportFileName = string.Format("APIExample_User_{0:yyyy-MM-dd_hh-
mm}.zip", DateTime.Now);
        string exportFilePath = FileHelper.GetFullPhysicalPath
(ImportExportHelper.GetSiteUtilsFolder(), websitePath) + "Export\\" +
exportFileName;
    }
}

```

```
    // Ensure there is no exported package with the same name
    if (!File.Exists(exportFilePath))
    {
        // Export
        ExportProvider.ExportObject(exportedUser, exportFilePath,
websitePath, CMSContext.CurrentUser);

        return true;
    }

    return false;
}
```

The following example exports the website imported by the first example on the [previous page](#) into a new export package.

```
private bool ExportSite()
{
    // Delete temporary data
    try
    {
        ExportProvider.DeleteTemporaryFiles();
    }
    catch
    {
    }

    // Prepare the properties
    string websitePath = Server.MapPath("~/");
    string exportFileName = string.Format("APIExample_Site_{0:yyyy-MM-dd_hh-mm}
.zip", DateTime.Now);
    string exportFilePath = FileHelper.GetFullPhysicalPath
(ImportExportHelper.GetSiteUtilsFolder(), websitePath) + "Export\\" +
exportFileName;
    string siteName = "MyNewImportedSite";

    // Ensure that site exists
    if (SiteInfoProvider.GetSiteInfo(siteName) != null)
    {
        // Ensure there is no exported package with the same name
        if (!File.Exists(exportFilePath))
        {
            // Export
            ExportProvider.ExportSite(siteName, exportFilePath, websitePath,
false, CMSContext.CurrentUser);

            return true;
        }
    }
}
```

```
return false;
}
```

5.6 Deleting sites

You can delete sites in the system in **Site Manager -> Sites**.

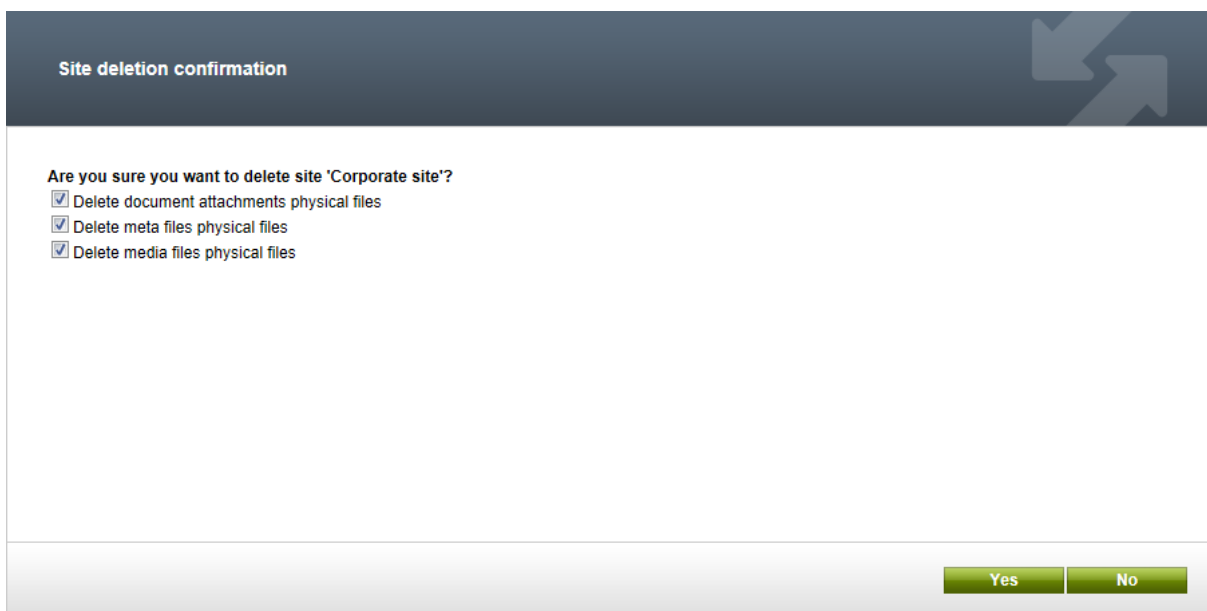

1. Clicking the **Delete** (✖) icon of the site that you want to delete.

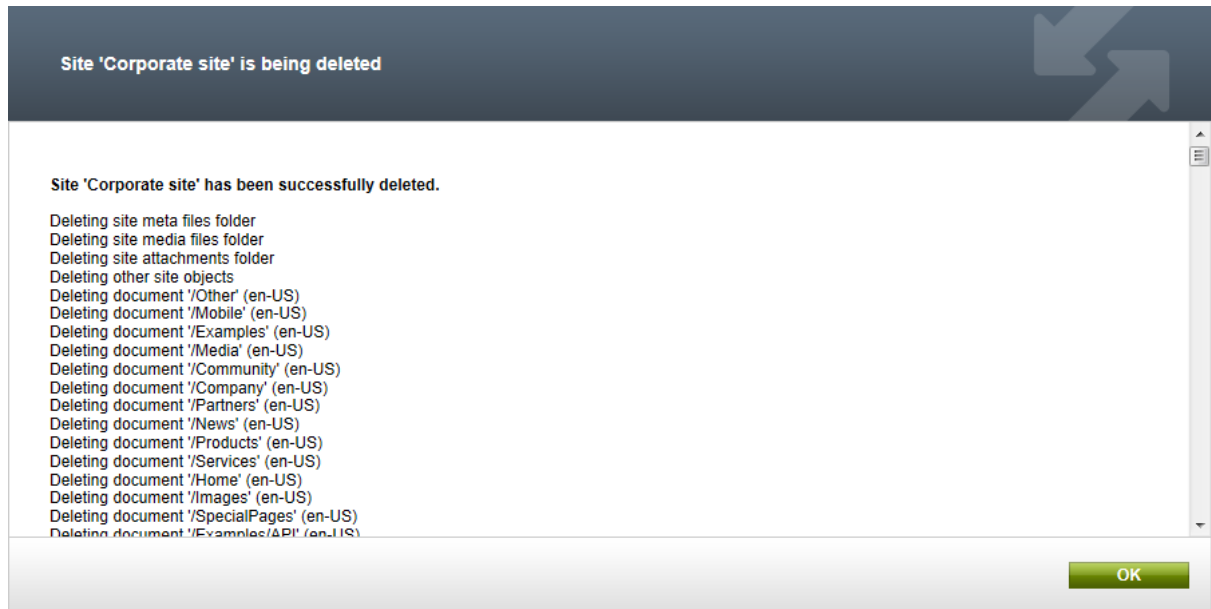

2. In the **Site deletion confirmation** dialog, you can select the following options:

- **Delete document attachments physical files** - if checked, document attachment files stored in the file system will be deleted; these files are stored in the `<web project>\<site name>\files` folder
- **Delete meta files physical files** - if checked, meta files stored in the file system will be deleted; these files are stored in the `<web project>\<site name>\metafiles` folder
- **Delete media files physical files** - if checked, physical files stored in media libraries will be deleted; these files are stored in the `<web project>\<site name>\media` folder

Make the selection and click **Yes** to continue deleting the site.

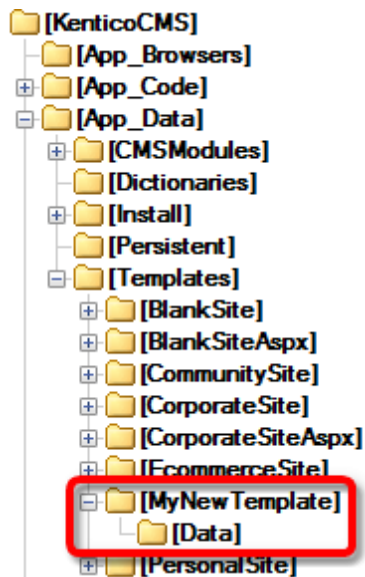

3. A log will be displayed, showing you the progress of site deletion. When the process finishes, click **OK**. You will be redirected back to **Site Manager -> Sites**, where the deleted site will not be listed.

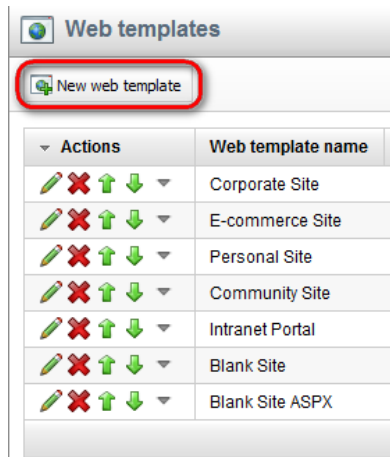

5.7 Creating web templates

In case that you want to use your current site created with Kentico CMS as a web template, so that you can use it as a starting point for developing new sites, you have to take the following steps:

1. Export your site. For a step-by-step tutorial on how to export a site, please refer to the [Exporting a site](#) chapter of this guide.
2. Go to **<web project>\App_Data\Templates**. As you can see, this is the folder where all the default templates, such as Community or Corporate site, are stored. Create a new folder with the name of your new page template. Then create one sub-folder under the newly created folder and give it the name **Data**.

3. Extract the content of your export package into the **Data** folder.
4. Go to **Site Manager -> Development -> Web templates** and click **New web template**.

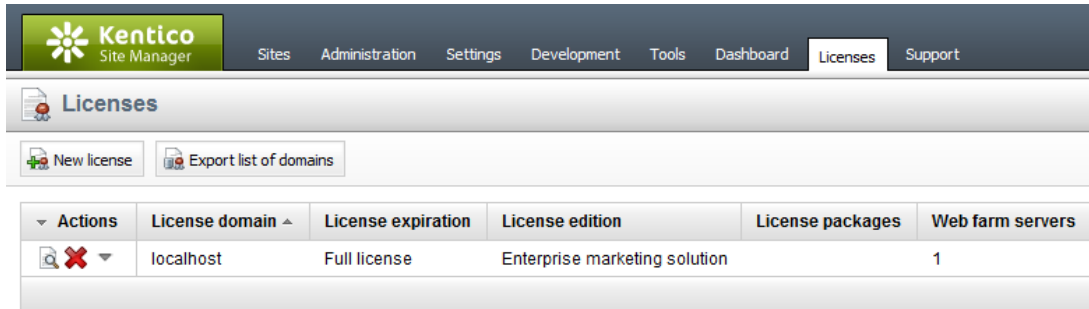

5. Enter the following details:

- **Web template display name** - name of the web template displayed in the administration interface
- **Web template code name** - name of the web template used in code
- **Web template folder name** - path to the folder where you have extracted the content of the export package; `~\App_Data\Templates\<your folder>`
- **Web template description** - text describing your new web template
- **License editions** - editions of Kentico CMS in that this web template will be available; check all for full availability

and click **OK**. Your new web template should now be present in the list.

5.8 License management

Kentico CMS requires an appropriate license key for every domain you use. The licenses can be managed in **Site Manager -> Licenses**:

Actions	License domain	License expiration	License edition	License packages	Web farm servers
 	localhost	Full license	Enterprise marketing solution		1

The list displays the information about licensed domain, expiration and edition. When you get full or trial key for a particular domain, you need to click  **New license** and enter the full text of the key into the **License key** field.

You can also use  **Export list of domains** to export your domains into a text file.

How licensing works

If you're running a website on domain *example.com*, you need a single license key that will work for the following domains:

- <http://example.com>
- <https://example.com>
- <http://www.example.com>
- <https://www.example.com>
- <http://localhost>
- <http://127.0.0.x> (where x is between 1 and 255)

If you use a domain alias (different domain name that points to the same website), such as *example1.com* or *example.net*, you need extra license keys for these domain aliases. Please ask [Kentico support](#) for generating the additional keys (they are free of charge if you already own a license for the main domain).

5.9 Managing site settings

Most of the site settings can be configured in **Site Manager -> Settings** section.

The screenshot shows the Kentico CMS 7.0 Settings page for Content. The page is divided into several sections:

- Web site content:**
 - Default alias path: /Home (with a Select button) and an 'Inherit from global settings' checkbox.
- Page not found:**
 - Page not found for non-published documents: checked, with an 'Inherit from global settings' checkbox.
 - Page not found URL: empty text field, with an 'Inherit from global settings' checkbox.
 - Log page not found exception: checked, with an 'Inherit from global settings' checkbox.
- Multilingual:**
 - Default content culture: English - United States (dropdown), with an 'Inherit from global settings' checkbox.
 - Combine with default culture: unchecked, with an 'Inherit from global settings' checkbox.
 - Combine files with default culture: checked, with an 'Inherit from global settings' checkbox.
- Metadata:**
 - Page key words prefix: empty text field, with an 'Inherit from global settings' checkbox.
 - Page description prefix: empty text field, with an 'Inherit from global settings' checkbox.
 - Page title format: {%prefix%} - {%pagetitle_orelse_name%}, with an 'Inherit from global settings' checkbox.
 - Page title prefix: Corporate site, with an 'Inherit from global settings' checkbox.
 - Control element: div (dropdown), with an 'Inherit from global settings' checkbox.

At the bottom of the page, there is a link for [Export these settings](#).

There are two basic types of settings:

- **Global** – such settings apply to all sites.
- **Site-specific** – such settings apply to the particular site and they override the global settings values.

If you want to inherit value from the global settings, you need to check the “inherit from global settings” button and click Save.

Tip: If you mouse-over the name of the settings key, you will see the description of the key.

5.10 Configuring multiple web sites

Kentico CMS allows you to run multiple websites from a single installation (code base) and database. All websites run as a single website in IIS. The following tutorial explains how to set up multiple websites on Windows XP and Windows Server 2003.

We will configure two websites:

- **mysite.com**
- **mysite2.com**

Configuring multiple sites in Kentico CMS (common for all operating systems)

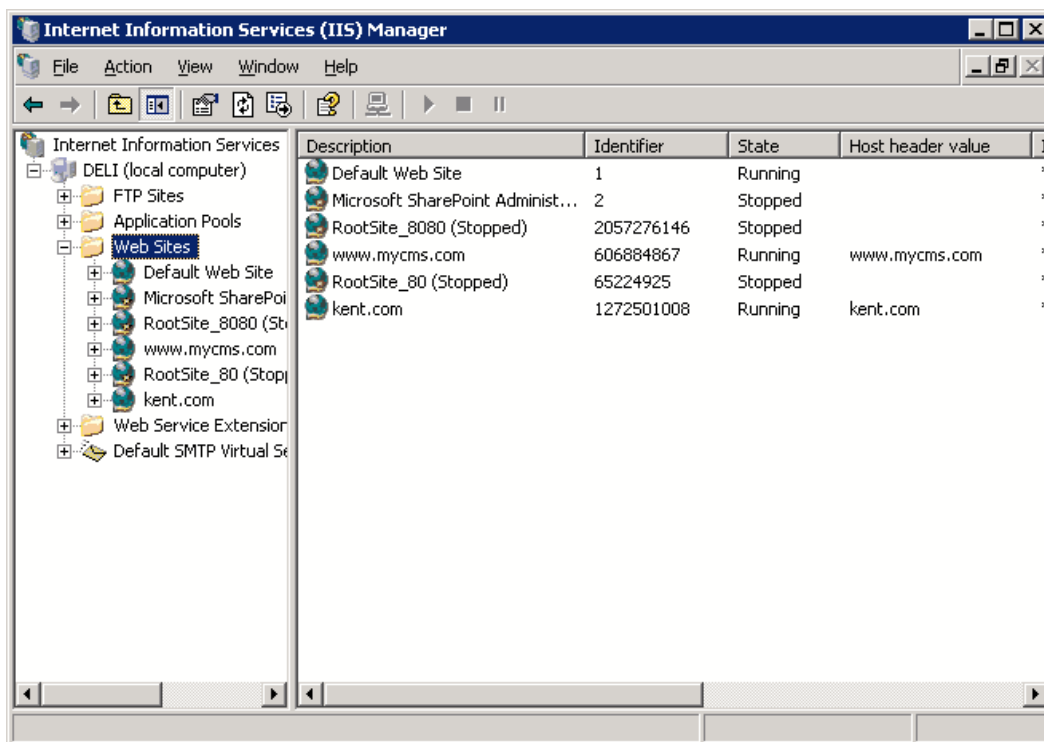

This part is common for all operating systems.

1. Create two websites in **Site Manager -> Sites** - you can either import your existing websites or you can create new websites using the New site wizard.
2. Edit the properties of each website in **Site Manager -> Sites** and set the **Site domain name** value of the each website to the appropriate domain (without www prefix and without http:// protocol).
3. Make sure both sites are running. You can check this in the Site list, in the Status column.
4. Make sure you have valid license keys for both domains in **Site Manager -> Licenses**.

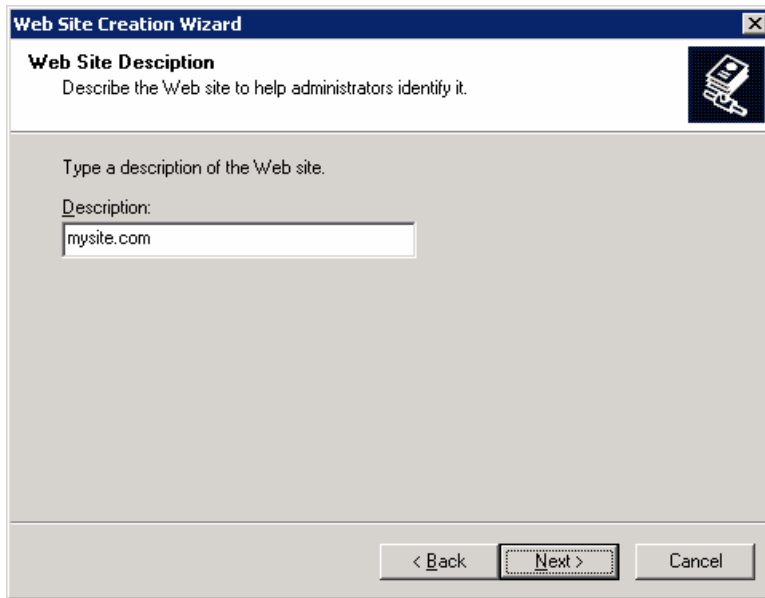

Configuring multiple sites on Windows Server 2003

Open **Start -> Administrative tools -> Microsoft Internet Information Services (IIS) Manager**, go to websites section and if the website does not exist yet, create it.

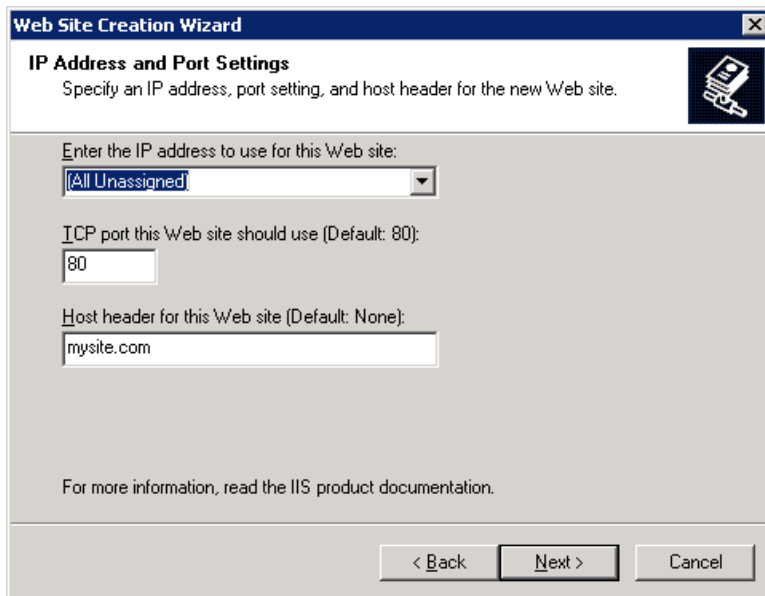

Right-click **websites** and choose **New -> website...** The website Creation Wizard starts. Enter the site descriptive name, such as **mysite.com**:

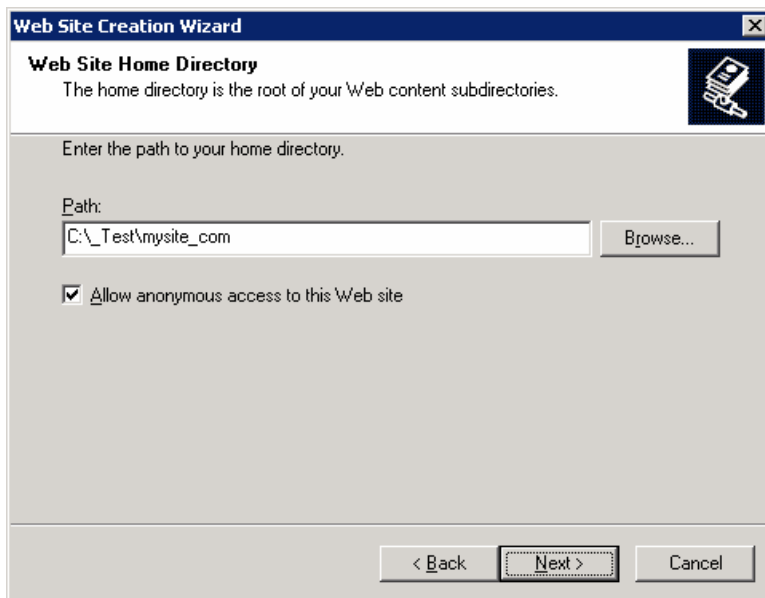

The screenshot shows the 'Web Site Creation Wizard' dialog box, specifically the 'Web Site Description' step. The title bar reads 'Web Site Creation Wizard'. Below the title bar, the section is titled 'Web Site Description' with the instruction 'Describe the Web site to help administrators identify it.' There is a small icon of a floppy disk with a plus sign in the top right corner. The main area contains the text 'Type a description of the Web site.' followed by a label 'Description:' and a text input field containing 'mysite.com'. At the bottom, there are three buttons: '< Back', 'Next >', and 'Cancel'. The 'Next >' button is highlighted with a dashed border.

Click **Next**. Enter the **Host header for this website** as **mysite.com**:

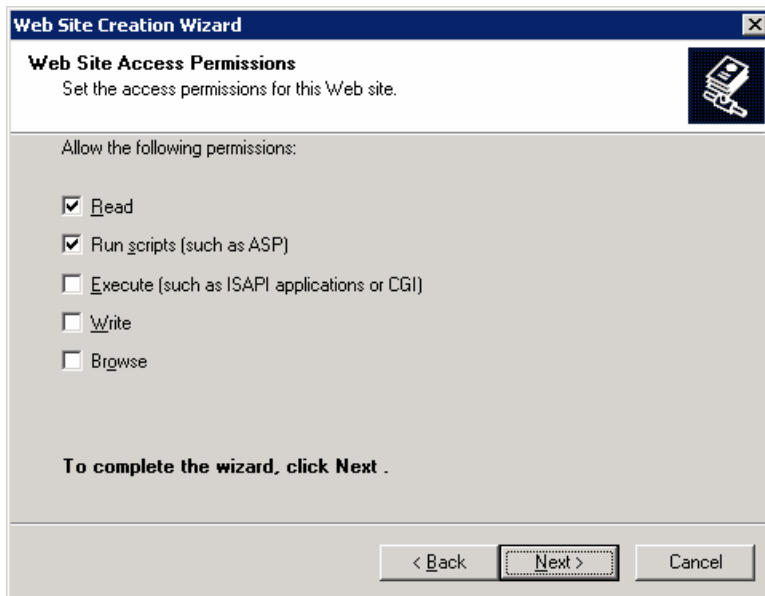

The screenshot shows the 'Web Site Creation Wizard' dialog box, specifically the 'IP Address and Port Settings' step. The title bar reads 'Web Site Creation Wizard'. Below the title bar, the section is titled 'IP Address and Port Settings' with the instruction 'Specify an IP address, port setting, and host header for the new Web site.' There is a small icon of a floppy disk with a plus sign in the top right corner. The main area contains the text 'Enter the IP address to use for this Web site:' followed by a dropdown menu with '(All Unassigned)' selected. Below that is the text 'TCP port this Web site should use (Default: 80):' followed by a text input field containing '80'. Then, the text 'Host header for this Web site (Default: None):' followed by a text input field containing 'mysite.com'. At the bottom, there are three buttons: '< Back', 'Next >', and 'Cancel'. The 'Next >' button is highlighted with a dashed border.

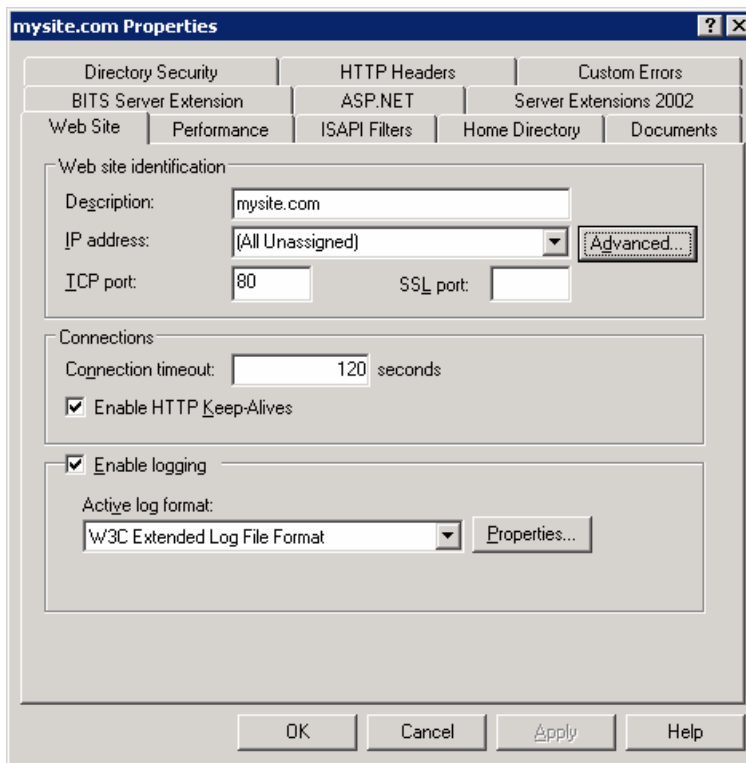

Click **Next**. Select the disk path where the root of your website is placed. This must be the folder where web.config file is placed.

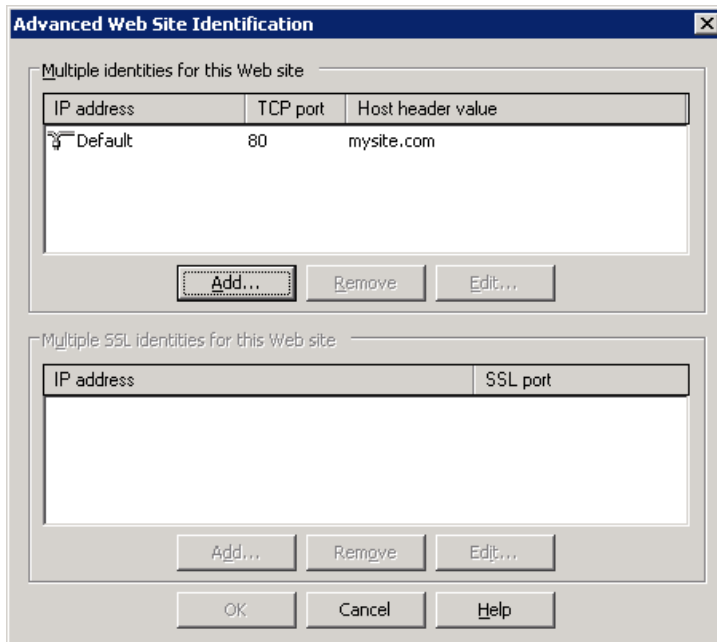

Click **Next**. In the next step, enable the **Read** and **Run scripts** boxes.

Click **Next**. The wizard is finished. Click **Finish**. Now we need to add the other domain name to the list of URLs hosted by this website. Right-click the newly created website and display website properties. On the **website** tab, click **Advanced...**

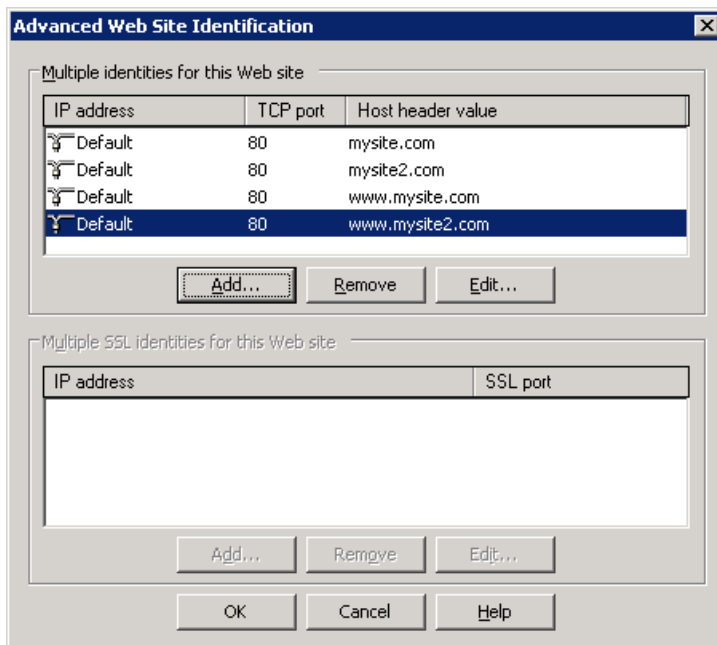

Now you need to add another host header value for your second domain:

Click the top **Add...** button and enter the appropriate values. The standard HTTP port is 80:

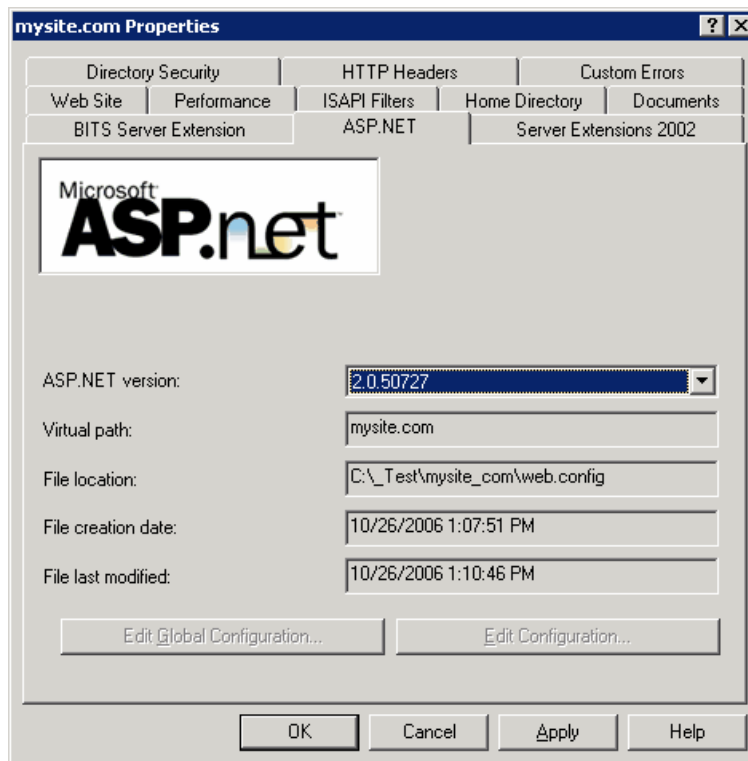

You need to repeat this also for `www.*` alternatives of your website:

Click **OK** on all dialogs.

Please note: You may also need to configure the website for ASP.NET 2.0 in website Properties, on the **ASP.NET** tab. IIS 6 may display the **ASP.NET version as 2.0.50727** even if you have **ASP.NET 3.5** or higher installed and registered:

Your new website is now configured to host all incoming requests for domains `mysite.com` and `mysite2.com` (or other domains depending on your particular situation). You may need to ask your network administrator to redirect the domain in the DNS records to your website.

If you do not own the domain, you can test it by modifying the `C:\WINDOWS\system32\drivers\etc\hosts` file in notepad and adding the following lines to the end of the file:

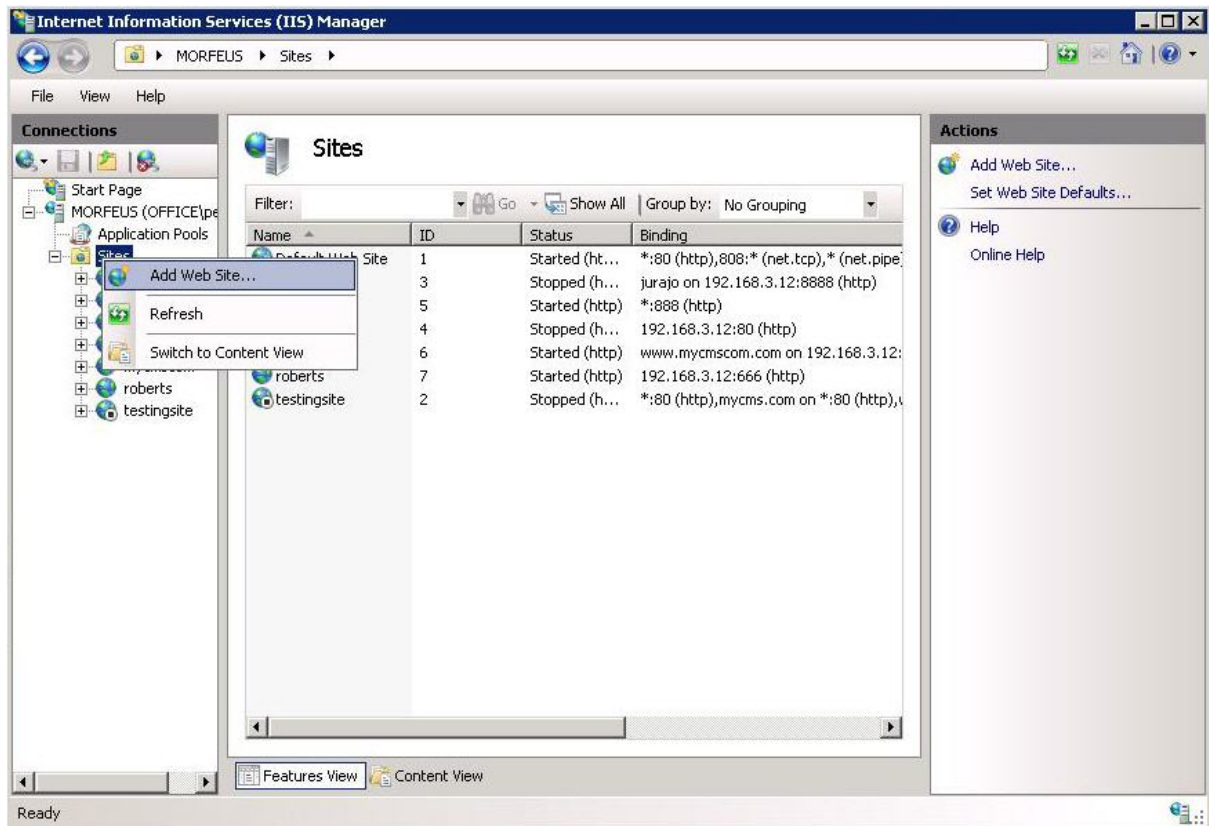

```
127.0.0.1    mysite.com
127.0.0.1    www.mysite.com
127.0.0.1    mysite2.com
127.0.0.1    www.mysite2.com
```

Save the file. Please note: these are client settings, which means they will work only if you use web browser on your server.

Now, when you go to `http://www.mysite.com` and to `http://www.mysite2.com` (or your own domain names), you should see two different websites.

Configuring multiple sites on Windows Vista / Server 2008

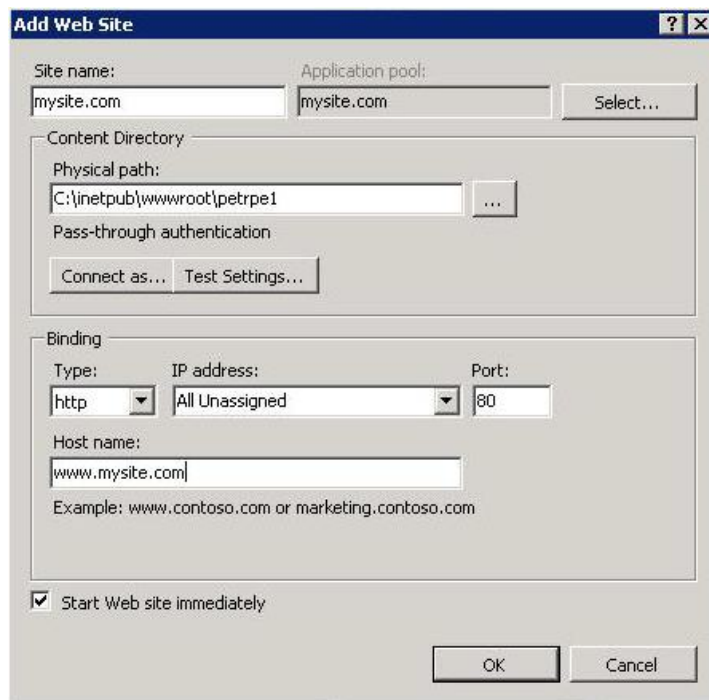

Go to **Start -> Control Panel -> Administrative tools -> Microsoft Internet Information Services (IIS) Manager**. In the tree view, right click **Sites** and choose **Add website....**

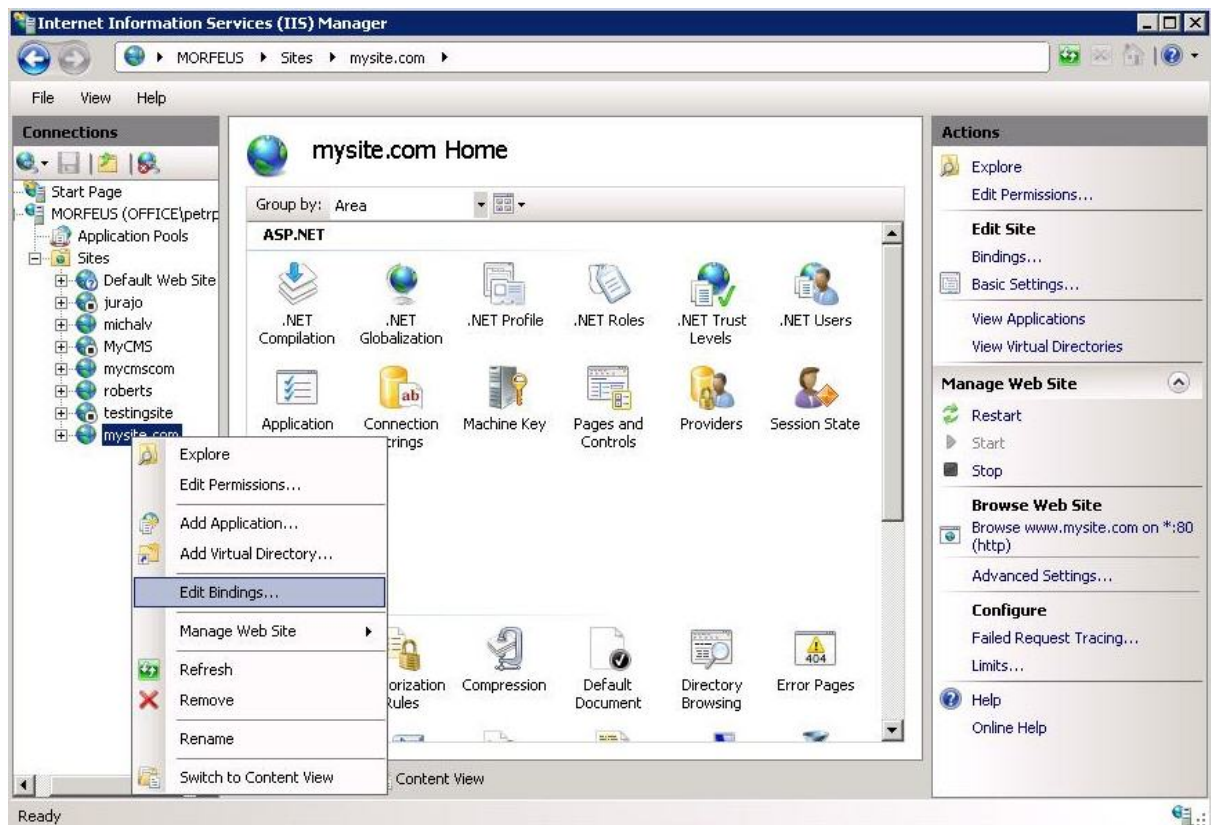

Enter the following details:

- **Site name:** mysite.com
- **Physical path:** disk path to the location where your website is placed; this must be the location where the *web.config* file is stored
- **Host name:** www.mysite.com

Click **OK**.

The site should now appear in the tree, under the **Sites** node. Right click the site and choose **Edit bindings** (or **Bindings** on Vista).

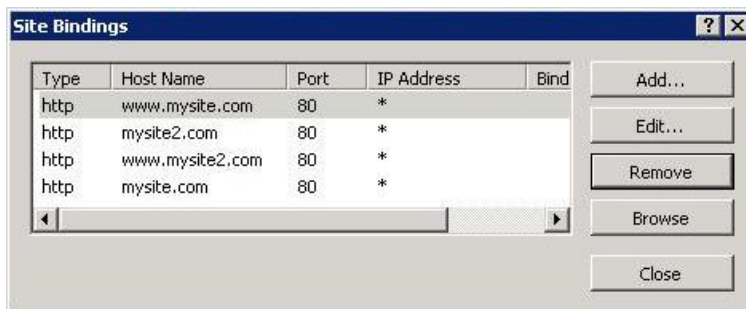

The site bindings dialog appears. Click **Add...**

Enter the domain name of your second website (*www.mysite2.com* in this case) into the **Host name** field and click **OK**. Repeat this for both of the sites without the 'www.' prefix.

The result should look like the following screenshot.

Your new website is now configured to host all incoming requests for domains *mysite.com* and *mysite2.com* (or other domains depending on your particular situation). You may need to ask your network administrator to redirect the domain in the DNS records to your website.

If you do not own the domain, you can test it by modifying the `C:\WINDOWS\system32\drivers\etc\hosts` file in notepad and adding the following lines to the end of the file:

```
127.0.0.1    mysite.com
127.0.0.1    www.mysite.com
127.0.0.1    mysite2.com
127.0.0.1    www.mysite2.com
```

Save the file.

Please note: these are client settings, which means they will work only if you use web browser on your server.

Now, when you go to <http://www.mysite.com> and to <http://www.mysite2.com> (or your own domain names), you should see two different websites.

Configuring multiple sites on Windows XP

On Windows XP, the support of multiple sites and domains in IIS is limited, so we will use a single IIS website and define "virtual" domains in our hosts file:

Open the `c:\WINDOWS\system32\drivers\etc\hosts` file in notepad and add the following lines to the end of the file:

```
127.0.0.1      mysite.com
127.0.0.1      www.mysite.com
127.0.0.1      mysite2.com
127.0.0.1      www.mysite2.com
```

Save the file. Please note: these are client settings, which means they will work only if you use web browser on your local computer.

Go to <http://www.mysite.com> or <http://www.mysite.com/kenticocms> (where `kenticocms` is the name of the virtual directory with Kentico CMS website) and to <http://www.mysite2.com>. You should see two different websites.

Multiple websites on a single domain (in subfolders)

If you cannot use (for some reason) multiple domain names, you can configure Kentico CMS so that it differentiates websites by subfolder (virtual directory). Read chapter [Multiple websites on a single domain \(in subfolders\)](#) for more details.

Using multiple websites on Windows XP

Windows XP allows you to run only one IIS website at a time. If you need to develop multiple websites (multiple Kentico CMS instances) in the root folder, you may need to create additional websites and switch between them using the IISAdmin utility that can be downloaded at <http://jetstat.com/iisadmin/download.asp>.

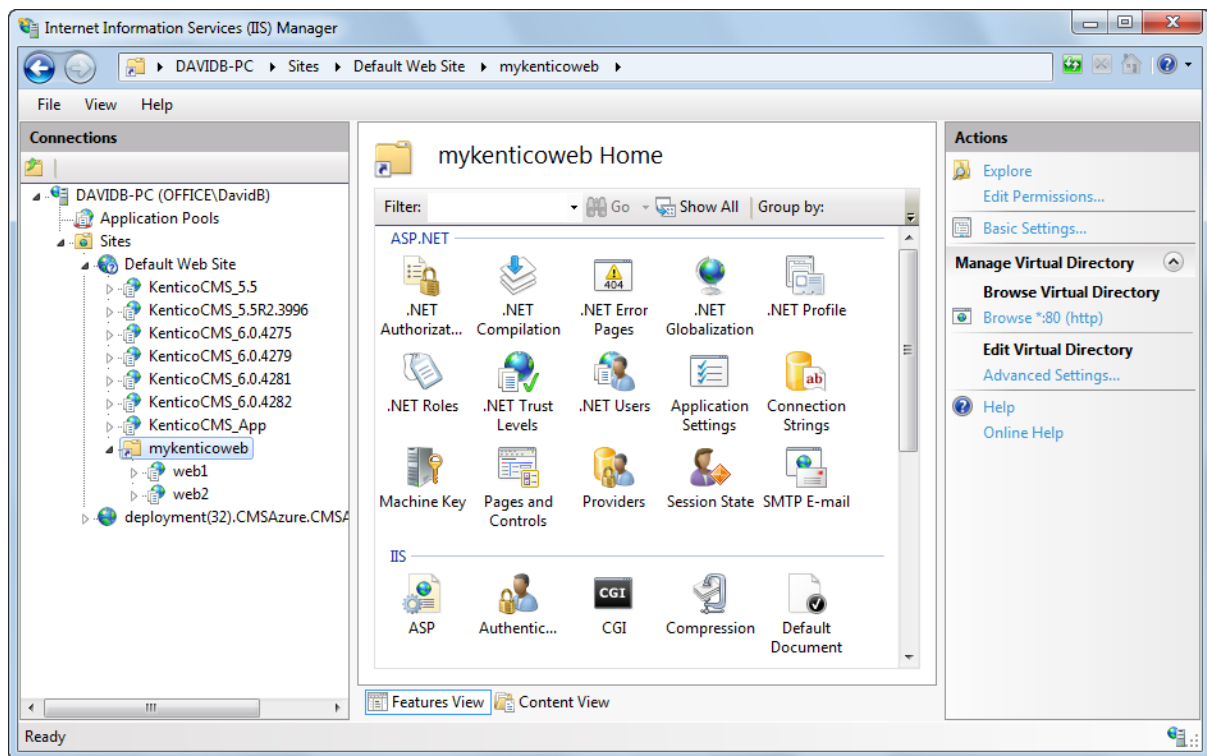

5.11 Multiple web sites on a single domain (in subfolders)

In some cases, you may want to run multiple websites in separate subfolders, without getting a new domain for each one. This can be achieved by configuring IIS and the domain names (or domain aliases)

of the websites like in the following example:

Example

1. Install Kentico CMS to the following folder: **C:\inetpub\wwwroot\mykenticofolder**. Make sure the name of the folder is different from the virtual directory name that you will later enter in IIS. In the same step of the installer, choose **This is an installation to the root (do not create virtual directory)**. When the setup finishes, the link to your new website will not work as the virtual directory is not created in IIS.
2. Open the IIS console (Control Panels -> Administrative Tools -> Internet Information Services) and create a new virtual directory named **mykenticoweb**. Assign it to a **non-website-root folder** on your disk. Ideally, create an empty folder on the disk for this purpose (e.g. c:\empty).
3. Create two applications under **mykenticoweb** called **web1** and **web2**. Both of them need to be have their physical path assigned to the installation folder on the disk, which is **C:\inetpub\wwwroot\mykenticofolder** in this example. Remember to set an appropriate application pool according to the type of installation that you specified.

4. Now open your browser and type in either **http://localhost/mykenticoweb/web1** or **http://localhost/mykenticoweb/web2**. [Kentico CMS Database setup](#) appears. Continue through the setup as usual and install the first site.
5. When the setup finishes, go to **Site Manager -> Sites** and install the second site.
6. Configure the domain name for website 1 as: **localhost/mykenticoweb/web1**
7. Configure the domain name for website 2 as: **localhost/mykenticoweb/web2**

Now when you go to <http://localhost/mykenticoweb/web1>, you will see website 1. If you go to <http://localhost/mykenticoweb/web2>, you will see website 2.

8. To ensure the synchronization of settings and global objects between the two sites, it is necessary to set up a [Web farm](#) scenario. This can be done by adding the following keys to the `<appSettings>` section of the `web.config` file in the installation directory shared by both websites:

```
<add key="CMSWebFarmEnabled" value="true" />
<add key="CMSWebFarmSynchronizeFiles" value="false" />

<add key="/mykenticoweb/web1:CMSWebFarmServerName" value="server1" />
<add key="/mykenticoweb/web2:CMSWebFarmServerName" value="server2" />
```

This enables web farms in general and disables synchronization of files, which is not needed since the applications already use the same physical folder. Notice that each application has a different web farm server name specified via a prefix in the name of the `CMSWebFarmServerName` key. This prefix must match the path that was set for the corresponding application in IIS, including the virtual directory.

Then go to **Site Manager -> Administration -> Web farm** on one of the sites and create a web farm server for each application according to the instructions in [Defining web farm servers](#).

9. Next, to prevent potential problems with conflicts during [Smart search](#) indexing operations, specify a different physical folder for each application's search index files through the keys shown below:

```
<add key="/mykenticoweb/web1:CMSSearchIndexPath"
value="App_Data\CMSModules\SmartSearch\Web1\" />
<add key="/mykenticoweb/web2:CMSSearchIndexPath"
value="App_Data\CMSModules\SmartSearch\Web2\" />
```

Once this is done, your websites should work without any further issues.

5.12 Configuring nested web sites

In the following example, you will learn how to set up two nested websites. It should be possible to achieve any level of nesting if the following steps are complied with.

1. Install two projects into two independent, not overlapping folders. Choose folder names that won't be the same as the names in the URL to prevent later collision when setting up the IIS. The installation folders may be for example like this:

- `Inetpub/wwwroot/NestedWeb/Web1` (first website from Web installer)
- `Inetpub/wwwroot/NestedWeb/Web2` (second website from Web installer)

This means that you have two completely independent projects, as you can see in the screenshot below:

2. Open IIS management console and create two applications under the *Default website*:

- **[Default website]/KenticoCMS1** (pointing to physical directory Web1)
- **[Default website]/KenticoCMS1/KenticoCMS2** (child directory pointing to physical directory Web2)

Like this, you have two independent projects configured as nested only in the IIS.

3. The last step is to avoid duplicate module and handler definition keys in the two projects' *web.config* files. To achieve this, open the nested application's (*Web2*) *web.config* file and remove all module and handler definitions from the two sections highlighted in the following code extract.

In case that you needed any additional custom keys in these sections, please ensure that they are not duplicate in the two *web.config* files, i.e. that they are only added in one of the two files.

```
<system.webServer>
  <validation validateIntegratedModeConfiguration="false" />
  <modules>

    // remove or comment out all keys in this section

  </modules>
  <handlers>

    // remove or comment out all keys in this section

  </handlers>
</system.webServer>
```

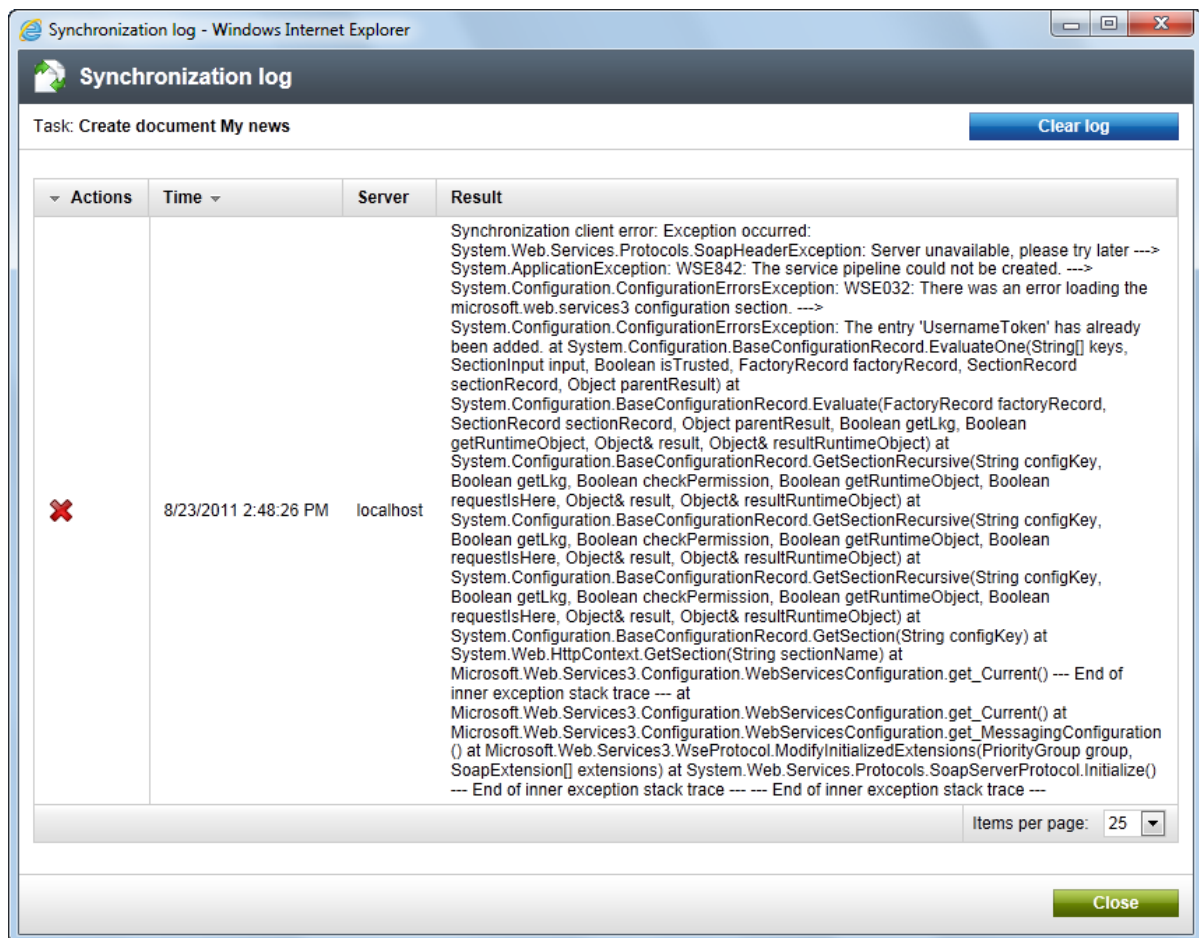

4. The websites are now accessible via nested URLs as you can see in the screenshot below. The websites can be configured independently without experiencing any issues.

Additional configuration for Staging

You may come to the point where you want to set up [Staging](#) from one of these sites to another. Staging has some sections in the `web.config` that collide. Config files are inherited within the IIS virtual directories structure (even when the projects are not nested on the file system), but you cannot have the same section of `web.config` twice in the config file.

So if we configure staging from the **KenticoCMS1** site to the **KenticoCMS1/KenticoCMS2** site (see details on how to configure the staging [here](#)), the inner project may have issues with the configuration. You would get an error like this:

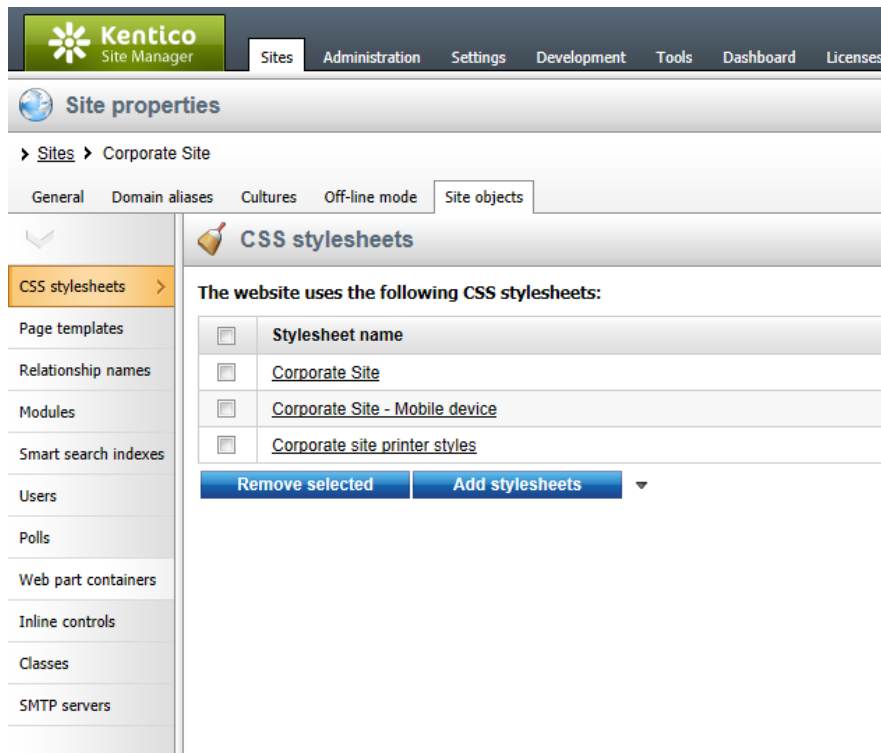

The important part of the error message is "**The username token has already been added**", that means that some of the **configuration is duplicate**.

User name token authentication is defined in the policy file which is referenced from the **<microsoft.web.services3>** section, so **remove the whole <microsoft.web.services3> section** from the **web.config** of the **inner project (Web2)**. Do not remove it from the Web1 (outer) project since this configuration will be used for both websites. After doing this, Staging should work flawlessly between the sites.

5.13 Site objects

Kentico Site Manager provides functionality that allows you to assign multiple objects to a site using a single interface. The interface is available in **Site Manager -> Sites -> Edit (✎) site -> Site objects**.

The screenshot shows the Kentico Site Manager interface. At the top, there is a navigation bar with 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', and 'Licenses'. Below this is the 'Site properties' section for 'Corporate Site'. The 'Site objects' tab is selected, and the 'CSS stylesheets' sub-tab is active. A list of stylesheets is shown with checkboxes: 'Corporate Site', 'Corporate Site - Mobile device', and 'Corporate site printer styles'. Below the list are 'Remove selected' and 'Add stylesheets' buttons. A left sidebar contains a tree view of site objects including 'CSS stylesheets', 'Page templates', 'Relationship names', 'Modules', 'Smart search indexes', 'Users', 'Polls', 'Web part containers', 'Inline controls', 'Classes', and 'SMTP servers'.

The following object types can be assigned to a site using this interface:

- CSS stylesheets
- Page templates
- Relationship names
- Modules
- Smart search indexes
- Users
- Polls
- Web part containers
- Inline controls
- Classes
- SMTP servers

Example

You may have created a new site using the Kentico CMS Site Manager. Now, you would like to have several of the users that you have created for a different site added to the new one.

1. Switch to **Site Manager** -> **Sites** -> **Edit** (✎) **site** -> **Site objects**.
2. Select **Users** (you will see a list of existing users) and then click on **Add users**.

The screenshot shows the 'Users' configuration page in the Kentico Site Manager. The left sidebar has 'Users' highlighted. The main content area is titled 'Users' and contains a table of users with checkboxes. The 'Add users' button is circled in red.

<input type="checkbox"/>	User
<input type="checkbox"/>	Andrew Jones
<input type="checkbox"/>	Global Administrator
<input type="checkbox"/>	Luke Hillman
<input type="checkbox"/>	Public Anonymous User
<input type="checkbox"/>	Sample Gold Partner
<input type="checkbox"/>	Sample Silver Partner
<input type="checkbox"/>	Sean Gaines

Buttons: Remove selected, Add users

3. The users created for the previous site will be deselected by default. Select the users that you want to be added to the site and click **OK**.

The screenshot shows the 'Select user' dialog box. The 'User name or its part' field is empty. The 'Search' button is highlighted. The list of users is shown with checkboxes. 'Adelaide Willson' and 'Patrick Metzen' are circled in red. The 'OK' button is also circled in red.

User name or its part: Search

Select all Deselect all

<input checked="" type="checkbox"/>	User
<input type="checkbox"/>	Adelaide Willson
<input checked="" type="checkbox"/>	Andrew Jones
<input checked="" type="checkbox"/>	Global Administrator
<input checked="" type="checkbox"/>	Luke Hillman
<input type="checkbox"/>	Patrick Metzen
<input type="checkbox"/>	Peter Holland
<input checked="" type="checkbox"/>	Public Anonymous User
<input checked="" type="checkbox"/>	Sample Gold Partner
<input checked="" type="checkbox"/>	Sample Silver Partner
<input checked="" type="checkbox"/>	Sean Gaines

Items per page: 10

Buttons: OK, Cancel

5.14 Sites internals and API

5.14.1 Overview

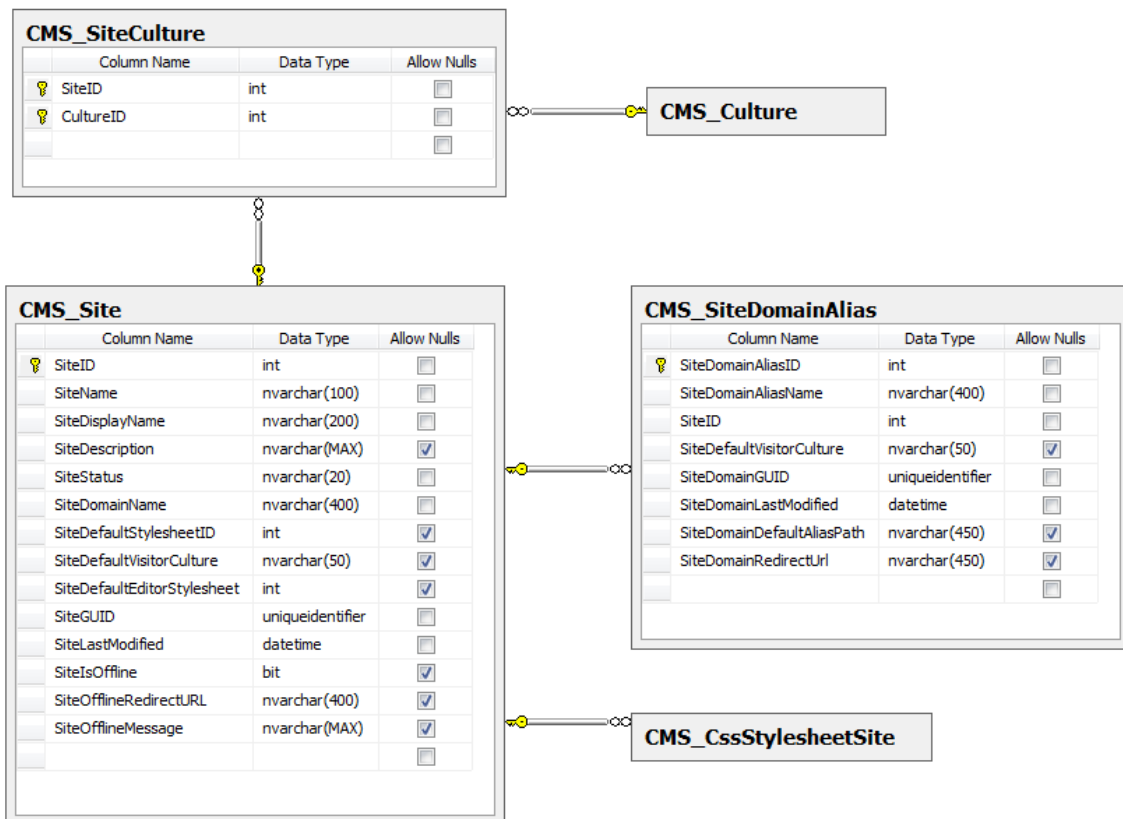

In this chapter, you will learn which [database tables](#) and [API classes](#) are used for websites. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide, specifically the [Site management, import and export](#) sub-chapter for website management. For detailed API documentation, such as a list of all members of the related classes, please refer to [Kentico CMS API Reference](#).

5.14.2 Database tables

The following database tables are used to store information about sites:

- **CMS_Site** - contains records representing websites and their settings.
- **CMS_SiteCulture** - stores relationships between sites and cultures. Each entry in this table indicates that a specific culture will be available for a given site.
- **CMS_SiteDomainAlias** - contains all domain aliases of sites.

5.14.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

**Please note**

The classes for managing sites can be found in the **CMS.SiteProvider** namespace.

CMS_Site table API:

- **SiteInfo** - represents one site object.
- **SiteInfoProvider** - provides management functionality for sites.

CMS_SiteCulture table API:

- **CultureSiteInfo** - represents a relationship between a site and a culture.
- **CultureSiteInfoProvider** - provides management functionality for site-culture relationships.

CMS_SiteDomainAlias table API:

- **SiteDomainAliasInfo** - represents a domain alias object.
- **SiteDomainAliasInfoProvider** - provides management functionality for domain aliases.

Other classes:

- **SiteContext** - provides site-related information depending on the current context.

5.14.4 API examples

5.14.4.1 Overview

These topics show examples of how the API for managing sites can be used:

- [Managing sites](#)
- [Managing site cultures](#)
- [Managing domain aliases](#)
- [Starting and stopping sites](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Sites\Default.aspx.cs**.

The site API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.DocumentEngine;
```

5.14.4.2 Managing sites

The following example creates a site.

```
private void CreateSite()
{
    // Create new site object
    SiteInfo newSite = new SiteInfo();

    // Set the properties
    newSite.DisplayName = "My new site";
    newSite.SiteName = "MyNewSite";
    newSite.Status = SiteStatusEnum.Stopped;
    newSite.DomainName = "127.0.0.1";

    // Save the site
    SiteInfoProvider.SetSiteInfo(newSite);
}
```

The following example gets and updates a site.

```
private bool GetAndUpdateSite()
{
    // Get the site
    SiteInfo updateSite = SiteInfoProvider.GetSiteInfo("MyNewSite");
    if (updateSite != null)
    {
        // Update the properties
        updateSite.DisplayName = updateSite.DisplayName.ToLower();

        // Save the changes
        SiteInfoProvider.SetSiteInfo(updateSite);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates sites.

```
private bool GetAndBulkUpdateSites()
{
    // Prepare the parameters
    string where = "SiteName LIKE N'MyNewSite%';

    // Get the data
    DataSet sites = SiteInfoProvider.GetSites(where, null);
    if (!DataHelper.DataSourceIsEmpty(sites))
    {
        // Loop through the individual items
        foreach (DataRow siteDr in sites.Tables[0].Rows)
        {
            // Create object from DataRow
            SiteInfo modifySite = new SiteInfo(siteDr);

            // Update the properties
            modifySite.DisplayName = modifySite.DisplayName.ToUpper();

            // Save the changes
            SiteInfoProvider.SetSiteInfo(modifySite);
        }

        return true;
    }

    return false;
}
```

The following example deletes a site.

```
private bool DeleteSite()
{
    // Get the site
    SiteInfo deleteSite = SiteInfoProvider.GetSiteInfo("MyNewSite");

    if (deleteSite != null)
    {
        TreeProvider treeProvider = new TreeProvider(CMSContext.CurrentUser);

        // Delete documents belonging under the site
        DocumentHelper.DeleteSiteTree("MyNewSite", treeProvider);

        // Delete the site
        SiteInfoProvider.DeleteSite(deleteSite);

        return true;
    }

    return false;
}
```

5.14.4.3 Managing site cultures

The following example assigns a culture to a site.

```
private bool AddCultureToSite()
{
    // Get site and culture objects
    SiteInfo site = SiteInfoProvider.GetSiteInfo("MyNewSite");
    CultureInfo culture = CultureInfoProvider.GetCultureInfo("ar-sa");

    if ((site != null) && (culture != null))
    {
        // Add culture to site
        CultureSiteInfoProvider.AddCultureToSite(culture.CultureID, site.SiteID);

        return true;
    }

    return false;
}
```

The following example removes a culture from a site.

```
private bool RemoveCultureFromSite()
{
    // Get site and culture objects
    SiteInfo site = SiteInfoProvider.GetSiteInfo("MyNewSite");
    CultureInfo culture = CultureInfoProvider.GetCultureInfo("ar-sa");

    if ((site != null) && (culture != null))
    {
        // Delete the culture site
        CultureSiteInfoProvider.RemoveCultureFromSite(culture.CultureID,
site.SiteID);

        return true;
    }

    return false;
}
```

5.14.4.4 Managing domain aliases

The following example adds a domain alias to a site.

```
private bool AddDomainAliasToSite()
{
    // Get the site object
    SiteInfo site = SiteInfoProvider.GetSiteInfo("MyNewSite");
```

```
if (site != null)
{
    // Create new site domain alias object
    SiteDomainAliasInfo newAlias = new SiteDomainAliasInfo();

    // Set the properties
    newAlias.SiteDomainAliasName = "127.0.0.1";
    newAlias.SiteID = CMSContext.CurrentSiteID;

    // Save the site domain alias
    SiteDomainAliasInfoProvider.SetSiteDomainAliasInfo(newAlias);

    return true;
}

return false;
}
```

The following example removes a domain alias from a site.

```
private bool DeleteSiteDomainAlias()
{
    // Get the site object
    SiteInfo si = SiteInfoProvider.GetSiteInfo("MyNewSite");

    if (si != null)
    {
        // Get the site domain alias
        SiteDomainAliasInfo deleteAlias =
        SiteDomainAliasInfoProvider.GetSiteDomainAliasInfo("127.0.0.1", si.SiteID);

        // Delete the site domain alias
        SiteDomainAliasInfoProvider.DeleteSiteDomainAliasInfo(deleteAlias);

        return (deleteAlias != null);
    }

    return false;
}
```

5.14.4.5 Starting and stopping sites

The following example runs a site.

```
private bool RunSite()
{
    // Get the site
    SiteInfo site = SiteInfoProvider.GetSiteInfo("MyNewSite");
    if (site != null)
    {
```

```
        // Start site
        SiteInfoProvider.RunSite(site.SiteName);

        return true;
    }

    return false;
}
```

The following example stops a site.

```
private bool StopSite()
{
    // Get the site
    SiteInfo site = SiteInfoProvider.GetSiteInfo("MyNewSite");
    if (site != null)
    {
        // Stop site
        SiteInfoProvider.StopSite(site.SiteName);

        return true;
    }

    return false;
}
```

5.15 Web templates internals and API

5.15.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used for web templates. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide, specifically the [Site management, import and export](#) sub-chapter for website management. For detailed API documentation, such as a list of all members of the related classes, please refer to [Kentico CMS API Reference](#).

5.15.2 Database tables

The following database tables are used to store information about sites:

- **CMS_WebTemplate** - contains records representing web templates.

CMS_WebTemplate			
	Column Name	Data Type	Allow Nulls
	WebTemplateID	int	<input type="checkbox"/>
	WebTemplateDisplayName	nvarchar(200)	<input type="checkbox"/>
	WebTemplateFileName	nvarchar(100)	<input type="checkbox"/>
	WebTemplateDescription	nvarchar(MAX)	<input type="checkbox"/>
	WebTemplateGUID	uniqueidentifier	<input type="checkbox"/>
	WebTemplateLastModified	datetime	<input type="checkbox"/>
	WebTemplateName	nvarchar(100)	<input type="checkbox"/>
	WebTemplateOrder	int	<input type="checkbox"/>
	WebTemplateLicenses	nvarchar(200)	<input type="checkbox"/>
	WebTemplatePackages	nvarchar(200)	<input checked="" type="checkbox"/>
			<input type="checkbox"/>

5.15.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes for managing web templates can be found in the **CMS.SiteProvider** namespace.

CMS_WebTemplate table API:

- **WebTemplateInfo** - represents one web template object.
- **WebTemplateInfoProvider** - provides functionality for management of web templates.

5.15.4 API examples

5.15.4.1 Overview

These topics show examples of how the API for managing web templates can be used:

- [Managing web templates](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Development\WebTemplates\Default.aspx.cs**.

The web templates API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.SiteProvider;
```

5.15.4.2 Managing web templates

The following example creates a web template.

```
private bool CreateWebTemplate()
{
    // Create new web template object
    WebTemplateInfo newTemplate = new WebTemplateInfo();

    // Set the properties
    newTemplate.WebTemplateDisplayName = "My new template";
    newTemplate.WebTemplateName = "MyNewTemplate";
    newTemplate.WebTemplateDescription = "This is web template created by API
Example";
    newTemplate.WebTemplateFileName = "~\\App_Data\\Templates\\MyNewTemplate";
    newTemplate.WebTemplateLicenses = "F;S;B;N;C;P;R;E;U;";
    newTemplate.WebTemplatePackages = "ECM;SCN;ADV;DOC;";

    // Set the web template order
    DataSet webTemplates = WebTemplateInfoProvider.GetWebTemplates(null, null, 0,
"WebTemplateID", false);
    if (!DataHelper.DataSourceIsEmpty(webTemplates))
    {
        newTemplate.WebTemplateOrder = webTemplates.Tables[0].Rows.Count + 1;
    }
    else
    {
        newTemplate.WebTemplateOrder = 1;
    }

    // Save the web template
    WebTemplateInfoProvider.SetWebTemplateInfo(newTemplate);

    return true;
}
```

The following example gets and updates the web template created by the API example above.

```
private bool GetAndUpdateWebTemplate()
{
    // Get the web template
    WebTemplateInfo updateTemplate = WebTemplateInfoProvider.GetWebTemplateInfo
("MyNewTemplate");
```

```
if (updateTemplate != null)
{
    // Update the properties
    updateTemplate.WebTemplateDisplayName =
updateTemplate.WebTemplateDisplayName.ToLower();

    // Save the changes
    WebTemplateInfoProvider.SetWebTemplateInfo(updateTemplate);

    return true;
}

return false;
}
```

The following example moves the web template created by the first example on this page down by one position in the order in which the templates are listed when creating a new website from a web template.

```
private bool GetAndMoveWebTemplateDown()
{
    // Get the web template
    WebTemplateInfo moveDownTemplate = WebTemplateInfoProvider.GetWebTemplateInfo
("MyNewTemplate");
    if (moveDownTemplate != null)
    {
        // Move template down
        WebTemplateInfoProvider.MoveTemplateDown(moveDownTemplate.WebTemplateId);

        return true;
    }

    return false;
}
```

The following example moves the web template created by the first example on this page up by one position in the order in which the templates are listed when creating a new website from a web template.

```
private bool GetAndMoveWebTemplateUp()
{
    // Get the web template
    WebTemplateInfo moveUpTemplate = WebTemplateInfoProvider.GetWebTemplateInfo
("MyNewTemplate");
    if (moveUpTemplate != null)
    {
        // Move template up
        WebTemplateInfoProvider.MoveTemplateUp(moveUpTemplate.WebTemplateId);

        return true;
    }
}
```

```
    return false;
}
```

The following example gets multiple web templates based on a WHERE condition and bulk updates them.

```
private bool GetAndBulkUpdateWebTemplates()
{
    // Prepare the parameters
    string where = "WebTemplateName LIKE N'MyNewTemplate%'";

    // Get the data
    DataSet templates = WebTemplateInfoProvider.GetWebTemplates(where, null);
    if (!DataHelper.DataSourceIsEmpty(templates))
    {
        // Loop through the individual items
        foreach (DataRow templateDr in templates.Tables[0].Rows)
        {
            // Create object from DataRow
            WebTemplateInfo modifyTemplate = new WebTemplateInfo(templateDr);

            // Update the properties
            modifyTemplate.WebTemplateDisplayName =
            modifyTemplate.WebTemplateDisplayName.ToUpper();

            // Save the changes
            WebTemplateInfoProvider.SetWebTemplateInfo(modifyTemplate);
        }

        return true;
    }

    return false;
}
```

The following example deletes the web template created by the first example on this page.

```
private bool DeleteWebTemplate()
{
    // Get the web template
    WebTemplateInfo deleteTemplate = WebTemplateInfoProvider.GetWebTemplateInfo
    ("MyNewTemplate");

    // Delete the web template
    WebTemplateInfoProvider.DeleteWebTemplateInfo(deleteTemplate);

    return (deleteTemplate != null);
}
```

Part

VI

Website settings

6 Website settings

6.1 Overview

Site settings

- **Built-in settings** - these settings are added during the installation process and cannot be modified. They are used to set the built-in modules, same as other features of the whole CMS. You can configure them in **Site Manager -> Settings**. Please refer to the [Configuring settings](#) topic for more details.
- **Custom settings** - the user can create their own settings for modules and other functionality they added to the CMS. This can be done in **Site Manager -> Development -> Custom settings**; please refer to the [Adding custom settings](#) and [Managing custom settings](#) topics for more details. If you need to configure custom settings, you can do it the same way like with the built-in settings, i.e. in **Site Manager -> Settings**; please refer to the [Configuring settings](#) topic for more details.

Web.config settings

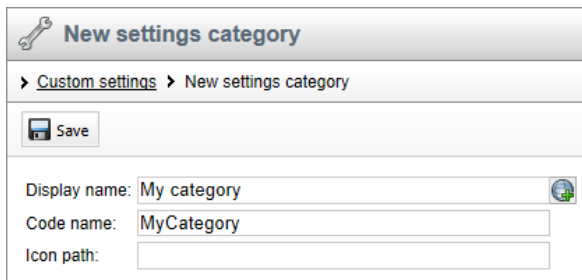

These settings are used for low-level configuration of the CMS system. More details can be found in [Appendix B - Web.config parameters](#).

6.2 Adding custom settings

Here you will learn how to add your own settings to a website. Please note that you first need to create a [category](#) with a [group](#) within where a settings [key](#) can be put.

Adding custom setting categories

If you need to create a new category, go to **Site Manager -> Development -> Custom settings**, click  **New category**, enter category properties and click  **Save**.

 **New settings category**

> [Custom settings](#) > New settings category

 Save

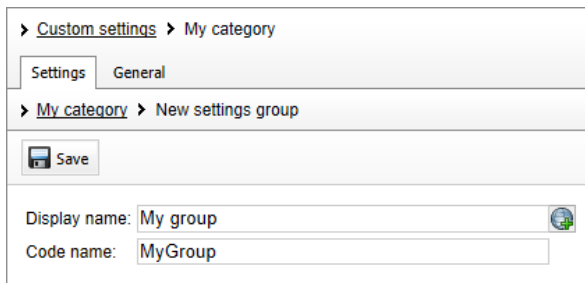

Display name: 

Code name:

Icon path:

Adding custom setting groups

If you need to create a new group, in the **Custom settings** categories tree, select a category and on its **Settings** tab click  **New settings group**. Enter group properties and click  **Save**.

Custom settings > My category

Settings General

My category > New settings group

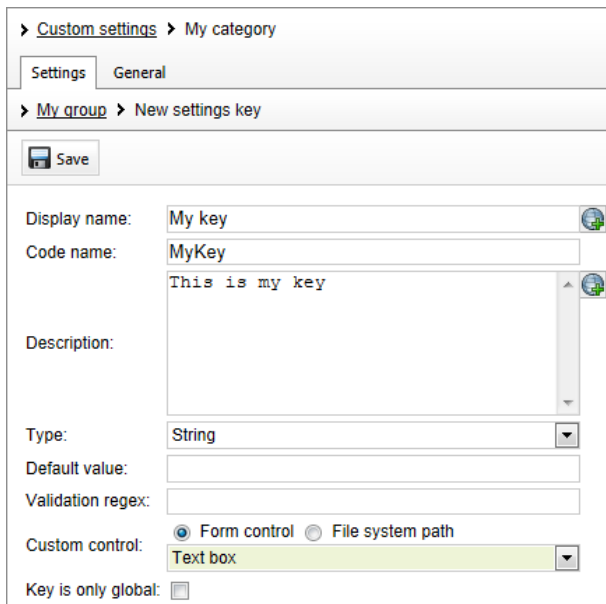

Save

Display name: My group

Code name: MyGroup

Adding custom setting keys

On the **Settings** tab of the selected category click **New settings key** beside the group where you would like to add the particular key. Enter key properties and click **Save**. For more information on these properties, please refer to the [Managing custom settings](#) topic.

Custom settings > My category

Settings General

My group > New settings key

Save

Display name: My key

Code name: MyKey

Description: This is my key

Type: String

Default value:

Validation regex:

Custom control: Form control File system path
Text box

Key is only global:

Result

The following screenshots show the result of adding a custom category, group and key:

1. In **Site Manager -> Development -> Custom settings**.

The screenshot displays the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The left sidebar is expanded to 'Development' > 'Custom settings'. The main content area is titled 'Custom settings' and shows a tree view with 'My category' selected. The right-hand pane shows the configuration for 'My group' under 'Custom settings > My category'. It includes a 'New settings group' button and a table of settings keys.

Actions	Display name	Code name
	My key	MyKey

If you would like to learn more about custom settings management, please refer to the [Managing custom settings](#) topic.

2. In Site Manager -> Settings.

The screenshot displays the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The left sidebar is expanded to 'Settings' > 'Custom settings' > 'My category'. The main content area is titled 'My category' and shows the configuration for the 'global' site. It includes a 'Save' button, a 'Reset these settings to default' button, and a text box for 'My key'.

If you would like to learn how you can configure your custom settings, please refer to the [Configuring settings](#) topic.

Please note

All custom settings added according to the description given in this topic can be configured along with the built-in settings in **Site Manager -> Settings**; if you would like to learn how to do it, please refer to the [Configuring settings](#) topic. By default, there are no custom settings available after installation.

6.3 Managing custom settings

Here you will learn how to manage custom settings [categories](#), [groups](#) and [keys](#) on your website. This can be done in **Site Manager -> Development -> Custom settings**.

Managing custom settings categories

If you need to edit properties of a category, click the category in the categories tree. On the **General** tab, you can modify its general properties:

The screenshot shows the 'Custom settings' management interface. On the left, there is a tree view under 'Custom settings' with three categories: 'First settings category' (highlighted), 'Second settings category', and 'Third settings category'. Above the tree are buttons for 'New category', 'Delete category', 'Up', and 'Down'. The main panel shows the 'General' tab selected for 'First settings category'. The 'Settings' menu is open, and the 'General' option is highlighted with a red box. Below the 'Save' button, there are four input fields: 'Display name' (containing 'First settings category'), 'Code name' (containing 'FirstSettingsCategory'), 'Icon path' (empty), and 'Parent category' (a dropdown menu set to 'Custom settings').

Category properties:

Display name	The name of the category displayed to website administrators.
Code name	The name of the category used in the code.
Icon path	The icon displayed next to the category caption; you can enter either a full relative path beginning with ~ (e.g. <code>~/App_Themes/Default/Images/CMSModules/list.png</code>) or a short path beginning under the <i>Images</i> folder of the current skin (e.g. <code>CMSModules/list.png</code>).
Parent category	The category where this custom category belongs; you can select another parent category to move the custom category under a different category.

The **Settings** tab allows you to manage category groups and their keys:

The screenshot shows the 'Custom settings' interface. On the left, there is a tree view with 'Custom settings' expanded, showing 'First settings category', 'Second settings category', and 'Third settings category'. The 'First settings category' is selected. The main area shows the 'Settings' tab for the 'General' group. Below this, there are two sections: 'First settings group' and 'Second settings group'. Each group has a 'New settings key' button and a table of settings keys. The 'First settings group' table has three rows: 'First settings key' (Code name: FirstSettingsKey), 'Second settings key' (Code name: SecondSettingsKey), and 'Third settings key' (Code name: ThirdSettingsKey). The 'Second settings group' table has one row: 'Global only settings key' (Code name: GlobalOnlySettingsKey). Both tables have 'Items per page: 25' at the bottom right.

Custom categories can also be deleted using **Delete category** and they can be moved **Up** and moved **Down** in the **Custom settings** categories tree.

This close-up shows the 'New category' button with an 'Up' arrow and the 'Delete category' button with a 'Down' arrow. Both buttons are highlighted with a red border. Below them is the same tree view as in the previous screenshot, with 'First settings category' selected.

Managing custom settings groups

If you need to edit properties of a group, on the **Settings** tab of the selected category choose to **Edit** () the particular group and make the required alterations:

The screenshot shows the 'Custom settings' interface with the 'Settings' tab selected. The breadcrumb path is 'Custom settings > First settings category > First settings group'. Below the breadcrumb, there is a 'Save' button. The form contains three fields: 'Display name: First settings group', 'Code name: FirstSettingsGroup', and 'Parent category: --First settings category'.

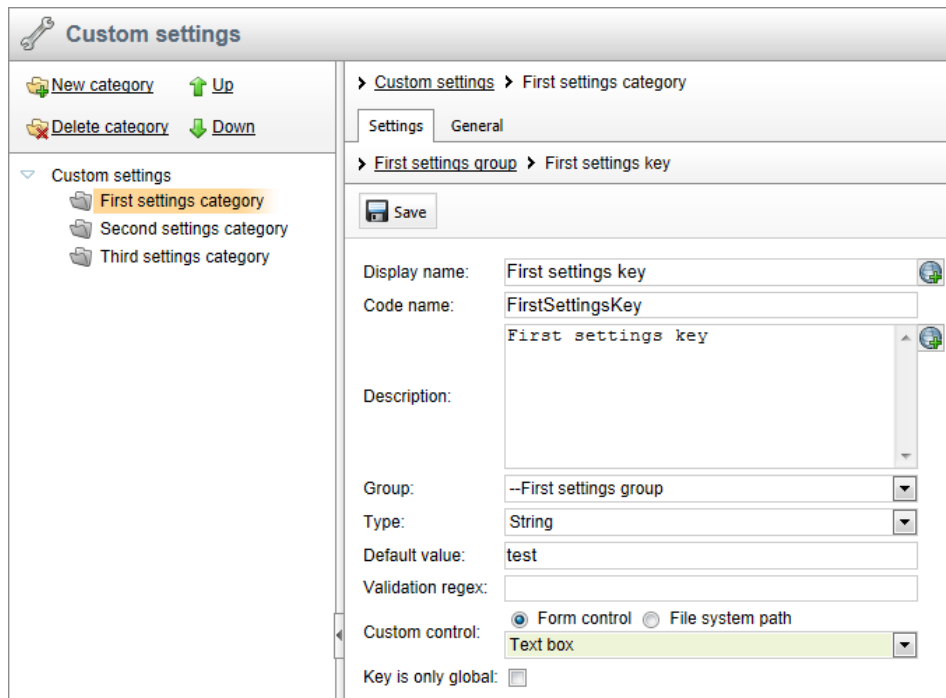

Group properties:

Display name	The name of the group displayed to website administrators.
Code name	The name of the group used in the code.
Parent category	The category where this group belongs; you can select another parent category to move the custom group to a different category.

The group can also be **Deleted** (✖), **Moved Up** (↑) and **Moved down** (↓).

**Managing custom settings keys**

If you need to edit properties of a key, on the **Settings** tab of the respective category choose to **Edit** (✎) the particular key and make the required alterations:

**Key properties:**

Display name	The name of the key displayed to website administrators.
Code name	The name of the key used in the code.
Description	Text describing the key and its purpose.
Group	The group under which this key belongs. You can move the key to a different group by selecting it from the list.
Type	The type of the key's value. You can choose the boolean, integer, double or string value type. The value entered in <i>Site Manager -> Settings -> Custom settings</i> will be validated against the <i>Type</i> property.
Default value	The default value of the key. Values of custom keys can be reset to default in <i>Site Manager -> Settings -> Custom settings</i> using the <i>Reset these settings to default</i> link.
Validation regex	If you wish to define custom validation rules for the setting's value, you can do so by entering a regular expression here.
Custom control	Specifies the control that will be used to edit the key's value in the settings form. The Form control option allows you to choose one of the form controls registered in the system. If you select File system path , you can directly specify the path to a user control file in the web project, e.g. ~/CMSFormControls/SimpleCountrySelector.ascx.
Key is only global	If checked, all available sites will share the same value for the custom key. Additionally, the key will only be available when editing (<i>global</i>) settings.

The key can also be **Deleted** (✖), **Moved Up** (↑) and **Moved Down** (↓).

First settings group ✎ ✖ ↑ ↓

[New settings key](#)

Actions	Display name	Code name
✎ ✖ ↑ ↓	First settings key	FirstSettingsKey
✎ ✖ ↑ ↓	Second settings key	SecondSettingsKey
✎ ✖ ↑ ↓	Third settings key	ThirdSettingsKey

Items per page: 25 ▾

Please note

If you check the **Key is only global** checkbox while editing a key, this key will not be available in **Site Manager -> Settings** unless you choose (**global**) from the **Site** drop-down list. See examples below:

a) The **(global)** option is selected -> the *Global only settings key* is visible.

The screenshot shows the Kentico CMS Settings page. The 'Site:' dropdown menu is set to '(global)'. The left sidebar shows a tree view of settings categories, with 'First settings category' selected. The main content area displays the 'First settings category' configuration. It includes a 'Save' button and a 'Reset these settings to default' button. Below these are instructions: 'These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.' The settings are organized into three groups: 'First setting group', 'Second setting group', and 'Third settings group'. The 'Second setting group' contains a 'Global only settings key' field, which is highlighted with a red box. The other groups contain 'First settings key', 'Second settings key', and 'Third settings key' fields.

b) A particular site is selected -> the *Global only settings key* is hidden.

The screenshot shows the Kentico CMS Settings page. The 'Site:' dropdown menu is set to 'Corporate site'. The left sidebar shows the same tree view of settings categories, with 'First settings category' selected. The main content area displays the 'First settings category' configuration. It includes a 'Save' button and a 'Reset these settings to default' button. Below these are instructions: 'These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.' The settings are organized into three groups: 'First setting group', 'Third settings group', and 'Global and site settings key'. The 'Third settings group' contains a 'Global and site settings key' field. The 'First setting group' contains 'First settings key', 'Second settings key', and 'Third settings key' fields. The 'Global and site settings key' field is visible, indicating that the 'Global only settings key' is hidden when a specific site is selected.

6.4 Configuring settings

Here you will learn how to configure settings. There are a lot of **built-in settings** which come with your Kentico CMS installation. Besides, you can also [create](#) your **custom settings** and configure them in the same way.

The screenshot shows the Kentico Site Manager interface. On the left, the 'Settings' menu is expanded, showing a list of categories. A blue box highlights the built-in settings (Content, URLs and SEO, Security & Membership, System, On-line marketing, E-commerce, Community, Intranet & Collaboration, Versioning & synchronization, Integration, Cloud services). A red box highlights the custom settings (My category1, My category2, My category3). The main content area shows the 'Content' settings page for the 'global' site. It includes sections for 'Web site content', 'Page not found', and 'Multilingual' settings. The 'Web site content' section has a 'Default alias path' field with a 'Select' button. The 'Page not found' section has checkboxes for 'Page not found for non-published documents' and 'Log page not found exception'. The 'Multilingual' section has a dropdown for 'Default content culture' set to 'English - United States' and checkboxes for 'Combine with default culture' and 'Combine files with default culture'.

- **Blue box** - built-in settings which come with the installation.
- **Red box** - custom settings which can be [created](#) in **Site Manager** -> **Development** -> **Custom settings**.

Please note

By hovering over the **Help** (🔍) icon to the left from the key input form, you can display the description of the key as defined in **Site Manager** -> **Development** -> **Custom settings**.

How to configure settings keys

From the **Site** drop-down list, you can choose either a particular site and thus define settings for this particular site - see [Site-specific settings keys](#) or you can choose (**global**) and define global settings - see [Global settings keys](#).

1. Site-specific settings keys

If you select a specific site, you can set a specific value for each key for the given site (the **Inherit from global settings** checkbox is unchecked and the value of the key is editable) or the corresponding global values can be used (the **Inherit from global settings** checkbox is checked and the value of the key is not editable). Make your site-specific settings as appropriate and click **Save**.

Please note

If one of the available sites is selected, all keys whose **Key is only global** property is set to true are hidden; for more information on how to set a key as global only, please refer [here](#).

My category

 Save
  [Reset these settings to default](#)

My group

My Key1	?	<input type="text" value="MyValue"/>	<input type="checkbox"/> Inherit from global settings
My key2	?	<input type="text"/>	<input checked="" type="checkbox"/> Inherit from global settings

The *My key 1* key is site-specific and thus has its own value, the *My key 2* key inherits its value from global settings and the *My key 3* key is hidden because it is set as a global only key.

2. Global settings keys

If you choose (*global*) from the **Site** drop-down list, you can configure global settings. That is why the **Inherit from global settings** checkbox is missing and the values of all keys are editable. Make your global settings as appropriate and click  **Save**.

My category

 Save
  [Reset these settings to default](#)

These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.

My group

My Key1	?	<input type="text" value="MyGlobalValue1"/>	
My key2	?	<input type="text" value="MyGlobalValue2"/>	
My Key3	?	<input type="text" value="MyGlobalValue3"/>	

All the three keys are visible and you can edit their values.

How to reset settings keys

Here you will learn how to reset values of settings keys to their default values.

1. Click  **Reset these settings to default** to reset each key in the given category.
2. In the message window that pops up, click **OK** to confirm the reset.
3. All keys in the given category have been reset to their default values as defined in the **Default value** property of the particular key.
4. Click  **Save** to save the changes; for more information on how to set default values for settings

keys, please refer [here](#).

 **My category**

 Save  **Reset these settings to default**

Settings keys were reset to default values.

These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.

My group

My Key1		<input type="text" value="default_value"/>
My key2		<input type="text" value="default_value"/>
My Key3		<input type="text" value="default_value"/>

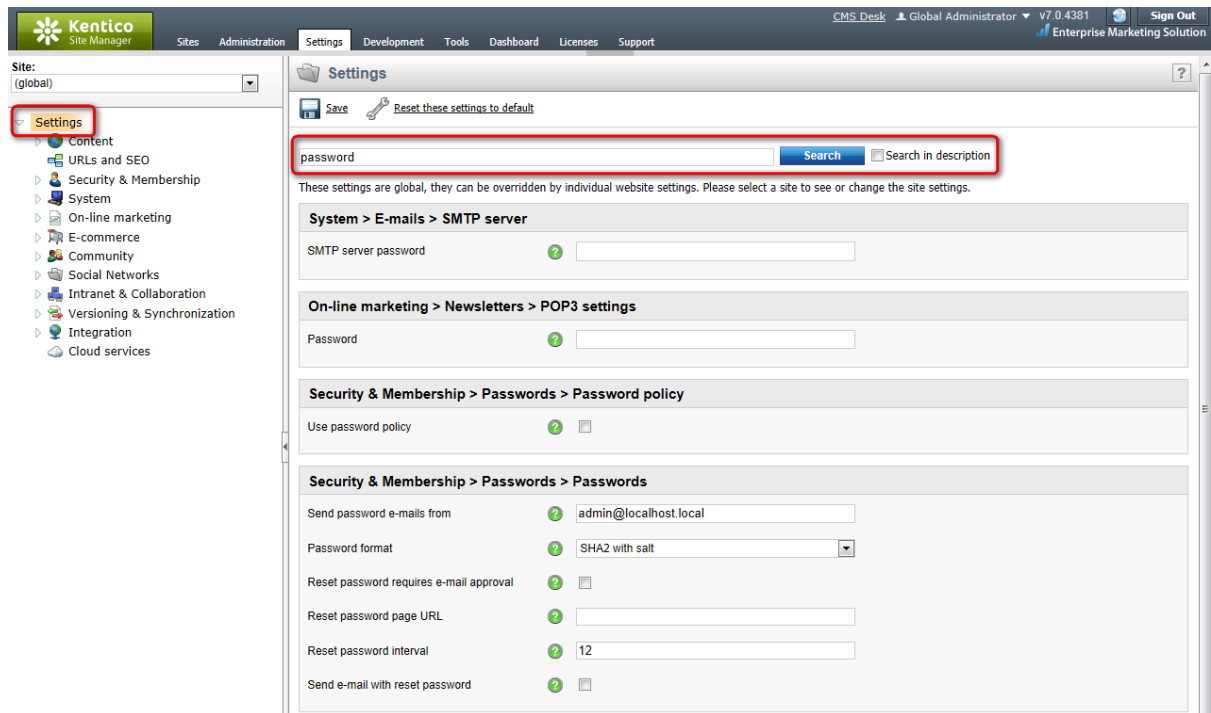

Please note

You can export the settings to a TXT file using **Export these settings** on bottom of the page. This may be useful if, for example, consulting an issue with the support staff who need the values of your settings.

Searching for specific settings

Because there is a very large number of built-in settings in Kentico CMS, it may sometimes be difficult to find a particular setting among all the categories. In these cases, you can select the root of the settings tree (**Settings**) and use the search function. Simply enter any text into the field at the top of the page and click the **Search** button. All settings that contain this text in their name will be displayed below, including the path of their category, and you can edit their values directly. If the **Search in description** box is checked, the search will also return those settings that have the given text in their description (tooltip).

6.5 Website settings internals and API

6.5.1 Overview

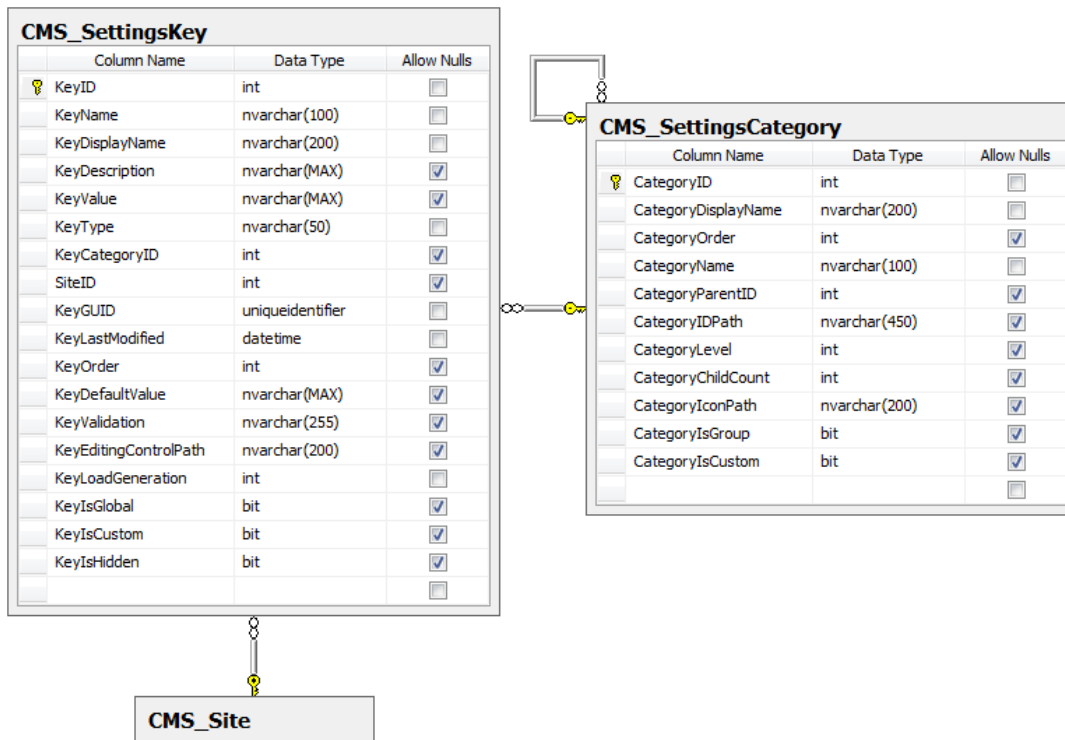

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in Website settings. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

6.5.2 Database tables

The following database tables are used in Website settings:

- **CMS_SettingsCategory** - contains records representing settings categories and groups.
- **CMS_SettingsKey** - contains records representing settings keys.

6.5.3 API classes

If you are not familiar with the database table data management by Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The Website settings classes use the **CMS.SiteProvider** namespace.

CMS_SettingsCategory table API:

- **SettingsCategoryInfo** - represents one settings category or group.
- **SettingsCategoryInfoProvider** - provides management of settings categories and groups.

CMS_SettingsKey table API:

- **SettingsKeyInfo** - represents one settings key.
- **SettingsKeyProvider** - provides management of settings keys.

6.5.4 API examples

6.5.4.1 Overview

Please note

All API examples can be simulated in the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Settings\Default.aspx.cs**.

Part

VII

Development

7 Development

7.1 Overview

This section provides reference on various topics related to website development and system administration. Open the particular sub-chapters in order to get the related topics displayed.

7.2 Web development overview

7.2.1 The role of a web developer

The role of a web developer is described in the following figure:

This figure shows how you develop a website and how roles are split between developers and editors. The typical development process consists of the following steps:

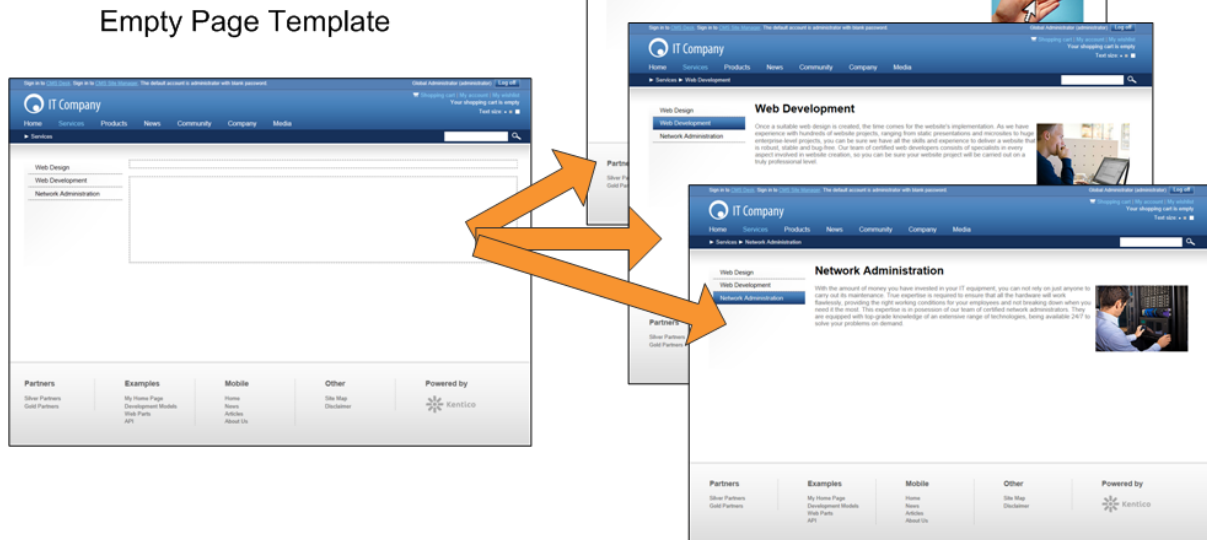

1. The developers analyze client requirements.
2. The developers prepare the site structure (site map) and the overall web design. During this stage, [Wireframing](#) may be used to create a rough outline of the website that can serve as a visual guide in the next steps.
3. The developers create **page templates** for every type of page required on the site (home page, solutions, products, news, etc.)
4. The content editors create new pages — they enter text and images into the page templates defined by the developer.

7.2.2 What is a page template

A page template is a predefined look for pages that allows content editors to enter the content. A single template can be re-used for multiple pages with the same structure and design, but with different content.

Templates allow content editors to focus just on content editing, without the need to take care of page formatting. They also help keep the web design consistent throughout the whole website. The following figure shows how a single page template can be used for multiple pages:

Pages Created Using the Page Template

The [next topic](#) describes the development models that may be used to create various types of page templates with Kentico CMS.

7.2.3 Development model overview

Kentico CMS provides three basic development models and you can choose the one that suits your needs best:

- **Portal Engine** - this model allows you to build websites using a portal engine. It is the recommended approach for most developers since it doesn't require programming in Visual Studio. Instead, you can simply build websites using web parts in the **browser-based** user interface.
- **ASPX Templates** - this model can be chosen by advanced ASP.NET developers who prefer to create websites using standard ASP.NET architecture and using standard development tools, such as **Visual Studio**. This model requires you to be familiar with ASP.NET web form development and have at least basic programming knowledge of C# or VB.NET.
- **MVC** - this option allows developers to create websites or specific pages using the Model-View-Controller architectural pattern (based on the ASP.NET MVC framework). Working with this model requires knowledge of programming and ASP.NET MVC.

We recommend using the portal engine, but if you are an advanced .NET developer or wish to integrate existing functionality built on standard ASP.NET architecture, you may want to use ASPX templates or the MVC development model.

If required, the models can be combined on a single website. For example, you can place documents using ASPX or MVC page templates onto a portal engine website, and even insert custom ASPX pages implementing your own applications. On the other hand, special areas can be defined on ASPX templates which you can edit through the portal engine.

The following table compares the available development models:

	Portal Engine	ASPX Templates	MVC
How you work	<p>You build the website and design pages using a browser-based interface.</p> <p>No programming knowledge is required for common tasks.</p>	<p>You build ASPX pages (web forms) that are used to display content from Kentico CMS.</p> <p>At least basic programming knowledge of ASP.NET and either C# or VB.NET is required.</p>	<p>You implement <i>model</i> objects, MVC <i>controller</i> classes and <i>views</i> for rendering pages.</p> <p>Requires knowledge of MVC architecture, ASP.NET and C# or VB.NET.</p>
How you assemble pages	<p>You use built-in or custom web parts that you place into customizable page layouts (HTML code with placeholder zones for web parts).</p>	<p>You use built-in or custom ASP.NET server controls and place them onto the ASPX pages. These are standard ASPX pages that are part of the web project, so you can also work with their code behind files.</p> <p>It is also possible to place web parts (which are actually ASCX user controls) on the page templates if the required server control is not available.</p>	<p>The appearance of pages is defined through MVC views, which are composed of HTML and inline code. The overall logic of pages and interaction with Kentico CMS data can be ensured through the controller and model classes.</p> <p>The controller and action used when a page is viewed are determined by the corresponding document's MVC page template or its specific URL pattern.</p>
Master pages and visual inheritance	<p>Sub-pages inherit content from their parent pages by default (so called "visual inheritance"). The inheritance can optionally be broken if you want to create a page without parent content.</p>	<p>Page templates may inherit content from a master page, which works just like a standard ASP.NET master page (.master file).</p> <p>Pages do not inherit content from their parents in the website content hierarchy, they only inherit from the master page (if it is used).</p>	<p>Content inheritance can be ensured through standard MVC master pages for views (master pages that inherit from the <i>ViewMasterPage</i> class). Nested views and Razor layouts are also supported.</p> <p>Pages do not inherit content from parents in the website content hierarchy, only from their specific master page or view.</p>
Custom code integration and extensibility	<p>You can create your own user controls (ASCX files) or web parts (ASCX files with a portal engine interface) if you need to</p>	<p>You build standard ASPX pages with code behind files, which means you can place any custom controls and code onto the page.</p>	<p>You prepare the content of the MVC views and the functionality of the controller and model classes in Visual Studio,</p>

	<p>integrate custom functionality.</p> <p>Any custom controls or code can be added to the web parts placed on the website.</p>		so have full control over customization.
Advantages	<ul style="list-style-type: none"> • Easier and faster way to build a website. • ASP.NET programming knowledge is not required for common tasks. • You can build the whole website very quickly, using only a web browser. 	<ul style="list-style-type: none"> • Standard ASP.NET architecture. • You can use your favorite development tools, such as Visual Studio. 	<ul style="list-style-type: none"> • Model-View-Controller architecture. • The option of using the Razor view engine • Development via standard tools (Visual Studio).
Disadvantages	<ul style="list-style-type: none"> • Proprietary architecture and development process. 	<ul style="list-style-type: none"> • Requires ASP.NET programming knowledge. • The design of the web pages cannot be fully managed via the browser-based administration interface. 	<ul style="list-style-type: none"> • Development tasks require knowledge of ASP.NET MVC and programming. • The design of the web pages cannot be managed via the browser-based administration interface. • Kentico CMS itself is not an MVC application, so you cannot use the built-in set of components and web parts while fully maintaining MVC architecture.

7.2.4 Portal engine development model

7.2.4.1 Portal engine overview

Every page on a Kentico CMS website is based on a page template. A **page template** consists of a layout and specific instances of web parts that are configured in a certain way. The portal engine page templates are physically stored in the database, so you will not find them on the disk.

The structure of a page template is determined by its **page layout**, which can either be defined through ASCX markup or standard HTML code. The code can be used to set up a two-column, three-column, or virtually any custom layout you can think of. The page layout contains special markup tags that define the areas where developers can place web parts — so called **web part zones**. Each web part zone may contain any number of web parts.

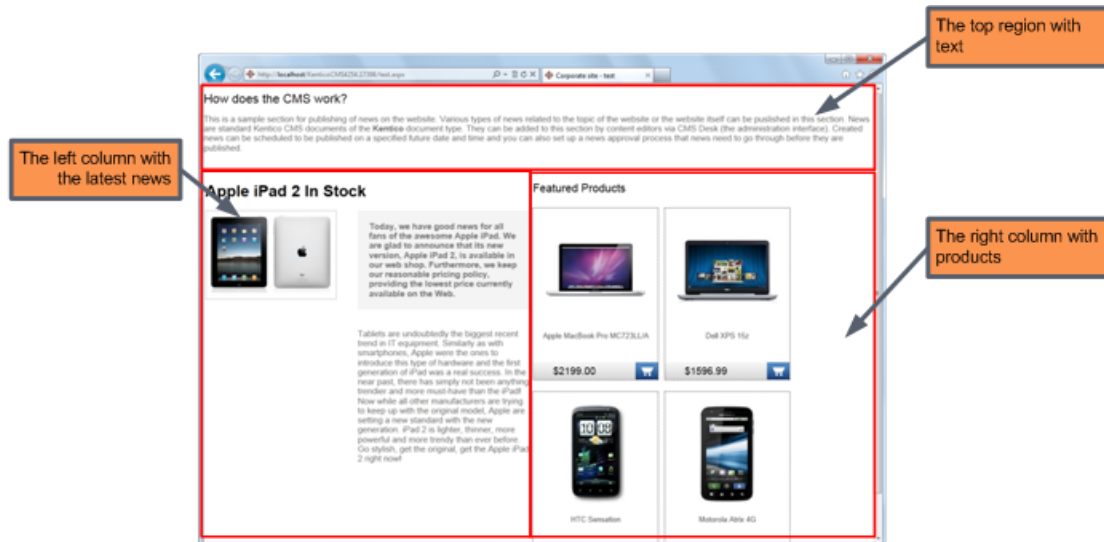

A **web part** (also called "servlet", "portlet" or "module" in other solutions) is a component that displays some type of content or provides background functionality. Technically, web parts are standard ASCX user controls with a predefined programming interface. Detailed information about web parts can be

found in the [Development -> Web parts](#) chapter.

The following figures show an example of a simple page, its page template, layout, web part zones and web parts:

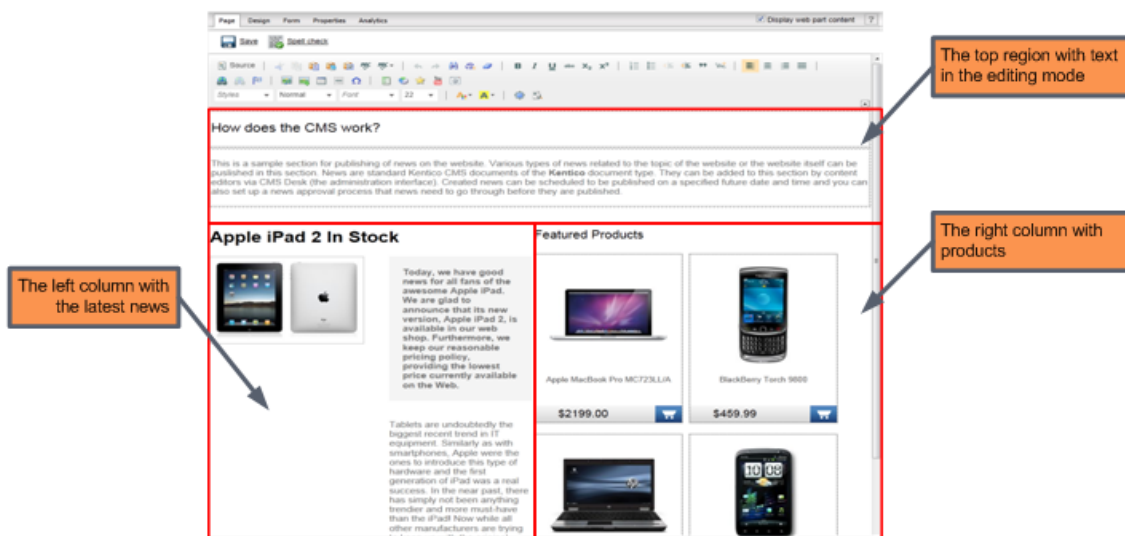

1) The sample page on the live site

This image shows a sample page on the live site. It displays text at the top, news in the left column and products on the right.

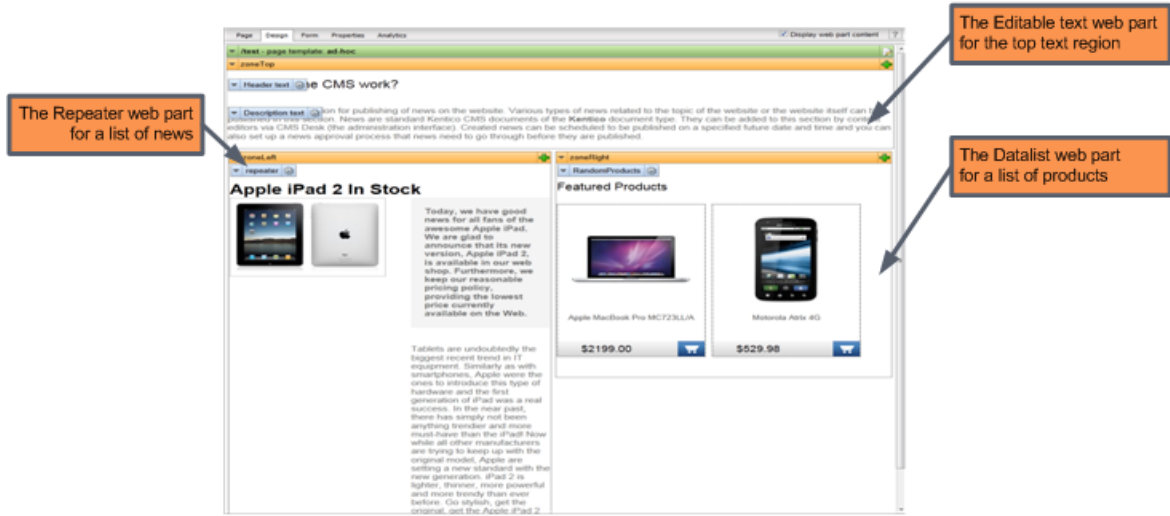

2) The sample page in editing mode

Here you can see the top section as an editable text region. The lists of news items and products are still shown as on the live site. Additional actions may also be available in the lists for editing and managing the related documents.

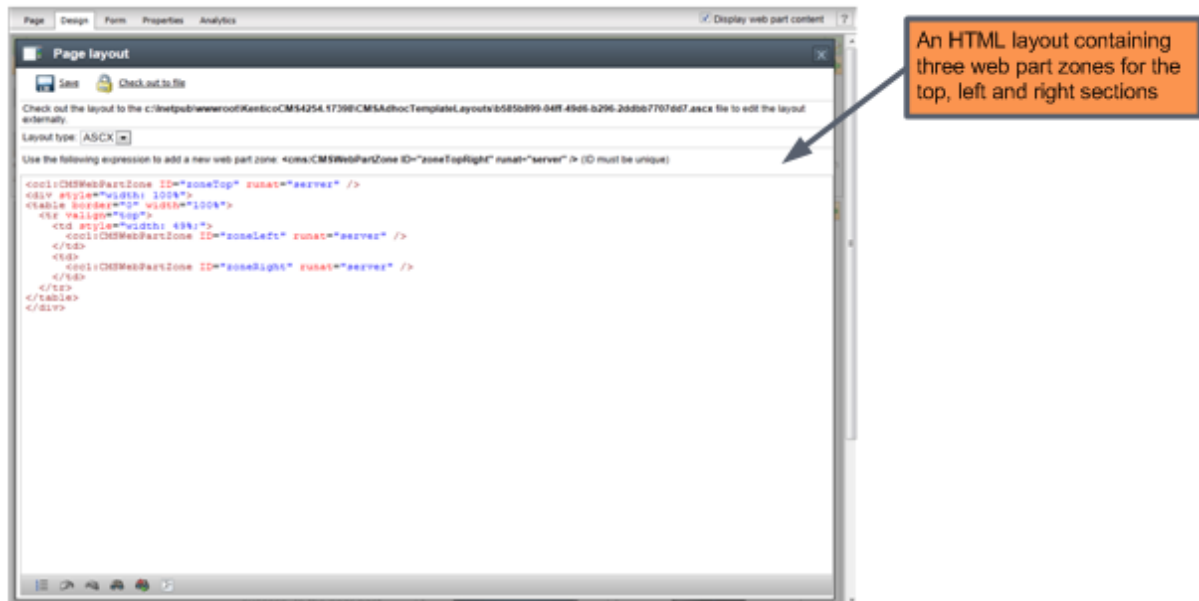

3) The page template of the sample page on the Design tab

This is the **Design** mode view of the page template used for the sample page. It consists of three web part zones - **zoneTop**, **zoneLeft** and **zoneRight**. The web part zones contain particular web parts.

4) Layout of the page template

This image shows the layout code of the page template with tags representing web part zones at the top and in the table columns. This example uses tables to build the desired layout, but you can easily implement a CSS-based layout instead — you have full control over the HTML code and CSS styles.

7.2.4.2 Creating a new page template

There are two ways to create a new page template:

- Creating a blank page using an ad-hoc template
- Cloning and modifying an existing page template

What is an ad-hoc template?

An ad-hoc template is a page template that is used only by one specific page. Ad-hoc templates do not have a particular name. If you want to re-use this type of template for multiple pages, you need to save it as a named template first.

Creating a blank page using an ad-hoc template

Note: It is recommended to use the sample **Corporate Site** for this example.

1. Go to **CMS Desk -> Content**, select the root of the content tree, click **New** and choose the **Page (menu item)** document type.
2. Enter *My test* into the **Page name** field, choose the **Create a blank page** option and click **Save**.

Save Save and create another Spell check

Page name: My test

Use existing page template
 Use parent page template
 Create a blank page with layout
 Create a blank page

The new page will use new ad-hoc page template with an empty layout.

3. The page will now be added to the content tree and automatically selected. Open the **Design** tab and you will see an empty page as shown in the screenshot below.

Page Design Form Properties Analytics

Sign in to CMS Desk. Sign in to CMS Site Manager. The default account is administrator with blank password. Global Administrator (administrator) Log off

IT Company Shopping cart | My account | My wishlist Your shopping cart is empty Text size: ■ ■ ■

Home My test Products News Community Services Company Media

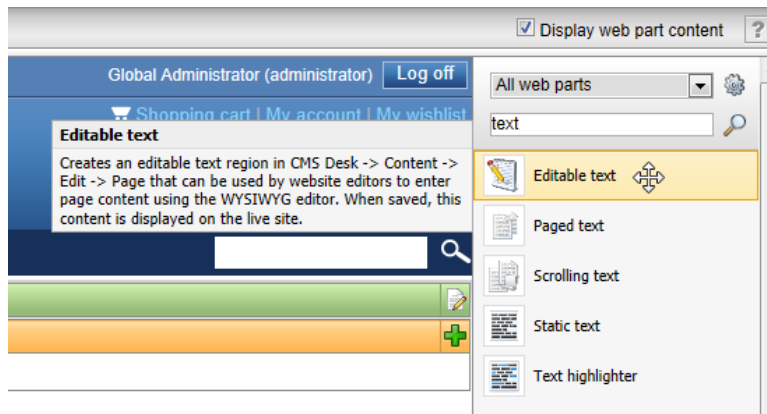

▶ My test

▼ /My test - page template: ad-hoc

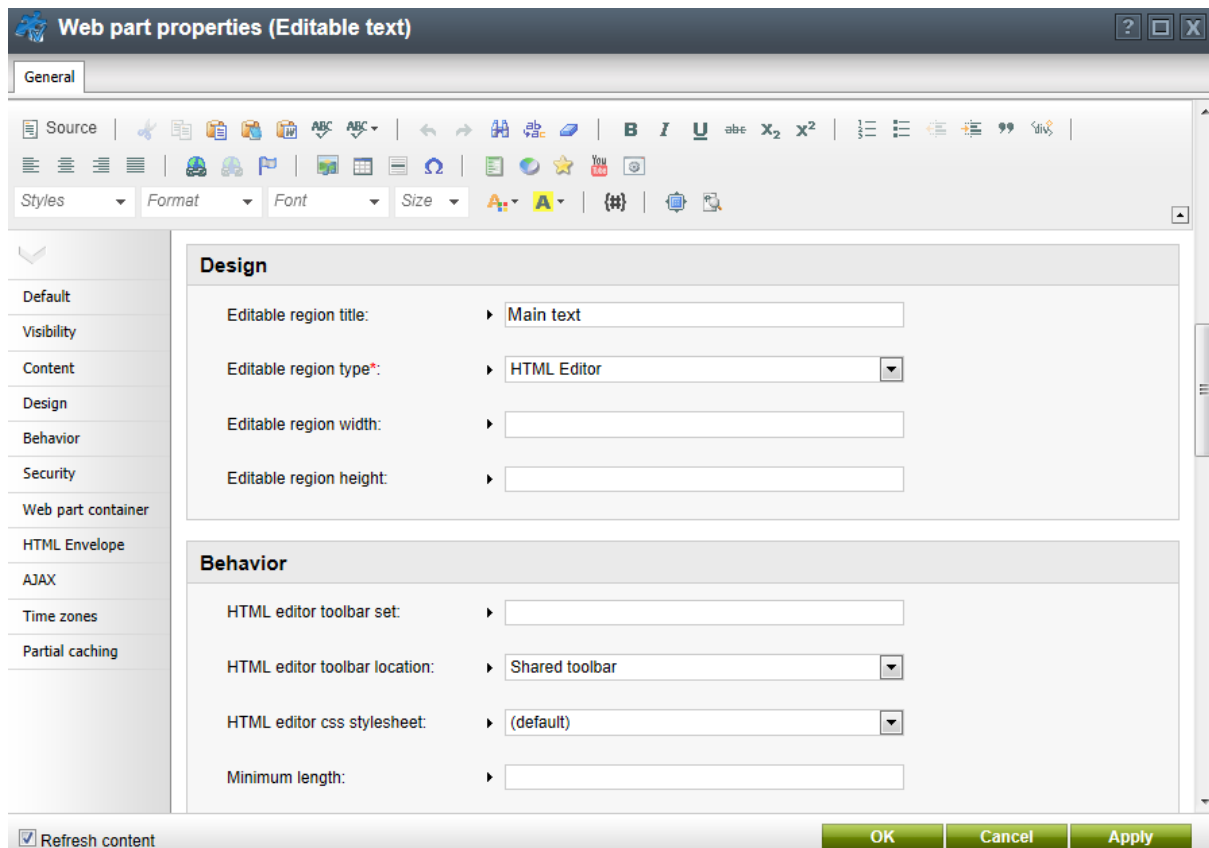

▼ zoneLeft

The green box with the **/My test** title displays the content of the current page template. As you can see, we are now using an ad-hoc template that was created specifically for this page. The yellow box with the **zoneLeft** title represents a web part zone, where web parts can be placed.

4. You can add web parts using the toolbar displayed on the right side of the tab (by default). Enter the word *text* into the search textbox (🔍) at the top of the toolbar, which will ensure that only web parts with this word in their name are offered.

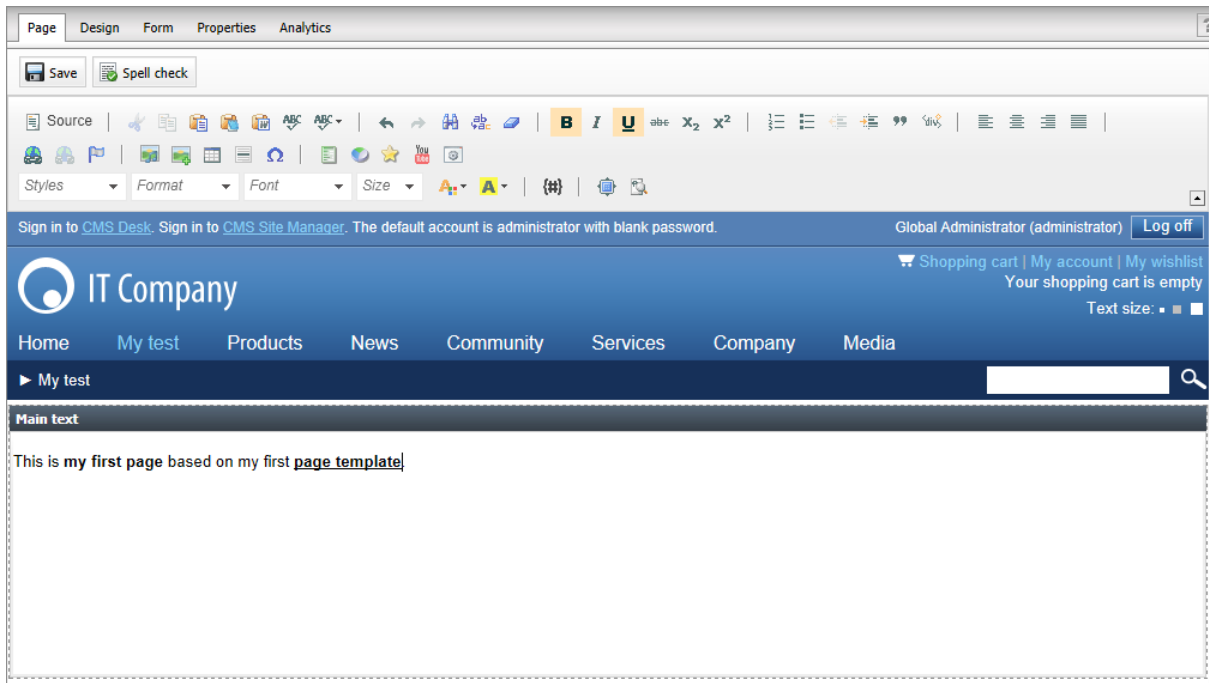

5. Now hover over the **Editable text** web part, hold down the mouse button and drag it from the toolbar into the **zoneLeft** web part zone. This web part allows you to create editable regions where editors can insert text and other content. Once you drop the web part into the zone, the **Web part properties** dialog will be opened.

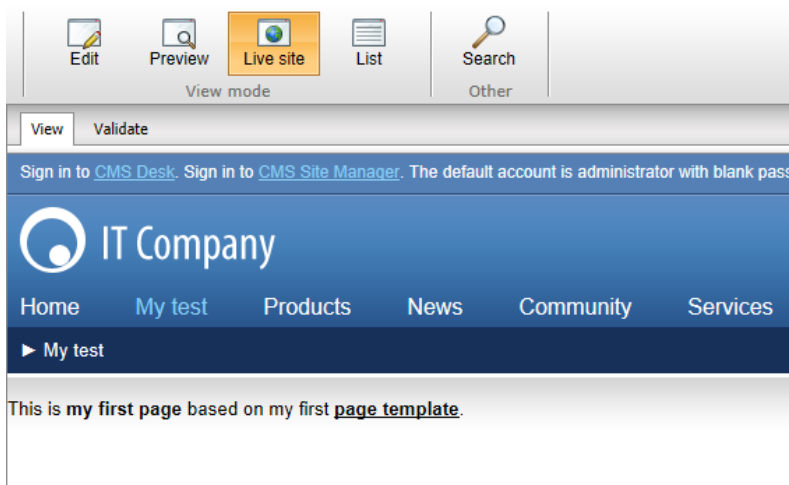

6. Scroll down to the **Editable region title** property, enter *Main text* as its value and click **OK**. The web part instance will now be added to the zone.

7. Next, switch to the **Page** tab, which displays the page in editing mode. The web part that you added provides an editable region that can be used in this mode. Enter some text into the region and click  **Save**.

8. Click **Live site** in the main toolbar. You will see the live version of the page that is displayed to the website's visitors.

Result

You have created a new page based on an ad-hoc page template. The page template defines the page structure and contains the editable text web part, which enables content editors to enter text onto the page.

Important!

Keep in mind that when you create a page based on an ad-hoc page template and later delete the page, the corresponding ad-hoc page template is deleted as well.

7.2.4.3 Re-using an ad-hoc page template

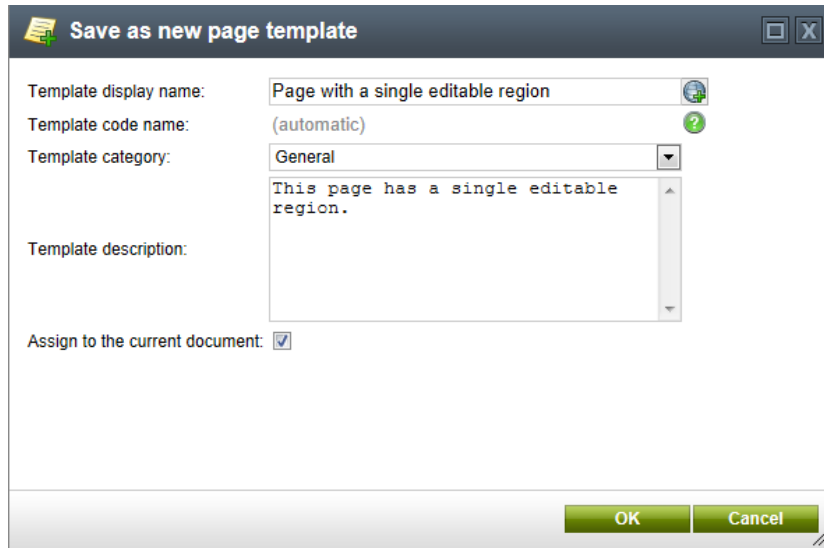

In many cases, you may want to re-use an ad-hoc page template for other pages. In this case, you need to **save the ad-hoc template as a new re-usable template**. The following example demonstrates how this can be done:

1. Open CMS Desk on the **Content** tab, switch to **Edit** mode using the main toolbar and select the new page created in the [previous example](#).
2. Go to the **Properties -> Template** tab, where you can see that the current page is based on an ad-hoc page template.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The main toolbar has buttons for 'New', 'Delete', 'Copy', 'Move', 'Up', 'Down', 'Edit', 'Preview', 'Live site', 'List', and 'Search'. The left sidebar shows a tree view of the 'Corporate Site' with folders like 'Home', 'My test', 'Products', 'News', 'Partners', 'Community', 'Services', 'Company', 'Media', 'Examples', 'Mobile', 'Other', 'Special Pages', and 'Images'. The main content area is divided into tabs: 'Page', 'Design', 'Form', 'Properties', and 'Analytics'. The 'Properties' tab is active, and the 'Template' sub-tab is selected. The 'Template' section shows three radio button options: 'Inherit from parent', 'All culture versions use the same page template' (which is selected), and 'Each culture version uses its own page template'. Below these options is a dropdown menu currently showing 'Ad-hoc: My test' and a 'Select' button. Below the dropdown is a 'Save as new template...' button, which is highlighted with a red box. There is also an 'Edit template properties' button. The 'Inherit content' section below has four radio button options: 'Use page template settings' (selected), 'Do not inherit any content', 'Inherit only master page', and 'Select inherited levels'.

3. Click **Save as new template**. The **Save as new page template** dialog opens. Fill in the following values:

- **Template display name:** Page with a single editable region
- **Template category:** General
- **Assign to the current document:** Yes (leave it checked)

The screenshot shows a dialog box titled "Save as new page template". It contains the following fields and options:

- Template display name: Page with a single editable region
- Template code name: (automatic)
- Template category: General
- Template description: This page has a single editable region.
- Assign to the current document:

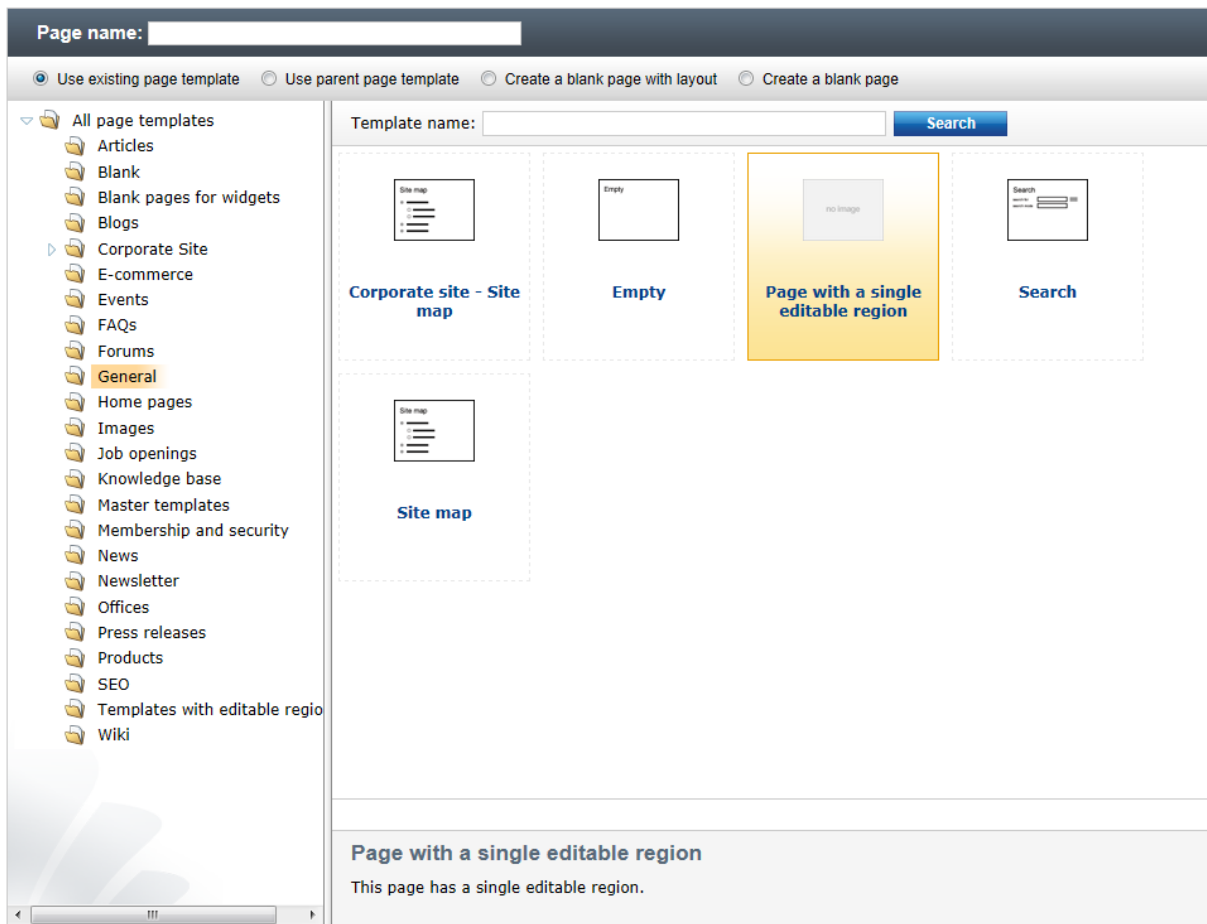

At the bottom of the dialog are two buttons: "OK" and "Cancel".

Confirm the creation of the new page template by clicking **OK**.

Result

When creating pages, you can now assign the new page template by selecting it from the **General** category. Because the **Assign to the current document** option was checked, the system also automatically assigns this template to the current page instead of the previous ad-hoc template.

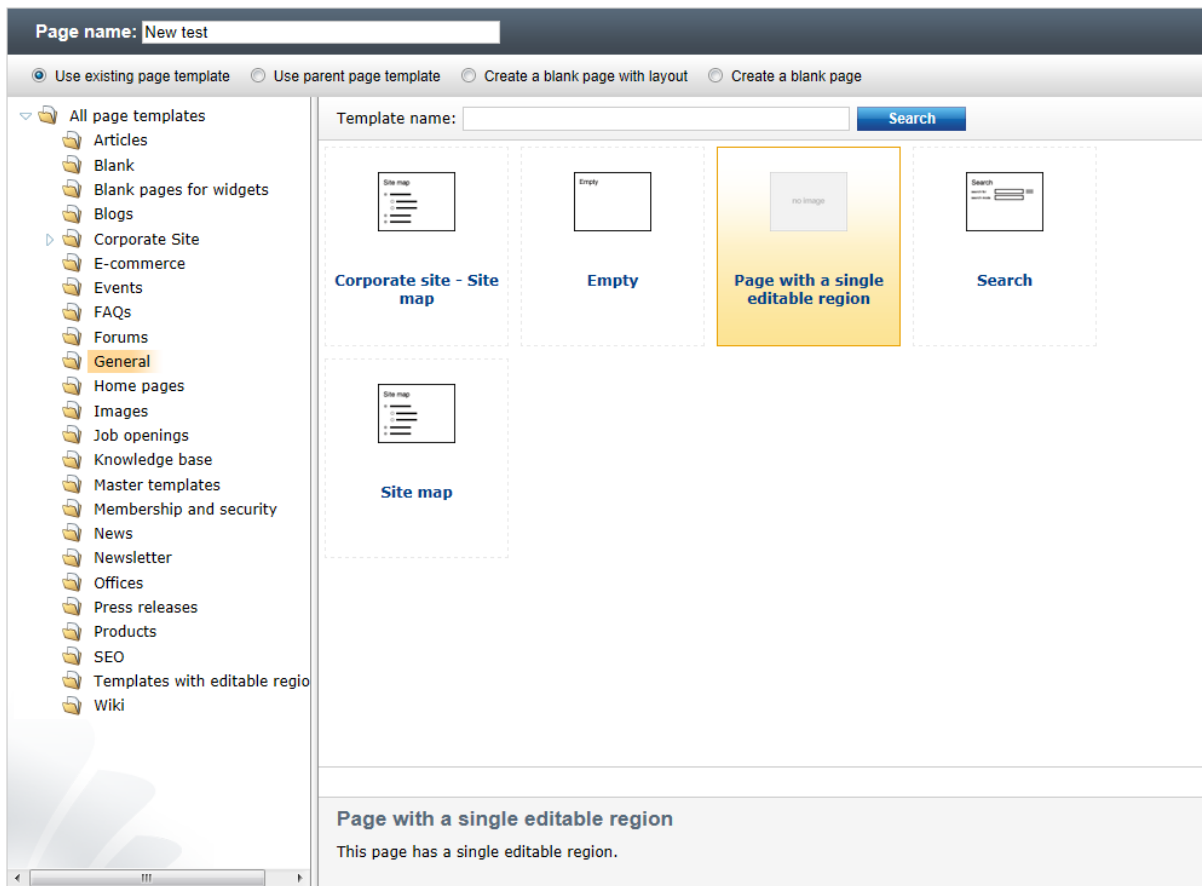

You have converted the previously created ad-hoc page template that was specifically bound to a single page into a re-usable page template that can be used for any number of pages.

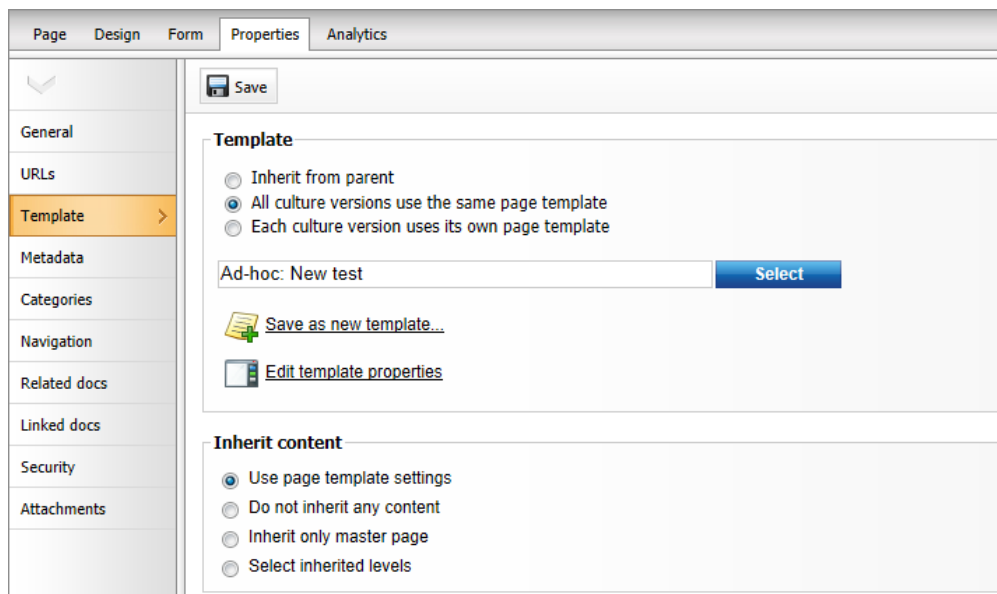

7.2.4.4 Cloning and modifying a page template

You may need to create a new page that will be similar to existing pages, but with some minor modifications of the page template. For example, if you wish to display the editable region from the previously created page template in a container box.

Instead of creating the page template from scratch, simply create a new page based on your existing page template.

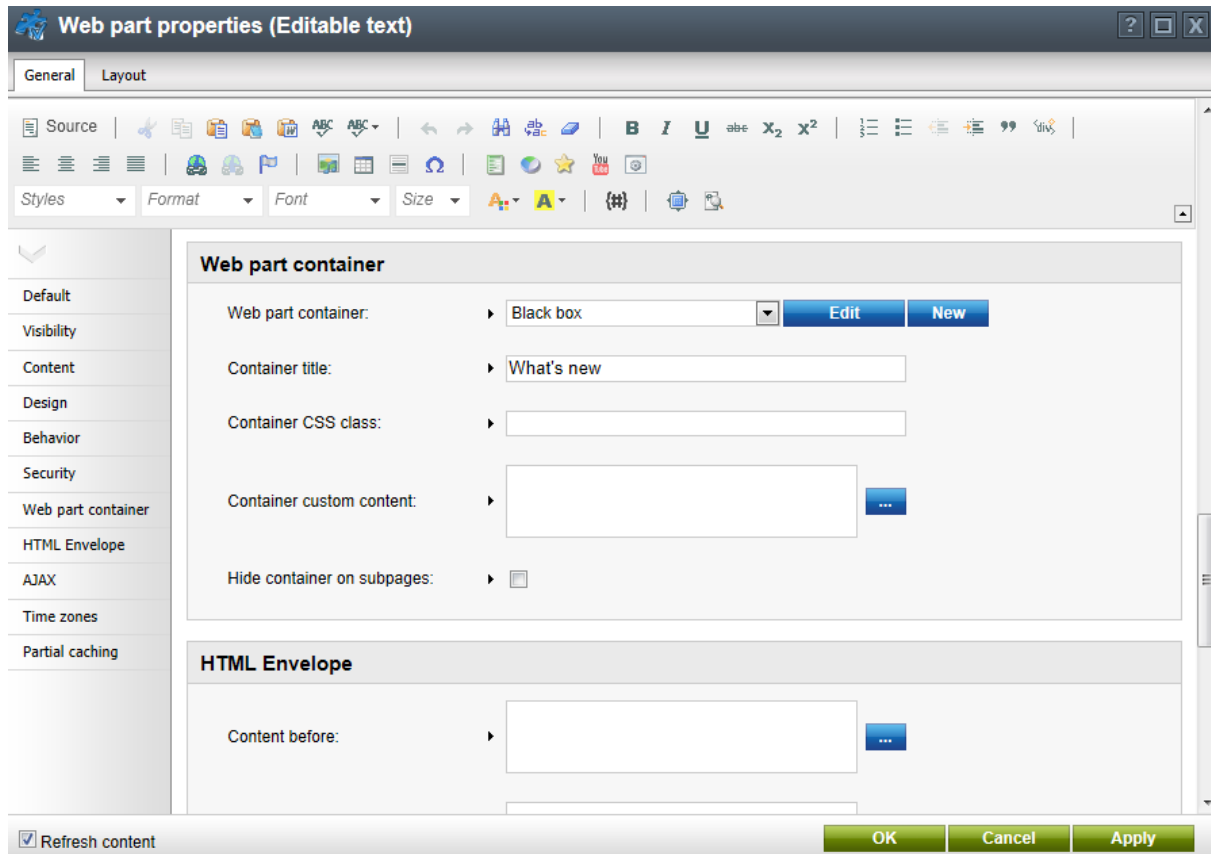

Then select the page in the content tree, navigate to its **Properties -> Template** tab and click  **Clone template as ad-hoc**. A new ad-hoc template is now created and you can edit it without modifying the existing pages based on the original template.

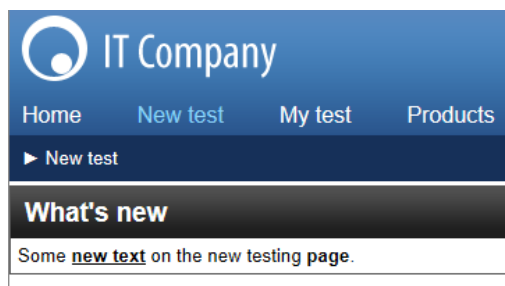

Now switch to the **Design** tab and click the **Configure** () button of the **Editable text** web part. Select

the *Black box* container from the **Web part container** drop-down list and enter *What's new* into the **Container title** property.

Click **OK**. Switch to the **Page** tab and enter some text into the editable region. Click **Save** and select **Live site** mode through the main toolbar. You will see a page like this:

As you can see, the text is now surrounded by a black container. When you check the original **My test** page, you will see that it still uses the original design and it wasn't affected by the change made to the new copy of the page template.

Re-using the modified template

If you want to use the new, adjusted page template for other pages, you can save it as

a named template by clicking the  **Save as new template** action on the **Properties -> Template** tab.

Important!

Please keep in mind that when you create a page based on an ad-hoc page template and later delete the page, the corresponding ad-hoc page template will also be deleted and **cannot be restored**.

7.2.4.5 Managing the page template catalog

You can manage page templates using the **Site Manager -> Development -> Page templates** interface. Here you can organize the templates into categories, configure their properties, create new templates, etc.

These configuration options can also be accessed for the templates of individual pages by selecting the appropriate document in the content tree of **CMS Desk**, and using the  **Edit template properties** action on the **Edit -> Properties -> Template** tab.

Each template has the following properties:

General tab

On this tab, you can specify the following properties of the page template:

Template display name	The name of the template displayed to users.
Template code name	The name of the template used in website code.
Category	Here you can choose the category of the page template.
Template description	Description of the template shown in the page template selection catalog.
Thumbnail	Teaser (preview) image assigned to the template. It is displayed in the page template catalog, e.g. when creating a new page.
Clone as ad-hoc for new documents	<p>When a user selects a template with this option enabled for a new page, the system automatically creates an ad-hoc copy of the template and assigns it to the page. This way, users can immediately modify the design of the new page without changing the default re-usable template.</p> <p>Only available if the Template type is set to <i>Portal page</i>.</p> <p>Note: The system always clones templates as ad-hoc when creating wireframes, even if this setting is disabled for the assigned template.</p>
Template type	Determines the type of pages that the template can be used for. The

	<p>following options are available:</p> <ul style="list-style-type: none"> • Portal page - functions as a standard portal engine page template. • ASPX page - uses the ASPX page template development model and is based on a standard ASPX web form. If selected, the path to the source file must be entered into the File name property. • ASPX + Portal page - works the same way as the <i>ASPX page</i> option, but also supports certain portal engine functionality, such as managing web parts or widgets in predefined zones on the <i>Design</i> tab of CMS Desk directly through the browser. • Dashboard page - provides a template for dashboard sections of the CMS interface. This type of page template cannot be used for standard content tree pages. • MVC - can be used to create pages defined through an MVC controller and action, which must be specified via the additional <i>Default controller</i> and <i>Default action</i> properties. Pages based on templates of this type automatically use the live URL and view in editing mode (i.e. on the <i>Page</i> tab of CMS Desk). Please see the MVC development model chapter for more information.
Master template	<p>Only available if the Template type is set to <i>Portal page</i>. Indicates if the pages that use the template should be Master pages. Master page templates are usually used for the main menu and logo of a website.</p> <p>Enabling this also causes the template to be selectable as the root master page template in the New site wizard.</p>
Inherit content	<p>Only available if the Template type is set to <i>Portal page</i>. Configures the visual inheritance as explained in the Visual inheritance topic.</p> <p>You can choose from the following options:</p> <ul style="list-style-type: none"> • Inherit all - inherits the content of all parent pages • Do not inherit any content - displays only the current page without any parent content • Inherit only master page - inherits from the first master page above the page in the content tree, i.e. if there are more master pages, it inherits only from the one which is the closest above it in the hierarchy • Select inherited levels - inherits only content from the chosen content tree levels
File name	<p>Only available if the Template type is set to <i>ASPX page</i> or <i>ASPX + Portal page</i>. Specifies the path to the .aspx file that the page template should be based on. The file may either be chosen using the Select button, or its path can be entered manually. The tilde character (~) represents the root directory of the project folder, e.g. ~/CMSTemplates/CorporateSite/Blog.aspx</p>
Default controller	<p>Only available if the Template type is <i>MVC</i>.</p> <p>Sets the name of the controller class containing the MVC action that should be performed when pages using this template are accessed (without the <i>Controller</i> part at the end). For example, if the class is</p>

	<p>called <i>NewsMVController</i>, enter <i>NewsMVC</i>.</p> <p>The system first searches for the specified class in the <i>CMS.Controllers.<current site code name></i> namespace. If it is not found there, the <i>CMS.Controllers.Global</i> namespace is searched.</p>
Default action	<p>Only available if the Template type is <i>MVC</i>.</p> <p>Specifies the exact action defined within the controller class that should be performed when pages based on this template are loaded.</p>

Design tab

This tab is available only for *Portal page* or *Dashboard page* type templates. It can be used to define the content of the page template in the same way as on the **Design** tab in **CMS Desk**, but without requiring the context of a specific site. Web parts and widgets can be added (+), removed (X), configured (⚙) or relocated using drag-and-drop. Individual zones may also be managed via their context menu that can be expanded by right clicking the header of the given zone or using the **Web part zone menu** (▼) action. Any changes made here will affect all pages using the edited page template.

Sites tab

On this tab, you can choose which websites the page template will be available for.

Scopes tab

Please refer to the [Page template scopes](#) topic for information about this tab.

Layout tab

Here you can edit the layout of the page template. You can either choose to use one of the pre-defined (shared) layouts or you can create a unique layout specifically for the given page template (custom layout). Learn more in the [Page layouts](#) topic.

Theme tab

This tab allows you to manage the files contained in the page template's theme folder. This usually includes any files required by the CSS styles added for the template's custom page layout on the **Layout** tab (e.g. images). For more information, please see the [Development -> CSS stylesheets and design -> App themes](#) topic.

Web parts

Here you can see the XML document with the configuration of the web parts. Use this dialog only in a situation when the standard **Design** mode isn't working as expected (e.g. due to an error or data inconsistency).

Header

Here you can define custom HTML code that will be placed into the **<head>** element (i.e. inserted between the **<head></head>** tags) of all pages that use this page template. This can be useful if you

need to link some additional CSS or JavaScript files.

The head content can also be inherited by child documents under pages that use this template. The inheritance depends on the following options, which can be specified on this tab for each template:

- **Allow child templates to inherit the current header** - if enabled, the head content of this template will be inheritable by child documents.
- **Inherit header(s) from parent template(s)** - indicates if documents based on this template should be allowed to inherit head content from the templates of documents that are above them in the content tree.

Please note that the header inheritance also follows the rules of the standard content inheritance, which can be configured for individual documents and templates. For example, all documents displayed within a master page would also inherit the head content of its template, but a child document without any visual inheritance would not. This way, the head code will only be added to pages where it is required to correctly display the master template's content.

Documents tab

On this tab, you can see a list of documents (pages) that are using the page template. By clicking a document in the list, you will be redirected to the document's **CMS Desk -> Edit** mode. The documents in the list can be filtered according to the **Site** they are on, their **Document name** and their **Document type**.

7.2.4.6 Page template scopes

Page template scopes define where a page template can be used. **Important - template scopes are not a security feature!** They only provide a way how to simplify the user experience by not offering too many page templates to the users!

This means that you can limit which page templates will be offered to the users in the page template catalog in a certain location. However, when a user creates a page there, they can move it to another location, even to one which is not allowed by the template scope.

Template scopes can be defined on the **Scopes** tab when selecting a page template from the tree in **Site Manager -> Development -> Page templates**. There are two basic options available:

- **Template can be used on all pages** - the use of the page template is not limited (it can be used in all parts of the website).
- **Template can be used only within following scopes** - if selected, the page can be used according to the rules defined by the template's scopes.

If you choose the second of the options mentioned above, UI controls for managing the scopes will be displayed below the line.

Based on the site selected in the **Site** drop-down list, you can display either site-related scopes or global scopes. Site-related scopes are applied only on the selected site, while the **(global scopes)** option indicates that the scopes are valid on all sites in the system.

Using  **New template scope**, you can create new template scopes. Listed scopes can be **Edited** () or **Deleted** (.

General Design Sites **Scopes** Layout Theme Web parts Header Documents Versions

7.2.4.7 Page layouts

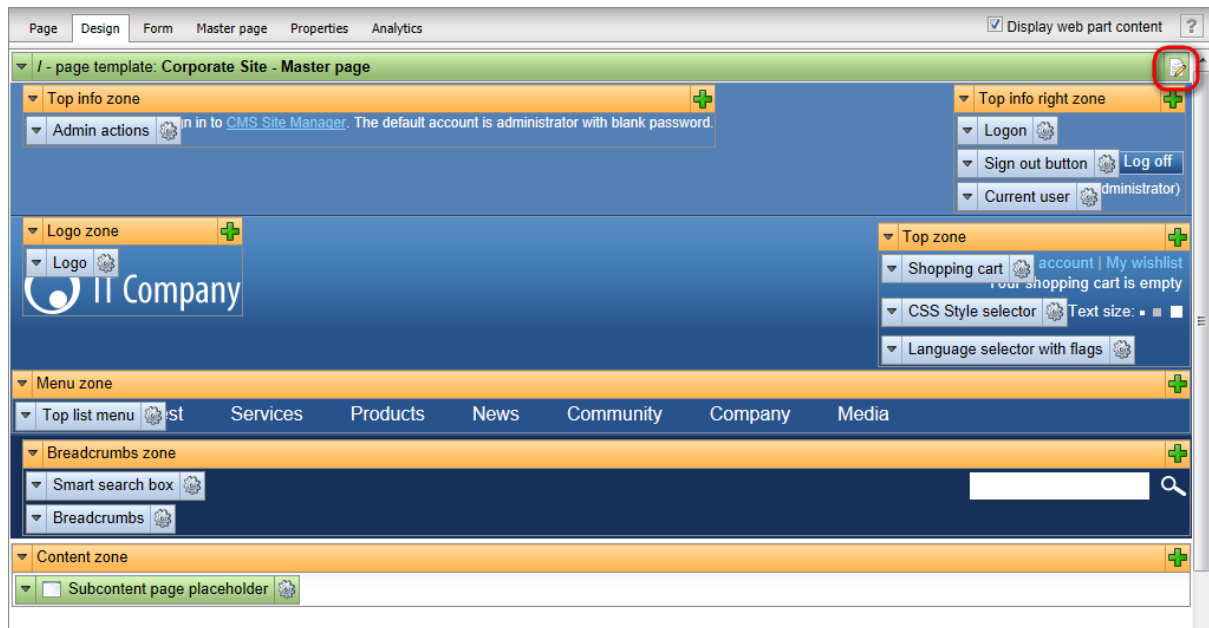

The structure of every page template is determined by a *page layout*. A page layout consists of **layout code** and **web part zones** that specify regions where designers can place web parts. Page layouts allow you to define the basic **layout and design of your site**.

There are two general types of page layouts:

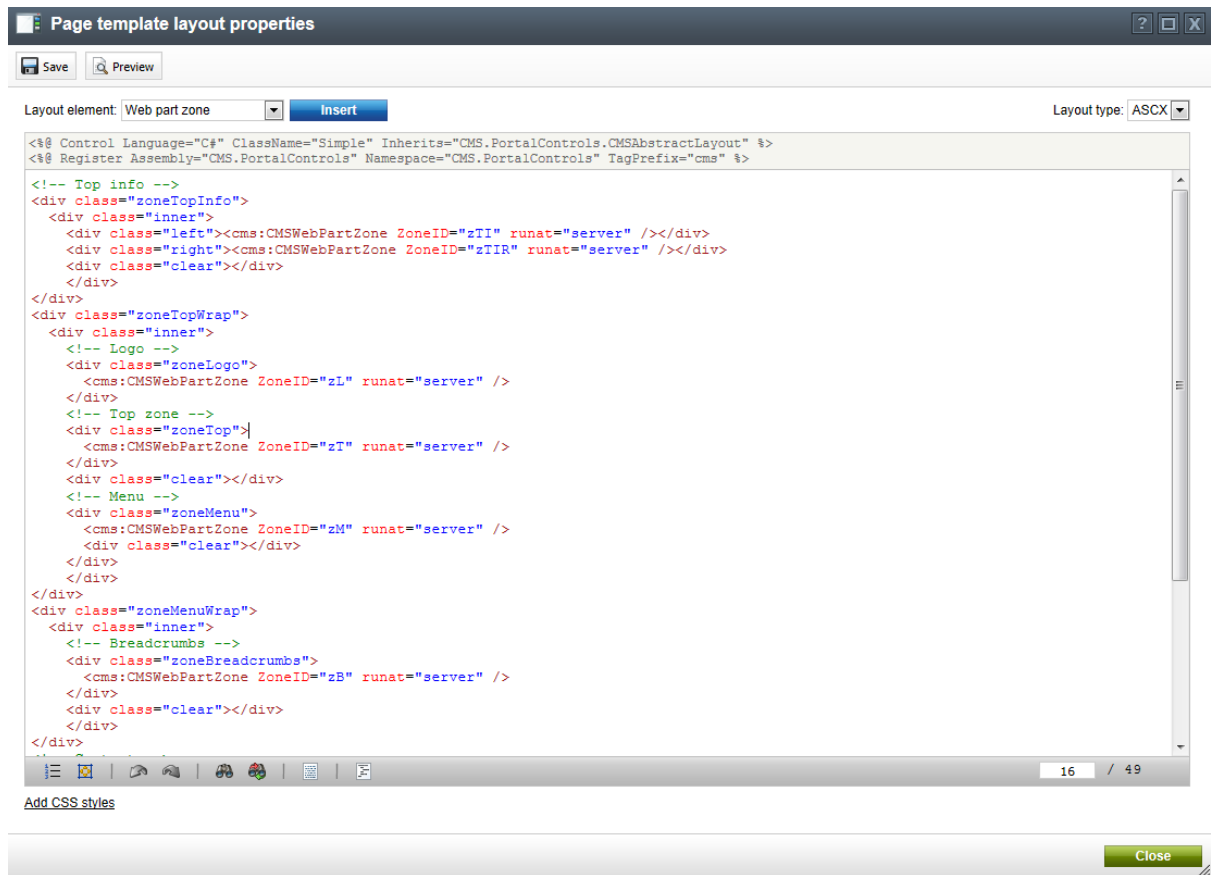

- **Custom** - used only by one specific page template.
- **Shared** - stored as separate objects that can be assigned to any number of page templates. Modifying a shared layout affects all templates that use it.

To edit the layout of a page:

1. Open CMS Desk and select the document representing the page in the content tree.
2. Switch to the **Design** tab.
3. Click the **Edit layout** (🔗) button at the top right of the green template area:

4. Modify the layout code as required.

The **Layout type** selector allows you to choose between two types of layout code:

| Layout type | Description |
|-------------|--|
| ASCX | <p>This type of layout code supports both HTML and ASCX markup, i.e. the same syntax that you would use to edit a standard web form or user control, including inline code and embedded controls.</p> <p>Important: For security reasons, ASCX layouts may only be edited by users who have the <i>Edit ASCX code</i> permission for the <i>Design</i> module. Only global administrators can assign this permission.</p> <p>You can Insert web part zones as control tags:</p> <pre><cms:CMSWebPartZone ZoneID="zoneA" runat="server" /></pre> <p>The <i>ZoneID</i> value must be unique for every web part zone within the given layout.</p> |
| HTML | <p>The system processes the layout code as basic HTML. This means that ASCX markup, such as controls or inline code, is not functional when the layout is rendered.</p> |

You can **Insert** web part zones into HTML layouts as macro expressions:

```
{^ WebPartZone | (id) zoneA ^}
```

The value of the *id* parameter must be unique for every web part zone within the given layout.

If you need to insert dynamic values into HTML layouts, you can enter Kentico CMS [Macro expressions](#) or methods.

HTML layouts do not need to be compiled, so you can use and modify them even if the Virtual path provider is not available, such as in a pre-compiled or medium trust environment.

Previewing the layout

By clicking the  **Preview** button in the header of the editing dialog, you can write the layout code side-by-side with a preview of how the changes affect the live site version of the page.

See the [Design preview](#) topic for additional details about the preview mode.

Sample layout code

Page layouts are composed of standard HTML elements, which means **you have full control over how the system renders the page**. You can choose between a table and CSS-based layouts.

The following sample page layout code uses a table to define a two-column layout:

```
<table>
  <tr>
    <td>
      <cms:CMSWebPartZone ID="zoneA" runat="server" />
    </td>
    <td>
      <cms:CMSWebPartZone ID="zoneB" runat="server" />
    </td>
  </tr>
</table>
```

The following layout code defines the same two-column layout, but using DIV elements and CSS styles:

```
<div style="width: 50%;">
  <div style="width: 80%; float: left;">
    <cms:CMSWebPartZone ID="zoneA" runat="server" />
```

```
</div>
<div style="width: 50%; float: right;">
  <cms:CMSWebPartZone ID="zoneB" runat="server" />
</div>
</div>
```

Adding CSS styles to layouts

Page layouts allow you to directly define any CSS classes used within the layout code.

Requirement: Enable the **Allow CSS from components** setting in **Site Manager -> Settings -> System -> Performance**.

1. Click [Add CSS styles](#) below the page layout's code. The **CSS styles** editor appears.
2. Enter the definitions of the required CSS classes.
3. Click  **Save**.

All pages that use the layout automatically load the specified styles. See also: [CSS for page components](#)

Conditional layouts

When editing the code of ASCX page layouts, you can **insert** *Conditional layout* elements. This allows you to create flexible layouts that display content based on certain criteria. The page layout renders the content between the *CMSConditionalLayout* tags only if the conditions specified by the properties are fulfilled.

For example:

```
<div class="padding">
  <cms:CMSConditionalLayout runat="server" id="goldLayout" GroupName="Roles"
  VisibleForRoles="GoldPartners">
    <cms:CMSWebPartZone runat="server" ZoneID="zGold" />
  </cms:CMSConditionalLayout>

  <cms:CMSConditionalLayout runat="server" id="silverLayout" GroupName="Roles"
  VisibleForRoles="SilverPartners">
    <cms:CMSWebPartZone runat="server" ZoneID="zSilver" />
  </cms:CMSConditionalLayout>

  <cms:CMSConditionalLayout runat="server" id="defaultLayout" GroupName="Roles" >
    <cms:CMSWebPartZone runat="server" ZoneID="zDefault" />
  </cms:CMSConditionalLayout>
</div>
```

This sample layout displays one of three possible web part zones based on the roles of the user viewing the page. Gold partners see the content of the *zGold* zone, Silver partners see the *zSilver* zone and all other users see *zDefault*.

The following properties are available for conditional layouts:

| Property | Description |
|--------------------------|---|
| GroupName | Allows you to group conditional layout elements together. When multiple conditional layouts use the same group name, the page only displays the first one (from the top of the code) that has its visibility condition fulfilled. |
| VisibleForDocumentTypes | Adds a visibility condition that checks if the current page is of a specific document type . Enter the value as a list of document type code names separated by semicolons.

For example: <i>VisibleForDocumentTypes="CMS.MenuItem;CMS.News"</i> |
| VisibleForRoles | Adds a visibility condition that checks if the user viewing the page belongs to specific roles . Enter the value as a list of role code names separated by semicolons.

For example: <i>VisibleForRoles="MarketingManager;ChatSupportEngineers"</i> |
| VisibleForDeviceProfiles | Adds a visibility condition that checks if the user viewing the page matches a specific device profile . Enter the value as a list of device profile names separated by semicolons.

For example: <i>VisibleForDeviceProfiles="iPad;iPhone"</i> |
| VisibleForDomains | Adds a visibility condition that checks if the site is being accessed under a specific domain name . Enter the value as a list of domain names separated by semicolons. |
| ActiveInDesignMode | If set to <i>true</i> , the conditional layout also evaluates its visibility condition in <i>Design</i> mode.

<i>False</i> by default. |

Creating pages with shared layouts

When creating a new page, you can select the **Create a blank page with layout** option and choose from a number of pre-defined page layouts:

Page name:

Use existing page template
 Use parent page template
 Create a blank page with layout
 Create a blank page

Layout name: Search

Two columns

Two columns - 20/80

Two columns - 30/70

Two columns - 70/30

Two columns - 80/20

Select layout

Copy this layout to my page template

The **Copy this layout to my page template** checkbox at the bottom of the selection dialog determines whether the system creates an ad-hoc copy of the layout specifically for the page template, or if the shared layout should be assigned directly. If you disable the option and then modify the layout code, the changes affect all pages with templates that use the shared page layout. Leave the option enabled unless your intention is to create pages with the same layout, that can be edited in one place.

Managing shared page layouts

You can manage the pre-defined (shared) page layouts in **Site Manager -> Development -> Page layouts**. When editing a layout on the **General** tab, you can modify its code and also configure the following properties:

| | |
|-----------------|---|
| Display name | Name of the layout displayed in the page layout list. |
| Code name | A unique name that serves as an identifier for the page layout (e.g. in the API). |
| Description | Allows you to enter an optional text description of the page layout. |
| Thumbnail | Upload field for the layout preview image. Users see this image in the page layout selection dialog when creating new blank pages. |
| Is convertible | If enabled, you can use automatic mapping to assign replacement layouts that the system loads instead of the current layout for specific device profiles. |
| Number of zones | Indicates how many web part zones the layout uses. The number of zones helps users find appropriate matches when mapping layouts for device profiles. |

| | |
|--|---|
| | The system automatically counts the number of zones in the layout code, but you can manually override the value (for example in the case of conditional layouts or layouts that load web part zones dynamically). |
|--|---|

On the **Page templates** tab, you can check which templates use the given layout. Templates with a custom page layout are not included here, even if they were created as a copy based on the currently edited shared layout.

Using layout web parts

It is also possible to define the layout of a page template by adding web parts of a special type designed for this purpose. This approach allows you to place web part zones onto a page template without the need to write or edit the page layout code.

Simply add a layout web part to a page containing a single zone and then you can configure the required layout via the web part's properties dialog or even directly on the **Design** tab. To learn more, read the [Development -> Web parts -> Layout web parts](#) chapter of this guide.

7.2.4.8 The master page concept

Master pages represent the powerful concept of sharing the same header and footer for all pages on the website. It allows you to manage repeated items, such as the site logo, main menu and footer content in a single place.

The root of the content tree is always a master page. You can also configure any other page template to be a master page by enabling the **Master page** option on the **General** tab of the page template editing interface at **Site Manager -> Development -> Page templates**.

The following figure shows how the same master page is used for the home page and product page. As you can see, the pages are inserted inside the master page:

7.2.4.9 Editing the master page

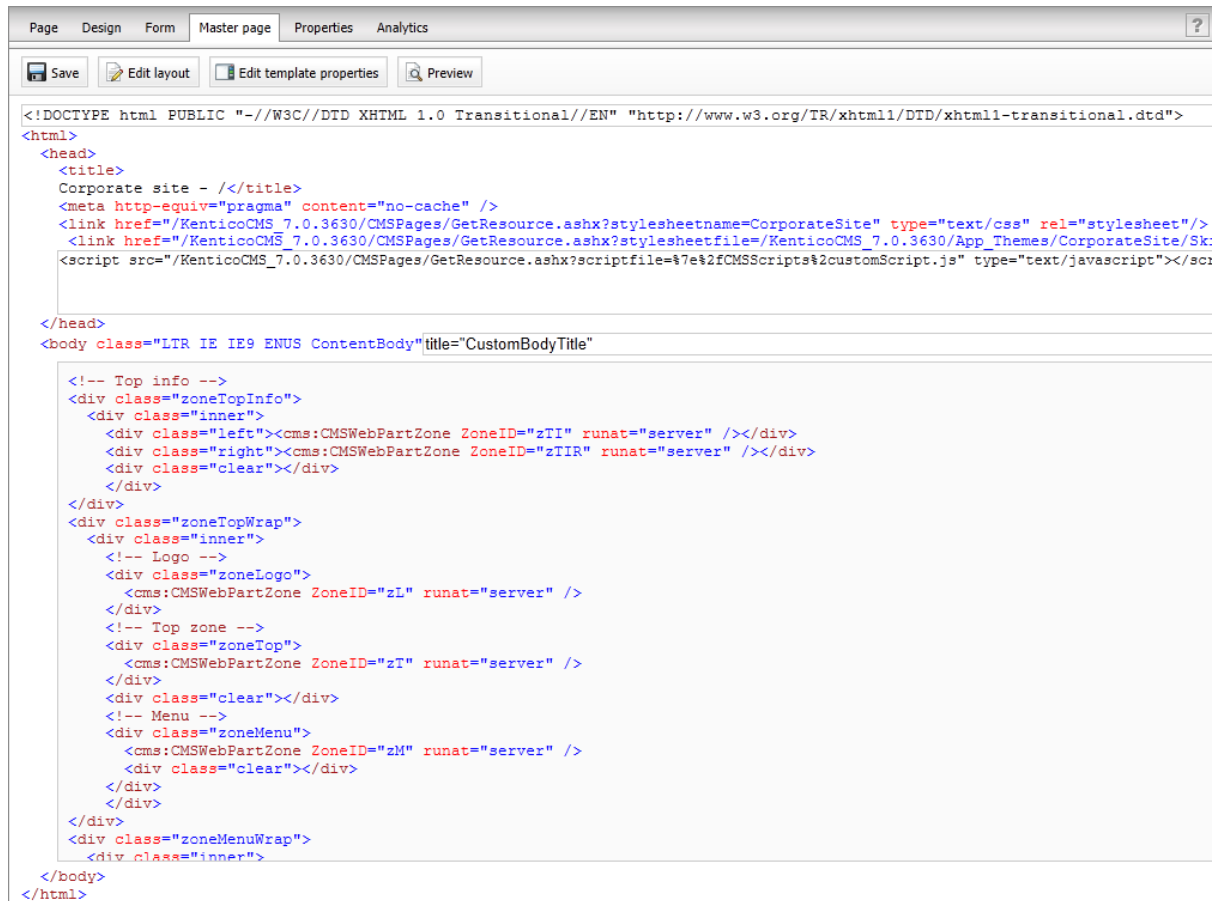

Master pages are either the root of the content tree or pages whose page template has the **Master template** option enabled on the **General** tab of the page template editing interface in **Site Manager -> Development -> Page templates**. They can be edited just like any other page. You can use the **Design** tab to edit the web parts and layout of the master page.

Page placeholder

A master page must always contain the [General -> Layout -> Page placeholder](#) web part that specifies where the content of sub-pages should be loaded. Visual inheritance is described in more detail in the next topic.

In addition, there's a special **Master page** tab available in CMS Desk only for master pages.

</div>
</div>
<div class="zoneMenuWrap">
<div class="inner">
</div>
</div>
</body>
</html>

```

This tab allows you to define sections of the master page's HTML code. This code is also added to all pages that inherit content from the master page.

- **DOCTYPE** - insert any code that needs to be placed at the beginning of the page's HTML source, typically the DOCTYPE definition.
- **HEAD** - allows you to add HTML code inside the **<head>** element of the master page and all child pages that inherit its content.
- **BODY** - here you can add custom attributes to the **<body>** element.
- **Master page layout** - the area between the **<body>** tags displays the [layout code](#) of the master page template. To modify the layout code, click  *Edit layout* in the tab header.

The code outside of the editable sections is only informative and may not be identical to the actual code rendered for pages.

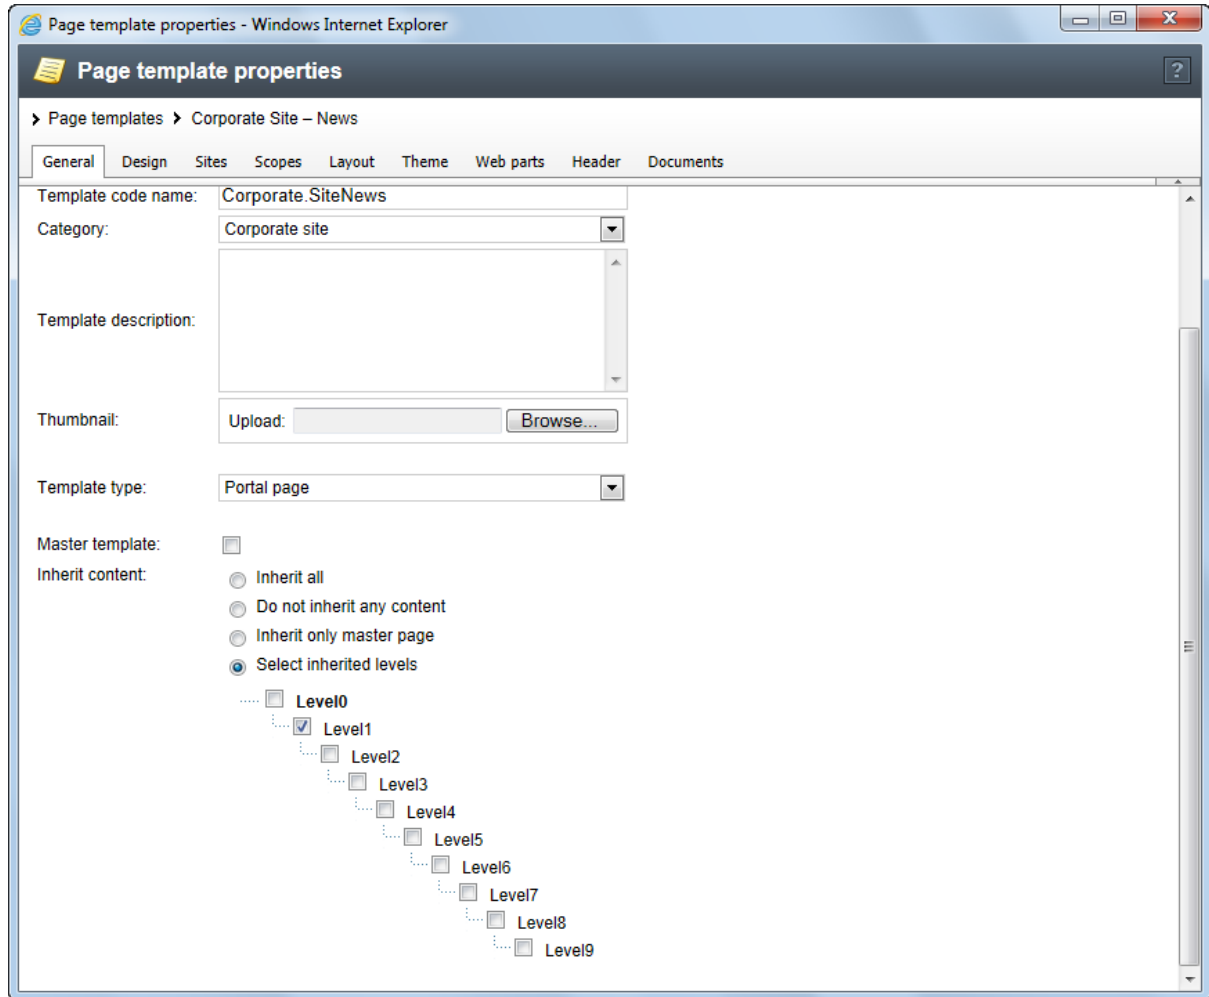

7.2.4.10 Visual inheritance

As you can see in the [The master page concept](#) topic, the content of sub-pages is displayed within the master page or generally within any parent page using the [Page placeholder](#) web part. The result of this approach is that the sub-page content is "nested" inside the content of the parent pages.

In some cases, you may wish to hide parts of the parent page. There are several ways to achieve that:

Using the "Inherit content" property of the page template

Select the **/News** page, go to its **Properties -> Template** tab and click the  **Edit template properties** action. Now you can set the **Inherit content** value to *Select inherited levels* and check only the **Level1** box. This means that only the content from the first level of the content hierarchy will be displayed and the master page (root) is not inherited. Click  **Save** to confirm the changes.

The page will now look like this:

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The 'Content' menu is expanded, showing options like 'New', 'Delete', 'Copy', 'Move', 'Up', 'Down', 'Edit', 'Preview', 'Live site', 'List', and 'Search'. The 'Preview' option is highlighted. The main content area displays the 'News' section, which includes a 'News List' and a sample news article titled 'Community Website Section' by Brad Summers, dated 6/29/2011 12:00:00 AM.

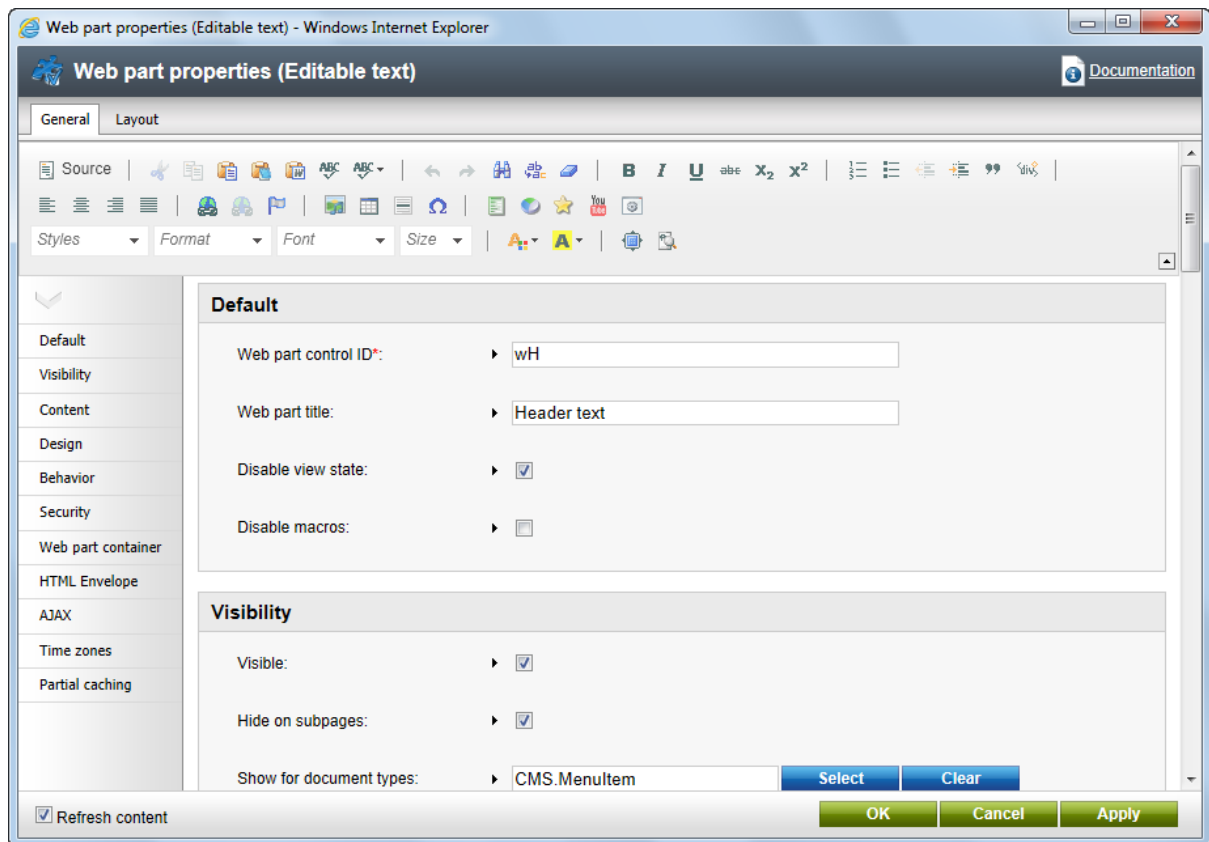

Set the **Inherit content** value back to **Level0** for now.

Similarly, you can set the content inheritance on the level of **individual pages** using the **Properties -> Template** dialog. The content inheritance settings you configure for documents override the page template settings:

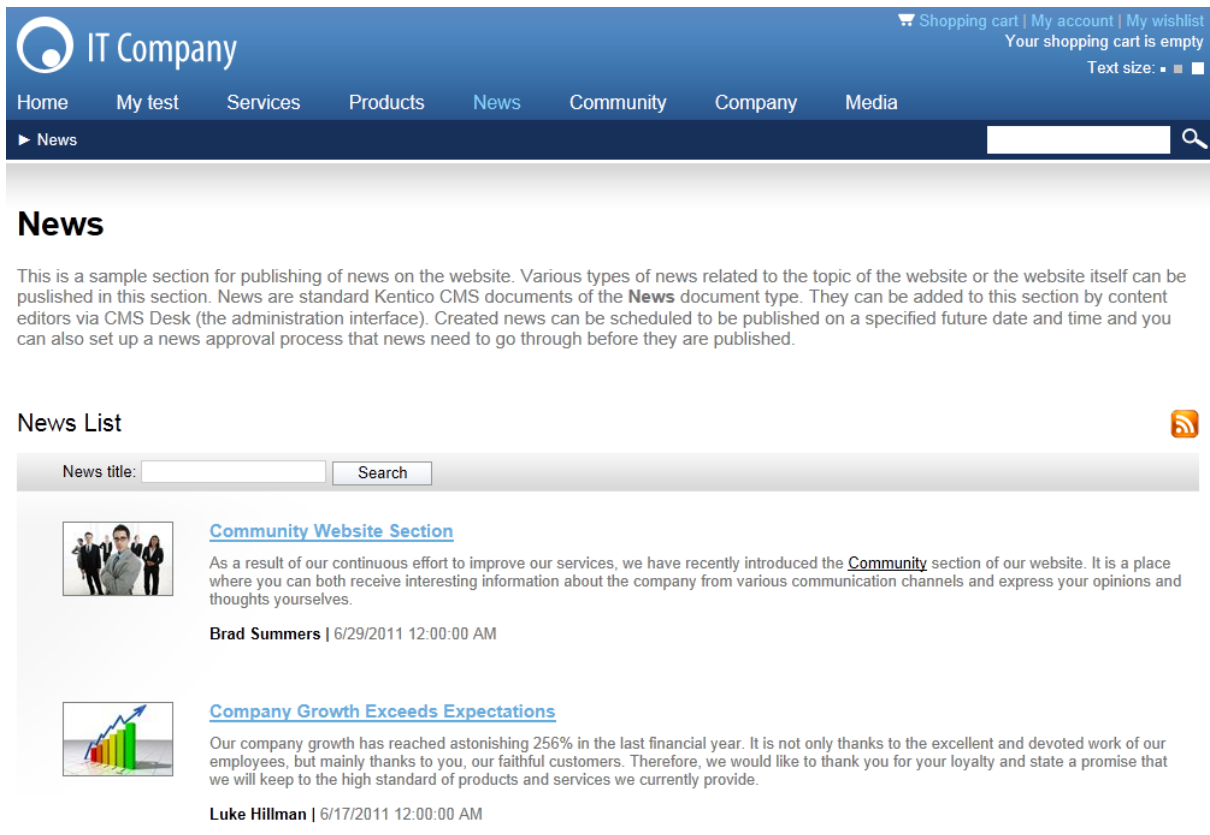

The screenshot shows the 'Properties' dialog for a page template. The 'Template' tab is selected. The 'Template' section has three radio buttons: 'Inherit from parent', 'All culture versions use the same page template', and 'Each culture version uses its own page template'. The 'Each culture version uses its own page template' option is selected. Below this, there is a text box containing 'Corporate Site - News' and a 'Select' button. There are also links for 'Save as new template...', 'Clone template as ad-hoc', and 'Edit template properties'. The 'Inherit content' section has four radio buttons: 'Use page template settings', 'Do not inherit any content', 'Inherit only master page', and 'Select inherited levels'. The 'Select inherited levels' option is selected, and a checkbox for 'Root' is checked.

Using the "Hide on subpages" web part property

Click **/News**, switch to the **Design** tab and click the **Configure** (⚙️) button of the **HeaderText** web part. The web part has the property **Hide on subpages** set to true:

Click **Cancel** and click **Live site**. Please note that when you display the list of news, the title **News** is displayed:

News Community Website Section

Community Website Section

As a result of our continuous effort to improve our services, we have recently introduced the [Community](#) section of our website. It is a place where you can both receive interesting information about the company from various communication channels and express your opinions and thoughts yourselves.

The community section consists of four separate sub-sections. The [Forums](#) let you discuss various topics, closely or remotely related to our company's activities. In [Blogs](#), you can read personal blogs of our employees and comment on the thoughts and ideas expressed in them. The [Events](#) sub-section lets you know about events that our company organizes, while registration for the events is possible too. Finally, the [Wiki](#) is a place where valuable information is provided to you, being a great source of information on various topics.

This is ensured by the **Hide on subpages** property that hides the web part displaying the **News** title.

Using the "Show for document types" web part property

The **Show for document types** property allows you to define a list of document types for which the web part will be displayed. To see how it works, select **/Community/Blogs/Brad-Summers-Blog** in the content tree. On the **Design** tab, click **Configure** (⚙️) for the **Header text**, **Description text** or **Blogs filter** web part. All of them have the **Show for document types** property set to *CMS.BlogMonth*; *CMS.Blog*. This means that the web part will only be displayed on blog month and blog documents, not on blog posts which are stored under blog months. Click **Cancel**.

Still viewing the **Brad Summers Blog** document, switch to the **Live site** mode. The header text, description text and filter are all displayed above the repeater displaying blog posts.

Brad Summers Blog

Hi, my name is Brad Summers and I am the head of web development in our company. I decided to start this blog in order to share the most interesting remarks and ideas that I come across during my day-to-day work. I will share all sorts of interesting information related to activities of our company and to web development in general. I believe that it will be interesting reading for all our customers, partners and all other individuals interested in web development. And of course, you can post comments on each blog post in case that you want to share your opinion, have something to add or if you want to raise a discussion related to a post's topic.

Blog post name: Search

Remote Management

In this blog post, I will share some remarks regarding communication between our former New York Office and the newly setup London Office.

Brad Summers | 3/23/2011 3:12:26 PM | [2 comments](#)

When you display some particular blog post, the web parts are not displayed because *CMS.BlogPost* is not among the enumerated document types.

► Community ► Blogs ► Brad Summers Blog ► March 2011 ► Expanding to Europe

Forums Blogs **27** Events Wiki

Expanding to Europe

In this blog post, I will try to share some of my impressions of the recent expansion of our operations to the Old Continent.

As you could already get to know from the News section, we have recently opened a new office in London, United Kingdom. The office has already started its operation and first projects are to be delivered soon, so I finally found some time to share my impressions from its setup.

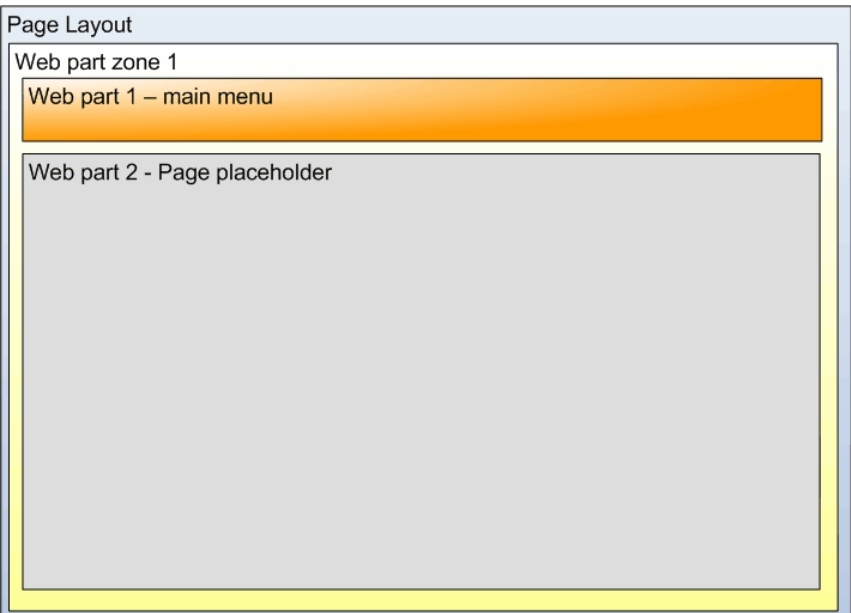

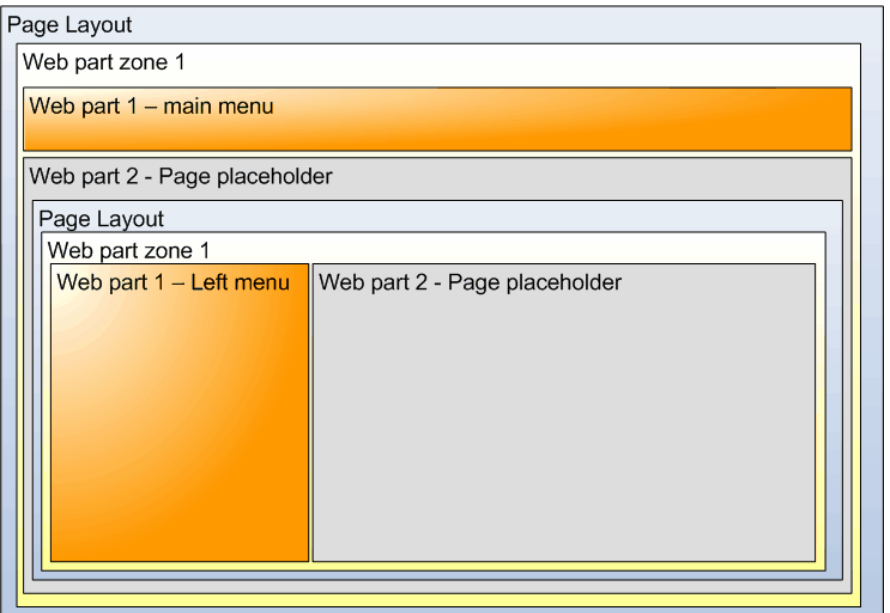

When the idea to expand our operations to Europe first came to mind, everyone was quite skeptical about it. However, after some market research, we found out that there is a place for a company with our know-how in the European market and it was decided to make the idea come alive. I, as the head of web development in our company, was assigned the goal of overseeing the setup of the European branch and to participate in hiring of the first employees.

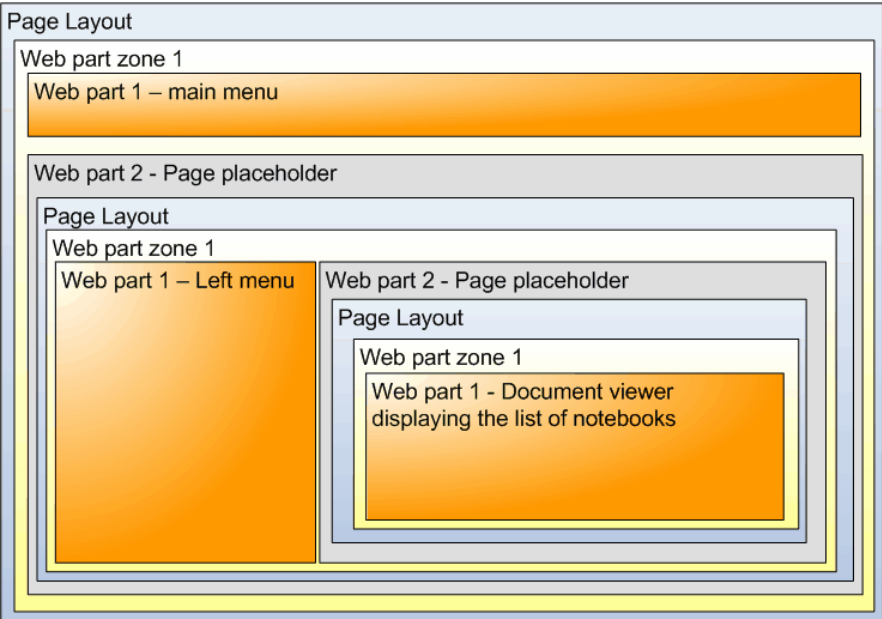

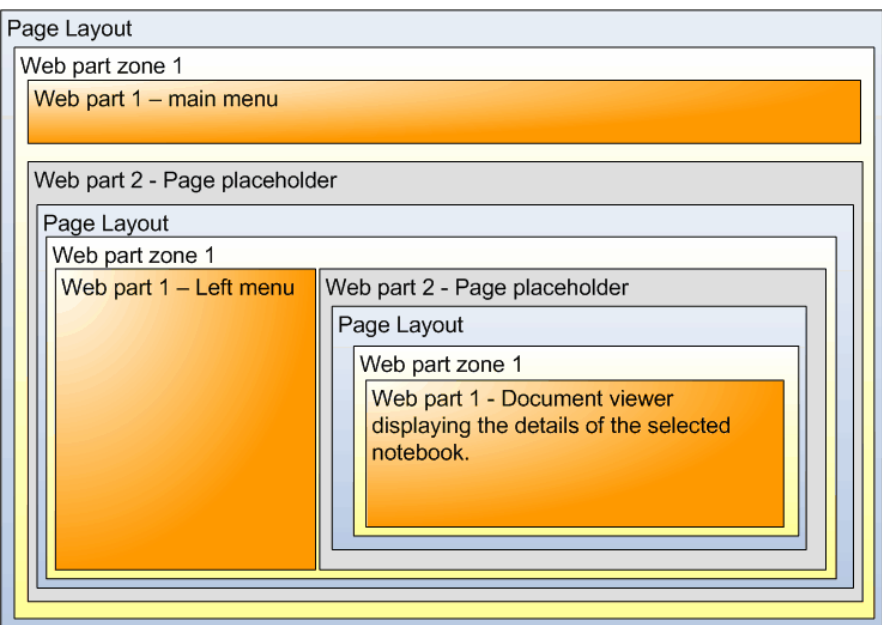

You have learned how to break inheritance of content, hide content on subpages and how to display content based on the current document type.

7.2.4.11 Content tree and page templates

The content tree defines not only the site map of your website, but it also defines how the pages are nested.

For example, when you request the */Products/Laptops/Acer-Aspire-3105WLMi* page, the portal engine loads the content in the following order:

| Processed path | Page template | Rendered page |
|------------------|-------------------------|--|
| / (root) | Main menu page template |  |
| /Products | Products page template |  |

| | | |
|--|---|---|
| <p>/Products/
Laptops</p> | <p>Laptops page template</p> |  |
| <p>/Products/
Laptops/
Acer-
Aspire-
3105WLMi</p> | <p><i>Inherits page template from parent page. The product detail is displayed automatically instead of the listing by the document viewer.</i></p> |  |

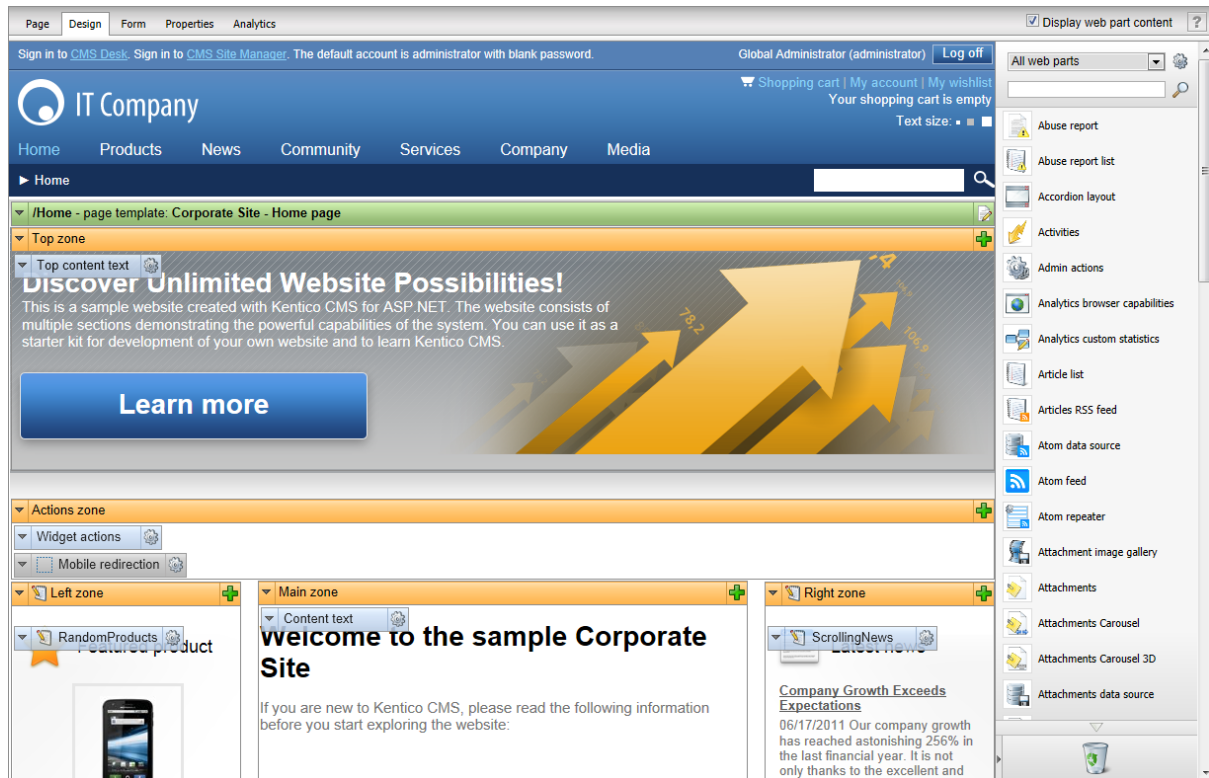

7.2.4.12 Using and configuring web parts

Web parts can be used on both portal page templates and ASPX templates. However, with ASPX page templates, you lose the friendly browser-based interface — the web parts need to be added and configured in Visual Studio just like standard user controls.

This topic describes how you can work with instances of web parts when editing page templates through the portal engine. Please see the [Development -> Web parts](#) chapter for detailed information about the management of web part objects and instructions on how to perform various types of development tasks.

Start by opening **CMS Desk** on the **Content** tab in **Edit** mode. Select any page document from the

content tree (for example *Home*) and switch to the **Design** tab. This tab allows you to view the structure of the page's template in design mode and modify its web part content as needed.

The most direct way to add a new web part to the template is provided by the *web part toolbar*, which is displayed on the right side of the tab by default. Because there is a large total number of web parts available, you can choose which of them should be listed in the toolbar by selecting an appropriate category from the drop-down list at the top. It is also possible to look up specific web parts by entering their name or its part into the search textbox (🔍). Once you find the web part that you wish to add, simply drag it from the toolbar and drop it into the desired location in one of the template's web part zones.

You can remove existing web part instances from the page template by dragging them into the "trash bin" area (🗑️) of the toolbar.

Web part toolbar settings

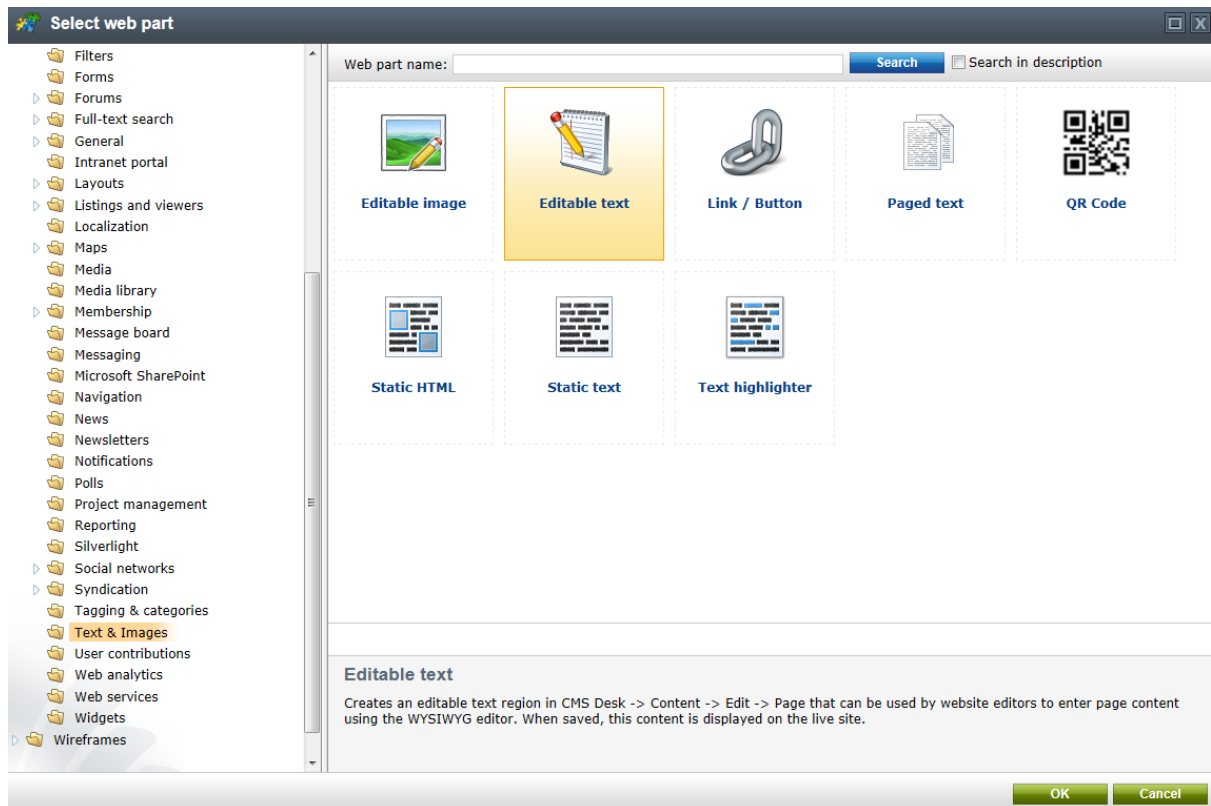

Each user can configure the toolbar according to their preferences. There are four available positions (all sides of the Design tab) and it can also be completely disabled.

These settings can be accessed directly on the toolbar by clicking the **Settings** (⚙️) button next to the category selector. The same options can also be found by going to **CMS Desk -> My Desk -> My profile -> Details**, so it is possible to change them even for users who have disabled their toolbar.

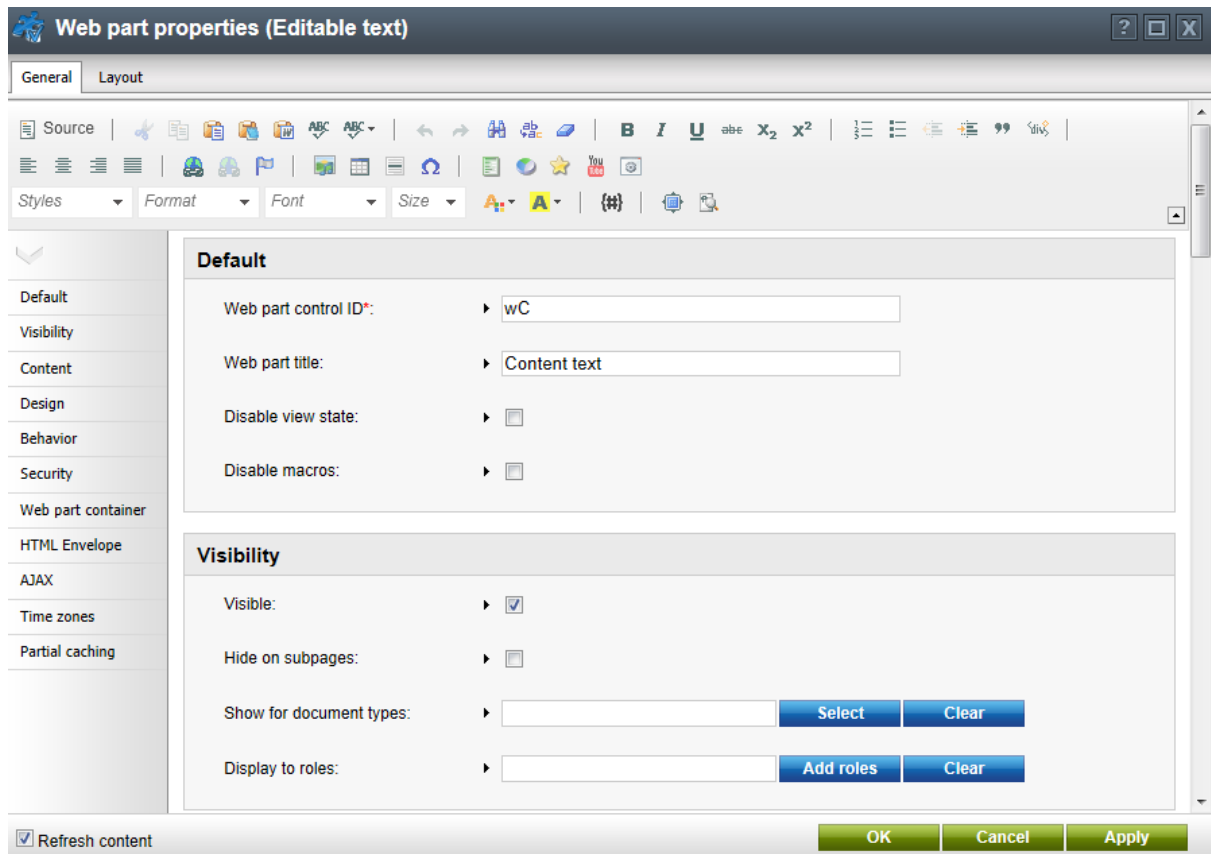

If you only need to increase the size of the Design tab workspace temporarily, you can

collapse the toolbar by clicking the arrow on the border next to the trash bin area.

If you do not wish to use the toolbar, you can instead click on the **Add web part (+)** icon in the top right corner of the zone where you want to insert the web part. This opens the **Select web part** dialog, which contains a catalog of all available web parts. You can locate a specific web part by browsing through the category tree and then confirm your selection by clicking **OK**.

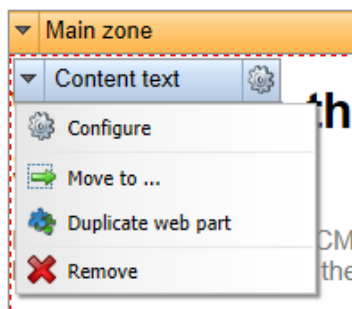

When a new web part instance is added into a zone, using either the toolbar or the zone action buttons, the **Web part properties** dialog will be opened (unless the given web part is configured to skip it). Here you can set up and fine tune the behavior of the web part by entering appropriate values for its properties.

The same configuration dialog can be opened for existing web part instances at any time by clicking the **Configure** (⚙️) button in their header on the Design tab. You can also use the drag-and-drop functionality to relocate web parts to different positions or other zones.

Additionally, every web part has a context menu that can be opened by right clicking on its header or using the arrow icon (▼). The actions in this menu provide an alternative way to perform common tasks.

A similar menu is also available for entire web part zones. This allows you to configure the zone's properties or carry out mass actions for all contained web parts.

All web part modifications are applied immediately and reflected on the live site. Page templates are not connected to workflow, but it is possible to use object versioning to keep track of the changes made to a template, including its web part content (and roll back to previous versions if necessary). Please read the [Development -> Object versioning](#) chapter to learn more.

Impacts of modifying page templates

When you edit a re-usable page template that is shared by several pages, the changes will affect all of the pages.

If you wish to modify the design of a single page only, you need to clone its template as an ad-hoc template or as a new page template. See the [Cloning and modifying a page template](#) topic to learn more.

Configuring web parts via on-site editing

Even though [On-site editing](#) is primarily intended for modifying basic page content and managing documents, users with design permissions may also use it to configure the properties of web parts directly while browsing the website.

When in on-site editing mode, you can highlight individual web parts simply by moving the mouse over the corresponding part of the page. Highlighted web parts are enclosed in a dotted outline, with an additional box displaying their title. The configure (⚙️) action next to the web part title may be used to open the same web part properties dialog as the one on the **Design** tab of CMS Desk.

All pages in this section are created using the **Page (menu item)** doc content tree. The sub-pages are accessible by clicking the links in the If you have a section like this on your website, Kentico CMS allows y web shop, as demonstrated in the [Products - > IT services section](#).

Text added via on-site editing.

CSS list menu ⚙️

If you wish to view the entire web part structure of a page, you can enable the **Highlight** action on the on-site editing toolbar. This highlights all web parts placed on the given page.

Some web parts may not have any visible output in the current state of the viewed page. For example, a

paging web part would only be shown if the connected listing contains a sufficiently large number of items. You will not be able to find such web parts directly on the page. However, their properties can still be accessed by clicking the **Hidden** button on the toolbar and configuring (⚙️) the appropriate item in the displayed drop-down.

Please note that the **Hidden** list only includes web parts that have the potential to affect the appearance of the page. Instances of invisible web parts that only perform background functionality must be configured in CMS Desk.

Please note

Because of master pages and visual inheritance, the content displayed on the website may often be loaded from several different page templates that are nested into each other.

On-site editing mode does not differentiate between templates, so it is possible to configure any web parts displayed on the current page, even those that actually belong to parent documents.

7.2.4.13 Common web part properties

Many web parts use the same or similar properties. The following table summarizes the most important properties found in web parts:

Default properties

| Property Name | Description | Sample Value |
|---------------------|---|--------------|
| Web part control ID | Serves as an identifier for the web part. This ID must be unique within the context of each page template.

The value of this property may only contain alphanumeric characters and the underscore character (_). | text1 |
| Web part title | Title of the web part displayed on the <i>Design</i> tab of CMS Desk and in on-site editing mode. If empty, the value of the Web part control ID property is used for this purpose. | |

Visibility

| Property Name | Description | Sample Value |
|-------------------------|--|-----------------------|
| Visible | Indicates if the web part should be displayed. | |
| Hide on sub-pages | Indicates if the web part should be hidden on sub-pages. If checked, the web part will not be displayed on documents that inherit the web part from a parent document. | |
| Show for document types | <p>Contains a list of document types on which the web part should be displayed. If the currently selected document uses the page template containing the web part, but its type is not specified by this property, the web part will be hidden.</p> <p>The document types in the list must be specified by their code names and separated by semicolons (;). If empty, the web part will be displayed on all document types.</p> | cms.news;cms.event |
| Display to roles | <p>Contains a list of roles to which the web part should be displayed. This may be used to implement documents with specific functionality for different types of users.</p> <p>The roles in the list must be specified by their code names and separated by semicolons (;). If empty, the web part will be displayed to all users.</p> | cmseditors;customrole |

Web part container

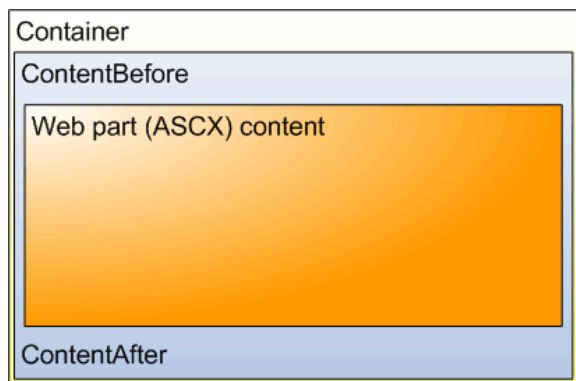

| Property Name | Description | Sample Value |
|---------------------|---|--------------|
| Web part container | <p>Specifies the name of the container (box) to be displayed around the web part. Only the containers defined at Site Manager -> Development -> Web part containers can be selected.</p> <p>The selected container can be edited directly by using the Edit button.</p> | |
| Container title | Sets a title for the container (if one is specified for the web part). This title is displayed only if the <code>{%ContainerTitle%}</code> macro is used in the code of the container. | Latest news |
| Container CSS class | CSS class used for the web part's container. | |

| | | |
|----------------------------|--|--|
| | Applied only if the <code>{%ContainerCSSClass%}</code> macro is used as the value of the <code>Class</code> attribute in the code of the container. | |
| Container custom content | Custom content to be used in the web part's container. Applied only if the <code>{%ContainerCustomContent%}</code> macro is used in the code of the container. | |
| Hide container on subpages | If enabled, the container will not be displayed around the web part on child documents that inherit it through visual inheritance. For example, this allows you to add a container only for the master page. | |

HTML Envelope

| Property Name | Description | Sample Value |
|----------------|---|--|
| Content before | HTML content placed before the web part. Can be used to display a header or add some encapsulating code, such as <code><div></code> or <code><table></code> elements to achieve the required layout. | <code><table style="background-color: red"><tr><td></code> |
| Content after | HTML content placed after the web part. Can be used to display a footer or close the tags contained in the ContentBefore value, such as <code></div></code> or <code></table></code> elements. | <code></td></tr></table></code> |

The structure of a web part and its envelope looks like this:

You can find more details on web part containers in the [Containers overview](#) topic.

Content

| Property Name | Description | Sample Value |
|---------------|-------------|--------------|
|---------------|-------------|--------------|

| | | |
|-----------------------|--|-----------------------|
| Path | <p>Path of the document(s) from the content tree that should be loaded.</p> <p>In addition to basic paths, the property also supports special characters that may be used to specify entire sections of the content or relative paths. For more information about path formatting options, please see Appendix A - Path expressions.</p> | /news/% |
| Highlighted node path | Alias path of the node that should be selected in a menu control. If you do not specify any value, the current path is used. | /products/nokia |
| Query | <p>Specifies the name of the query that the web part uses to retrieve data from the Kentico CMS database.</p> <p>You can define queries for document types and custom tables. To manage the queries, edit a particular item in Site Manager -> Development -> Document types / Custom tables on the Queries tab, or use the buttons next to the field in the web part properties dialog.</p> | cms.news.selectlatest |

Content filter

| Property Name | Description | Sample Value |
|----------------|--|---------------------------------------|
| Document types | <p>Determines which types of documents should be selected. Specified through the document type code names, separated by semicolons (;).</p> <p>The * wildcard can be used as a substitute for a random sequence of characters. For example <i>Product.*</i> would include the document types <i>Product.Camera</i>, <i>Product.CellPhone</i>, <i>Product.Computer</i> etc.</p> <p>If the property is left empty, web parts retrieve all document types by default. In the case of menu and navigation web parts, page (<i>cms.MenuItem</i>) documents are selected by default.</p> <p>Please note: If all document types are loaded (empty value), only the common data columns from the <i>View_CMS_Tree_Joined</i> view will be available in the retrieved data. The specific fields of individual document</p> | cms.article;cms.news;
cms.menuitem |

| | | |
|--------------------------------|---|--|
| | types will not be included. This should be considered in the code of transformations, WHERE conditions, ORDER BY expressions etc. | |
| Combine with default culture | Indicates if the default language version of the document should be displayed if the document is not translated to the current language. | You can choose between Yes and No or you can use website-level settings. |
| Culture code | Culture of the content to be displayed. | en-us |
| Maximum nesting level | Maximum nesting level. It specifies the number of sub-levels in the content tree that should be included in the displayed content.

The value 1 indicates that only the current document should be returned.
The value -1 indicates all child documents. | |
| ORDER BY expression | ORDER BY part of the SELECT query. | ProductName ASC, ProductPrice DESC |
| Select only published | Indicates if only published documents should be displayed. | |
| Site name | Code name of the website from which you want to display the content.

If you leave the value empty, the content is retrieved from the current website. | CorporateSite |
| WHERE condition | WHERE part of the SELECT query. | ProductPrice > 100 AND ProductColor='green' |
| Filter out duplicate documents | If the displayed data contains multiple links to the same document (see Linked docs for details), you can choose to display only one of them. | |

System settings

| Property Name | Description | Sample Value |
|-------------------|--|--------------|
| Check permissions | Indicates if the permissions of the current user should be checked for the content of the web part. If enabled, only documents for which the user has the <i>read</i> permission will be loaded. | |
| Cache item name | Sets the name of the cache key used for the content of the web part. If not specified, this name is generated automatically based on the site, document path, Web part control ID and current user. | |

| | | |
|--------------------|--|----|
| | A cache key can be shared between multiple web parts displaying the same content on different pages in order to avoid keeping redundant data in the memory. | |
| Cache minutes | <p>Sets the number of minutes for which the content of the web part should remain cached before its latest version is reloaded from the database.</p> <p>If left empty, the value entered into the Site Manager -> Settings -> System -> Performance -> Server content caching -> Cache content (minutes) setting will be used instead.</p> <p>If set to 0, caching will be disabled for the web part.</p> | 10 |
| Cache dependencies | <p>Contains a list of cache keys on which the content cache of the web part depends. When the specified cache items change, the content cache of the web part is deleted. Each line may only contain a single item.</p> <p>If the Use default cache dependencies box is checked, the default dependencies will be used, which include all possible object changes that could affect the content of the specific web part.</p> | |

Design

| Property Name | Description | Sample Value |
|-----------------------------|--|---------------------|
| CSS prefix | Prefix used for CSS class names. This property allows you to set up different CSS styles for particular menu levels. Every level of the menu will use the prefix for CSS class names that you specify. | Main;Sub1;Sub2 |
| Highlight all items in path | Indicates if all items in the currently selected path of the menu control should be displayed as highlighted. | |
| Submenu indicator | Path to the image that should be displayed next to items that have sub-items. | /images/submenu.gif |
| Use alternating styles | Indicates if odd and even items should have different styles. | |

Paging

| Property Name | Description | Sample Value |
|-----------------------------|---|--------------|
| Enable paging | Indicates if displayed data should be paged. | |
| Paging mode | Type of paging parameter - it can be passed either through the URL (Query string) or through postback (Postback). | |
| Pager position | Position of the pager - top or bottom | |
| Page size | Number of records per page. | 10 |
| Query string key | The name of the URL parameter that will contain the current page number. | mylistpage |
| Show first and last buttons | Indicates the buttons that link to the first and last page should be displayed. | |

Relationships

These settings allow you to configure the web part so that it displays only content that is related to the specified (main) document.

| Property Name | Description | Sample Value |
|-----------------------------------|---|---------------|
| Main document | Document for which you want to display related documents. | |
| Relationship name | Name of the relationship between documents. | Is related to |
| Main document is on the left side | Indicates if the main document is on the left side of the relationship. | |

No data behavior

| Property Name | Description | Sample Value |
|-------------------------|---|----------------|
| Hide if no record found | Indicates if the web part should be hidden when no record is found. | |
| No record found text | Text that should be displayed if no data is found. | No data found. |

Editing buttons

| Property Name | Description | Sample Value |
|-----------------|--|--------------|
| Show New button | Indicates if the button for adding new items | |

| | | |
|------------------------------|---|---------------|
| | should be displayed in the Edit mode when viewing the page. | |
| New button text | New button description text. | Add new news. |
| Show edit and delete buttons | Indicates if edit and delete buttons should be automatically shown for each displayed item in the Edit mode. | |

Transformations

| Property Name | Description | Sample Value |
|------------------------------|--|------------------------------|
| Alternating transformation | Transformation used for even items in list view mode in format <code><class prefix>.<document type>.<transformation name></code> . | cms.news.preview_alternating |
| Transformation | Transformation used for items in list view mode in format <code><class prefix>.<document type>.<transformation name></code> . | cms.news.preview |
| Selected item transformation | Transformation used for items in detail view mode in format <code><class prefix>.<document type>.<transformation name></code> . | cms.news.default |
| Item separator | Item separator displayed between records. | <hr/> |

Macros in web part properties

All web part properties also support macro expressions, which allow you to insert dynamic values instead of constants. Such dynamic values are evaluated at run-time, which means the web part will be able to work with context-dependent values. See [Development -> Macro expressions](#) for details.

7.2.4.14 Adding custom code to a portal page template

The most direct way to insert custom code into a portal engine-based website is using standard ASCX user controls. This chapter will show you how to do this. If you're not familiar with Visual Studio development, you can skip this chapter.

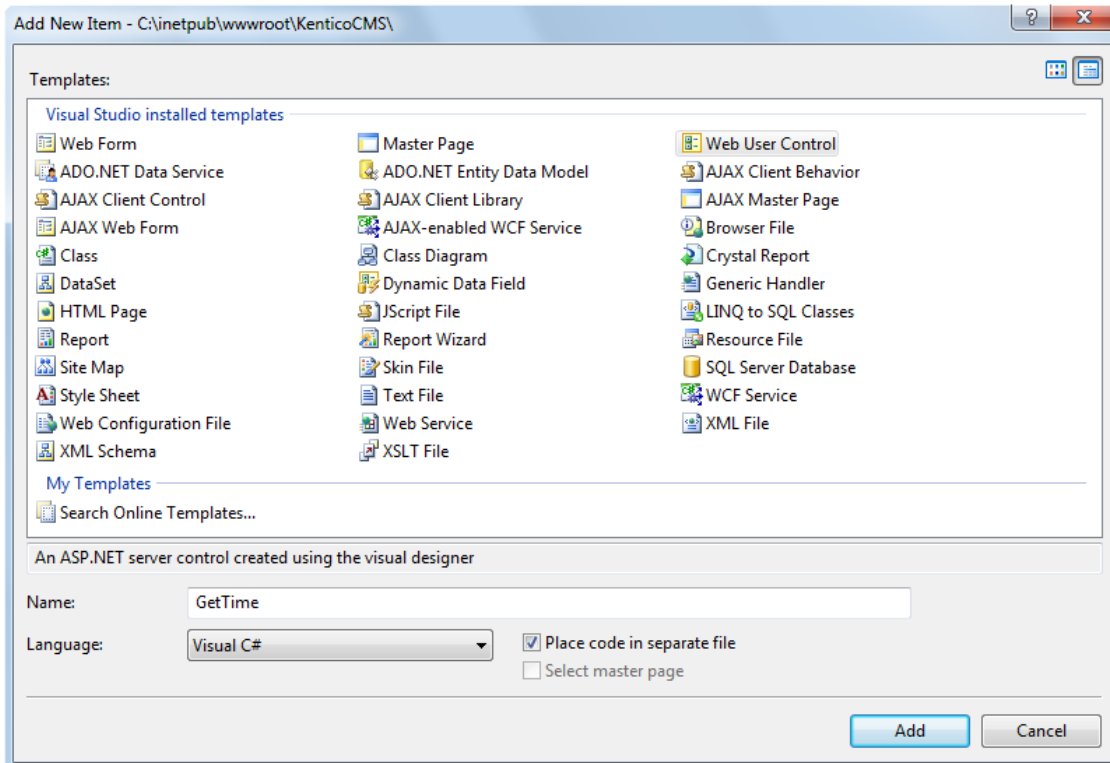

Current time example

In this example, we will create a simple user control (ASCX) using Visual Studio and integrate it into our home page.

Open the website project using the WebProject.sln file that is placed in the folder where you deployed the website. Right-click the web project in the Solution Explorer window and click **New Folder**. Name the folder the same as the code name of your site, e.g. CorporateSite - this folder will be exported with

your project when you decide to export the site and import it on a live server.

Right-click the new folder and click the **Add new item...** option. Choose to create a new Web User Control and set its name to **GetTime.ascx**. You can set the programming language option to either Visual C# or Visual Basic.

Click **Add**. Switch to the **Design** tab and drag and drop the following controls and set their properties:

Button control:

- **ID:** Button1
- **Text:** Show current time

Label control:

- **ID:** Label1
- **Text:** <clear the value>

Double-click the **Show current time** button and enter the following code into the **Button1_Click** method:

[C#]

```
Label1.Text = DateTime.Now.ToString();
```

[VB.NET]

```
Label1.Text = DateTime.Now.ToString()
```

This code ensures that the label displays the current date and time when the button is clicked.

Save all changes. It's not necessary to compile the project — user controls are compiled automatically at run time.

Adding the user control on the page

Sign in to **Kentico CMS Desk**, select the **Home** page and open the **Design** tab. Use the web part toolbar or the **Add web part** (+) button to insert the **User control** web part from the **General** category into the **Main zone**. Enter the following value into the **User control virtual path** property:

```
~/CorporateSite/GetTime.ascx
```

(the folder name must reflect the folder that you previously created)

The ~ character represents the root of your web application. Click **OK**. Switch to **Live site** mode and you will be able to see the user control on the page. When you click the **Show current time** button now, the current date and time is displayed next to the button.

The screenshot shows a corporate website for "IT Company". The navigation menu includes Home, Services, Products, News, Community, Company, and Media. The main content area features a banner with the text "Discover Unlimited Website Possibilities!" and a "Learn more" button. Below the banner, there is a "Show current time" button displaying "8/25/2011 11:13:28 AM". At the bottom, there is a "Newsletter" sign-up form with a "First Name:" input field and the text "Welcome to the sample Corporate Site".

In this short example, you have seen that you can easily add any custom code developed as an ASCX user control in Visual Studio. This user control can contain any .NET controls, third-party controls or ADO.NET code that will retrieve data from an external database.

User controls versus web parts

Another option how to insert custom code into the page is creating your own web part. A web part is basically an ASCX user control, but it inherits some standardized properties and methods from the *CMSAbstractWebPart* class. You will usually build web parts in cases where you need to create reusable, parameterized user controls. Web part development is described in the [Development -> Web parts -> Developing web parts](#) topic.

7.2.4.15 Displaying data from an external database or Web Service

Besides displaying Kentico CMS content, you can also display data from your external database or Web Service. In this case, you need to develop a user control (ASCX) that will use ADO.NET to retrieve the data or that will contact the Web Service and call its methods. Since you can place any custom code into the user control, you will simply use the standard ASP.NET code you would use when creating the website from scratch.

Example: Retrieving data from the sample Northwind database

In this simple example, you will see how to display data on the sample Corporate Site from the *Categories* table of the Northwind database using ADO.NET. You may need to use some other database if you do not have the sample Northwind database on your server.

Open the web project in Visual Studio using the **WebProject.sln** file. Create the folder **CorporateSite** and create a new user control **CustomData.ascx** in this folder. It's important to create the control in this folder so that it's exported with your website later, when you decide to import the website on your live server.

Drag and drop the standard ASP.NET **GridView** control on your user control and set its ID to **GridView1**.

Add the following line to the beginning of the code behind file:

[C#]

```
using System.Data;  
using System.Data.SqlClient;
```

Add the following code to the **Page_Load** method and replace the sample details in the connection string (database, server, user id, password, ...) with appropriate real ones:

[C#]

```
// create sql connection - you could use Oracle or OLEDB provider as well
```

```
SqlConnection cn = new SqlConnection("Persist Security Info=False;
database=northwind;server=server1;user id=sa;password=psswd;Current
Language=English;Connection Timeout=120;");

// create data adapter
SqlDataAdapter da = new SqlDataAdapter("SELECT * FROM categories", cn);
DataSet ds = new DataSet();

// fill the dataset with data from database
da.Fill(ds);

// bind data to the grid view
GridView1.DataSource = ds;
GridView1.DataBind();
```

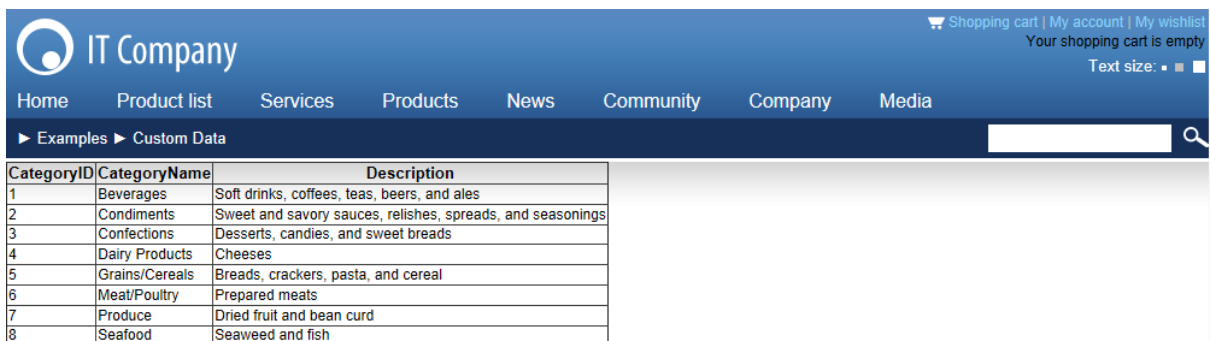

Save all changes.

Sign in as administrator to **CMS Desk**, select the **/Examples** document in the content tree and create a new **Page (menu item)**. Call it **Custom Data**, choose the **Create a blank page** option and click **Save**.

Switch to the **Design** tab, add a new web part **General/User control** and set its **User control virtual path** property value to `~/corporatesite/customdata.ascx`.

Click **OK** and switch to the **Live site** mode of the page. You will see a grid with data from the external database:

The screenshot shows the live website interface. At the top, there is a blue header with the 'IT Company' logo and navigation links: 'Home', 'Product list', 'Services', 'Products', 'News', 'Community', 'Company', and 'Media'. In the top right corner, there are links for 'Shopping cart', 'My account', and 'My wishlist', along with the text 'Your shopping cart is empty' and a 'Text size' selector. Below the header, there is a breadcrumb trail: 'Examples > Custom Data'. The main content area displays a table with the following data:

| CategoryID | CategoryName | Description |
|------------|----------------|--|
| 1 | Beverages | Soft drinks, coffees, teas, beers, and ales |
| 2 | Condiments | Sweet and savory sauces, relishes, spreads, and seasonings |
| 3 | Confections | Desserts, candies, and sweet breads |
| 4 | Dairy Products | Cheeses |
| 5 | Grains/Cereals | Breads, crackers, pasta, and cereal |
| 6 | Meat/Poultry | Prepared meats |
| 7 | Produce | Dried fruit and bean curd |
| 8 | Seafood | Seaweed and fish |

As you can see we used standard ASP.NET methods to display external data on the website.

7.2.4.16 Page template internals and API

7.2.4.16.1 Overview

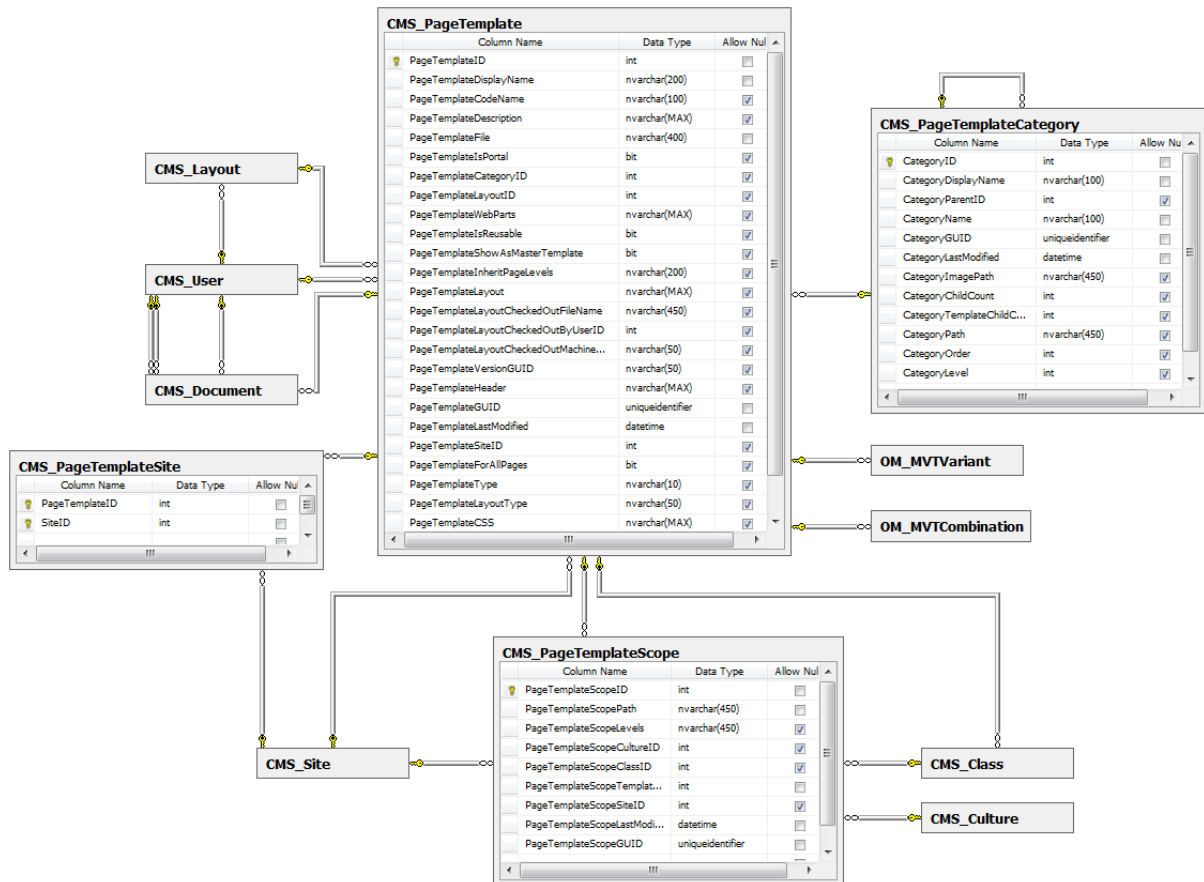

In this chapter, you will learn which [database tables](#) and [API classes](#) are used by page templates. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the related classes, please refer to [Kentico CMS API Reference](#).

7.2.4.16.2 Database tables

The following database tables are used to store information about page templates:

- **CMS_PageTemplateCategory** - contains records representing page template categories.
- **CMS_PageTemplate** - contains page templates and their content, including custom page layout code and web part content/configuration (in XML format).
- **CMS_PageTemplateSite** - stores relationships between page templates and sites. Each entry indicates that a specific page template can be used on a given site.
- **CMS_PageTemplateScope** - contains records representing page template scopes.

7.2.4.16.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

**Please note**

The classes of page templates can be found in the **CMS.PortalEngine** namespace.

CMS_PageTemplateCategory table API:

- **PageTemplateCategoryInfo** - represents one page template category.
- **PageTemplateCategoryInfoProvider** - provides management functionality for page template categories.

CMS_PageTemplate table API:

- **PageTemplateInfo** - represents one page template object.
- **PageTemplateInfoProvider** - provides management functionality for page templates.

CMS_PageTemplateSite table API:

- **PageTemplateSiteInfo** - represents a relationship between a page template and a site.
- **PageTemplateSiteInfoProvider** - provides management functionality for page template-site relationships.

CMS_PageTemplateScope table API:

- **PageTemplateScopeInfo** - represents one page template scope.
- **PageTemplateScopeInfoProvider** - provides management functionality for page template scopes.

Other classes:

- **PageTemplateInstance** - represents a specific instance of a page template.

7.2.4.16.4 API examples

7.2.4.16.4.1 Overview

These topics show examples of how the API of the page template can be used:

- [Managing page template categories](#)
- [Managing page templates](#)
- [Page templates and sites](#)
- [Managing page template scopes](#)

**Please note**

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Development\PageTemplates\Default.aspx.cs**.

The page template API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.PortalEngine;
```

7.2.4.16.4.2 Managing page template categories

The following example creates a page template category.

```
private void CreatePageTemplateCategory()
{
    // Create new page template category object
    PageTemplateCategoryInfo newCategory = new PageTemplateCategoryInfo();

    // Set the properties
    newCategory.DisplayName = "My new category";
    newCategory.CategoryName = "MyNewCategory";

    // Save the page template category
    PageTemplateCategoryInfoProvider.SetPageTemplateCategoryInfo(newCategory);
}
```

The following example gets and updates a page template category.

```
private bool GetAndUpdatePageTemplateCategory()
{
    // Get the page template category
    PageTemplateCategoryInfo updateCategory =
    PageTemplateCategoryInfoProvider.GetPageTemplateCategoryInfo("MyNewCategory");
    if (updateCategory != null)
    {
        // Update the properties
        updateCategory.DisplayName = updateCategory.DisplayName.ToLower();

        // Save the changes
        PageTemplateCategoryInfoProvider.SetPageTemplateCategoryInfo
```

```
(updateCategory);  
  
    return true;  
}  
  
return false;  
}
```

The following example gets and bulk updates page template categories.

```
private bool GetAndBulkUpdatePageTemplateCategories()  
{  
    // Prepare the parameters  
    string where = "CategoryName LIKE N'MyNewCategory%'";  
  
    // Get the data  
    DataSet categories = PageTemplateCategoryInfoProvider.GetCategoriesList  
(where, null);  
    if (!DataHelper.DataSourceIsEmpty(categories))  
    {  
        // Loop through the individual items  
        foreach (DataRow categoryDr in categories.Tables[0].Rows)  
        {  
            // Create object from DataRow  
            PageTemplateCategoryInfo modifyCategory = new PageTemplateCategoryInfo  
(categoryDr);  
  
            // Update the properties  
            modifyCategory.DisplayName = modifyCategory.DisplayName.ToUpper();  
  
            // Save the changes  
            PageTemplateCategoryInfoProvider.SetPageTemplateCategoryInfo  
(modifyCategory);  
        }  
  
        return true;  
    }  
  
    return false;  
}
```

The following example deletes a page template category.

```
private bool DeletePageTemplateCategory()  
{  
    // Get the page template category  
    PageTemplateCategoryInfo deleteCategory =  
    PageTemplateCategoryInfoProvider.GetPageTemplateCategoryInfo("MyNewCategory");  
  
    // Delete the page template category  
    PageTemplateCategoryInfoProvider.DeletePageTemplateCategory(deleteCategory);  
}
```

```
    return (deleteCategory != null);  
}
```

7.2.4.16.4.3 Managing page templates

The following example creates a page template.

```
private bool CreatePageTemplate()  
{  
    // Get the page template category  
    PageTemplateCategoryInfo category =  
    PageTemplateCategoryInfoProvider.GetPageTemplateCategoryInfo("MyNewCategory");  
    if (category != null)  
    {  
        // Create new page template object  
        PageTemplateInfo newTemplate = new PageTemplateInfo();  
  
        // Set the properties  
        newTemplate.DisplayName = "My new template";  
        newTemplate.CodeName = "MyNewTemplate";  
        newTemplate.Description = "This is page template created by API Example";  
        newTemplate.PageTemplateSiteID = CMSContext.CurrentSiteID;  
        newTemplate.FileName = " ";  
        newTemplate.ShowAsMasterTemplate = false;  
        newTemplate.IsPortal = true;  
        newTemplate.InheritPageLevels = ""; // inherits all  
        newTemplate.IsReusable = true;  
        newTemplate.CategoryID = category.CategoryID;  
  
        // Save the page template  
        PageTemplateInfoProvider.SetPageTemplateInfo(newTemplate);  
  
        return true;  
    }  
  
    return false;  
}
```

The following example gets and updates a page template.

```
private bool GetAndUpdatePageTemplate()  
{  
    // Get the page template  
    PageTemplateInfo updateTemplate = PageTemplateInfoProvider.GetPageTemplateInfo  
    ("MyNewTemplate");  
    if (updateTemplate != null)  
    {  
        // Update the properties  
        updateTemplate.DisplayName = updateTemplate.DisplayName.ToLower();  
    }  
}
```

```
        // Save the changes
        PageTemplateInfoProvider.SetPageTemplateInfo(updateTemplate);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates page templates.

```
private bool GetAndBulkUpdatePageTemplates()
{
    // Prepare the parameters
    string where = "PageTemplateName LIKE N'MyNewTemplate%'";

    // Get the data
    DataSet templates = PageTemplateInfoProvider.GetTemplates(where, null);
    if (!DataHelper.DataSourceIsEmpty(templates))
    {
        // Loop through the individual items
        foreach (DataRow templateDr in templates.Tables[0].Rows)
        {
            // Create object from DataRow
            PageTemplateInfo modifyTemplate = new PageTemplateInfo(templateDr);

            // Update the properties
            modifyTemplate.DisplayName = modifyTemplate.DisplayName.ToUpper();

            // Save the changes
            PageTemplateInfoProvider.SetPageTemplateInfo(modifyTemplate);
        }

        return true;
    }

    return false;
}
```

The following example deletes a page template.

```
private bool DeletePageTemplate()
{
    // Get the page template
    PageTemplateInfo deleteTemplate = PageTemplateInfoProvider.GetPageTemplateInfo(
        "MyNewTemplate");

    // Delete the page template
    PageTemplateInfoProvider.DeletePageTemplate(deleteTemplate);
}
```

```
    return (deleteTemplate != null);  
}
```

7.2.4.16.4.4 Page templates and sites

The following example assigns a page template to a site.

```
private bool AddPageTemplateToSite()  
{  
    // Get the page template  
    PageTemplateInfo template = PageTemplateInfoProvider.GetPageTemplateInfo  
("MyNewTemplate");  
    if (template != null)  
    {  
        int templateId = template.PageTemplateId;  
        int siteId = CMSContext.CurrentSiteID;  
  
        // Save the binding  
        PageTemplateSiteInfoProvider.AddPageTemplateToSite(templateId, siteId);  
  
        return true;  
    }  
  
    return false;  
}
```

The following example removes a page template from a site.

```
private bool RemovePageTemplateFromSite()  
{  
    // Get the page template  
    PageTemplateInfo removeTemplate = PageTemplateInfoProvider.GetPageTemplateInfo  
("MyNewTemplate");  
    if (removeTemplate != null)  
    {  
        int siteId = CMSContext.CurrentSiteID;  
  
        // Get the binding  
        PageTemplateSiteInfo templateSite =  
PageTemplateSiteInfoProvider.GetPageTemplateSiteInfo  
(removeTemplate.PageTemplateId, siteId);  
  
        // Delete the binding  
        PageTemplateSiteInfoProvider.DeletePageTemplateSiteInfo(templateSite);  
  
        return true;  
    }  
  
    return false;  
}
```

7.2.4.16.4.5 Managing page template scopes

The following example creates a page template scope and assigns it to a template.

```
private bool CreatePageTemplateScope()
{
    // Get template object
    PageTemplateInfo template = PageTemplateInfoProvider.GetPageTemplateInfo
("MyNewTemplate");

    // If template exists
    if (template != null)
    {
        // Page template isn't available for all pages
        template.PageTemplateForAllPages = false;

        // Create new template scope
        PageTemplateScopeInfo newScope = new PageTemplateScopeInfo();

        // Set some properties
        newScope.PageTemplateScopeTemplateID = template.PageTemplateId;
        newScope.PageTemplateScopeSiteID = CMSContext.CurrentSiteID;
        newScope.PageTemplateScopePath = "/";
        newScope.PageTemplateScopeLevels = "{0}/{1}";

        // Save scope to database
        PageTemplateScopeInfoProvider.SetPageTemplateScopeInfo(newScope);

        // Update page template
        PageTemplateInfoProvider.SetPageTemplateInfo(template);

        return true;
    }

    return false;
}
```

The following example removes a page template scope from a template and deletes it.

```
private bool DeletePageTemplateScope()
{
    string columns = "";
    string where = "";

    // Get template object
    PageTemplateInfo template = PageTemplateInfoProvider.GetPageTemplateInfo
("MyNewTemplate");

    // If template exists
    if (template != null)
    {
```

```
        where = "PageTemplateScopeTemplateID = " + template.PageTemplateId;
    }

    DataSet scopes = PageTemplateScopeInfoProvider.GetTemplateScopes(columns,
where, null, 0);

    if (!DataHelper.DataSourceIsEmpty(scopes))
    {
        // Get the page template scope
        PageTemplateScopeInfo deleteScope = new PageTemplateScopeInfo
(scopes.Tables[0].Rows[0]);

        // Delete the page template scope
        PageTemplateScopeInfoProvider.DeletePageTemplateScopeInfo(deleteScope);

        return true;
    }

    return false;
}
```

7.2.4.17 Page layout internals and API

7.2.4.17.1 Overview

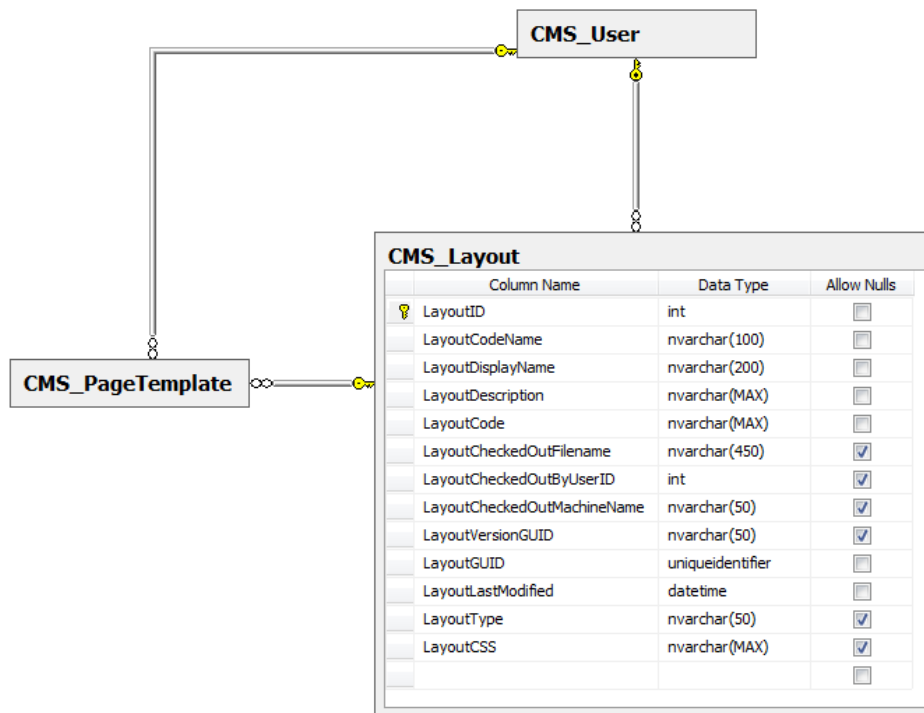

In this chapter, you will learn which [database tables](#) and [API classes](#) are used by page layouts. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the related classes, please refer to [Kentico CMS API Reference](#).

7.2.4.17.2 Database tables

The following database table is used to store information about page layouts:

- **CMS_Layout** - contains records representing shared page layouts.

Custom page layouts

Only pre-defined page layouts are stored in the **CMS_Layout** table. These can be shared by multiple page templates.

However, the code of custom layouts that are unique for specific page templates is saved in the **PageTemplateLayout** column of the corresponding record in the **CMS_PageTemplate** table. This table also has columns that track the check-out status of custom page layouts.

7.2.4.17.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes for managing page layouts can be found in the **CMS.PortalEngine** namespace.

CMS_Layout table API:

- **LayoutInfo** - represents one page layout object.
- **LayoutInfoProvider** - provides management functionality for page layouts.

7.2.4.17.4 API examples

7.2.4.17.4.1 Overview

The following topic shows examples of how the API of page layouts can be used:

- [Managing page layouts](#)

**Please note**

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Development\PageLayouts\Default.aspx.cs**.

The page layout API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.PortalEngine;
```

7.2.4.17.4.2 Managing page layouts

The following example creates a page layout.

```
private void CreateLayout()
{
    // Create new layout object
    LayoutInfo newLayout = new LayoutInfo();

    // Set the properties
    newLayout.LayoutDisplayName = "My new layout";
    newLayout.LayoutCodeName = "MyNewLayout";
    newLayout.LayoutDescription = "This is layout created by API Example";
    newLayout.LayoutCode = "<cc1:CMSWebPartZone ZoneID=\"zoneLeft\"
runat=\"server\" />";

    // Save the layout
    LayoutInfoProvider.SetLayoutInfo(newLayout);
}
```

The following example gets and updates a page layout.

```
private bool GetAndUpdateLayout()
{
    // Get the layout
    LayoutInfo updateLayout = LayoutInfoProvider.GetLayoutInfo("MyNewLayout");
    if (updateLayout != null)
    {
        // Update the properties
        updateLayout.LayoutDisplayName = updateLayout.LayoutDisplayName.ToLower();

        // Save the changes
        LayoutInfoProvider.SetLayoutInfo(updateLayout);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates page layouts.

```
private bool GetAndBulkUpdateLayouts()
{
    // Prepare the parameters
    string where = "LayoutCodeName LIKE N'MyNewLayout%'";

    // Get the data
    DataSet layouts = LayoutInfoProvider.GetLayouts(where, null);
    if (!DataHelper.DataSourceIsEmpty(layouts))
    {
        // Loop through the individual items
        foreach (DataRow layoutDr in layouts.Tables[0].Rows)
        {
            // Create object from DataRow
            LayoutInfo modifyLayout = new LayoutInfo(layoutDr);

            // Update the properties
            modifyLayout.LayoutDisplayName =
            modifyLayout.LayoutDisplayName.ToUpper();

            // Save the changes
            LayoutInfoProvider.SetLayoutInfo(modifyLayout);
        }

        return true;
    }

    return false;
}
```

The following example deletes a page layout.

```
private bool DeleteLayout()
```

```
{  
    // Get the layout  
    LayoutInfo deleteLayout = LayoutInfoProvider.GetLayoutInfo( "MyNewLayout" );  
  
    // Delete the layout  
    LayoutInfoProvider.DeleteLayoutInfo( deleteLayout );  
  
    return (deleteLayout != null);  
}
```

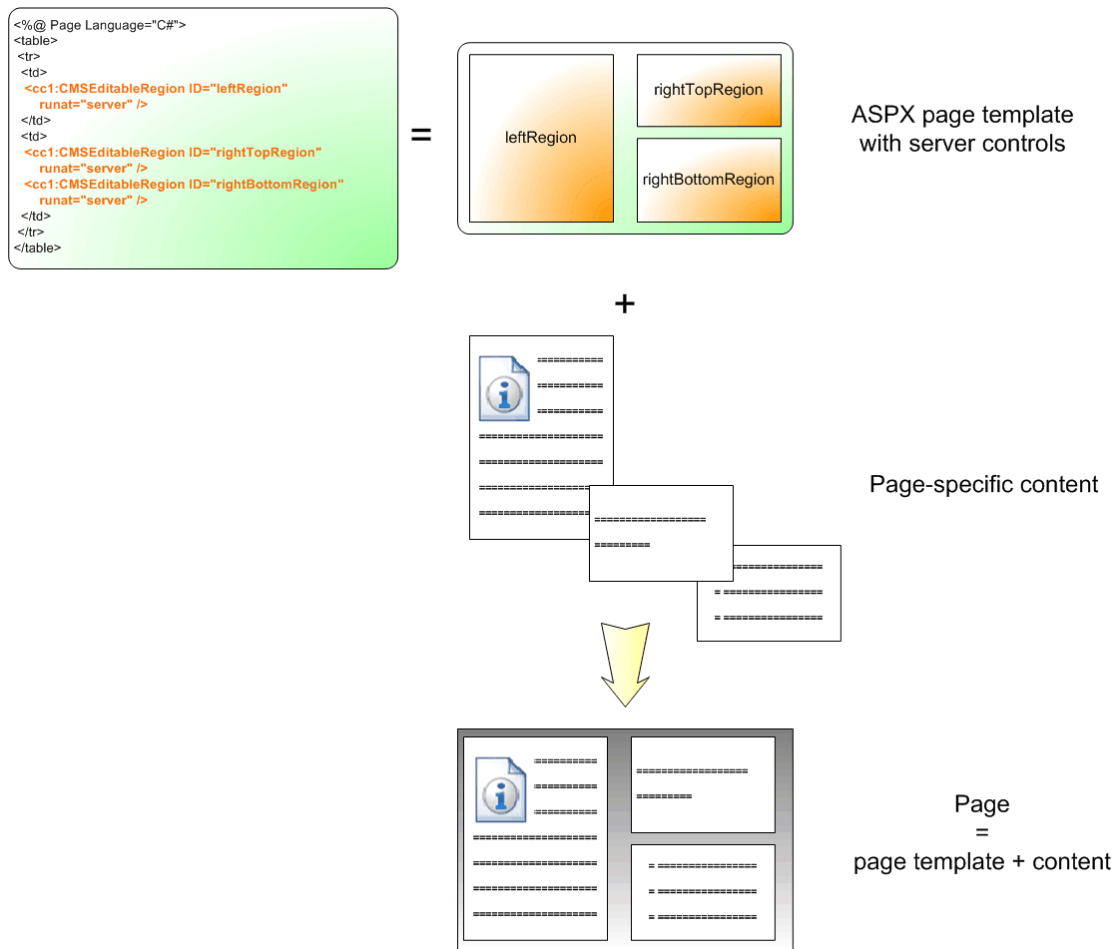

7.2.5 ASPX page template development model

7.2.5.1 Overview

If you are familiar with ASP.NET development in Visual Studio, you may want to choose to develop websites using standard ASPX page templates. ASPX page templates in Kentico CMS are standard ASP.NET pages that display content from Kentico CMS. They receive the document **aliasPath** as a URL parameter that informs the page template which page should be displayed.

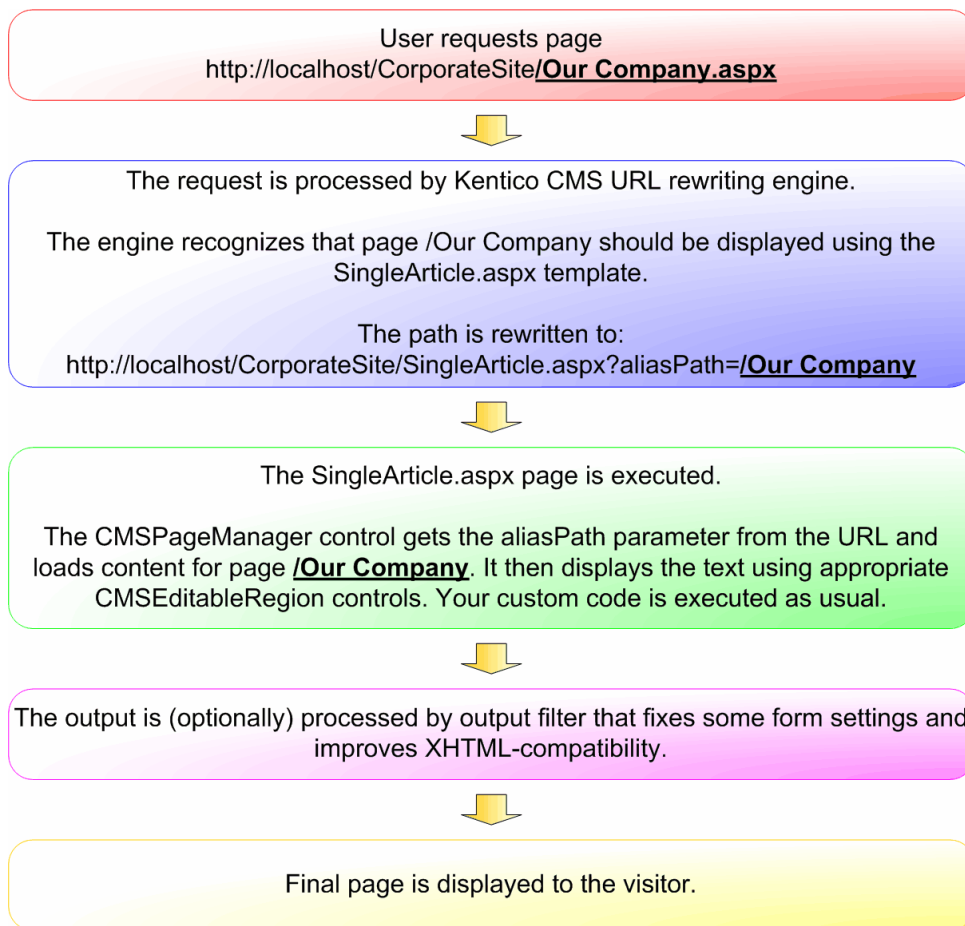

What does an ASPX page template consist of?

A page template is a combination of static HTML code and ASP.NET server controls (or user controls) that render dynamic content. You can also use code behind (using either VB.NET or C#) to modify page behavior and add custom functionality. The following figure illustrates how an ASPX page template and page content are combined to display a page:

How are ASPX page templates processed?

When a user requests a page, such as `~/services/web-development.aspx`, the system calls the assigned page template with the **aliasPath** URL parameter, which specifies what content (which page from the content tree) should be displayed using the given template:

The built-in Kentico CMS controls understand the **aliasPath** parameter in the URL and render the appropriate content automatically.

As you can see, the system uses standard ASP.NET architecture. If you developed the website without Kentico CMS, you would most likely use URLs like this: `/news.aspx?newsid=127` which is similar to `/news.aspx?aliaspath=/news/your-first-news.aspx` as used in Kentico CMS. Kentico CMS also uses friendly URLs in format `/news/your-first-news.aspx` that are better for search engine optimization.

7.2.5.2 Creating a new ASPX page template

This topic describes how to create a new ASPX page template. We will create a new page with two columns that contain editable regions.

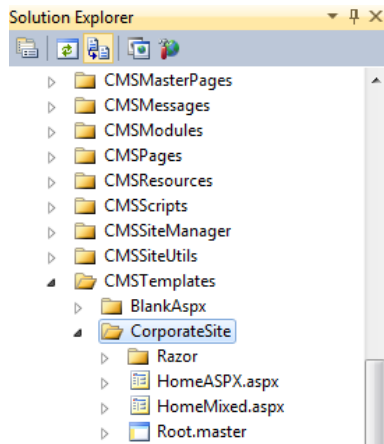

Adding Kentico CMS Controls to your Visual Studio Toolbox

Before you start developing ASPX page templates, it is recommended to add the Kentico CMS Controls to your Visual Studio Toolbox so that you can drag-and-drop the controls onto the ASPX pages.

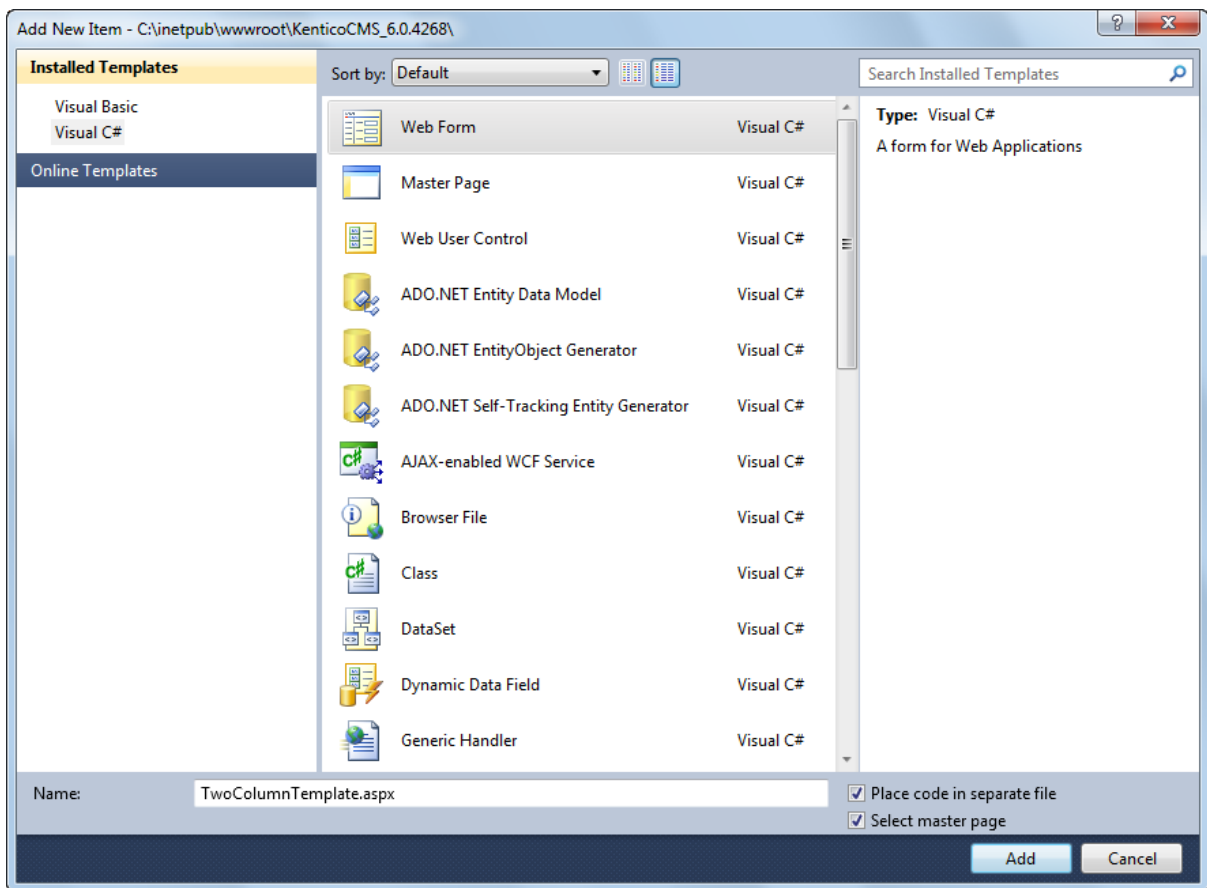

See the [Adding Kentico CMS Controls to the Toolbox](#) topic for step-by-step

instructions.

1. Open the web project in Visual Studio. You can open it either through the **WebProject.sln** file or using the **File -> Open Web Site** option in the menu.
2. Right-click the **CMSTemplates/CorporateSite** folder in the Solution Explorer and select **Add New Item**.

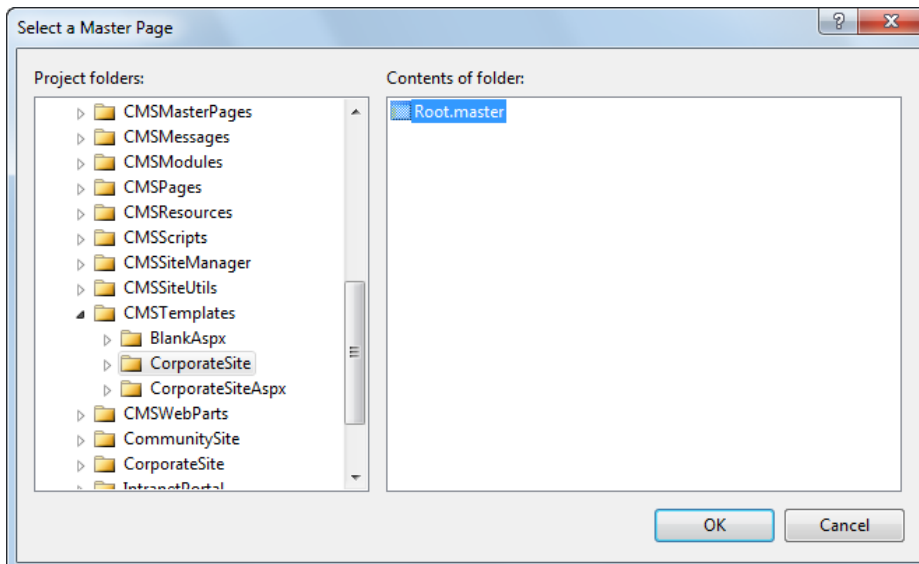

3. Create a new **Web form** named *TwoColumnTemplate.aspx* and check the **Select master page** box. Click **Add**.

The **Select a Master Page** dialog opens.

4. Choose the **CMSTemplates/CorporateSite** folder, select the **Root.master** file and click **OK**.

Writing the ASPX code

5. Open the **Source** view of the newly created ASPX page and add the following code inside the **<asp:Content>** element:

```
<table width="100%">
  <tr valign="top">
    <td width="50%">
      <cms:CMSEditableRegion ID="txtLeft" runat="server" DialogHeight="400"
        RegionType="HtmlEditor" RegionTitle="Left column" />
    </td>
    <td width="50%">
      <cms:CMSEditableRegion ID="txtText" runat="server" DialogHeight="400"
        RegionType="HtmlEditor" RegionTitle="Right column" />
    </td>
  </tr>
</table>
```

The **<asp:Content>** control allows you to use standard ASP.NET master pages. When the system renders the page, it loads the content of the control into the assigned master page (as defined in the *Root.master* file).

The **CMSEditableRegion** control defines an editable region that the page displays as an HTML editor on the **Content -> Edit -> Page** tab of **CMS Desk**. On the live site, the control renders the content entered into the editor.

Note

This example uses a table layout. If you prefer a CSS layout, replace the surrounding HTML code with <DIV> elements. You have full control over the content.

6. Switch to the code behind file (*TwoColumnTemplate.aspx.cs*) and add a reference to the **CMS.UIControls** namespace:

[C#]

```
using CMS.UIControls;
```

7. Modify the class definition so that it inherits from the **TemplatePage** class:

[C#]

```
public partial class CMSTemplates_CorporateSite_TwoColumnTemplate : TemplatePage
```

Inheriting from this class allows you to use the web form as a page template in Kentico CMS.

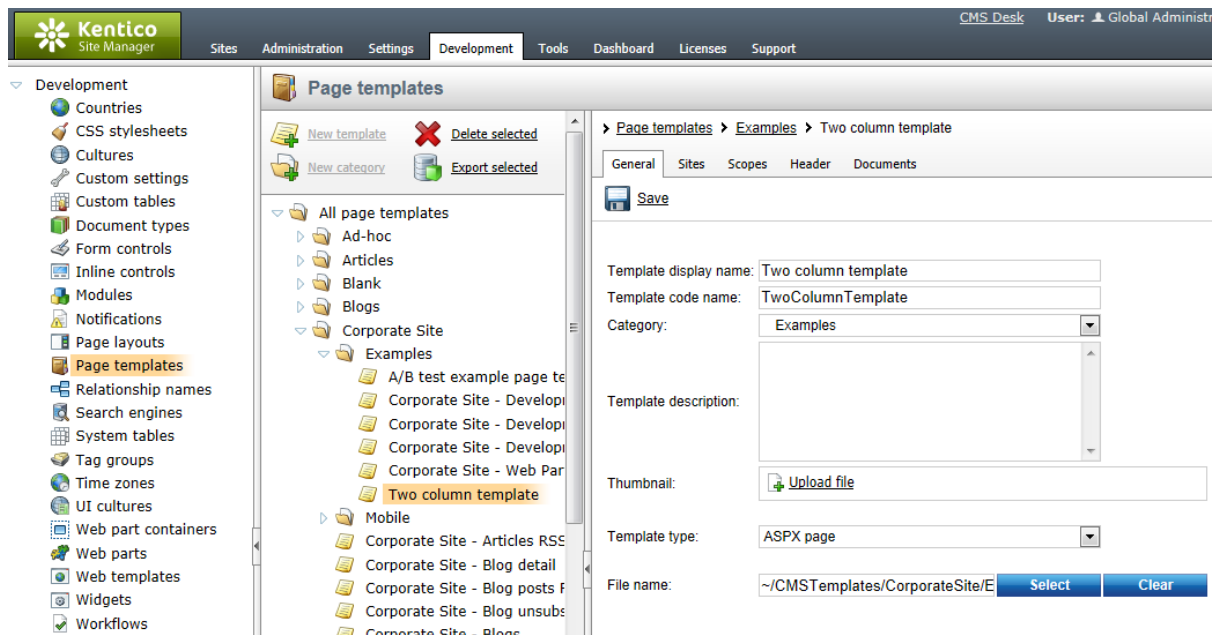

Keep in mind that the name of the class must be identical to the value of the **Inherits** attribute of the `<% @ Page %>` directive on the ASPX page. This is case sensitive.

Registering the ASPX page as a page template

Now that we have created a new ASPX page, we need to register it in Kentico CMS as a page template, so that it can be used by content editors.

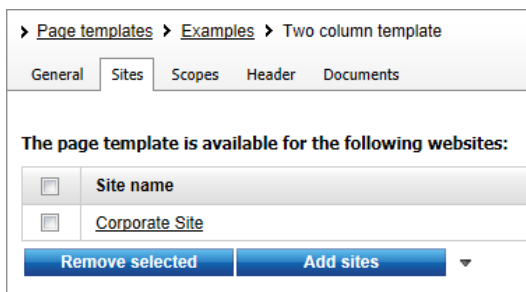

1. Sign in to **Site Manager** and go to **Development -> Page templates**.
2. Select the **Corporate Site/Examples** folder, click  **New template** and type *Two column template* into the **Template display name** field.
3. Click  **Save**. The system creates the template and displays its **General** tab.
4. Set the following values on the **General** tab:
 - **Template type:** ASPX
 - **File name:** `~/CMSTemplates/CorporateSite/TwoColumnTemplate.aspx`

This is the virtual path of the ASPX page. Alternatively, you can click the **Select** button and manually select the file.

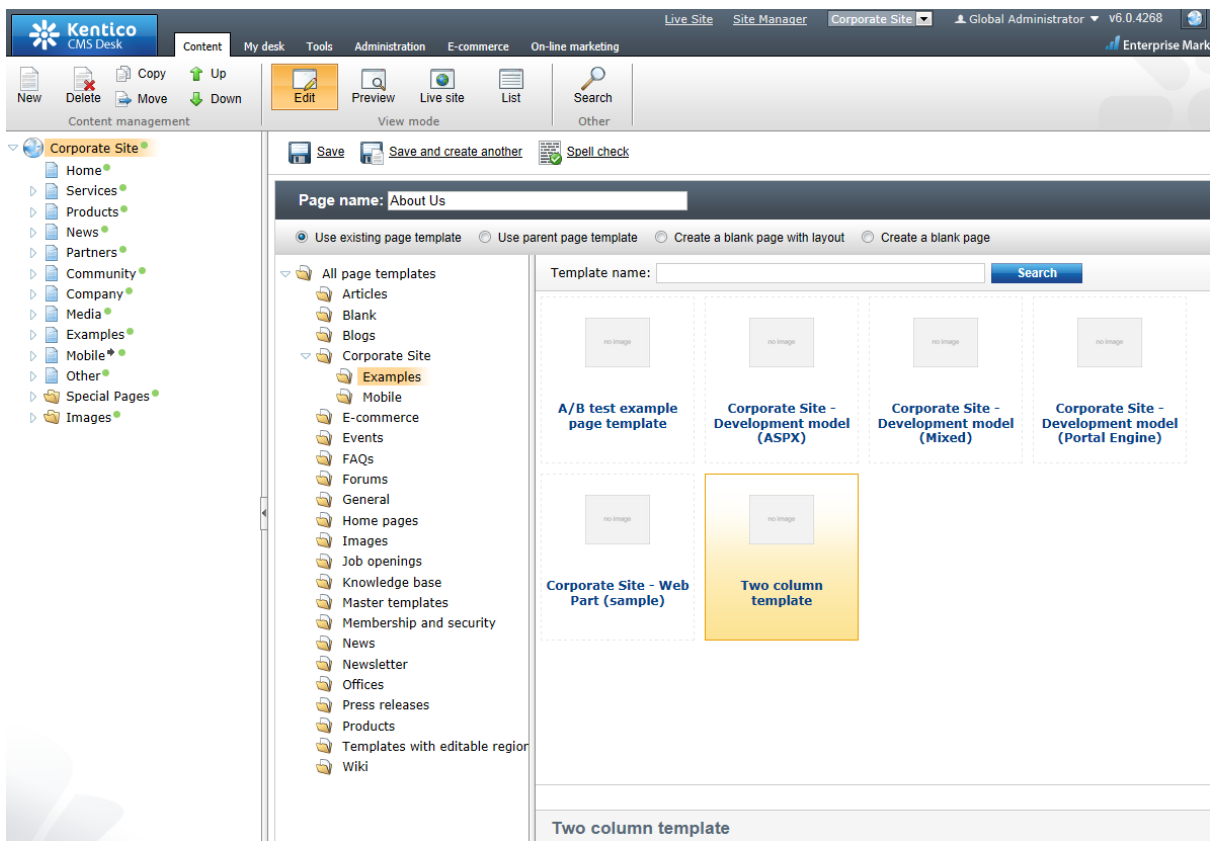

The screenshot shows the Kentico CMS Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The 'Development' tab is active. The left sidebar shows a tree view of 'Page templates' with various categories like 'All page templates', 'Ad-hoc', 'Articles', 'Blank', 'Blogs', 'Corporate Site', 'Examples', 'Mobile', etc. The main content area shows the 'Page templates' configuration screen for 'Two column template'. The 'General' tab is selected, and the 'Save' button is visible. The 'File name' field is set to `~/CMSTemplates/CorporateSite/E` and has 'Select' and 'Clear' buttons.

5. Click  **Save**.
6. Switch to the **Sites** tab and click the **Add sites** button. Choose the sites where you wish to use the page template and click **OK**.

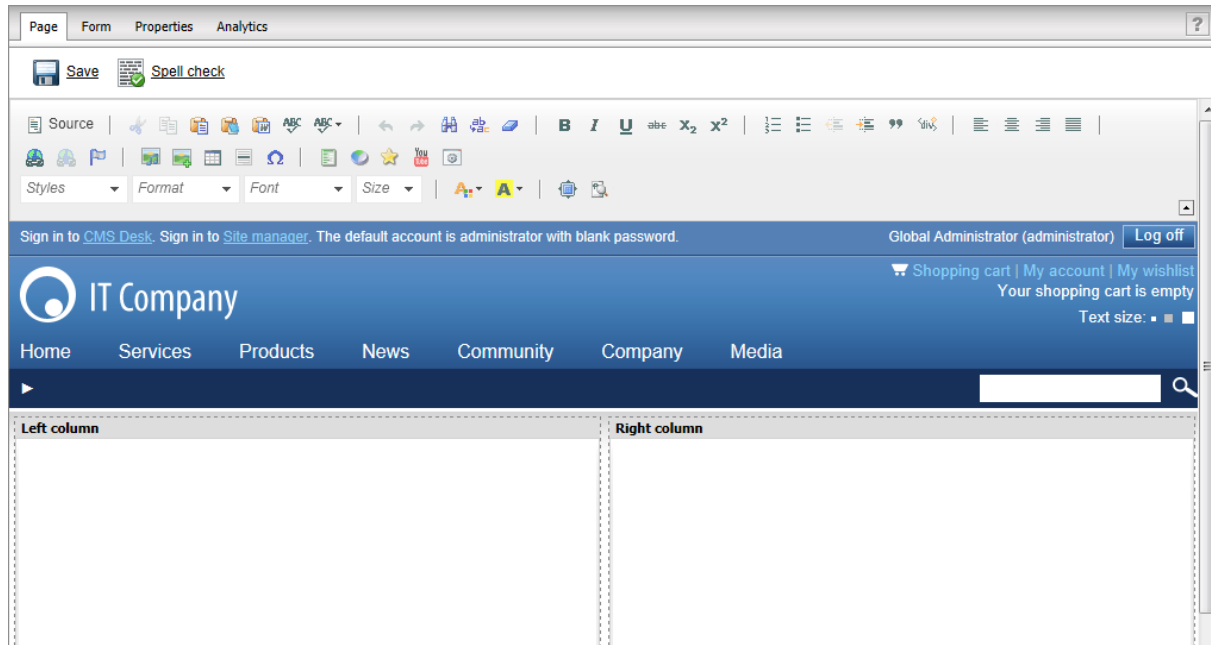

Creating an About Us page based on the new page template

1. Go to **CMS Desk -> Content**.
2. Select **Corporate Site** (the root of the content tree) and click **New** in the main menu of the **Content** section.
3. Choose the **Page (menu item)** document type.
4. Type *About Us* into the **Page name** field and choose the **Use existing page template** option. Select the **Corporate Site/Examples** category and the **Two column template** page template.

5. Click **Save** to create the new page.

On the **Page** tab, you can see the page and its editable regions.

You have created your first page based on an ASPX page template. Now you can enter some text and click **Save** to store the content.

7.2.5.3 Creating ASPX master pages

You can use standard ASP.NET [master pages](#) together with ASPX page templates. This is a powerful concept that allows you to share content across all pages without having to add it separately to every page template. For example, you can create master pages containing header and footer sections with a logo, navigation menu, search box etc.

Master pages are defined in files with the **.master** extension. You can assign one master page to every ASPX page. Master pages must always contain one or more **ContentPlaceHolder** controls as shown here:

```
<asp:ContentPlaceHolder ID="plcMain" runat="server"></asp:ContentPlaceHolder>
```

The **ContentPlaceHolder** control specifies where child pages display their content inside the master page.

It is recommended to store master pages in the **CMSTemplates** folder together with the page template files, so that the system can export them along with your website when you deploy it to another instance of Kentico CMS.

Preparing master pages for ASPX templates

The following code sample shows the markup of a basic master page.

Important!

If you installed the Kentico CMS project as a web application, you need to rename the *CodeFile* attribute on the first line to *Codebehind* for the code example to be functional. This attribute's value needs to match the name of the master page's code behind file.

Set the value of the *Inherits* attribute according to the location and name of the master page file.

```
<%@ Master Language="C#" AutoEventWireup="true" CodeFile="Custom.master.cs"
Inherits="CMSTemplates_CorporateSite_Custom" %>

<%=DocType%>

<html xmlns="http://www.w3.org/1999/xhtml" <%=XmlNamespace%>>
<head id="Head1" runat="server">
  <title id="Title1" runat="server">My site</title>
  <asp:literal runat="server" id="l1Tags" enableviewstate="false" />
</head>
<body class="<%=BodyClass%>" <%=BodyParameters%>>
  <form id="form1" runat="server">
    <asp:Placeholder runat="server" ID="plcManagers">
      <ajaxToolkit:ToolkitScriptManager ID="manScript" runat="server"
EnableViewState="false" ScriptMode="Release" />
      <cms:CMSPortalManager ID="CMSPortalManager1" runat="server"
EnableViewState="false" />
    </asp:Placeholder>

    <cms:CMSMenu ID="cmsmenu1" runat="server" Cursor="Pointer"
HighlightAllItemsInPath="true" Layout="Horizontal" Padding="0" Spacing="1" />

    <asp:ContentPlaceHolder ID="plcMain" runat="server">
      </asp:ContentPlaceHolder>
    </form>
  </body>
</html>
```

All ASPX page templates require the following manager controls, so it is a good practice to add them onto your website's master page:

- **ajaxToolkit:ToolkitScriptManager** - allows pages to use AJAX components. This is required by all pages that contain the *CMSPortalManager* control.
- **CMSPortalManager** - ensures the transferring of content between the database and editable regions. It also provides the management functionality needed for portal engine zones. Always place this control after the *ToolkitScriptManager* control.

CMSPageManager control

You may use the **CMSPageManager** control instead of the *CMSPortalManager*. This control is an older equivalent available for the purposes of backwards compatibility. It does not support ASPX templates containing portal engine web part or widget zones.

The **CMSSMenu** control is one of the options that you can use to generate a drop-down menu for website navigation.

Writing the master page code behind

You also need to modify the code behind file of the master page:

1. Add a reference to the **CMS.UIControls** namespace:

[C#]

```
using CMS.UIControls;
```

[VB.NET]

```
Imports CMS.UIControls
```

2. Change the class definition to match the following (the name of the class may be different):

[C#]

```
public partial class CMSTemplates_CorporateSite_Custom : TemplateMasterPage
```

[VB.NET]

```
Partial Class CMSTemplates_CorporateSite_Custom  
    Inherits TemplateMasterPage
```

Master pages must always inherit from the **TemplateMasterPage** class.

3. Add the following code into the master page's code behind class:

[C#]

```
protected override void CreateChildControls()  
{  
    base.CreateChildControls();  
    PageManager = CMSPortalManager1;  
}
```

```
protected override void OnPreRender(EventArgs e)
{
    base.OnPreRender(e);
    this.ltlTags.Text = this.HeaderTags;
}
```

[VB.NET]

```
Protected Overrides Sub CreateChildControls()
    MyBase.CreateChildControls()
    PageManager = CMSPortalManager1
End Sub

Protected Overrides Sub OnPreRender(e As EventArgs)
    MyBase.OnPreRender(e)
    Me.ltlTags.Text = Me.HeaderTags
End Sub
```

Adjust the value of the **PageManager** property according to the ID of the *CMSPortalManager* (or *CMSPageManager*) control placed on the master page.

This code ensures that ASPX templates using the given master page support all required functionality.

7.2.5.4 Adding portal engine functionality to ASPX templates

When developing or maintaining a website built on ASPX page templates, one of the drawbacks is that the code of a page must be modified manually every time you wish to change its design. It is possible to add flexibility to ASPX templates by defining areas that may be edited directly through the browser in the CMS administration interface, just like when using the [Portal engine development model](#). Depending on their configuration, these areas allow [Web parts](#) or [Widgets](#) to be used on ASPX page templates.

This is achieved by placing the following elements into the code of a page template:

```
<cms:CMSPagePlaceholder ID="plcZones" runat="server">
    <LayoutTemplate>

        ...

        <cms:CMSWebPartZone ID="zoneCenter" runat="server" />

        ...

    </LayoutTemplate>
</cms:CMSPagePlaceholder>
```

The **CMSPagePlaceholder** control creates an area on the page that behaves in a way similar to a portal engine page template. You may place multiple controls of this type onto a single page.

The **<LayoutTemplate>** element defines the layout of the area. This is typically done by specifying a table structure or a CSS-based layout applied through HTML elements (e.g. `<div>`, ``, etc.).

The layout may contain multiple **CMSWebPartZone** controls, which represent fully functional portal engine zones. You can configure every zone to serve as either a standard web part zone or any type of widget zone. Users may manage these zones when editing pages based on the page template on the **Edit -> Design** tab of **CMS Desk**. When web part or widget content is added to a zone, information about it is stored in the database along with the respective page template object, not in the actual code of the ASPX page.

CMSPortalManager control required!

In order for portal engine functionality to be possible on pages using ASPX templates, the **CMSPortalManager** control must be present. Usually it is located on the [master](#) page set for the template.

Some master pages may use the older **CMSPageManager** control, which does not support web part/widget zones. If this is the case, you need to replace the control before adding any of the elements described in this topic.

Page templates with this type of content also require additional configuration in **Site Manager -> Development -> Page templates**. You need to set the **Template type** to *ASPX + Portal page* in order for the **Design** tab to be available when editing pages using the given template in **CMS Desk**.

The screenshot shows the Kentico Site Manager interface. The left sidebar contains a navigation menu with categories like 'Development', 'Administration', 'Settings', and 'Tools'. The main area is titled 'Page templates' and shows a tree view of templates. The 'Corporate Site' folder is expanded, showing sub-folders like 'Examples' and 'Mobile'. The 'Corporate Site - Development model (Mixed)' template is selected. The right-hand pane shows the configuration for this template, including fields for 'Template display name', 'Template code name', 'Category', 'Template description', 'Thumbnail', and 'Template type'. The 'Template type' dropdown is highlighted with a red box and set to 'ASPX + Portal page'. The 'File name' field is also visible, showing the path '~/CMSTemplates/CorporateSite/H'.

Example

The following example demonstrates the creation of a simple ASPX page template with zones that users can design via the portal engine:

1. Build a new page template according to the guide in the [Creating a new ASPX page template](#) topic. When writing its ASPX code, place the following inside the `<asp:Content>` element:

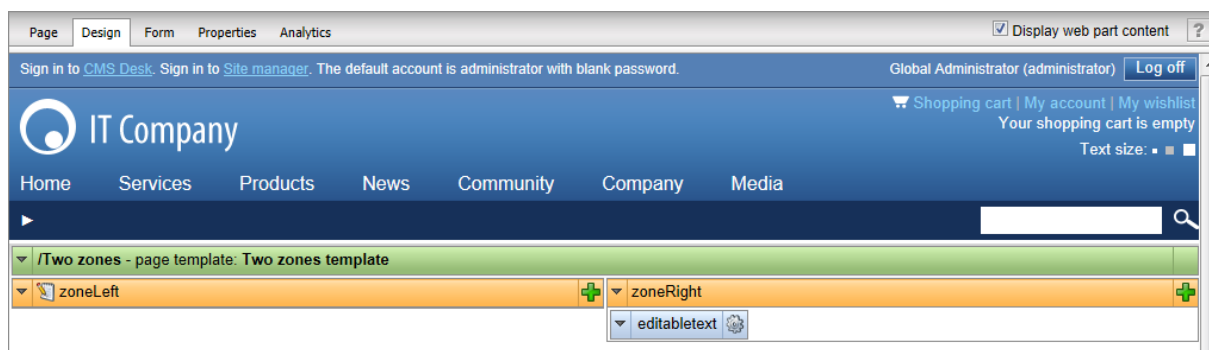

```
<cms:CMSPagePlaceholder ID="plcZones" runat="server">
  <LayoutTemplate>
    <table width="100%" cellpadding="0" cellspacing="0">
      <tr valign="top">
        <td width="50%">
          <cms:CMSWebPartZone ID="zoneLeft" runat="server" />
        </td>
        <td width="50%">
          <cms:CMSWebPartZone ID="zoneRight" runat="server" />
        </td>
      </tr>
    </table>
  </LayoutTemplate>
</cms:CMSPagePlaceholder>
```

This code defines two editable web part zones in a basic two column table layout.

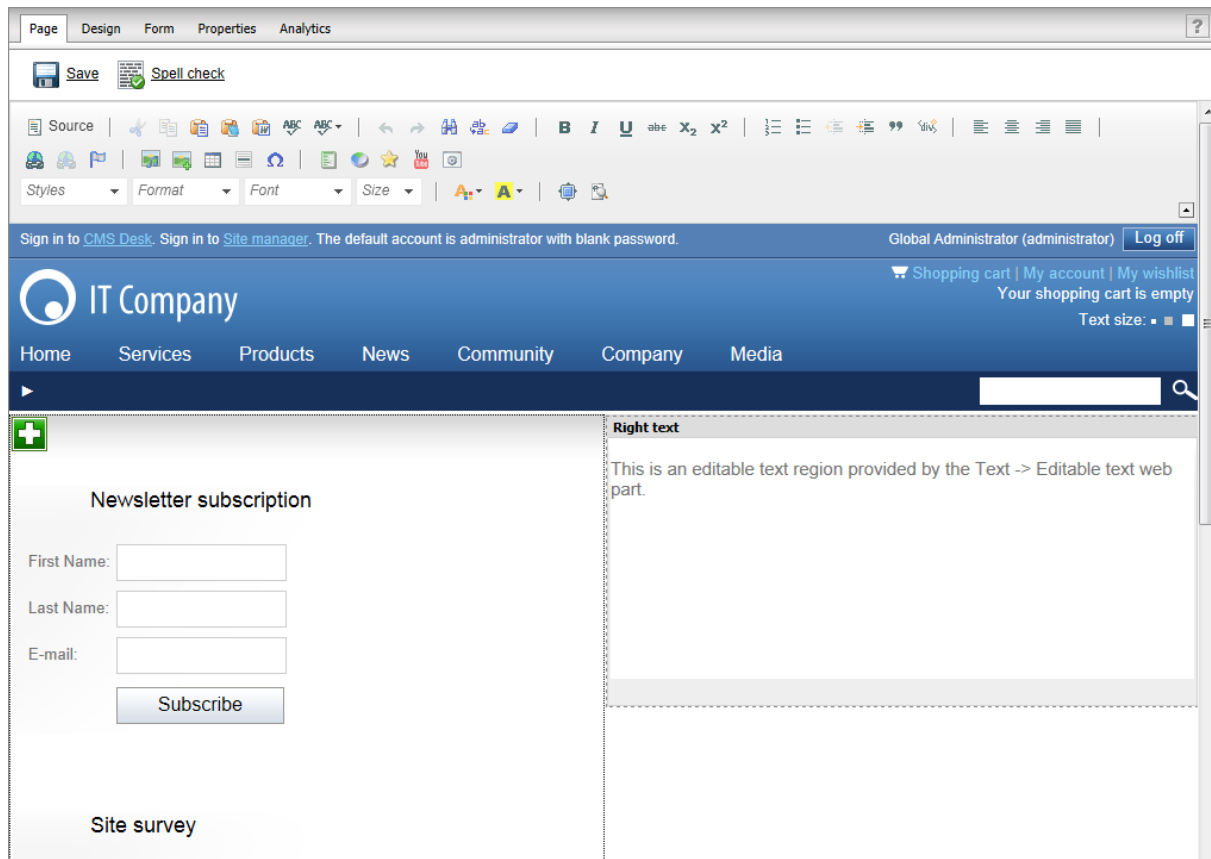

2. When registering the page template in **Site Manager -> Development -> Page templates**, select the *ASPX + Portal page* option for the **Template type** property.
3. Go to **CMS Desk** and add a *Page (Menu item)* document to the content tree using the new page template.
4. Switch to the **Design** tab of the new page, where you can see two web part zones.
5. Expand the menu (▼) of the **zoneLeft** zone, select **Properties** and switch the **Widget zone type** property from *None* to *Customization by page editor*.

This zone now serves as a widget zone for page editors.

6. Add (+) some web part to the **ZoneRight** zone, for example **Text & Images -> Editable text**.

7. Open the **Page** tab, where you can manage the editor widget zone on the left and enter content into the editable text region displayed by the web part on the right. Try placing some widgets onto the page using the **Add widget (+)** button in the top left corner of the widget zone.

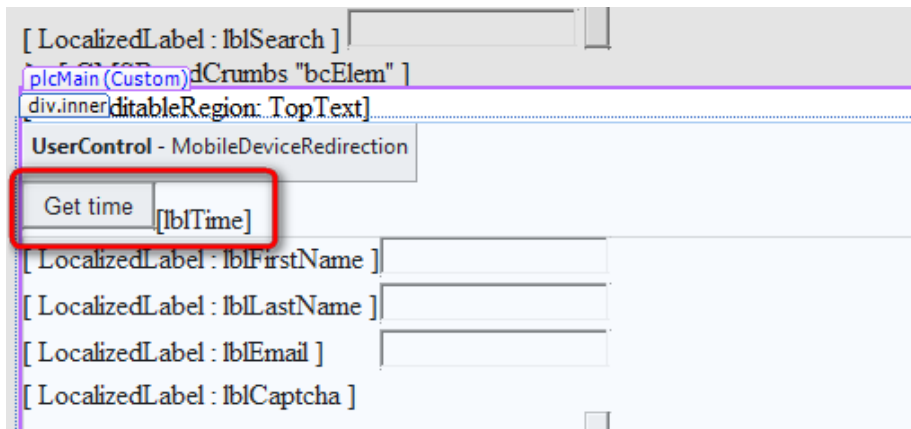

The example demonstrates how to use web parts or widgets to build the design of pages based on ASPX page templates. This approach combines the standard architecture and development process of ASPX templates with the flexibility and user-friendliness of the portal engine.

7.2.5.5 Adding custom code to an ASPX template

In this simple example, you will see how you can easily add custom code to an ASPX page template. You will see that you can add custom code in Visual Studio, as you usually would. You will need to use the sample **Corporate Site** website for this example.

1. Open the web project in Visual Studio using the **WebProject.sln** file and edit the **Home.aspx** page located in the **CMSTemplates\CorporateSite** folder.
2. Switch to the **Design** tab and add a new button to the page from the toolbox. Set its **ID** to *btnGetTime* and set its **Text** property to *Get time*. Then add a new label, name it *lblTime* and clear its text.

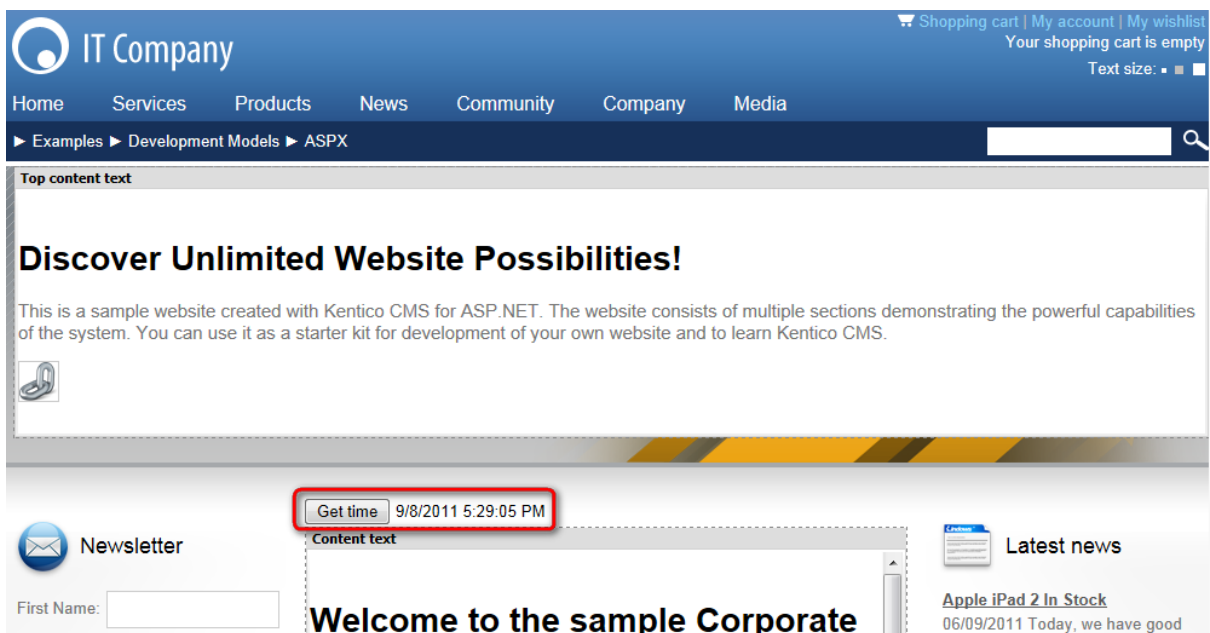

3. Double-click the button and add the following code inside the click event handler:

[C#]

```
lblTime.Text = DateTime.Now.ToString();
```

4. Save the changes and open the Corporate Site in your browser. Go to the **Examples -> Development Models -> ASPX** page, which is based on the edited template and view it in live site mode. When you click the added button, you can see that the label displays the current date and time:

As you can see, you can use standard programming methods as usual. You can also use the standard debugging process in Visual Studio.

7.2.5.6 Combining ASPX templates and portal engine templates

It is possible to combine [ASPX page templates](#) and [Portal engine page templates](#) on the same website.

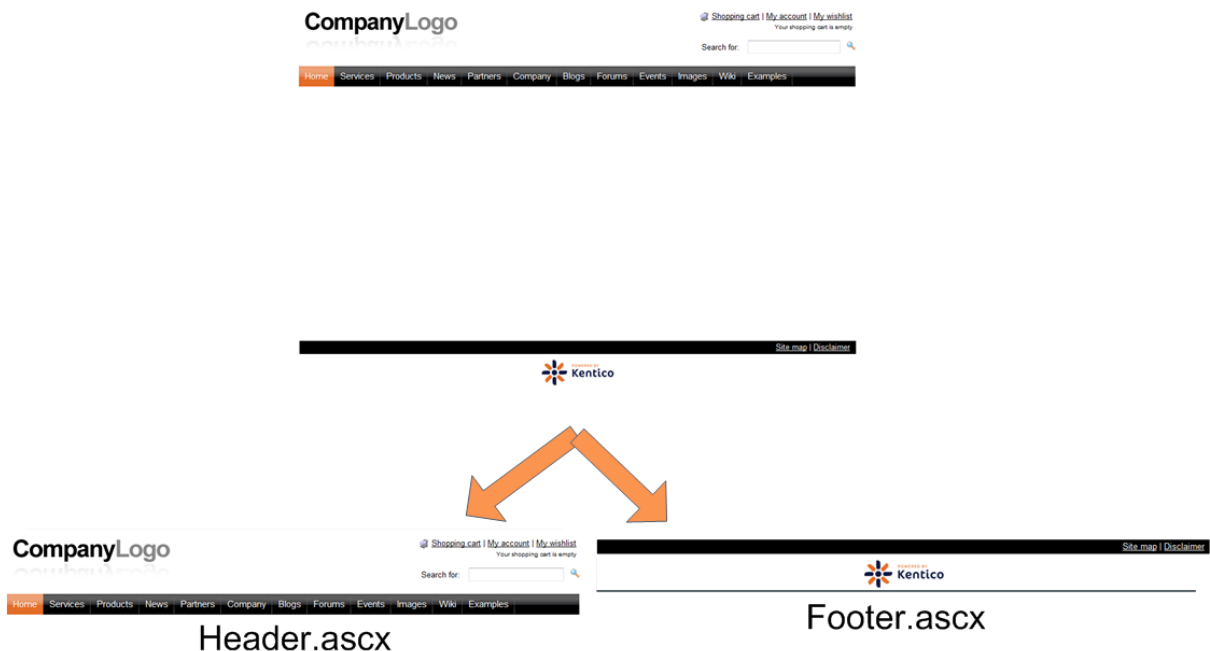

Note: When creating websites with both ASPX template and portal engine pages, you need to make sure that the portal engine pages have [visual inheritance](#) disabled for all ancestors that use ASPX page templates.

Sharing a master page on hybrid websites

If you have a website built using the portal engine development model, the master page and all other pages use portal engine page templates. Unfortunately, you cannot "insert" ASPX pages directly into the portal engine master page.

However, you can use the following workaround:

1. Create a copy of your portal engine master template as an [ASPX master page](#) (.master file) and assign it to your ASPX templates.
 - o This scenario works, but the drawback is that you now need to manage the master page in two locations.
2. Take all content (HTML and controls) that you have above the **Page placeholder** web part on the portal master page and place it into a new user control named **Header.ascx**.
3. Take all content from below the Page placeholder and place it into a user control named **Footer.ascx**.

4. Delete the content of your portal engine master page and replace it with the following web parts:

- **User control** - set the *User control virtual path* property to load **Header.ascx**
- **Page placeholder**
- **User control** - set the *User control virtual path* property to load **Footer.ascx**

5. Remove the content from your ASPX master page and replace it with the following controls:

- the **Header.ascx** user control
- the **ContentPlaceHolder** control
- the **Footer.ascx** user control

You can now manage the header and footer in a single place for both the portal engine and ASPX master page.

7.2.5.7 Integration with your existing ASP.NET application

If you need to integrate some existing ASP.NET application with a Kentico CMS website, there are several issues you need to consider. This chapter contains a summary of this topic, if you need more details or help with some particular issues, please contact Kentico support.

Location of CMS and your application

There are three ways how you can organize the CMS web project and your application web project:

1. Mixing both together

It makes sense to mix both applications into a single project if you wish to share functionality, content, security information and session or application variables between the CMS and your application. The easiest way is to use the Kentico CMS web project, as the main project since it's already correctly configured for the CMS, and add your own ASPX pages and other files to this project.

If you need to display your own ASPX pages inside the context of the website, you can simply register them as page templates and then create new pages based on these page templates in the standard website navigation (in the content tree). You will also need to modify your ASPX pages so that they use the master page (.master file) of the Kentico CMS website.

If you wish to use a website built using the Kentico CMS portal engine development model, please also read the [Combining ASPX templates and portal engine templates](#) topic.

2. Having the CMS in the root and your application in a sub-folder

If your application can or needs to run separately from the CMS and you want the CMS to manage the main website, you can place the Kentico CMS web project in the root of the website and your application into a sub-folder. You will need to create a virtual directory for the sub-folder so that your application runs correctly.

3. Having your application in the root and the CMS in a sub-folder

If your application can or needs to run separately from the CMS and your application is the main part of the website and you wish to use the CMS only for some sub-section of the website where you publish the content, you need to place the CMS into a sub-folder and create a virtual directory for it.

Interaction between the CMS and your application

If you need to include your application inside the website (front-end), you can do so either through ASPX pages (see paragraph **Mixing both together** above) or you need to create ASCX user controls that you

place into the CMS website.

If you need to build an application that will interact with the CMS system, but will mostly provide back-end user interface, you can create a custom module as described in the [Custom modules](#) topic.

Sharing security information between the CMS and your application (single-sign-on)

If you wish to use single-sign-on for both your application and the CMS, you need to configure your environment as described in the [Single sign-on](#) topic. If you wish to use a single system of permissions (authorization), you can leverage the permission system for custom modules as described in the [Custom modules](#) topic.

7.2.5.8 Displaying data from an external database

Besides displaying Kentico CMS content, you can also display data from your external database or Web Service. In this case, you need to add custom code to your ASPX page that will use ADO.NET to retrieve the data or that will contact the Web Service and call its methods. Since you can place any custom code into the page (page template), you will simply use the standard ASP.NET code you would use when creating the website from scratch.

Example: Retrieving data from the sample Northwind database

In this simple example, you will see how to display data on the sample Corporate Site website from the *Categories* table of the Northwind database using ADO.NET. You may need to use some other database if you do not have the sample Northwind database on your server.

Open the web project in Visual Studio using the **WebProject.sln** file. Open the *CMSTemplates/CorporateSite/Home.aspx* page.

Drag and drop the standard ASP.NET **GridView** Data control onto the page and set its ID to **GridView1**.

Add the following line to the beginning of the code behind file:

[C#]

```
using System.Data;  
using System.Data.SqlClient;
```

Add the following code to the **Page_Load** method:

[C#]

```
// create sql connection - you could use Oracle or OLEDB provider as well  
SqlConnection cn = new SqlConnection("Persist Security Info=False;  
database=northwind;server=server1;user id=sa;password=psswd;Current  
Language=English;Connection Timeout=120;");
```

```
// create data adapter
SqlDataAdapter da = new SqlDataAdapter("SELECT * FROM categories", cn);
DataSet ds = new DataSet();

// fill the dataset with data from database
da.Fill(ds);

// bind data to the grid view
GridView1.DataSource = ds;
GridView1.DataBind();
```

Save all changes. Open the Corporate Site and look at the **Examples -> Development Models -> ASPX** page on the live website. You will see a grid with data from the external database:

| CategoryID | CategoryName | Description |
|------------|--------------|------------------------------|
| 1 | Animals | Dogs, cats, horses |
| 2 | Colors | Red, green, blue, orange,... |
| 3 | Names | John, Kevin, Julia, Robin |

As you can see we used standard ASP.NET methods to display external data on the website.

7.2.6 MVC development model

7.2.6.1 MVC development overview

Kentico CMS supports website development using [ASP.NET MVC](#). You can find an example of a page developed using the MVC development model in the **Examples/Development-models/MVC** section of the sample **Corporate Site**.

Document configuration

The document uses an **MVC** type page template, which specifies the default controller, as well as the action that is executed when the page is viewed. If you edit the document on the **Properties -> Template** tab and click the  **Edit template properties** button, you can see the configuration of the page's template as shown below:

- **Default controller** - sets the name of the controller class containing the MVC action that should be performed when pages using the template are accessed (without the *Controller* part at the end). For example, if the class is called *NewsMVCController*, enter *NewsMVC*. The system first searches for the specified class in the *CMS.Controllers.<current site code name>* namespace. If it is not found there, the *CMS.Controllers.Global* namespace is searched.
- **Default action** - specifies the exact action defined within the controller class that is performed when pages based on this template are loaded.

The screenshot shows the 'Page template properties' dialog box for the 'MVC News List' template. The dialog has a title bar with a help icon, maximize icon, and close icon. Below the title bar, there is a breadcrumb path: 'Page templates > MVC News List'. There are four tabs: 'General', 'Header', 'Documents', and 'Versions'. A 'Save' button is located below the tabs. The main area contains the following fields:

- Template display name: MVC News List
- Template code name: CorporateSite.MVCNewsList
- Category: MVC
- Template description: This template displays the list of news of the current site
- Thumbnail: Upload file

A red box highlights the following fields:

- Template type: MVC
- Default controller: NewsMVC
- Default action: List

At the bottom right of the dialog, there is a 'Cancel' button.

Close the template editing dialog and open the document's **Properties -> URLs** tab. In this case, the page's URL is defined as an ASP.NET **Route**, but the standard alias path reflecting the document's position in the content tree can also be used for MVC pages as long as they use the appropriate template type.

The document has a registered document alias, which handles the `/NewsMVC/Detail/{id}` pattern. If you edit (✎) the alias, you can see that its **Default controller** is set to `NewsMVC` and the **Default action** is `Detail`. These will be used instead of the default template configuration when the page is accessed through the alias URL.

Further advanced options are also available for MVC URL patterns:

- **{controller}, {action}** - allows you to specify controllers and actions dynamically through URL parameters. For example, the `{controller}/{action}/{id}` pattern provides the same controller, action and page output as the example above when the `/NewsMVC/Detail/My-First-News` URL is accessed. However, it could also be used to direct the users to pages generated by other controllers or actions

(the parameter parts of the URL may vary).

- **{name;value}** - provides a way to set the default value of the parameters in the URL path. For example, `/{controller;NewsMVC}/{action;Detail}/{id;My-First-News}` has the same functionality as the previous option, but the system is able to automatically generate the default URL `/NewsMVC/Detail/My-First-News` for the document if the parameters are not specified.
- **{*name;value*}** - hidden value, which is passed as a parameter to the action handler in the controller class, but is not incorporated into the URL itself. For example, `/NewsMVC/List{*TopN;10*}` generates the `/NewsMVC/List` pattern and provides the value of the `TopN` parameter during the processing of the request. Note that the TOP N functionality is not implemented in the sample controller and you need to handle it in the code if you want to try it. The URL of the page will still be the same as before (the parameter is hidden). This way, the pages can be parametrized by the developer even if they use the same controller and action.

Using MVC views in editing mode

To configure documents to show the MVC view in editing mode (i.e. when working with documents on the *Page* tab of CMS Desk), enable the **Use live URL for editing modes** setting in **Site Manager -> Settings -> Content -> Content management**.

You do not need to enable this setting if your documents are based on *MVC* type page templates, which automatically use the MVC view in editing mode.

MVC code files

The **NewsMVC** controller specified in the **Default controller** field above is physically located in `~\App_Code\Controllers\Global\NewsMVCController.cs` (or `~\Controllers\Global\NewsMVCController.cs` if you installed Kentico CMS as a web application). The **List** action specified in the **Default action** field of the sample page's template is implemented in its code, along with the **Detail** action, which is used when the page is accessed through the document alias URL. The following is the full code of the controller class:

```
using System.Data;
using System.Web.Mvc;

using CMS.CMSHelper;
using CMS.DocumentEngine;
using CMS.URLRewritingEngine;

namespace CMS.Controllers.Global
{
    /// <summary>
    /// Sample controller for the news.
    /// </summary>
    public class NewsMVCController : Controller
    {
        /// <summary>
        /// Processes the detail action.
        /// </summary>
        public ActionResult Detail()
        {
        }
    }
}
```

```

        // Prepares the data for the view.
        TreeNode document = TreeHelper.GetDocument(CMSContext.CurrentSiteName,
"/News/" + RouteData.Values["id"], CMSContext.PreferredCultureCode, true,
"CMS.News", true);
        if (document != null)
        {
            document.SetValue("NewsTitle", document.GetValue("NewsTitle"));
            ViewData["Document"] = document;
        }
        else
        {
            // Return a page not found error if the document does not exist.
            URLRewriter.PageNotFound();
            return null;
        }

        return View();
    }

    /// <summary>
    /// Processes the list action.
    /// </summary>
    public ActionResult List()
    {
        // Prepares the data for the view.
        var documents = TreeHelper.GetDocuments(CMSContext.CurrentSiteName, "/"
News/%", CMSContext.PreferredCultureCode, true, "CMS.News", null, "NewsReleaseDate
DESC", -1, true, 0);
        if (documents != null)
        {
            ViewData["NewsList"] = documents;
        }

        return View();
    }
}
}
}

```

The views that display the pages when the respective actions are performed are located under `~/Views/Global/NewsMVC/`. The following code is the full code of the `Detail.aspx` file of the **Detail** view:

```

<%@ Page Language="C#" AutoEventWireup="true" CodeFile="Detail.aspx.cs"
Inherits="Views_Global_NewsMVC_Detail" MasterPageFile="Root.master" %>

<asp:Content ID="cntMain" ContentPlaceHolderID="plcMain" runat="Server">
    <div class="innerContent">
        <h1>
            MVC Example</h1>
        <p>
            This is a sample for the page rendered by MVC. It displays the news
            detail. The detail is provided by <strong>NewsMVC</strong> controller and
            <strong>~/Views/Global/NewsMVC/Detail.aspx</strong> view and routed through MVC
            URL pattern <strong>/NewsMVC/Detail/{id}</strong> added as document alias to the
            same document as the main document. This way, there is no need to provide separate
            documents for detail view.
        </p>
    </div>

```

```
<div class="LightGradientBox ">
  <h2>
    <%=Document.GetValue("NewsTitle")%></h2>
  <p>
    <%=Document.GetValue("NewsText")%></p>
  <p>
    <a href="<%=ResolveUrl("~/newsmvc/list/")%>">Back to the list of
news</a>
  </p>
</div>
</div>
</div>
</asp:Content>
```

And the following code is the full code of its *Detail.aspx.cs* code behind file:

```
using System;
using System.Data;
using System.Web.Mvc;

using CMS.DocumentEngine;

/// <summary>
/// Sample view for the news.
/// </summary>
public partial class Views_Global_NewsMVC_Detail : ViewPage
{
    /// <summary>
    /// Returns the displayed document
    /// </summary>
    public TreeNode Document
    {
        get
        {
            return (TreeNode)ViewData["Document"];
        }
    }
}
```

How it works on the live site

When you navigate to the page on the live site, you can initially see the list mode view, which is specified as the default option for the page's template (the **List** action from the **NewsMVC** controller is executed). It displays a list of all news items from the **News** section, as can be seen in the screenshot below.

[Home](#) [Products](#) [News](#) [Community](#) [Services](#) [Company](#) [Media](#)

MVC Example

This is a sample for the page rendered by MVC. It displays the news list. The list is routed by using Route URL pattern `/NewsMVC/List` to provide extension-less URL, and then displayed with an MVC page template type using `NewsMVC` controller and `~/Views/Global/NewsMVC/List.aspx` view.

Community Website Section

The community section consists of four separate sub-sections. The [Forums](#) let you discuss various topics, closely or remotely related to our company's activities. In [Blogs](#), you can read personal blogs of our employees and comment on the thoughts and ideas expressed in them. The [Events](#) sub-section lets you know about events that our company organizes, while registration for the events is possible too. Finally, the [Wiki](#) is a place where valuable information is provided to you, being a great source of information on various topics.

Company Growth Exceeds Expectations

Annual growth of 256% was reported by our financial department, exceeding all our plans and expectations. We would like to express sincere thanks to all our customers. It is a pleasure for us to provide you with top-grade products and services and we promise that your trust in our company will not be let down. We promise that we will not get greedy and invest the money we made into improvements of all imaginable aspects of our business. Thank you once again and please keep up your loyalty, we ensure you that it will be continuously rewarded as your satisfaction is our primary goal.

The titles of the news items contain links to the `/NewsMVC/Detail/{id}` URL, where the `{id}` wildcard parameter is substituted by the alias of the corresponding news document. If you click it, the **Detail** action of the **NewsMVC** controller is executed, which displays a detail of the given news item. This is all handled by a single document, the different content is ensured through the special document alias URL, which triggers the detail view.

[Home](#) [Products](#) [News](#) [Community](#) [Services](#) [Company](#) [Media](#)

MVC Example

This is a sample for the page rendered by MVC. It displays the news detail. The detail is provided by `NewsMVC` controller through MVC URL pattern `/NewsMVC/Detail/{id}` added as document alias to the same document as the main document for detail view.

Community Website Section

The community section consists of four separate sub-sections. The [Forums](#) let you discuss various topics, closely or can read personal blogs of our employees and comment on the thoughts and ideas expressed in them. The [Events](#) sub-section lets you know about events that our company organizes, while registration for the events is possible too. Finally, the [Wiki](#) is a place where valuable information is provided on various topics.

[Back to the list of news](#)

7.3 Caching and performance

7.3.1 Overview

The performance of your website depends on many aspects:

1. Hardware on which your website and database server are running.
2. Available system performance when you're sharing system resources with other applications (relevant in a shared hosting environment).
3. Amount of documents on your website.
4. Complexity of the website (number of nesting levels, number of web parts on a page, etc.)
5. Custom code added to the website.
6. Use of caching.
7. Other special circumstances, such as network connectivity between web server and SQL server, etc.

7.3.2 Caching options

Cache is a storage space which duplicates commonly used data to provide faster access to the data. Kentico CMS stores all its data in an SQL database, which requires the application to connect to the SQL server and transfer data over ineffective lines. This is why the application has a built-in cache, which copies the data that it uses the most to the application memory, and then retrieves the data from the memory instead of the database.

Cache types

Kentico CMS provides the following types of caching:

- [Content cache](#) - stores data used by web parts and controls that display structured content, such as repeaters and listings.
- [Files cache](#) - stores images. Supports both server and client-side caching
- [Output cache \(full page\)](#) - caches the full HTML output of pages.
- [Page info cache](#) - stores the basic information about documents, such as document's name and properties.
- [Partial cache](#) - caches the HTML output of specific web parts or controls.

Enabling page info cache

When a visitor requests a page, the system first queries the database for information about the page. Page info cache allows the system to send the queries only once and serve the results from the application's memory the next time. The basic page information includes:

- alias path
- ID and name
- metadata
- properties
- SKU information
- workflow information

For the full list of database columns that the page info cache stores, see [View_CMS_Tree_Joined](#) in the [database reference](#).

To enable page info cache:

1. Open **Site Manager** and go to **Settings -> System -> Performance**.
2. Type a number of minutes into the **Cache page info (minutes)** setting. This is how long the cache will retain a particular page info item.
3. Save the settings.

When you request a page, its basic info will be stored in the cache. You can check that in the [cache debugging interface](#). The cache keys begin with "pageinfo" or "pageinfofyurl". The information stays in the cache for the amount of time you specified in the **Cache page info** setting, or until someone modifies the related document.

Enabling content cache

Content cache helps the system to ease the load on SQL servers by storing structured data in the application's memory. You can set it up on two levels - either on a global level, which influences a whole site, or you can enable content cache for individual instances of web parts.

To enable content cache globally:

1. Open **Site Manager** and go to **Settings -> System -> Performance**.
2. Type a number of minutes into the **Cache content (minutes)** setting. This is how long the cache will retain cache items.
3. Save the settings.

With content cache enabled globally, the system stores structured data displayed by all web parts such as repeaters or listings. The data stays in the cache for the amount of time specified in the Cache content setting.

To enable content cache for particular web part instances:

1. Edit the web part in design mode.
2. Type a number of minutes into the **Cache minutes** property. This is how long the cache will store the web part's data.
 - o The Cache minutes property is only available for web parts that load structured data from the database (i.e. data sources).
3. (Optional) Define [Cache dependencies](#).
4. Click **OK** to save the web part's properties.

With content cache enabled, the system stores data displayed by the particular web part instance. The data stays in the cache for the amount of time specified in the Cache minutes property.

To disable content cache for a particular web part when content cache is globally enabled:

1. Edit the web part in design mode.
2. Type **0** (zero) into the **Cache minutes** property.

3. Click **OK** to save the web part's properties.

When you disable content cache for a particular web part, it doesn't store any of its structured data in the cache.

Enabling files cache

The system supports two types of file caching:

- **Server-side** - stores images in the application's memory so that the CMS doesn't have to access the database and file system every time an image is requested.
- **Client-side** - uses HTTP request headers to control file caching in client browsers and intermediate network caches.

To enable server-side file caching:

1. Open **Site Manager** and go to **Settings -> System -> Performance**.
2. Type a number of minutes into the **Cache images (minutes)** setting. This is how long the cache will retain images.
3. Save the settings.

With files cache enabled, the system stores images in the memory when they are requested. On subsequent requests, the system serves the images from the memory. Images stay in the cache for the amount of time specified in the **Cache images** setting.

Please note

Even when the files cache is off, the system still caches images for one minute to prevent the application from overloading in case of a [DoS attack](#).

To enable client-side file caching:

1. Open **Site Manager** and go to **Settings -> System -> Performance**.
2. Type a number of minutes into the **Client cache (minutes)** setting. This determines the expiration time in the client cache.
3. Save the settings.

With client cache enabled, the system allows browsers to cache files for the number of minutes specified in the **Client cache** setting.

Enabling output cache

The most effective way to increase website performance is output cache. Output cache stores the full HTML source of pages. This way the application doesn't have to communicate with SQL servers and

process data every time a page is requested.

This option is not suitable for pages with web parts that need to be refreshed very often (e.g., the Random document web part) since you cannot disable caching for particular web parts. For such pages, it's recommended that you do not use output caching and use content caching instead.

If you wish to use output cache, you need to enable it globally in settings and then enable it for specific documents. Documents can inherit output cache settings from their parent document.

To allow output cache globally:

1. Open **Site Manager** and go to **Settings -> System -> Performance**.
2. Set **Enable output caching** to true.
3. Save the settings.

To enable output cache for documents:

1. Open the document's properties and select the **General** tab.
 - o To apply output caching on all documents on your site, select the root document. Note that the underlying documents need to have the **Use output cache** property set to **Inherit**.
2. In the **Output cache** section, select Yes next to **Use output cache**.
3. Type a number of minutes into **Cache minutes**.
4.  **Save** the document.

When a page is requested, the system stores its HTML source into the output cache. The data stays in the cache for the amount of time specified in **Cache minutes** or until someone modifies the page. However, if the page displays other documents (such as a news list) and you modify these documents, the page will stay in the cache and won't be updated until the cache expires.

Enabling partial cache

Partial cache stores the HTML output of web parts and controls as individual cache items. You can use partial cache when full page output caching is not feasible.

To allow partial caching globally:

1. Open **Site Manager** and go to **Settings -> System -> Performance**.
2. Set **Enable partial caching** to true.
3. Save the settings.

The website now allows partial caching for web parts and controls. By default, web parts do not use partial caching and you need to enable it for individual instances.

To enable partial caching for particular web part instances:

1. Edit the web part's properties.
2. Locate the Performance section and type a number of minutes into the **Partial cache minutes** property.
3. Specify [cache dependencies](#).
4. Click **OK**.

When a page containing the web part is requested, the system stores the HTML output of the web part into the cache. The data stay in the cache for the amount of time specified in **Partial cache minutes** or until a dependent object is modified.

Cache dependencies

Cache dependencies allow the application to clear cached data based on relationships with other objects. A cache dependency is represented by a dummy cache key (a cache item that doesn't contain any data) that identifies an object or a set of objects. When an object that matches the dummy key is modified, the dummy key is "touched" and all cache items depending on the dummy key are removed from the cache.

For example, you have a page (with alias path */Products*) that contains a repeater. The repeater displays a list of products that reside under the Products page. Only the content cache is turned on. A visitor requests the Products page, the repeater fetches the products from the database and stores them in the cache. The system also creates the following dummy key: *node|corporatesite|products|childnodes*. The dummy key ensures that once a child node of the Products node is modified, the depending cache items get cleared.

Entering custom cache dependencies

You can use cache dependencies to specify conditions that should be met in order to delete a web part's output from the memory. Each web part has its default dependencies which include all possible object changes that the content of the web part could depend on.

Note: The following steps describe how to specify dependencies for partial cache. Before you specify partial cache dependencies, [enable partial caching](#) for the given web part.

You can also define custom dependencies for output cache of a page using the [Output cache dependencies](#) web part.

To specify custom cache dependencies for partial cache:

1. Open the web part's properties.
2. Locate the Performance section.
3. Type one dummy key per line into the **Partial cache dependencies** field.

The following table shows which dummy cache keys get touched when an object gets changed. The table also lists examples of the dummy keys.

| Object | Touched keys | Sample values |
|--------|--------------|---------------|
|--------|--------------|---------------|

| | | |
|---|--|---|
| Document
(TreeNode) | node <sitename> <aliaspath> <culture>
node <sitename> <aliaspath> nodeid <nodeid>
nodeid <linkednodeid>
nodes <sitename> <classname> all
+ for every parent node:
node <sitename> <aliaspath> childnodes | node corporatesite /home en-us
node corporatesite /home nodeid 12
nodeid 34
nodes corporatesite cms.menuitem all

node sitename / childnodes |
| Any object
(except documents) | <classname> all
<classname> byid <id>
<classname> byname <codename>
<classname> byguid <guid> | cms.user all
cms.user byid 53
cms.user byname administrator
cms.user byguid 1ced44f3-f2fc- ... |
| Metafile | metafile <guid> | metafile 1ced44f3-f2fc- ... |
| Document attachment | attachment <guid> | attachment 1ced44f3-f2fc- ... |
| Forum attachment | forumattachment <guid> | forumattachment 1ced44f3-f2fc- ... |
| Avatar | avatarfile <guid> | avatarfile 1ced44f3-f2fc- ... |
| Media file | mediafile <guid>
mediafile preview <guid> | mediafile 1ced44f3-f2fc- ...
mediafile preview 1ced44f3-f2fc- ... |
| Page template | template <id> | template 12 |
| CacheHelper
.ClearFullPageCache | fullpage | fullpage |

Example 1: you have a web part displaying some information about users. Therefore, whenever some user gets their details modified, the web part's cache should be cleared. To ensure this, you need to enter **cms.user|all** into the field, which is the dummy key that would get touched whenever some user's details get changed.

Example 2: your web part is displaying information about one particular user - the administrator. Their user name is *administrator*, ID is *53* and GUID is something beginning with *1ced44f3-f2fc*. So if you want to have the cache cleared whenever this user's details are changed, you can use any of the following three keys that identify the user by the previously named properties:

- **cms.user|byid|53**
- **cms.user|byname|administrator**
- **cms.user|byguid|1ced44f3-f2fc-...**

Clearing the cache

Kentico CMS allows you to clear the contents of its cache.

To delete all items from the cache:

1. Go to **Site Manager -> Administration -> System**.
2. Click **Clear cache**.

The system empties the cache, including all dummy keys.

To delete a particular page from the output cache:

1. Select the document in CMS Desk content tree,
2. Navigate to **Properties -> General**.
3. Click **Clear output cache** in the Output cache section.

The system deletes the document's HTML output from the cache.

Debugging cache

The system debugging interface in **Site Manager -> Administration -> System** allows you to see the [list of items that are in the system's cache](#) and the list of dummy keys (cache dependencies). You can also view what [cache operations](#) the system performed when serving a particular page request.

Reference: Cache settings

Global

The following cache settings are available in **CMS Site Manager -> Settings -> System -> Performance**:

| Server content caching | |
|---------------------------|--|
| Cache page info (minutes) | <p>Sets the number of minutes for which the system caches page information. This option caches page properties and metadata. Kentico CMS retrieves page information many times during the processing of a single page, so always set this value to at least 10 minutes!</p> <p>When a page is modified, the system automatically clears the corresponding part of the page info cache, so the website will not display outdated information.</p> |
| Cache content (minutes) | <p>Sets the number of minutes for which all web parts/controls cache the content that they retrieve from the Kentico CMS database.</p> <p>You can override this value for specific web part instances by setting their Cache minutes property. Using 0 as the value disables content caching for the given web part instance.</p> <p>It is recommended to cache all possible content that is not modified often. The drawback of this option is that if content is modified, the changes appear on the live site only after the old version expires in the cache.</p> |
| Use progressive caching | <p>If checked, the system optimizes access to uncached data so that concurrent threads only use a single data access operation and share the results. This leads to better performance if the website is under a heavy load, without the drawback of not having the latest data available.</p> |

| Server file caching | |
|---------------------------------------|--|
| Cache images (minutes) | <p>Sets the number of minutes for which the system caches image files on the server.</p> <p>It is recommended to always use image caching. Kentico CMS automatically removes images from the cache if they are modified, so image caching cannot cause the website to display outdated content.</p> |
| Maximum file size to cache | Specifies the maximum file size in kilobytes that is allowed to be cached. |
| Redirect files to disk | If checked, file requests are redirected to the corresponding physical file in the file system if possible. |
| File client caching | |
| Client cache (minutes) | <p>Sets the number of minutes for which client browsers are allowed to cache files.</p> <p>If the value is 0, client caching for files is disabled.</p> |
| Client cache must revalidate | If enabled, client browsers need to revalidate cached content by calling the server. If disabled, browsers do not perform server requests if the requested content is already cached. |
| Output caching | |
| Enable output caching | <p>If checked, the system allows output caching. Output cache stores the full HTML source of pages. If unchecked, output caching is disabled on the whole website.</p> <p>To enable output caching for pages, configure the Output cache properties of individual documents in CMS Desk on the Properties -> General tab. Both the main website setting and document settings must be enabled to use output caching.</p> |
| Cache output in file system (minutes) | <p>Specifies the number of minutes for which the system stores output cache in the file system. This provides persistent cache storage in case of application restarts.</p> <p>If not set, only the standard caching mechanism (in memory) is used. If you enter a value, the system checks both types of cache.</p> <p>To enable output caching in the file system for pages, configure the Allow file system cache property of individual documents in CMS Desk on the Properties -> General tab.</p> |
| Enable partial caching | <p>If checked, the system allows partial caching of web parts and controls. The partial cache stores the HTML output of individual web part or control instances. If unchecked, partial caching is disabled on the whole website for all web parts.</p> <p>By default, web parts do not use partial caching and you need to enable it for individual instances using their Partial cache minutes property.</p> |

Documents

Individual documents have the following output cache settings in CMS Desk on the **Properties -> General** tab:

| Output cache | |
|-------------------------|---|
| Use output cache | <p>Indicates if the system caches the full HTML output of the page. Output caching can greatly improve the performance of the page, but is not suitable for pages with dynamic content.</p> <p>You can inherit the output cache settings from the parent document.</p> <p>Important: Output caching must also be allowed in the website's settings. Administrators can enable output caching in Site Manager -> Settings -> System -> Performance.</p> |
| Cache minutes | <p>Determines how long the system keeps the output code of the page in the cache (if output caching is enabled).</p> <p>The page's output cache is automatically cleared if someone modifies the page. You can manually remove the page from the output cache by clicking Clear output cache.</p> |
| Allow file system cache | <p>Indicates if the system stores the page's output cache on the server's file system. This provides persistent caching in case of application restarts.</p> <p>If disabled, the application only caches the page output in its memory. If enabled, the system checks both types of cache.</p> <p>You can inherit the setting from the parent document.</p> <p>The file system cache is stored for the number of minutes specified in the Cache output in file system (minutes) setting in Site Manager -> Settings -> System -> Performance.</p> |

Web parts

Instances of web parts provide the following properties for configuring content caching and partial output caching:

| System settings | |
|-----------------|--|
| Cache item name | <p>Sets the name of the cache key used for the content of the web part. If not specified, this name is generated automatically based on the site, document path, Web part control ID and current user.</p> <p>A cache key can be shared between multiple web parts displaying the same content on different pages in order to avoid keeping redundant data in the memory.</p> |

| | |
|----------------------------|---|
| Cache minutes | <p>Sets the number of minutes for which the content of the web part remains cached before the latest version is reloaded from the database.</p> <p>If empty, the web part uses the value entered into the Site Manager -> Settings -> System -> Performance -> Server content caching -> Cache content (minutes) setting.</p> <p>If set to 0, the web part does not use content caching.</p> |
| Cache dependencies | <p>Contains a list of cache keys on which the content cache of the web part depends. When the specified cache items change, the content cache of the web part is deleted. Each line may only contain a single item.</p> <p>If you check Use default cache dependencies, the web part uses dependencies that include all possible object changes that could affect the content of the given web part.</p> |
| Performance | |
| Partial cache (minutes) | <p>Sets the number of minutes for which system caches the output HTML code of the web part. Partial caching is similar to full-page caching, but only for the code of the web part specifically.</p> <p>If left empty or set to 0, partial caching is not used for the web part.</p> <p>Important: Partial caching must also be allowed in the website's settings. Administrators can enable partial caching in Site Manager -> Settings -> System -> Performance.</p> |
| Partial cache dependencies | <p>Allows you to specify a list of cache keys on which the partial cache of the web part depends. When the specified cache items change, the system clears the partial cache of the web part. Each line may only contain a single item.</p> <p>If you check Use default cache dependencies, the web part uses dependencies that include all possible object changes that could affect the given web part.</p> |

7.3.3 Code minification and compression

An important factor that influences the performance of a website is the size of code resources, which are requested by the client browser when it renders a page. The most significant among these are CSS stylesheets and JavaScript source files, which may in some cases reach sizes that considerably impact page load time.

Kentico CMS has two types of built-in functionality that can be used to optimize the performance of requests for the above mentioned resources:

- **Code minification** - removes all unnecessary characters from the code that are not required by the browser to correctly process the resource. This includes white spaces, line break characters, comments, bookmarks etc. The behavior of a minified resource remains exactly the same as the original and it can immediately be handled by the browser, without any additional steps. Minified

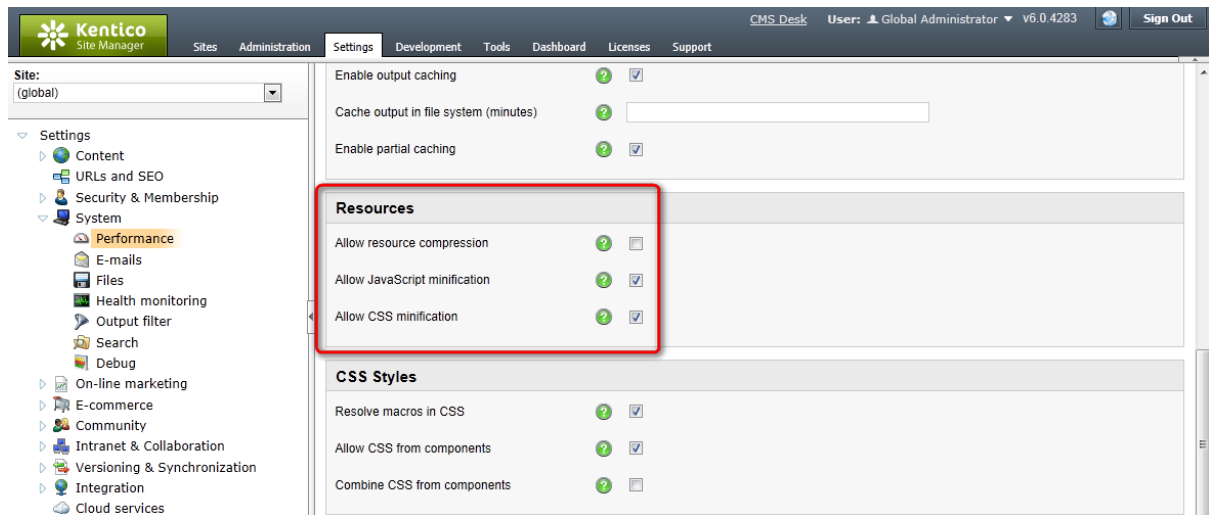

code is generally difficult to read (for humans) and is therefore unsuitable for debugging.

- **Resource compression** - encodes the data of the resource so that its size is reduced. In order for compression to be applied, minification must also be enabled for resources of the given type. When the client browser receives a compressed resource, it must first decompress the data. All browsers officially supported by Kentico CMS should be able to correctly decompress files. In cases where the client cannot process compressed data, the unmodified resource is sent instead.

Reducing the size of requested resources saves bandwidth and improves the response time of your website. Minification can decrease the size of a resource by approximately 20–40%, depending on the code of the given object. If compression is also used, resources can be reduced to roughly 30% of their original size.

Please note that these reductions are only applied to external resources stored individually in the file system or database. Inline code inserted into the HTML markup of pages is not affected.

Code minification and compression can be enabled or disabled globally for all sites in **Site Manager -> Settings -> System -> Performance**.

The minification or compression process slightly increases the server CPU load and may also cause a short time delay. To counter this issue, the server only performs minification/compression once per resource (when it is requested for the first time) and stores the results in the application's cache. When a given resource is requested, the appropriate transformed version is taken from the cache. Both compressed and uncompressed versions of resources are cached, so they are readily available even for clients without compression support.

Additionally, client-side browser caching can be used (enabled by default), which means that resources have to be reloaded from the server only if the cache expires or the content of the resource is outdated. Client caching of minifiable resources specifically can be enabled or disabled by setting the **CMSAlwaysCacheResources** key, which can be added into the **appSettings** section of your web.config file, for example:

```
<add key="CMSAlwaysCacheResources" value="false" />
```

All of the mentioned functionality is automatically ensured by the `~/CMSPages/GetResource.ashx`

handler, which manages resource requests according to the specified settings. If minification is enabled, CSS and JavaScript requests generated by the system use this handler. If you need to manually write resource requests in your code, the following URL parameters can be used with the handler to specify which resource should be loaded:

- **stylesheetname** - used to request a [CSS stylesheet](#) from the database. The code name of the requested stylesheet must be entered as the value of the parameter.
Link example:

```
<link href="/KenticoCMS/CMSPages/GetResource.ashx?stylesheetname=CorporateSite" type="text/css" rel="stylesheet">
```
- **_transformations, _layouts, _templates, _devicelayouts, _webparts, _webpartlayouts, _containers** - used to request the internal stylesheets of the corresponding type of page component. The object ID values of the given components must be entered as the value of the parameter, separated by semicolons (if multiple component stylesheets are requested). See [CSS stylesheets and design -> CSS for page components](#) for additional information.
Link examples:

```
<link href="/KenticoCMS/CMSPages/GetResource.ashx?_containers=1;14" type="text/css" rel="stylesheet"/>  
<link href="/KenticoCMS/CMSPages/GetResource.ashx?_transformations=3511" type="text/css" rel="stylesheet">
```
- **stylesheetfile** - used to request static CSS resources from the file system. The relative path of the requested .css file must be entered into the parameter.
Link example:

```
<link href="/KenticoCMS/CMSPages/GetResource.ashx?stylesheetfile=/KenticoCMS/App_Themes/Design/OnSiteEdit.css" type="text/css" rel="stylesheet">
```
- **scriptfile** - used to request static JavaScript resources from the file system. The relative path of the requested .js file must be entered into the parameter.
Link example:

```
<script src="/KenticoCMS/CMSPages/GetResource.ashx?scriptfile=%7e%2fCMSScripts%2fmootools.js" type="text/javascript"></script>
```

Requests with minification disabled

If minification is disabled, the system generates requests with a direct URL (for JavaScript files) or using the `~/CMSPages/GetCSS.aspx` system page (for CSS stylesheets).

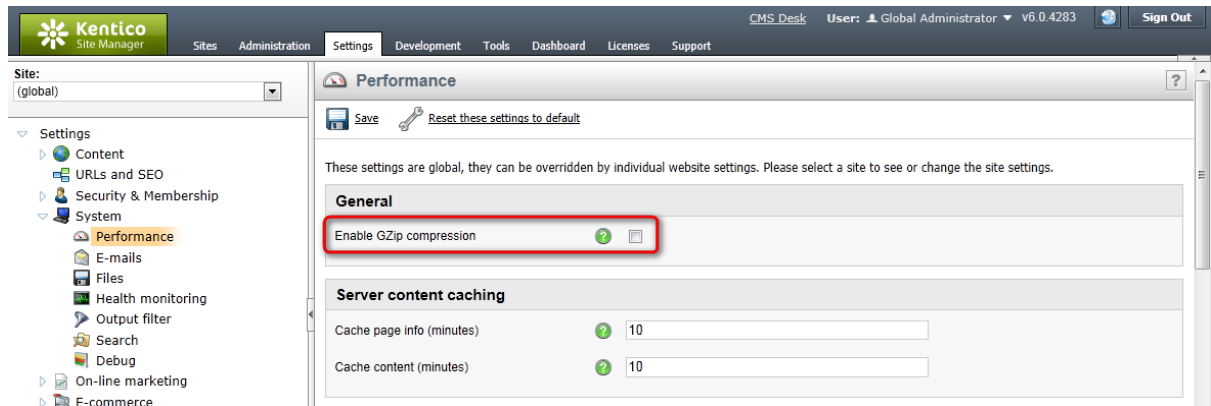

Requests with this URL format are always supported, but they do not perform minification or compression of resources.

GZip compression of page output

It is also possible to enable GZip compression of the output code of all pages rendered by Kentico CMS. This can be done either by adding the following key into the **appSettings** section of your web.config file:

```
<add key="CMSAllowGZip" value="true" />
```

or by enabling the **Enable GZip compression** option in **Site Manager -> Settings -> System -> Performance**.

7.3.4 File management and performance

Files can be stored in the file system (faster) or in database. If you're experiencing problems with slow image viewing, please try to configure the following values in the **Site Manager -> Settings -> System -> Files** section:

- **Store files in file system:** yes
- **Generate thumbnails:** yes

Enabling the **Redirect files to disk** setting in the **Settings -> System -> Performance** section could also be helpful.

You can find more details on file management in the [Where the files are stored](#) topic.

7.3.5 Troubleshooting performance issues

If you encounter performance issues, please try to follow these steps to make sure that your system is optimized for best performance:

1. Make sure you're using the latest version of Kentico CMS

We improve the performance with every new release. Especially the 2.0 and 2.1 versions didn't provide a very good performance. You can find the version number in the lower right corner of Kentico CMS Desk -> Content dialog or on the logon screen of the administration interface.

2. Make sure caching is configured on your website.

Go to **Site Manager -> Settings**, choose the appropriate website in the **Sites** drop-down list and choose the **System -> Performance** category. Make sure the values are set like these:

- **Cache content** ≥ 0
- **Cache images** > 0 , at least 10 minutes recommended (images are automatically removed from the cache and reloaded if you modify them)
- **Always set Cache page info** > 0 , at least 10 minutes recommended (page data is automatically

removed from the cache and reloaded if you modify it)

3. Try configuring full-page caching

Full-page caching is the most powerful caching option. Once the page is cached in the memory during the first view, it's displayed without contacting SQL server and running the page code. You can configure full-page caching in **CMS Desk -> Content -> Properties -> General -> Cache**.

The page is automatically removed from the memory and reloaded when you modify it's content. Please note that the performance improvement will be visible only during the second load of the page.

4. Turning off output filters

In special cases, the website may be slowed down by output filters. Go to **Site Manager -> Settings**, choose the appropriate website in the **Sites** drop-down list and choose the **System -> Output filter** category. You can try to temporarily turn off all output filters by setting the following values to / (slash), which will disable the given filter for the whole website:

- **Excluded output form filter URLs**
- **Excluded resolve filter URLs**
- **Excluded XHTML filter URL**

If it helps, please contact us and we will help you find a workaround (if possible).

5. Configure file caching

Displaying files stored in Kentico CMS repository may require lots of CPU time and may harm the overall website performance. Please try to configure these values in the **Site Manager -> Settings -> System -> Files** section (your web application needs to have Modify permissions on the disk):

- Generate thumbnails: yes
- Redirect files to disk: yes
- Store files in file system: yes

6. Check your code

If you integrated any custom .NET code into the website, please make sure it works properly. Please be sure to avoid too many database operations and be sure to close the database connections properly. Try to comment out your code and see if it improves the performance.

7. Check your hardware

It's recommended that your system has at least 1 GB RAM and Pentium 4 or Pentium Core 2 Duo (or similar) processor.

8. Check the other applications/websites running on the same server

Whether you use your own server or shared hosting, make sure that the other applications do not take all the server performance. It's highly recommended that you run Kentico CMS in a **separate application pool** on Windows Server 2003.

9. Setting application pool Idle time-out in IIS

If your website is accessed not very frequently (less than every 20 minutes by default), users may experience long delays on first access to the site. To prevent this, you need to set the **Idle time-out (minutes)** property of the application pool to a higher value. This property can be accessed through:

IIS 6: open **IIS Manager -> select <machine>/Application Pools ->** right click the application pool -> select **Properties -> switch to the Performance tab -> set the Shutdown worker process after being idle for (time in minutes)** to a higher value or disable the option completely by unchecking

the box

IIS 7: open **IIS Manager** -> select **<machine>/Application Pools** -> right click the application pool -> select **Advanced Settings** -> the property is located in the **Process Model** section

If the above mentioned settings don't help, please send us an exported copy of your website and we will try to analyze it.

7.3.6 Caching in custom code

In the following code extract, you can see how a *CachedSection* object can be used to cache data in your custom code. It checks if the item is in the cache (it also handles if the item should be cached or not based on the given cache minutes and boolean result of a specified condition). If it is in the cache, it returns the item, if not, it reports that the data should be loaded, you handle the loading and put the result back to the object. Then, the object stores the data to the cache automatically.

```
using CMS.SiteProvider;
using CMS.GlobalHelper;

private void CachingExample()
{
    DataSet data = null;

    // Cache the data for 10 minutes with key "mykey"
    using (CachedSection<DataSet> cs = new CachedSection<DataSet>(ref data, 10,
true, null, "mykey"))
    {
        if (cs.LoadData)
        {
            data = UserInfoProvider.GetAllUsers(); // Get data from database
            cs.CacheDependency = CacheHelper.GetCacheDependency("somekey"); //
Cache dependency
            cs.Data = data; // Save data to cache
        }
    }
}
```

7.4 Cookies

7.4.1 Overview

The cookie law consent functionality was implemented because of the Cookie law (you can find more information at <http://www.ico.gov.uk/>), which is in effect in some European countries and which requires website developers to ask site visitors for consent with using cookies.

We divided cookies that Kentico CMS uses into several [cookie levels](#) according to their importance in the system. We also created three main levels designed for you to be able to comply with the law regulations quickly and easily.

To display a text message and buttons asking for site visitors' consent with storing cookies on their computers, you can use two provided [web parts](#). With the preconfigured **Simple cookie law consent**

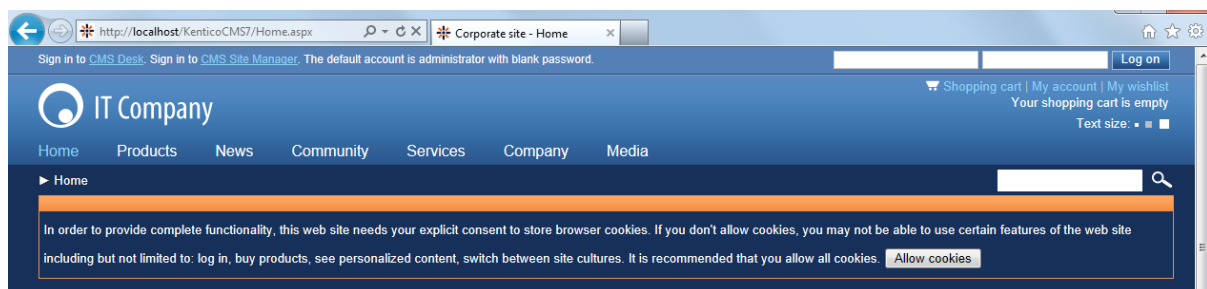

web part, you can introduce the consent on your website quickly and easily.

For the information to be complete, we provide a [list of all cookies](#) that Kentico CMS may currently use with assigned levels and a brief description.

If you need details about cookies API, you can find more information in the [Cookie Law Support in Kentico CMS 6](#) blog post.

How to quickly include a cookie consent in your website

1. Navigate to a page and zone, where you want to place the message of the consent.
2. Choose the **Simple cookie law consent** web part under the **General -> Cookies** category in the web part catalog.
 - You are not required to configure any settings. It can be useful though, to visually separate the text from the rest of the content using a web part container (e.g, **Orange box**).

7.4.2 Cookie levels

We divide cookies into several levels to differentiate their purpose and to provide the option of setting a certain cookie level for the user. We provide more levels than you probably need in order to offer more options for configuration and future updates. These are the default levels available in Cookie helper API (CookieLevel class):

- **None (-1000)** - Absolutely no cookies are allowed, including the cookie indicating the cookie level that the user chose. This makes sense only in the case when you want to disable absolutely every cookie by default.
- **System (-100)** - This level allows the session cookie (due to security on postback), and CookieLevel cookie which remembers the cookie level that the user chose. In terms of the end user and the Cookie law, this means "Cookies are not allowed"
- **Essential (0)** - Cookies which are required for all website functionality needed by site visitors. This includes authentication, shopping cart, votes in polls etc. From the visitor's perspective, this means "Allow only cookies that I may need, but do not track me".
- **Editor (100)** - Cookies which are needed for the admin UI to work properly. This mainly includes the view mode, remembering tabs and sliders and a few others.
- **Visitor (200)** - All cookies which aren't assigned to any explicit level (which also includes your custom cookies if you use any) are considered to be cookies identifying the visitor, i.e. user tracking cookies, which are not really needed, but are useful for the site owner if using EMS.
- **All (1000)** - This is a system level, not a particular cookie level. This level allows all cookies, no matter what their level is. From the site visitor's perspective this means "Allow all cookies now and in the future".

The numbers associated with each cookie level are integer constants, which allow you to further customize the levels or make custom levels in case you need it. Also for this reason, the levels "None" and "All" have an absolute value of 1000 to provide enough space for potential future updates.

For simplicity, we created 3 main levels, which represent choices to be offered to the user when asking for the user's consent with the cookies:

- **No cookies** (level System) - Enables the minimum cookies required for the website to work, and remembers whether the user allows cookies or not.
- **Only essential cookies** (level Essential) - Enables all cookies required for website functionality, but no tracking cookies.
- **All cookies** (level All) - Enables all cookies used in the website.

These three levels are also used in the provided cookie web parts.

Administrator and cookies

If a user logs in to admin UI, all cookies are automatically enabled for the user to provide full editing functionality. We expect that login to admin UI identifies the user as staff; therefore there is no need for cookie consent in this case.

7.4.3 Available web parts

To offer the user an option to choose the desired level of allowed cookies, you can use these two web parts. Technically, it is a single web part implemented in `~/CMSWebParts/General/CookieLaw.ascx` and the "simple" one is just a preconfigured version of the same web part. These web parts are not visually designed, and you need to update your CSS style to get the desired look and feel.

You can find both of these web parts under the **General -> Cookies** category in the web part catalog.

Cookie law consent

This web part can be used to ask a user for a consent with using cookies. It offers three levels to choose from (as described in [Cookie levels](#) topic) - **No cookies**, **Only essential cookies** and **All cookies**. On each level, actions to switch to the remaining levels are offered. You may customize the text messages, available actions as well as button texts.

The option **Compare current cookie level to** is a basis for other settings in the web part. It defines a level to which the user's current cookie level is compared. Then, according to this setting, three states with their own settings are defined: One state is when the current level is below the compared level, the second when the level exactly matches it, and the third when the current level is above the compared level. This should give you enough options to configure the web part to suit your needs.

Note that changing the cookie level works only in the live site mode, as you do not need to clear your cookies in the design mode. For designing purposes, there is another property which simulates the user level in the Edit and Preview mode.

The default cookie level is currently not set in this web part so it keeps the level "All" as the starting level, but you may change this setting too.

Simple cookie law consent

This is a preconfigured version of the previous web part. It allows you to easily implement a simple cookie law consent. The preset behavior is: Disable cookies by default, request allowing, and once allowed, hide the web part.

Live site

Once you place the web part into your website, you might not see its message after switching to the Live site. The reason is that administrators have cookies enabled by default and the cookies are already stored on the computer you are working on. To check whether your configuration of the cookie web part is correct, log out of CMS Desk and clear all cookies in your browser. Or try the website in a different browser or computer.

7.4.4 Reference: Kentico CMS cookies

In the following table, you can find a list of cookies used in the system with their assigned [levels](#) and a brief description.

| Cookie name | Level | Description |
|-----------------------|------------------|--|
| CMSCookieLevel | System | Specifies which cookies are enabled by the visitor. |
| ASP.NET_SessionId | System | Keeps the user session ID for security reasons. |
| CMSPreferredCulture | Essential | Stores the visitor's preferred content culture . |
| CMSMobileRedirected | Essential | Indicates if the visitor has been redirected to the mobile version of the website by the Mobile device redirection web part. |
| CMSCurrentTheme | Essential | Stores the name of the current visual theme to provide proper design to the dialog windows. |
| Webauthtoken | Essential | Live ID authentication cookie. |
| CMSForumPostAnswer | Essential | Keeps a list of Question-Answer forum posts in which the user user voted for an answer to prevent repeated votes. |
| CMSVotedPolls | Essential | Keeps a list of polls where the user voted to prevent repeated votes. |
| CMSRatedDocuments | Essential | Keeps a list of documents that the user rated to prevent repeated votes. |
| CMSShowDesktopVersion | Essential | Indicates that the visitor has switched to the desktop (default) version of the website from a specific device profile. |
| .ASPXFORMSAUTH | Essential | Stores the user's encrypted authentication ticket when using forms authentication. |
| FormState | Editor | Form state flag to allow restoration of failed requests. |

| | | |
|---|----------------|---|
| CMSPreferredUICulture | Editor | Stores the preferred UI culture of the user. |
| CMSViewMode | Editor | Stores the user's current view mode (Edit, Preview, Design, etc.). |
| CMSUserWords | Editor | User's custom word dictionary kept by the spell checker. |
| DisplayContentInDesignMode | Editor | Remembers the user's setting of the <i>Display web part content</i> checkbox on the Design tab in CMS Desk. |
| CMSMacroDesignerTab | Editor | Remembers the last active tab of the macro designer . |
| CMSSiteFilter | Editor | Remembers the state of the site selector within the UI. |
| CMSSplitMode | Editor | Remembers the state of the language version split-view mode when editing multilingual websites. |
| CMSAnalyticsTab | Editor | Remembers the last active tab of the Analytics section in CMS Desk -> Content. |
| CMSPropertyTab | Editor | Remembers the last active tab of the Properties section in CMS Desk -> Content. |
| CMSPreviewState | Editor | Stores the user's latest page design preview preferences. |
| CMSViewTab | Editor | Remembers the last active tab of the View section in CMS Desk -> Content. |
| CMSValidationTab | Editor | Remembers the last active tab of the Validation section in CMS Desk -> Content. |
| CMSProductTab | Editor | Remembers the last active tab of the Product section in CMS Desk -> Content. |
| CMSEdVariantSliderPositions<templateid> | Editor | Remembers the position of the variant slider when defining variants for MVT or Content personalization . |
| CMSOnSiteButtonMinimized | Editor | Remembers if the user minimized the button used to open the website in On-site editing mode. |
| CMSWebPartToolbarCategory | Editor | Stores the selected web part category on the web part toolbar . |
| CMSWebPartToolbarMinimized | Editor | Remembers if the user minimized the web part toolbar on the Design tab. |
| CMSCurrentDeviceProfileName | Editor | Stores the selected device profile when editing documents. |
| CMSDeviceProfileRotate | Editor | Stores the rotation preferences applied in Preview mode when using device profiles . |
| CMSUniGraph | Editor | Stores the user's <i>Snap to grid</i> preference in the advanced workflow and marketing automation designer. |
| CMSSessionToken | Editor | Stores the token used by the web service that provides the advanced workflow and marketing automation designer. |
| VisitorStatus | Visitor | Indicates if the visitor is new or returning. Used for tracking the visitors statistic by the Web analytics module. |
| Campaign | Visitor | Stores the web analytics Campaign assigned to the |

| | | |
|------------------------------------|---------|---|
| | | visitor. |
| UriReferrer | Visitor | Stores the URL referrer from which the user arrives on the website. |
| CurrentContact | Visitor | Stores the GUID of the contact related to the current site visitor. Used to track activities on the website. |
| CMSAB<ABtestname> | Visitor | Stores the name of the page variant assigned to the visitor by an A/B test . Used to track conversions for the test and maintain consistent page content for the visitor. |
| CMSMVT<mvtestname> | Visitor | Stores the combination of variants assigned to the visitor by an MVT test. Used to track conversions for the test and maintain consistent page content for the visitor. |
| CMSNoTestMVT<templateid> | Visitor | Stores the currently selected MVT combination for editors in the administration interface. |
| CMSShoppingCart | Visitor | Stores a reference to the user's active shopping cart. |
| CMSBodyClass | Visitor | Body element class to provide accessibility standards. |
| CMSEd<GUID>Current | Visitor | Stores the current step of Wizard layout web parts. |
| ChatLoggedInToken | Visitor | Stores the login state for the Chat module (indicates if the user is in the online state). |
| ChatSupportLoggedInToken | Visitor | Indicates if the user is logged in to the support chat. |
| <Window name>_<Group ID>_roomId | Visitor | Stores bindings between groups of chat web parts and chat rooms (for a specific window or tab). |
| chat_autoinitchat_displayed_<GUID> | Visitor | Remembers if the <i>Automatically initiated chat</i> web part was shown to the user (prevents multiple chat initiation messages). |
| chat_kick_roomid_<room ID> | Visitor | Indicates that the user was kicked from the specified chat room (and is not allowed to return). |

7.5 CSS stylesheets and design

7.5.1 Overview

CSS stylesheets allow you to modify the appearance and design of your website. You can use standard [CSS styles](#) with Kentico CMS just like you normally would during website development.

Every website has a **default CSS stylesheet**. To assign it, edit (✎) a site in **Site Manager -> Sites** and select an option from the **Site CSS stylesheet** field.

Individual pages can either use the default website stylesheet or override it with their own stylesheet. The stylesheet used by a specific page can be configured in **CMS Desk -> Content -> Properties -> General**, through the **CSS stylesheet** selector. The stylesheet assigned to a page is automatically requested when the given page is displayed.

CSS styles may also be defined for various types of components that can be placed on pages. Please see the [CSS for page components](#) topic for further information.

You can check individual pages to detect if the styles they use are valid against the CSS 2.1 standard. For more information, see [Content management -> Validators -> CSS validator](#).

Tip

You can create stylesheets using the [LESS](#) dynamic language. LESS syntax allows you to write stylesheets that are shorter and easier to maintain.

Download the free [LESS stylesheets](#) module from the Kentico Marketplace.

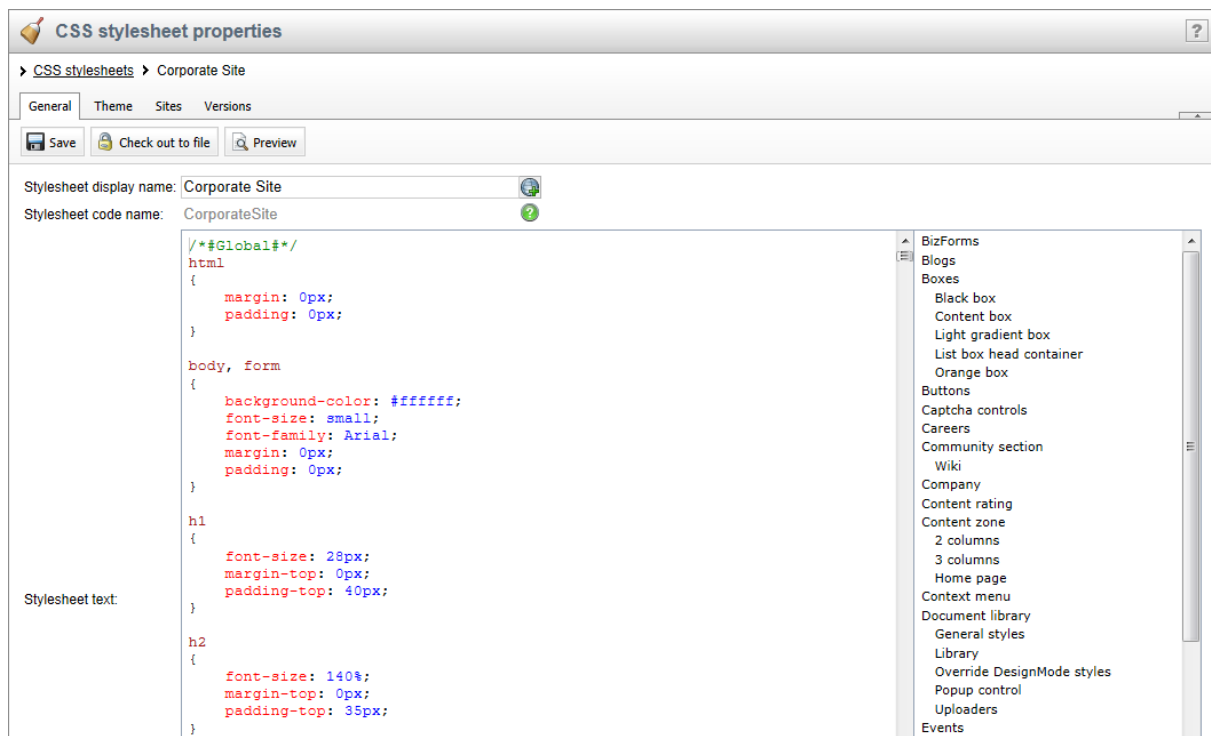

Creating and managing stylesheets

You can create and manage CSS stylesheets in **Site Manager -> Development -> CSS stylesheets**.

| Actions | Display name ^ | Code name |
|---------|--------------------------------|----------------------|
| | Community Site | CommunitySite |
| | Corporate Site | CorporateSite |
| | Corporate Site - Mobile device | CorporateSiteMobile |
| | Corporate site printer styles | CorporateSitePrinter |
| | My site stylesheet | MySite |
| | Personal Site | PersonalSite |
| | Personal Site - Blue | PersonalSiteBlue |
| | Personal Site - Green | PersonalSiteGreen |
| | Personal Site - Red | PersonalSiteRed |

When editing () a stylesheet, the following property fields are available on the **General** tab:

- **Stylesheet display name** - name of the stylesheet displayed in the administration interface.
- **Stylesheet code name** - a unique name used to identify the stylesheet in code and URLs.
- **Stylesheet text** - here you can enter the definitions of the classes that should be included in the stylesheet (using standard CSS code). This field uses the [code editor](#) to make working with the code more user-friendly. You can click the *Preview* button in the tab's header to edit the stylesheet's code side-by-side with a preview of how it affects the design of the website's pages. Please see the [Design preview](#) topic for additional details about the preview mode.

The **Theme** tab allows the management of files used by the edited stylesheet, such as external stylesheets, images or skin files. More information about associated files can be found in the [App themes](#) topic.

A stylesheet must also be assigned to particular websites on the **Sites** tab.

Stylesheets can also be created or edited directly in **Site Manager -> Sites -> edit (✎) a site**. New stylesheets can be created by clicking the **New** button or by selecting (**new stylesheet...**) from the **Site CSS stylesheet** drop-down list. If an existing stylesheet is selected from this drop-down list, you can edit its code by clicking the **Edit** button.

Site properties

> Sites > Corporate Site

General Domain aliases Cultures Off-line mode

Site display name: Corporate Site

Site code name: CorporateSite

Site domain name: localhost

Live URL: [/KenticoCMS4253.14802/default.aspx](#)

Published: Yes

Stylesheet URL

You can view the code of any stylesheet using a URL in the following format:

```
<domain>/CMSPages/GetCSS.aspx?stylesheetname=<stylesheet code name>
```

The **GetCSS.aspx** system page retrieves unmodified, user-friendly stylesheet code even if [Minification](#) of stylesheet resources is enabled.

Browser and language-specific styles

Pages automatically have CSS classes assigned to their `<body>` element according to the characteristics of their [language](#) (its text direction and specific culture) and depending on the browser in which they are currently viewed. For example:

```
<body class="LTR IE IE9 ENUS">
```

As you can see, four types of classes are added:

- **Text direction** - the *LTR* class is assigned for left-to-right languages and *RTL* for right-to-left.
- **Browser type** - this class is added according to the browser in which the page is currently opened. The following classes are used:

| Browser | Class name(s) |
|-------------------|----------------|
| Internet Explorer | IE |
| Firefox | Gecko |
| Google Chrome | Chrome, Safari |
| Safari | Safari |
| Opera | Opera |

- **Browser version** - the class name is the same as for the browser type, but with the number of the browser's major version appended, e.g. *IE9*, *Gecko5* etc.
- **Culture** - the name of the class is added based on the culture code of the page's content (without the hyphen), for example *ENUS* for pages using the *en-US* culture.

This feature allows you to style page elements differently according to the browsing environment of the current visitor. You can define styles for any combination of the classes mentioned above.

For example, you can add the following into a website's stylesheet:

[CSS]

```
.IE8 .MyFont
{
    font-size: 20px;
}

.Opera .MyFont
{
```

```
font-size: 18px;
}
```

Now elements styled using the *MyFont* class will have a different font size when viewed in the Internet Explorer 8 or Opera (all versions) browsers.

Using CSS blocks for easier navigation in CSS code

You can use comments in format `/* #BLOCKNAME# */` to make navigation in the CSS code of long stylesheets easier. This creates a code block within the stylesheet and adds a bookmark to the list on the right side of the code editor. Blocks may be organized into a hierarchy of sub-blocks by separating the names of individual levels using a slash, such as for example `/* #BLOCKNAME/SUBBLOCK# */`.

Example:

[CSS]

```
/* #Menu# */

// some CSS code

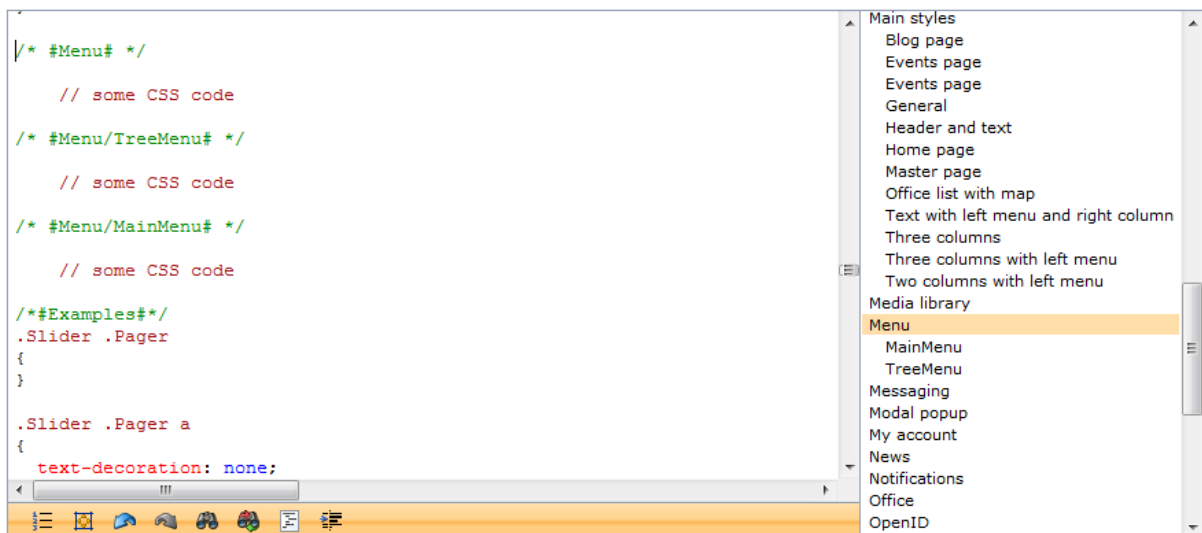

/* #Menu/TreeMenu# */

// some CSS code

/* #Menu/MainMenu# */

// some CSS code
```

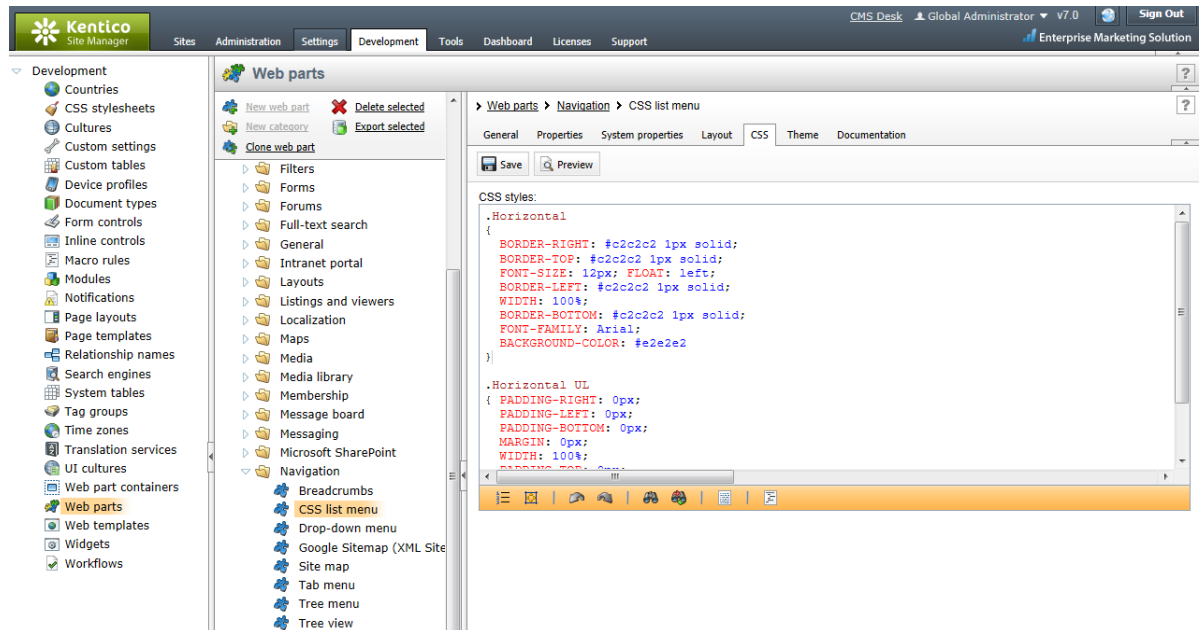

The outlined structure will look like this:

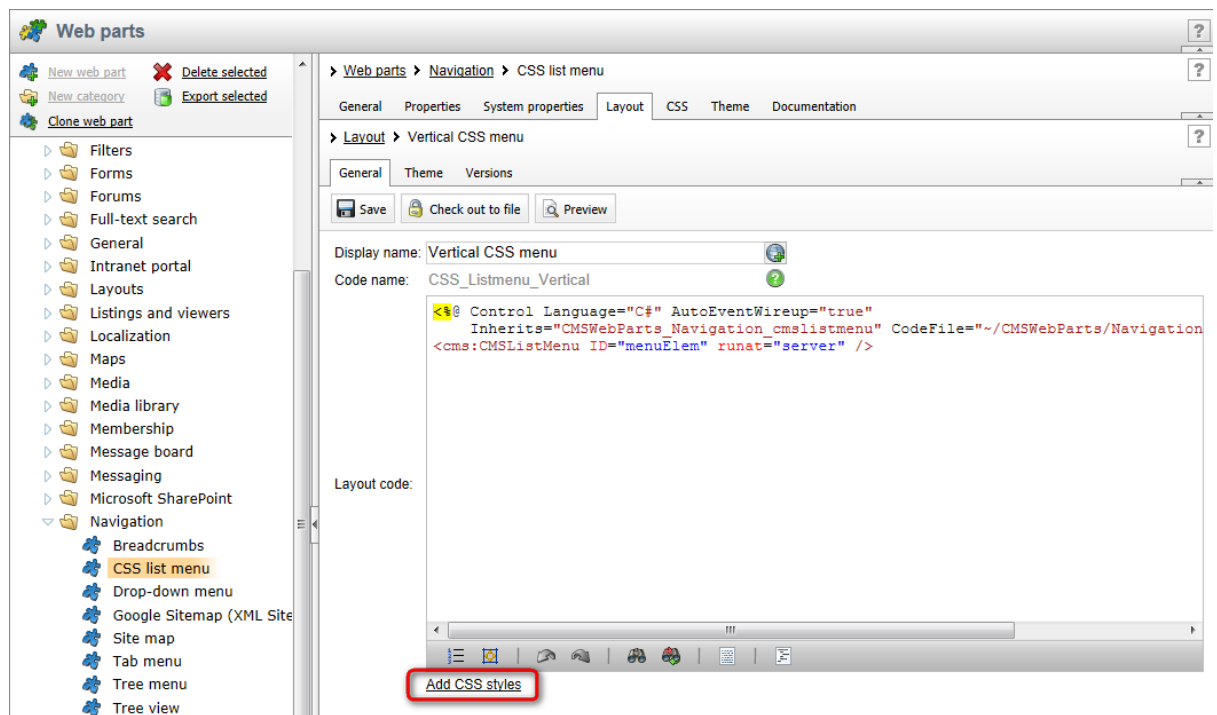

7.5.2 CSS for page components

In addition to the main stylesheet objects that can be assigned to sites or individual pages, it is possible to specify CSS styles directly for various types of components that make up the content of pages. This includes the following types of Kentico CMS objects:

- **Web parts** - CSS styles can be added to a [Web part](#) by editing it in *Site Manager* -> *Development* -> *Web parts* on its *CSS* tab. These styles will then be requested on pages containing the given web part.

- **Web part layouts** - to define styles for a specific [Web part layout](#), navigate to the *Layout* tab of the given web part's configuration interface, edit (✎) the layout and click the [Add CSS styles](#) link below the layout code editor.

The *CSS styles* field will be displayed, where you can add any required CSS classes. The styles entered here will only be requested on pages that contain a web part using the specific layout.

- **Web part containers** - to manage the styles of [Web part containers](#), go to *Site Manager -> Development -> Web part containers*, edit the given container and click the [Add CSS styles](#) link. The entered styles will be loaded by pages where the container is used.
- **Transformations** - when editing the [Transformation](#) of a document type or custom table, you can define its CSS styles by clicking [Add CSS styles](#) below the transformation code editor. These styles will be requested on pages where the given transformation is used to display data (e.g. through a viewer web part).
- **Shared (pre-defined) page layouts** - CSS styles can be added to [Page layouts](#) in *Site Manager -> Development -> Page layouts*, where the [Add CSS styles](#) link is available when editing a specific layout. Once the shared layout is assigned to a [Page template](#), the specified styles will be loaded on all pages that use the given template.
- **Custom page layouts for specific page templates** - in many cases, page templates use a custom page layout that is unique for the given template. To add CSS styles to this type of template, edit it in *Site Manager -> Development -> Page templates*, switch to its *Layout* tab and click [Add CSS styles](#) below the code of the custom layout.
- **Custom device layouts of specific page templates** - page templates support the creation of custom [page layouts for specific device profiles](#). To add CSS styles to device layouts, edit the template in *Site Manager -> Development -> Page templates*, open the *Device layouts* tab, edit the device layout and click [Add CSS styles](#) below the code of the custom layout.

When a page is displayed in a user's browser, the system loads the assigned stylesheet (as described in the [Overview](#) topic) and then requests any styles defined for the components used on the given page. The final stylesheet available for the page is a combination of the main stylesheet and all component

styles. If any of the components contain an alternative definition for a CSS class that already exists in the main stylesheet, then the component style has a greater priority and overrides the original class.

By defining styles directly for components, you can reduce the size of your site (or page) stylesheets and organize them into more manageable sections. It also means that pages need to load less total CSS data, since each page only has to request styles for those components that are actually used on it. Additionally, the styles of components are automatically exported and imported along with the corresponding objects, which makes it easier to deploy them to websites that use a different stylesheet. The disadvantage of this approach is that at least one additional resource request must be added to pages containing styled components to ensure that all required CSS code is loaded.

Configuring component CSS

There are two global settings that affect the behavior of component CSS on all sites in the system. You can configure them in **Site Manager -> Settings -> System -> Performance** (only available if the *global*) option is selected from the **Site** drop-down list).

The screenshot shows the Kentico Site Manager interface. The left sidebar contains a navigation tree with 'Settings' expanded, and 'Performance' selected. The main content area displays several configuration sections: 'Server file caching', 'Client caching', 'Output caching', 'Resources', and 'CSS Styles'. In the 'CSS Styles' section, the 'Allow CSS from components' and 'Combine CSS from components' settings are checked and highlighted with a red rectangular box. The 'Export these settings' link is visible at the bottom of the settings area.

The **Allow CSS from components** setting indicates if the styles of components should automatically be requested by the pages where they are placed. This is enabled by default. If disabled, it is necessary to either have all styles defined directly in the main stylesheet, or to link the styles of the required components into the stylesheet via CSS macros. Component styles may be linked into other stylesheets using the following expressions, depending on their type:

- `{%CSS.WebParts["<web part code name>"]%}`
- `{%CSS.WebPartLayouts["<web part code name>.<layout code name>"]%}`
- `{%CSS.Containers["<container code name>"]%}`

- `{%CSS.Transformations["<full transformation name>"]%}` - the transformation name must include the class name of the parent document type or custom table, for example:
CMS.News.Preview
- `{%CSS.Layouts["<page layout code name>"]%}`
- `{%CSS.Templates["<page template code name>"]%}`

These macros are dynamically resolved into the CSS content defined for the specified component. The **Resolve macros in CSS** setting must be enabled if you wish to link styles using macros.

Style priority

Please note that component styles do not automatically take priority when linked through macros. The styles that are processed last (i.e. those which are "lower" in the code) are applied to the page.

As a result, it is recommended to place the linking macros below all other code in the given stylesheet if you want your components to override the definitions of existing CSS classes.

If **Combine CSS from components** is enabled, pages will load the CSS styles of all contained components via a single request. Otherwise, different types of components will each generate a separate request. The styles of multiple components of the same type (e.g. several web parts) are always retrieved by one request. Combining CSS requests may improve the load time of individual pages and is recommended in most cases.

7.5.3 App themes

When creating styles for your websites, you may leverage the built-in support for [ASP.NET themes](#). You can use them to set styles for controls that do not have their own CSS class name, such as the *Datagrid* or *Calendar*.

Themes must be defined in a folder located under the **App_Themes** directory. The name of this folder needs to be the same as the code name of the used CSS stylesheet. For example, if you use the *Green* stylesheet on your site, your themes must be stored in the *App_Themes\Green* sub-folder.

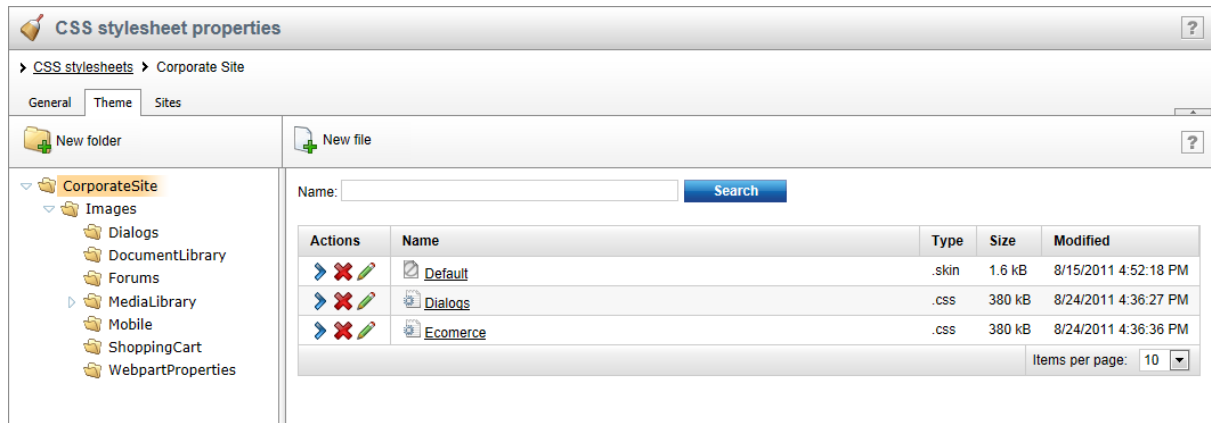

Skins for your controls need to be added to the **Default.skin** file under this folder. Here's an example of a skin for the **CMSCalendar** control / **Calendar** web part:

```
<cms:CMSCalendar Runat="server">
  <NextPrevStyle ForeColor="Red"></NextPrevStyle>
  <WeekendDayStyle BackColor="#E0E0E0"></WeekendDayStyle>
</cms:CMSCalendar>
```

Website design files

It is recommended to store all image files, flash movies and other resources that are part of the website design template under the theme folder of the stylesheet that uses them. This ensures that the files are exported together with the stylesheet if you deploy it to some other server.

The content of a stylesheet's theme folder may be managed directly from the administration interface in **Site Manager -> Development -> CSS stylesheets** by editing (✎) the given stylesheet and switching to the **Theme** tab.

Only file formats commonly used by CSS stylesheets are displayed here. This includes files with the following extensions:

.css, .skin, .gif, .png, .bmp, .jpg

Individual files of all types can be edited (✎). Text files (.css or .skin) can be modified using an editor with syntax highlighting support and images are opened in the built-in [Image editor](#).

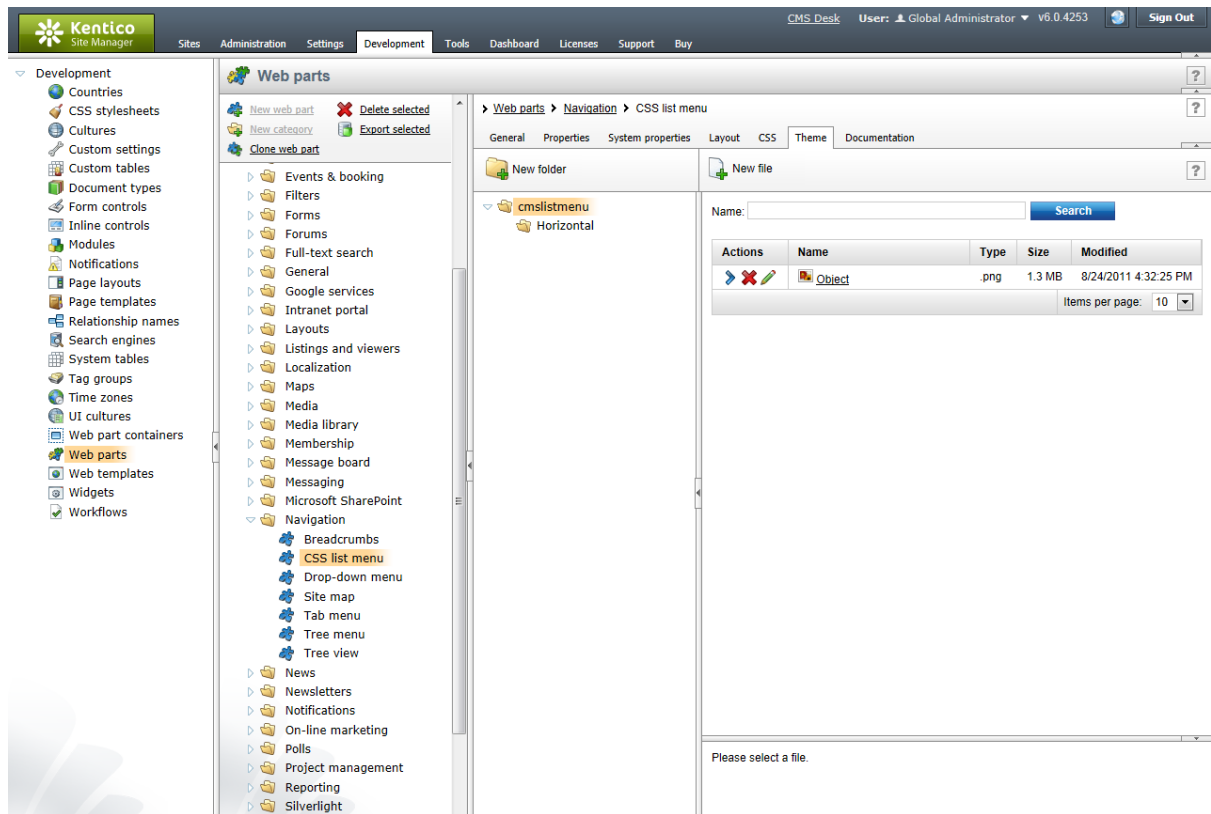

Themes folders for component styles

Design files may also be stored separately for the CSS styles assigned to the page components described in the [CSS for page components](#) topic. The theme folders of these components are located under the **App_Themes\Components** directory. Further sub-folders depend on the type of the given component:

- **WebParts\<web part code name>**
- **WebParts\<web part code name>\Layouts\<layout code name>**
- **Containers\<container code name>**
- **Transformations\<class name>\<transformation name>**
- **Layouts\<layout code name>**
- **PageTemplates\<template code name>**

Just like for stylesheets, it is recommended to store all required files in the appropriate theme folder for each component. The files in the theme folders are automatically exported and imported along with the objects representing the given component.

The content of these theme folders may be managed directly from the administration interface through the same type of dialog that is used for CSS stylesheets. It can be accessed on the **Theme** tab, which is available when editing any of the component types in **Site Manager -> Development**.

7.5.4 Printer friendly CSS styles

This chapter explains how to use printer friendly CSS styles on your website. These styles are used only if a document is sent to a printer.

1. Create a new CSS stylesheet in **Site Manager** -> **Development** -> **CSS stylesheets**, name it *Printer styles* and set its code name to *Printer_styles*, for example. See the simple example below for an illustration of the printer friendly CSS styles created for our default sample **Corporate site**.

[CSS]

```
.zoneLeft, .zoneRight, .zoneTopInfo, .zoneTop, .horizontalmenu, .zoneBottom
{
    display: none;
}
.eventCalendarDetail .zoneLeft, .eventCalendarDetail .zoneRight
{
    display: block;
}
.eventCalendarDetail .zoneRight
{
    float: left;
}
.logonReg .zoneLeft, .logonReg .zoneRight
{
```

```
        display: block;
    }
    .logonReg .zoneRight
    {
        float: left;
    }
    .zoneContent
    {
        float: left !important;
    }
}
```

Please note that you have to hide all the elements that should not be visible in the print version. You can do this by adding **display:none**; to the given style.

2. Add a link to this CSS stylesheet into the *<head>* tag of your master page. This can be done by selecting the root document of your website in **CMS Desk -> Content -> Edit** and switching to the **Master page** tab. For example:

```
<link href="CMSPages/GetResource.ashx?stylesheetname=Printer_styles" type="text/css" rel="stylesheet" media="print" />
```

7.5.5 Print page

Kentico CMS allows you to add a link button to your web page that will create print version of the given document. The following example shows you on the sample Corporate Site how to create the given button for the news section.

1. Go to **CMS Desk -> Content -> News**, switch to the **Design** tab and click the **Add web part (+)** button of the **Main zone** web part zone.

The screenshot displays the Kentico CMS Desk interface. The top navigation bar includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The left sidebar shows a tree view of the 'Corporate Site' with folders for Home, Services, Products, News, Partners, Community, Company, Media, Examples, Mobile, Other, Special Pages, and Images. The main content area shows a preview of a news article titled 'News' under the 'Main zone'. The article content includes a header, a description, a news filter, and a news list. The news list shows a single entry: 'Community Website Section' by Brad Summers, dated 6/29/2011 12:00:00 AM. The article text reads: 'As a result of our continuous effort to improve our services, we have recently introduced the [Community](#) section of our website. It is a place where you can both receive interesting information about the company from various communication channels and express your opinions and thoughts yourselves.'

2. Select Text & Images -> Static Text.

The screenshot shows the 'Select web part' dialog box. The left sidebar lists various web part categories, with 'Text & Images' selected. The main area displays a grid of web part options: Editable image, Editable text, Link / Button, Paged text, QR Code, Static HTML, Static text, and Text highlighter. The 'Static text' web part is highlighted with a yellow border. Below the grid, the 'Static text' web part is selected, and its description is shown: 'The Static text web part allows developers to enter plain text content and renders it on the live site version of the page. Unlike with the Editable text web part, page editors cannot modify the content.'

3. In the web part properties, enter *PrintLink* as the **Web part control ID** and choose **CMS.News** in the **Show for document types** property. Then enter the following code into the **Text** field and click **OK**.

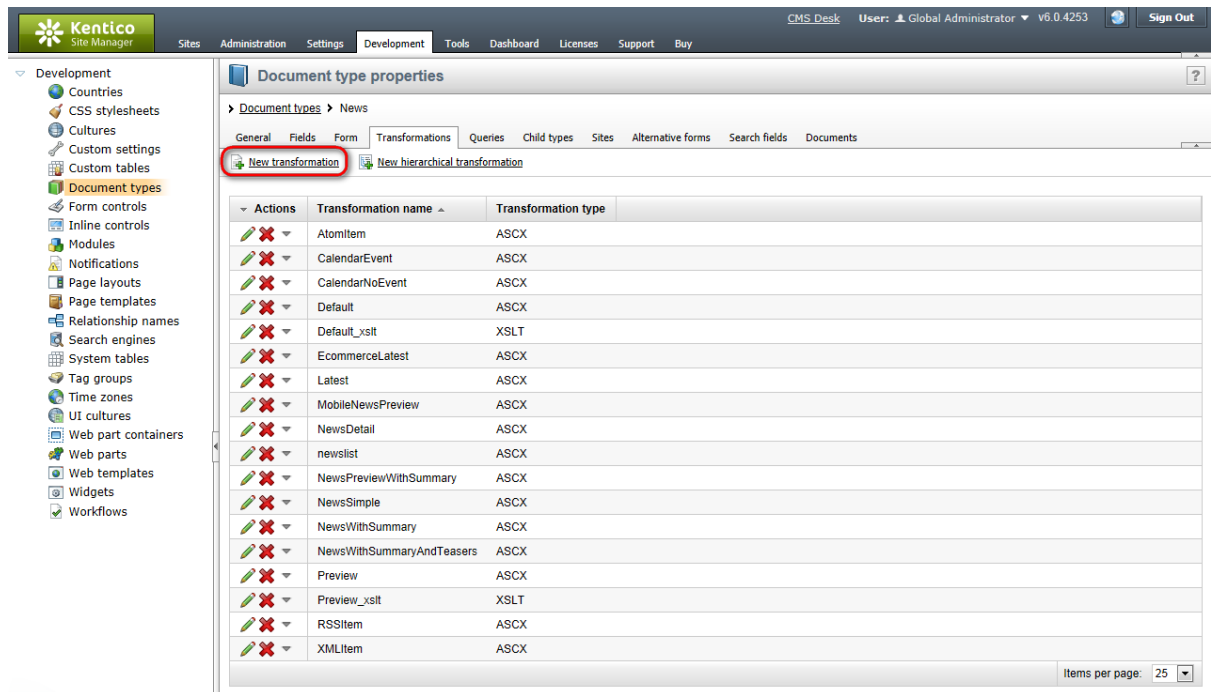

```
<div class="PrintLink">
  <br />
  <a href="~/SpecialPages/E-Shop/Print.aspx?printpath={%NodeAliasPath%}
  &classname={%ClassName%}" target="_blank" >
    
    Print
  </a>
</div>
```

The screenshot shows the 'Web part properties (Static text)' dialog box with the following settings:

- Default:** Web part control ID* is set to `PrintLink`.
- Visibility:** Visible is checked. Show for document types is set to `CMS.News`.
- Content:** The text field contains the HTML code from the previous block.

At the bottom, the 'OK' button is highlighted in green.

4. Now you need to create the print transformation for the News document type. Go to **CMS Site Manager** -> **Development** -> **Document types** and click the **Edit** (✎) button next to the **News** document type. Switch to the **Transformation** tab and click **New Transformation**.

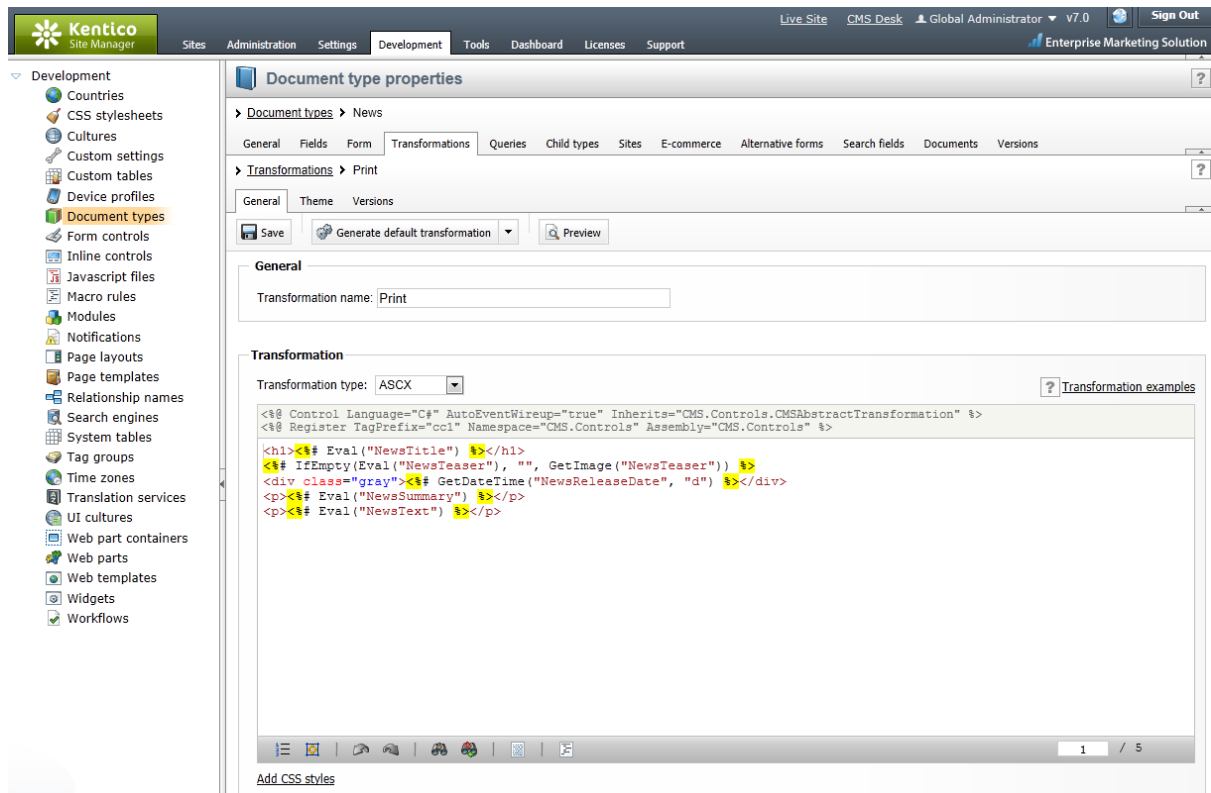

The screenshot shows the Kentico CMS 7.0 Developer's Guide interface. The 'Development' menu is open, and the 'New transformation' button is highlighted with a red circle. The 'Document type properties' window is open, showing the 'Transformations' tab. The table below lists the existing transformations.

| Actions | Transformation name | Transformation type |
|---------|---------------------------|---------------------|
| | AtomItem | ASCX |
| | CalendarEvent | ASCX |
| | CalendarNoEvent | ASCX |
| | Default | ASCX |
| | Default_xslt | XSLT |
| | EcommerceLatest | ASCX |
| | Latest | ASCX |
| | MobileNewsPreview | ASCX |
| | NewsDetail | ASCX |
| | newslist | ASCX |
| | NewsPreviewWithSummary | ASCX |
| | NewsSimple | ASCX |
| | NewsWithSummary | ASCX |
| | NewsWithSummaryAndTeasers | ASCX |
| | Preview | ASCX |
| | Preview_xslt | XSLT |
| | RSSItem | ASCX |
| | XMLItem | ASCX |

5. Type *Print* as the **Transformation name** and copy the following content into the code editor.

```
<h1><%# Eval( "NewsTitle" ) %></h1>
<%# IfEmpty(Eval( "NewsTeaser" ), " ", GetImage( "NewsTeaser" )) %>
<div class="gray"><%# GetDateTime( "NewsReleaseDate", "d" ) %></div>
<p><%# Eval( "NewsSummary" ) %></p>
<p><%# Eval( "NewsText" ) %></p>
```

Click **Save**.

The screenshot shows the Kentico Site Manager interface. The left sidebar contains a navigation menu with categories like 'Development', 'Form controls', and 'Workflows'. The main area is titled 'Document type properties' and is currently showing the 'Transformations' tab for a 'News' document type. A 'Print' transformation has been created. The transformation type is set to 'ASCX'. The transformation code is as follows:

```
<%@ Control Language="C#" AutoEventWireup="true" Inherits="CMS.Controls.CMSAbstractTransformation" %>
<%@ Register TagPrefix="ctl" Namespace="CMS.Controls" Assembly="CMS.Controls" %>

<h1><# Eval("NewsTitle") </h1>
<# IfEmpty(Eval("NewsTeaser"), "", GetImage("NewsTeaser")) </div class="gray"><# GetDateTime("NewsReleaseDate", "d") </div>
<p><# Eval("NewsSummary") </p>
<p><# Eval("NewsText") </p>
```

6. Now, go back to **CMS Desk** -> **Content** -> **News** -> **New Consulting Services** and click the newly created **Print** button. You will be redirected to the Corporate site's **Print** page that displays the print version of the given news item.

New Consulting Services

6/5/2011

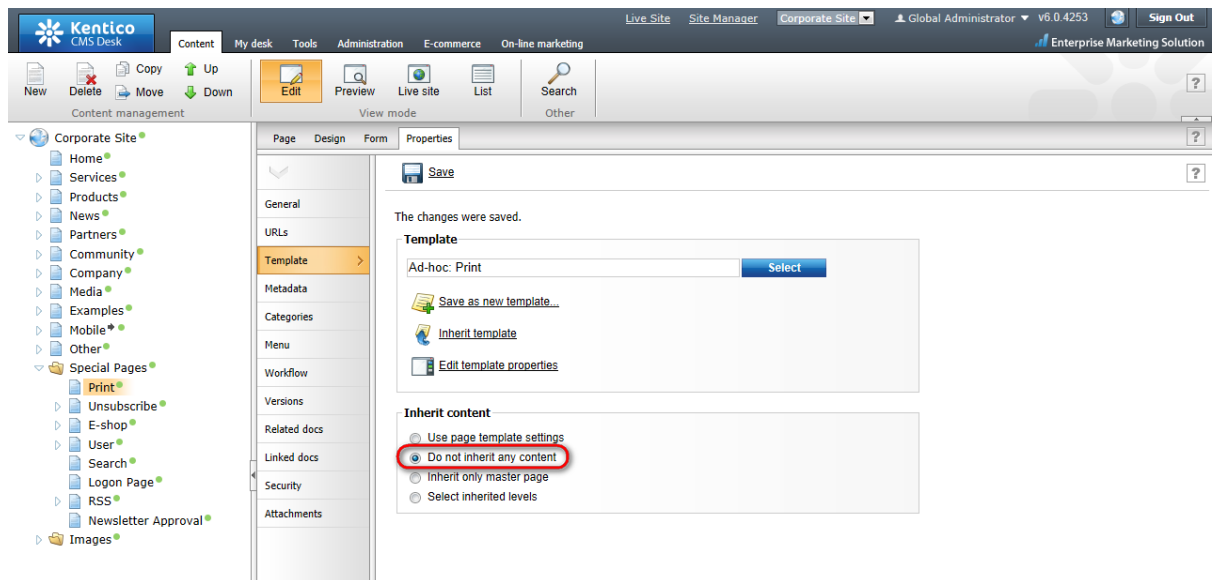

We are proud to announce that the range of services we provide was extended by web development consulting. The most department have been promoted to consultants and are here to help you with your web development projects.

We are proud to announce that the range of services we provide was extended by web development consulting. These ser coming from our web development team. With extensive professional background and hundreds of successful projects in tl your running or forthcoming web development projects. No matter how complicated your projects are or how tight are the u project into clear success.

Creating the Print page on your site

The **Print** page used in the previous example is already included as part of the sample Corporate Site. On your own website, you will have to create it by yourself. The following steps need to be taken in order for the Print page to be created:

1. Add a new **Page (menu item)** document under the **Special pages** folder. Name it **Print** and use the **Create a blank page** option when selecting the page template.
2. First, you have to disable content inheritance in **Properties -> Template**.

3. Every **Print** page should contain a Repeater web part that renders the **Print** transformation for the given document type. The transformation can be specified in **Site Manager -> Development -> Document Types -> <edit () document type> -> Transformations**.

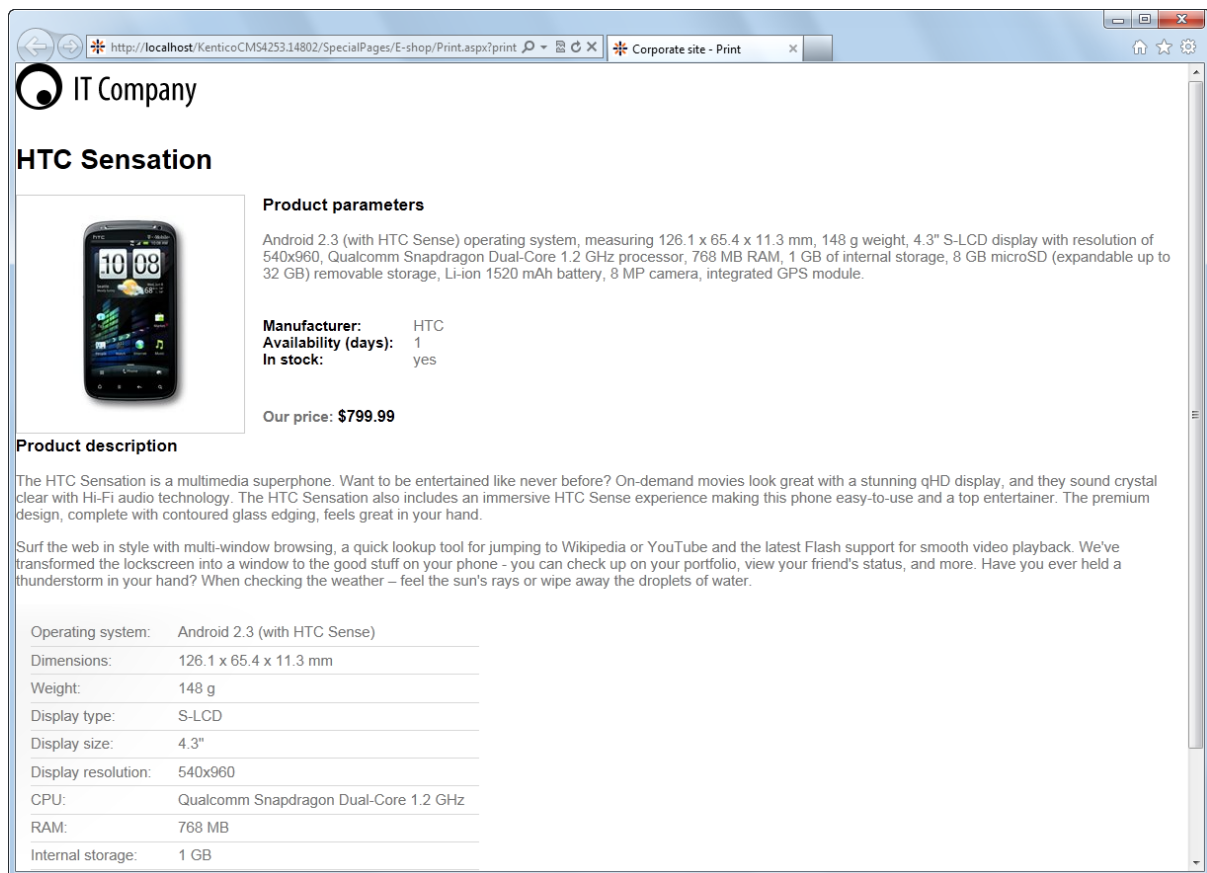

Therefore, add the **Repeater** web part and set its properties to the following values:

- **Path:** `{?printpath|/%?}`
- **Document types:** `{?classname|cms.root?}`
- **Transformation:** `{?classname|cms.root?}.print`

The **Path** property specifies the path to the document whose print version you want to make. The **Document types** specifies the document types that should be displayed. The **Transformation** property sets the name of the transformation that should be used to render the print version of the page.

The values above are macro expressions that load the actual values from the URL query string parameters included in the print link (*printpath* and *classname*). If no value is supplied in the URL (for instance if you go directly to the **Print** page from the content tree and not through the print link button), the default **Print** transformation for **cms.root** is displayed.

4. You can try out the functionality of the **Print** page by printing the detail of any product, because the **Print** link button is already created for all products on the Corporate Site.

7.5.6 Combining stylesheets

Kentico CMS allows you to easily combine the content of different stylesheets by entering special macros into stylesheet text. When such macros are resolved, they are replaced by the content of the specified stylesheet. This can be useful in certain situations, e.g. when creating a page-specific stylesheet as an extension of the main website stylesheet with some additional CSS classes.

You can link a stylesheet into the code of another one by inserting a special [macro expression](#) in the following format:

- `{% CSS["<stylesheet code name>"] %}`, e.g. `{% CSS["CorporateSite"] %}`
- `{% CSS.Stylesheets["<stylesheet code name>"] %}`, e.g. `{% CSS.Stylesheets["CorporateSite"] %}`

If the code name of the stylesheet does not contain any dots, you can also use the following simplified notation:

- `{% CSS.<stylesheetname> %}`, e.g. `{% CSS.CorporateSite %}`

Similarly, you can link [component stylesheets](#) the following way:

- `{% CSS.Containers["<web part container code name>"] %}`, e.g. `{% CSS.Containers["BlackBox"] %}`
- `{% CSS.Templates["<page template code name >"] %}`, e.g. `{% CSS.Templates["CorporateSite.HomePage"] %}`
- `{% CSS.WebParts["<web part code name>"] %}`, e.g. `{% CSS.WebParts["AbuseReport"] %}`

- `{% CSS.WebPartLayouts["<web part layout full name>"] %}`, e.g. `{% CSS.WebPartLayouts ["AbuseReport.MyCustomLayout"] %}`
- `{% CSS.Transformations["<transformation full name>"] %}`, e.g. `{% CSS.Transformations ["CMS.Article.Default"] %}`

The simplified notation can also be used if the component name does not contain any dots (web part layouts and transformations always contain dots in their full names, hence their stylesheets can only be linked using the notation above):

- `{% CSS.Containers.<web part container code name> %}`, e.g. `{% CSS.Containers.BlackBox %}`
- `{% CSS.Templates.<page template code name > %}`, e.g. `{% CSS.Templates.MyTemplate %}`
- `{% CSS.WebParts.<web part code name> %}`, e.g. `{% CSS.WebParts.AbuseReport %}`

Disabling resolving of CSS macros

Resolving of CSS macros is enabled by default, but can be disabled if needed via the **Resolve macros in CSS** setting in **Site Manager -> Settings -> System -> Performance** (only available if the *global* option is selected from the **Site** drop-down list).

Warning!

If you wish to disable the **Resolve macros in CSS** setting, it is first necessary to remove all occurrences of macros from your stylesheets. Unresolved macro expressions are not valid CSS code and as a result, the given stylesheets will not be processed correctly by browsers.

The screenshot shows the Kentico Site Manager interface. The 'Settings' tab is active, and the 'Performance' section is expanded. The 'Resolve macros in CSS' checkbox is checked and highlighted with a red box. Other settings include 'Cache output in file system (minutes)', 'Enable partial caching', 'Resources' (Allow resource compression, Allow JavaScript minification, Allow CSS minification), and 'CSS Styles' (Allow CSS from components, Combine CSS from components).

Using the @import directive

You can alternatively load the content of other stylesheets by adding the standard **@import** directive to the beginning of the stylesheet code, for example:

```
@import url(/KenticoCMS/CMSPages/GetResource.ashx?stylesheetname=corporatesite);
```

This may also be used to import external CSS stylesheets from static files under your web project, e.g.:

```
@import url(/KenticoCMS/CMSPages/GetResource.ashx?stylesheetfile=/KenticoCMS/
App_Themes/CorporateSite/Blue.css);
```

7.5.7 CSS stylesheet internals and API

7.5.7.1 Overview

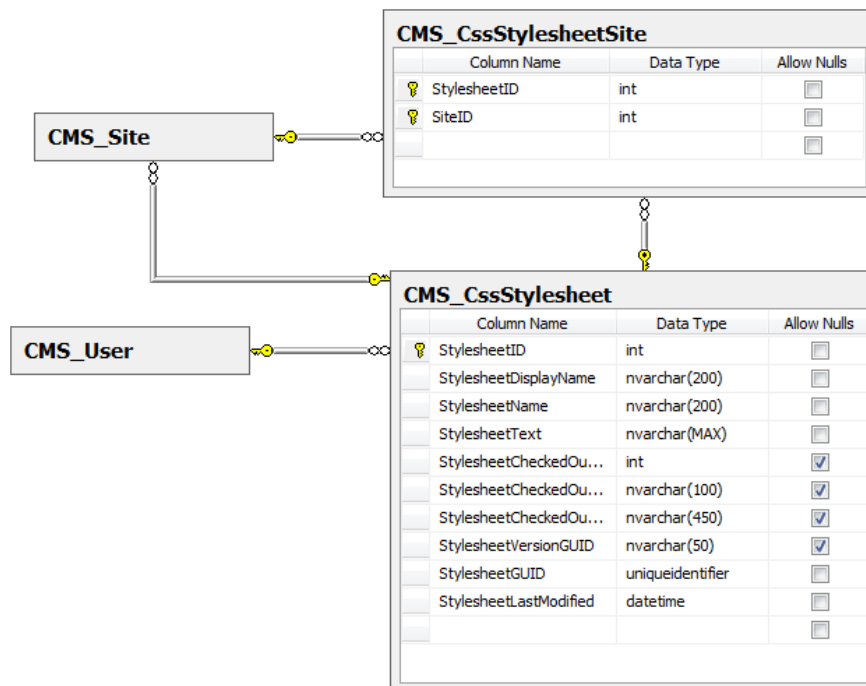

In this chapter, you will learn which [database tables](#) and [API classes](#) are used by CSS stylesheets. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module's classes, please refer to [Kentico CMS API Reference](#).

7.5.7.2 Database tables

The following database tables are used to store information about CSS stylesheets:

- **CMS_CssStylesheet** - contains records representing css stylesheets.
- **CMS_CssStylesheetSite** - stores relationships between stylesheets and sites. Each entry in this table indicates that a specific stylesheet can be used on a given site.

7.5.7.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of CSS stylesheets can be found in the **CMS.SiteProvider** namespace.

CMS_CssStylesheet table API:

- **CssStyleSheetInfo** - represents one stylesheet object.
- **CssStyleSheetInfoProvider** - provides management functionality for stylesheets.

CMS_CssStylesheetSite table API:

- **CssStyleSheetSiteInfo** - represents a relationship between a stylesheet and a site.
- **CssStyleSheetSiteInfoProvider** - provides management functionality for stylesheet-site relationships.

7.5.7.4 API examples

7.5.7.4.1 Overview

These topics show examples of how the API of CSS stylesheets can be used:

- [Managing CSS stylesheets](#)
- [CSS stylesheets and sites](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Development\CSSStyleSheets\Default.aspx.cs**.

The CSS stylesheet API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.SiteProvider;
```

7.5.7.4.2 Managing CSS stylesheets

The following example creates a CSS stylesheet.

```
private void CreateCssStylesheet()
{
    // Create new css stylesheet object
    CssStylesheetInfo newStylesheet = new CssStylesheetInfo();

    // Set the properties
    newStylesheet.StylesheetDisplayName = "My new stylesheet";
    newStylesheet.StylesheetName = "MyNewStylesheet";
    newStylesheet.StylesheetText = "Some CSS code";

    // Save the css stylesheet
    CssStylesheetInfoProvider.SetCssStylesheetInfo(newStylesheet);
}
```

The following example gets and updates a stylesheet.

```
private bool GetAndUpdateCssStylesheet()
{
    // Get the css stylesheet
    CssStylesheetInfo updateStylesheet =
    CssStylesheetInfoProvider.GetCssStylesheetInfo("MyNewStylesheet");
    if (updateStylesheet != null)
    {
        // Update the properties
        updateStylesheet.StylesheetDisplayName =
        updateStylesheet.StylesheetDisplayName.ToLower();

        // Save the changes
        CssStylesheetInfoProvider.SetCssStylesheetInfo(updateStylesheet);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates stylesheets.

```
private bool GetAndBulkUpdateCssStylesheets()
{
    // Prepare the parameters
    string where = "StylesheetName LIKE N'MyNewStylesheet%'";

    // Get the data
    DataSet stylesheets = CssStylesheetInfoProvider.GetCssStylesheets(where,
    null);
    if (!DataHelper.DataSourceIsEmpty(stylesheets))
```

```
{
    // Loop through the individual items
    foreach (DataRow stylesheetDr in stylesheets.Tables[0].Rows)
    {
        // Create object from DataRow
        CssStylesheetInfo modifyStylesheet = new CssStylesheetInfo
        (stylesheetDr);

        // Update the properties
        modifyStylesheet.StylesheetDisplayName =
        modifyStylesheet.StylesheetDisplayName.ToUpper();

        // Save the changes
        CssStylesheetInfoProvider.SetCssStylesheetInfo(modifyStylesheet);
    }

    return true;
}

return false;
}
```

The following example deletes a stylesheet.

```
private bool DeleteCssStylesheet()
{
    // Get the css stylesheet
    CssStylesheetInfo deleteStylesheet =
    CssStylesheetInfoProvider.GetCssStylesheetInfo("MyNewStylesheet");

    // Delete the css stylesheet
    CssStylesheetInfoProvider.DeleteCssStylesheetInfo(deleteStylesheet);

    return (deleteStylesheet != null);
}
```

7.5.7.4.3 CSS stylesheets and sites

The following example assigns a CSS stylesheet to a site.

```
private bool AddCssStylesheetToSite()
{
    // Get the css stylesheet
    CssStylesheetInfo stylesheet = CssStylesheetInfoProvider.GetCssStylesheetInfo
    ("MyNewStylesheet");
    if (stylesheet != null)
    {
        int stylesheetId = stylesheet.StylesheetID;
        int siteId = CMSContext.CurrentSiteID;
    }
}
```

```
        // Save the binding
        CssStyleSheetSiteInfoProvider.AddCssStyleSheetToSite(stylesheetId,
siteId);

        return true;
    }

    return false;
}
```

The following example removes a stylesheet from a site.

```
private bool RemoveCssStyleSheetFromSite()
{
    // Get the css stylesheet
    CssStyleSheetInfo removeStylesheet =
    CssStyleSheetInfoProvider.GetCssStyleSheetInfo("MyNewStylesheet");
    if (removeStylesheet != null)
    {
        int siteId = CMSContext.CurrentSiteID;

        // Get the binding
        CssStyleSheetSiteInfo stylesheetSite =
        CssStyleSheetSiteInfoProvider.GetCssStyleSheetSiteInfo
        (removeStylesheet.StylesheetID, siteId);

        // Delete the binding
        CssStyleSheetSiteInfoProvider.DeleteCssStyleSheetSiteInfo(stylesheetSite);

        return true;
    }

    return false;
}
```

7.6 Debugging and system information

7.6.1 Overview

Kentico CMS provides a useful user interface where general information about the system can be viewed. If you need to find out more detailed information internal activity within the system, you can use one of the many available debugs.

General system information

General information about the system and the environment where it is running can be viewed on the **General** tab in **Site Manager -> Administration -> System**. More information about the information displayed in this UI and the actions that can be performed there can be found in the [System information UI](#) topic.

Debugging in the UI

The **Administration -> System -> Debug** tab can be used for system debugging, i.e. finding and fixing performance or setting issues on your website. Debugs can also be particularly useful when reporting an issue to our support department. Every extra bit of information related to your issue that you find in the debugs can significantly shorten the time needed to find the solution.

The debugging interface is divided into several sub-tabs. Only the following two tabs are displayed by default. Click the name of the tab to learn more.

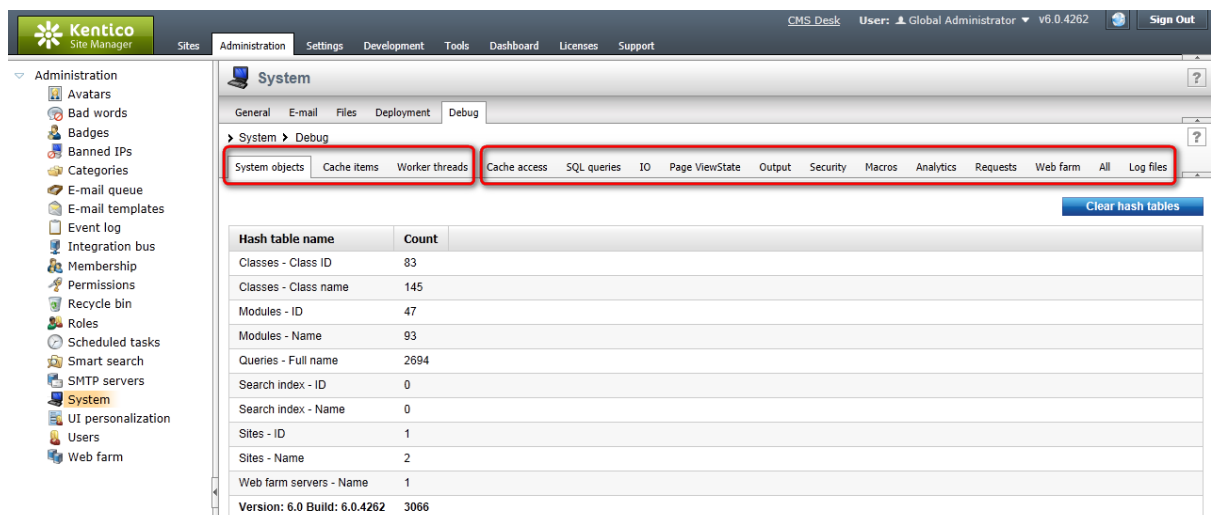

- [System objects](#)
- [Cache items](#)
- [Worker threads](#)

The other sub-tabs are displayed only after enabling certain settings in **Site Manager -> Settings -> System -> Debug** (recommended) or adding certain keys into the **AppSettings** section of your **web.config** file. Here again, click the name of the tab to get detailed information.

- [Cache access](#)
- [SQL queries](#)
- [IO](#)
- [Page ViewState](#)
- [Output](#)
- [Security](#)
- [Macros](#)
- [Analytics](#)
- [Requests](#)
- [Web farm](#)
- [All](#)
- [Log files](#)

E-mail debugging is enabled via modifying the web.config file exclusively and does not have its own tab in **Administration -> System -> Debug**. Refer to the [E-mail debugging](#) topic for more information.

You can also enable all these debugs at once using the [general settings and keys](#).

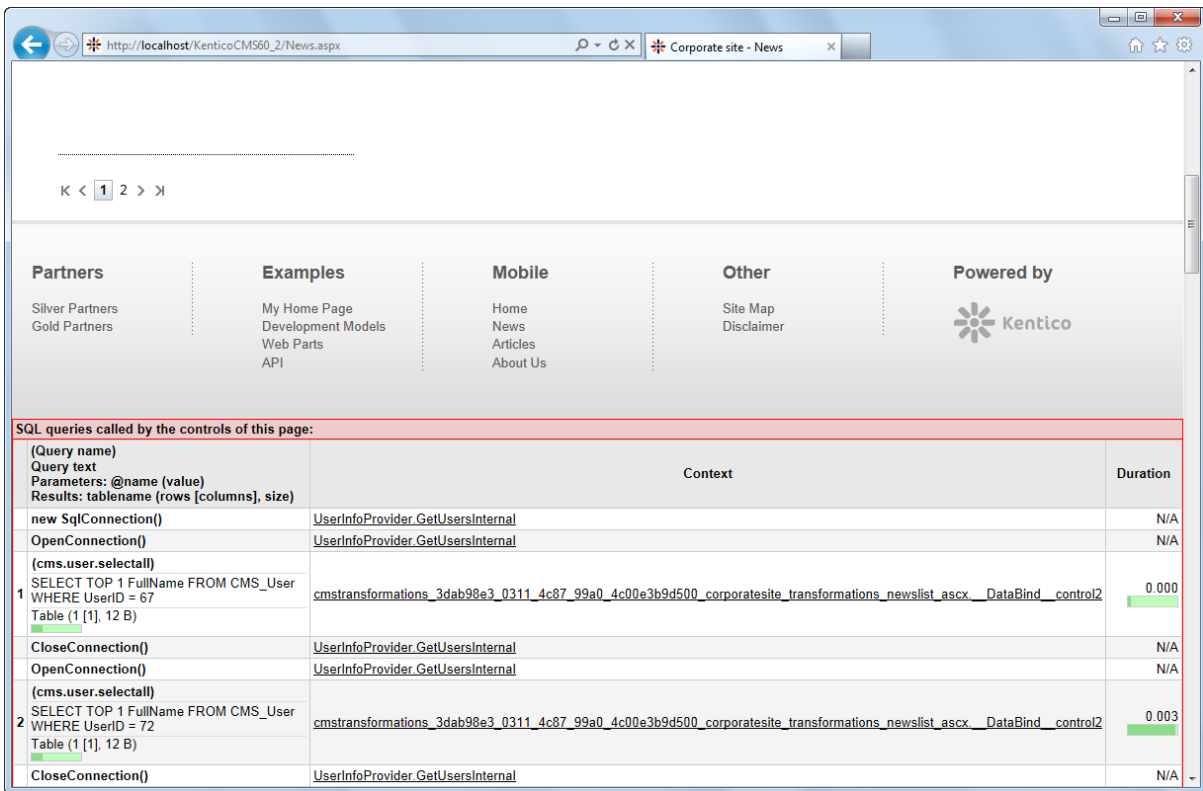

The screenshot shows the Kentico CMS Administration interface. The top navigation bar includes 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The left sidebar lists various administration categories, with 'System' highlighted. The main content area is titled 'System' and has sub-tabs for 'General', 'E-mail', 'Files', 'Deployment', and 'Debug'. The 'Debug' sub-tab is active, and its sub-tabs are 'System objects', 'Cache items', 'Worker threads', 'Cache access', 'SQL queries', 'IO', 'Page ViewState', 'Output', 'Security', 'Macros', 'Analytics', 'Requests', 'Web farm', 'All', and 'Log files'. The 'System objects', 'Cache items', and 'Worker threads' sub-tabs are highlighted with a red box. Below the sub-tabs is a 'Clear hash tables' button and a table with the following data:

| Hash table name | Count |
|------------------------------|-------|
| Classes - Class ID | 83 |
| Classes - Class name | 145 |
| Modules - ID | 47 |
| Modules - Name | 93 |
| Queries - Full name | 2694 |
| Search index - ID | 0 |
| Search index - Name | 0 |
| Sites - ID | 1 |
| Sites - Name | 2 |
| Web farm servers - Name | 1 |
| Version: 6.0 Build: 6.0.4262 | 3066 |

Debugging on the live site

You can also enable debugging directly on the live site. In this case, each loaded page also displays a debug log below its regular content. Only information related to the given page is shown. Like UI debugs, live site debugging can also be enabled either separately using the dedicate settings and keys (follow the links above), or all at once using the [general settings and keys](#).

Debug request details

You can display request details for each debugged request by clicking its URL in respective debug logs in the **Site Manager -> Administration -> System -> Debug** interface.

The screenshot shows the Kentico CMS Administration interface. The left sidebar contains various system management options. The main content area is titled 'System' and has tabs for 'General', 'E-mail', 'Files', 'Deployment', and 'Debug'. Under the 'Debug' tab, there are sub-tabs for 'System objects', 'Cache items', 'Worker threads', 'Cache access', 'SQL queries', 'IO', 'Page ViewState', 'Output', 'Security', 'Macros', 'Analytics', 'Requests', and 'All'. The 'SQL queries' sub-tab is active, showing a table of queries. The URL `/KenticoCMS60_3/Forums.aspx` is highlighted in a red box. The table shows the following data:

| (Query name) | Context | Duration |
|---|---|----------|
| new SqlConnection() | ForumInfoProvider.GetForums | N/A |
| OpenConnection() | ForumInfoProvider.GetForums | N/A |
| (forums.forum.selectall)
SELECT * FROM Forums_Forum WHERE (ForumOpen = 1) AND (ForumGroupID = 3) ORDER BY ForumOrder ASC, ForumName ASC
Table (2 [38], 376 B) | CMSModules_Forum_Controls_Layouts_Flat_Forum_OnLoad | 0.000 |
| CloseConnection() | ForumInfoProvider.GetForums | N/A |
| 1 queries, 111 B write, 376 B read | Version: 6.0 Build: 6.0.4253 | 0.000 |

After doing so, a new pop-up window opens, listing the request's debug log for all enabled debugs.

The screenshot shows a browser window with the URL `http://localhost/KenticoCMS60_3/CMSModules/System/Debug/System_ViewRequest.aspx`. The page title is 'Request details'. The content area shows the following information:

SQL queries called by the controls of this page:

| (Query name) | Context | Duration |
|---|---|----------|
| new SqlConnection() | ForumInfoProvider.GetForums | N/A |
| OpenConnection() | ForumInfoProvider.GetForums | N/A |
| (forums.forum.selectall)
SELECT * FROM Forums_Forum WHERE (ForumOpen = 1) AND (ForumGroupID = 3) ORDER BY ForumOrder ASC, ForumName ASC
Table (2 [38], 376 B) | CMSModules_Forum_Controls_Layouts_Flat_Forum_OnLoad | 0.000 |
| CloseConnection() | ForumInfoProvider.GetForums | N/A |
| 1 queries, 111 B write, 376 B read | Version: 6.0 Build: 6.0.4253 | 0.000 |

Cache items accessed by the controls of this page:

| Access | Cache key | Dependencies | Context |
|--------|--|--|--|
| 1 GET | pageinfo[url] personalsite http://localhost/kentocms60_3/forums.aspx en-us true true | CMS.PortalEngine.CachedPageInfo (667 B) | CMSApplicationModule.app_MapRequestHandler |
| 2 GET | pageinfo/personalsite /en-us false | CMS.PortalEngine.PageInfo (466 B) | CMSPortalManager.LoadContent |
| 3 GET | cmsmenudatasource en-us personalsite /en-us false cms.menuitem cms.blog 1 true false false | DataSet: CMS.Document (4 [37], 677 B) | CMSListMenu.OnInit |
| 4 GET | currentdocument/personalsite forums en-us | CMS.WorkflowEngine.ContentDocument (550 B) | CMSModules_Forum_Controls_ForumDivider.Page_Load |

Version: 6.0 Build: 6.0.4253

Close

7.6.2 System information UI

On the **General** tab in **Site Manager** -> **Administration** -> **System**, you can find general information about the system and the environment in which it is running. The following information and actions are available on the tab:

System information

- **Machine name** - name of the machine on which the system is running.
- **ASP.NET account** - name of the user account used by ASP.NET in the operating system on your machine.

- **ASP.NET version** - version of ASP.NET on which the system is running.
- **Application pool name** - name of the application pool in which this instance of Kentico CMS is running.
- **Application trust level** - trust level of the environment where the application is running.
- **Your IP address** - IP address from which you are accessing the system.

Database information

- **Server name** - name of the database server on which the system database is running.
- **Server version** - version of SQL Server installed on the database server.
- **Database name** - name of the system database on the database server.
- **Database size** - current size of the database, including the actual database data (the *.mdf* file) and the database log (the *.ldf* file).

Contact management database separation

If the application has a [separated](#) contact management (on-line marketing) database, the information will be displayed for both databases.

Using the **Refresh interval (seconds)** drop-down list, you can set the interval after which the values in the sections below will be refreshed.

Memory statistics

- **Allocated memory** - size of memory allocated for the CMS.
- **Peak memory usage** - maximum memory used by the process.
- **Process physical memory** - physical memory used by the process.
- **Process virtual memory** - memory allocated by the process in the virtual memory space.

- **Clear unused memory** - clicking this button clears unused data stored in the memory so that more free memory is available.

Garbage collection statistics

- **GC collection of gen 0** - number of unused memory cleanings initiated by the garbage collector for generation 0 objects.
- **GC collection of gen 1** - number of unused memory cleanings initiated by the garbage collector for generation 1 objects.
- **GC collection of gen 2** - number of unused memory cleanings initiated by the garbage collector for generation 2 objects.

Page view statistics

- **View of content pages** - number of content pages displayed since last restart.
- **File downloads and views** - number of files downloaded and viewed since last restart.
- **Views of system pages** - number of system pages viewed since last restart.
- **Non-page requests** - number of non-page requests handled since last restart.
- **Number of pages not found** - number of page view requests which resulted in the *404: Page Not Found* error since the last restart.

- **Pending requests** - number of currently pending (not yet processed) page requests.

Cache statistics

- **Cache items** - number of items in the system cache.
 - **Expired** - number of expired cache items in the system cache.
 - **Removed** - number of items removed from the system cache since last restart.
 - **Dependency changed** - cache items dropped based on the change of their dependencies.
 - **Underused** - cache items dropped earlier than configured, possible due to lack of memory.
-
- **Clear cache** - clears all items stored in the cache.
-
- **Time since last restart** - time since the system was last restarted (or since it was launched if no restart was performed).

You can also perform the following actions using the buttons at the bottom part of the tab:

- **Restart application** – restarts Kentico CMS (in need to take effects of some changes).
- **Restart all web farm servers** - restarts all web farm servers running this instance of Kentico CMS. This action is only displayed when the system is configured to run in web farm environment. See [Modules -> Web farm synchronization](#) for more details.
- **Restart windows services** - restarts all Kentico CMS Windows services related to this instance. This action is only displayed when there is at least one Windows service installed for this instance of Kentico CMS. See [External utilities -> Service Manager](#) for more details.
- **Clear counters** - clears the values currently stored in all performance counters registered for the current Kentico CMS instance. See [Modules -> Health monitoring](#) for more details. Clicking this button also resets the *Page view statistics* section of this tab.

The screenshot displays the Kentico Administration console. The top navigation bar includes 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The left sidebar lists various administration tasks such as 'Avatars', 'Bad words', 'Badges', 'Banned IPs', 'Categories', 'E-mail queue', 'E-mail templates', 'Event log', 'Integration bus', 'Membership', 'Permissions', 'Recycle bin', 'Roles', 'Scheduled tasks', 'Smart search', 'SMTP servers', 'System', 'UI personalization', 'Users', and 'Web farm'. The main content area is titled 'System' and contains several panels:

- System information:** Machine name: DAVIDB-PC; ASP.NET account: NT AUTHORITY\NETWORK SERVICE; ASP.NET version: 4.0.30319.269; Application pool name: KenticoCMS_KenticoCMS_7.0.4532; Application trust level: Unrestricted; Your IP address: ::1.
- Database information:** Server name: GURU; Server version: 9.00.5057.00; Database name: davidb_7.0_4532; Database size: 87 MB.
- Memory statistics:** Allocated memory: 105 MB; Peak memory usage: 619 MB; Process physical memory: 554 MB; Process virtual memory: 3 GB. Includes a 'Clear unused memory' button.
- Garbage collection statistics:** GC collections of gen 0: 275; GC collections of gen 1: 111; GC collections of gen 2: 31.
- Page view statistics:** Views of content pages: 6; File downloads and views: 10; Views of system pages: 20; Non-page requests: 6; Number of pages not found: 0; Pending requests: 1.
- Cache statistics:** Cache items: 131; Expired: 0; Removed: 0; Dependency changed: 0; Underused: 0. Includes a 'Clear cache' button.
- System time information:** Time since the last restart: 00:06:17; Server time: 5/31/2012 10:32:32 AM (GMT - 06:00).

At the bottom of the console, there are four buttons: 'Restart application', 'Restart all web farm servers', 'Restart windows services', and 'Clear counters'.

7.6.3 Particular debug tabs

7.6.3.1 System objects

On the **Debug** -> **System objects** tab, you can see the number of objects currently stored in hash tables on the server.

The first table shows the names of particular **hash tables** and the number of records in them. The second table shows particular **Object types** and the number of currently hashed objects of each type.

All hash tables can be cleared using the **Clear hash tables** button.

The screenshot shows the Kentico CMS 7.0 Administration interface. The left sidebar contains a tree view of system components, with 'System' selected. The main content area is titled 'System' and has tabs for 'General', 'E-mail', 'Files', 'Deployment', and 'Debug'. The 'Debug' tab is active, and within it, the 'Cache items' sub-tab is selected. A table displays the following data:

| Hash table name | Count |
|-------------------------------|-------|
| Classes - Class ID | 87 |
| Classes - Class name | 152 |
| CSS stylesheets - ID | 1 |
| CSS stylesheets - Name | 2 |
| Cultures - Culture alias | 0 |
| Cultures - Culture code | 265 |
| Modules - ID | 47 |
| Modules - Name | 93 |
| Page templates - ID | 1 |
| Page templates - Name, SiteID | 2 |
| Queries - Full name | 2713 |
| Search index - ID | 6 |
| Search index - Name | 12 |
| Sites - ID | 2 |
| Sites - Name | 4 |
| Web parts - ID | 341 |
| Web parts - Name | 641 |
| Version: 6.0 Build: 6.0.4253 | 4369 |

Below the table is another section with columns 'Object type' and 'Count', which is currently empty. A 'Clear hash tables' button is located at the top right of the table area.

7.6.3.2 Cache items

On the **Debug -> Cache items** tab, you can see which **Keys** and **Dummy keys** are currently stored in the system cache.

Both real and dummy keys can be deleted from within this part of the user interface using the **Delete** (✘) icon next to them. All dummy keys can be cleared from the cache using the **Clear cache** button.

The screenshot shows the Kentico CMS 7.0 Administration interface with the 'Cache items' sub-tab selected. The main content area displays a table of 'Data items' and a section for 'Dummy keys (Cache dependencies)'. The 'Data items' table is as follows:

| Action | Key | Data | Expiration | Priority |
|--------|---|--|----------------------|----------|
| ✘ | getresource(c:\inetpub\wwwroot\kenticocms60_3\cmsscripts\autotitle.js) | CMS.UIControls.CMSOutputResource (2 kB) | 8/31/2011 5:23:48 PM | High |
| ✘ | getresource(c:\inetpub\wwwroot\kenticocms60_3\cmsscripts\icontextmenu.js) | CMS.UIControls.CMSOutputResource (28 kB) | 8/31/2011 5:23:53 PM | High |
| ✘ | getresource(c:\inetpub\wwwroot\kenticocms60_3\cmsscripts\jquery\jquery-core.js) | CMS.UIControls.CMSOutputResource (180 kB) | 8/31/2011 5:23:53 PM | High |
| ✘ | getresource(c:\inetpub\wwwroot\kenticocms60_3\cmsscripts\jquery\jquery-dialog.js) | CMS.UIControls.CMSOutputResource (16.7 kB) | 8/31/2011 5:23:53 PM | High |
| ✘ | getresource(c:\inetpub\wwwroot\kenticocms60_3\cmsscripts\tooltipwz_tooltip.js) | CMS.UIControls.CMSOutputResource (57 kB) | 8/31/2011 5:23:53 PM | High |
| ✘ | getresource(c:\inetpub\wwwroot\kenticocms60_3\cmsscripts\updateprogress.js) | CMS.UIControls.CMSOutputResource (869 B) | 8/31/2011 5:23:48 PM | High |

At the bottom right of the 'Data items' table, there is a dropdown menu for 'Items per page' set to 25. Below the 'Data items' table is a section for 'Dummy keys (Cache dependencies)' with a table:

| Action | Dummy key |
|--------|-----------|
| ✘ | css |

At the bottom right of the 'Dummy keys' table, there is a dropdown menu for 'Items per page' set to 25. A 'Clear cache' button is located at the top right of the 'Data items' section.

If you click the **View object** (🔍) icon in a particular row, a pop-up window gets opened as in the screenshot below. There, you can see detailed information about the cached object:

- **Key** - the key under which the object is stored in the cache.
- **Expiration** - date and time when the cache item will expire (i.e. will be removed from the cache).
- **Priority** - priority of the cache item. The same as ASP.NET cache item priorities, while only *High* and *NotRemovable* are used in Kentico CMS.
- **Dependencies** - dummy keys on which the cache item is enabled.
- **Object type** - type of the cached object.

Finally, the table under the **Object type** value represents the actual data of the cached object. Displayed fields vary based on the currently displayed object type. The cache item can be cleared from cache using the **Delete** button in the top part of the window.

| Action | Dummy key |
|--------------------------|----------------------------------|
| <input type="checkbox"/> | filenode |
| <input type="checkbox"/> | filenode dotnetgroup |
| <input type="checkbox"/> | node dotnetgroup files/icons/pdf |

| Field name | Value |
|---------------|------------------|
| NodeID | 474 |
| NodeAliasPath | /files/icons/pdf |
| NodeName | pdf |
| NodeAlias | pdf |
| NodeClassID | 1685 |
| NodeParentID | 443 |
| NodeLevel | 3 |
| NodeACLID | 9 |
| NodeSiteID | 3 |

For more information about caching in Kentico CMS, please refer to [Development -> Caching and performance -> Caching options](#).

7.6.3.3 Worker threads

On the **Debug -> Worker threads** tab, you can see which worker threads are currently running in the system and which threads have finished recently. This is particularly useful if your application is consuming significantly more resources than it normally should. It may often be caused by threads running in the background, e.g. threads for [Smart Search](#) re-indexing or when [sending mass e-mails](#).

The screenshot shows the Kentico CMS 7.0 Administration interface. The left sidebar contains a navigation menu with categories like Administration, System, and Web farm. The main content area is titled 'System' and has tabs for 'General', 'E-mail', 'Files', 'Deployment', and 'Debug'. Under the 'Debug' tab, there are sub-tabs for 'System objects', 'Cache items', 'Worker threads', 'Cache access', 'SQL queries', 'IO', 'Page ViewState', 'Output', 'Security', 'Macros', 'Analytics', and 'Requests'. The 'Worker threads' sub-tab is selected, showing a 'Run testing thread' button. Below this, there are two tables: 'Running threads' and 'Finished threads'. The 'Running threads' table has one entry with a duration of 1.401. The 'Finished threads' table has nine entries with various durations, the highest being 0.219.

| Actions | Calling context / URL | Thread ID | Status | Start time | Duration |
|---|--|-----------|---------------|-----------------------|----------|
| 1   | ASP.cmsmodules_system_debug_system_debugthreads_aspx.RunTest
/KenticoCMS60_3/CMSModules/System/Debug/System_DebugThreads.aspx
Version: 6.0 Build: 6.0.4253 | 23 | WaitSleepJoin | 8/25/2011 11:17:19 AM | 1.401 |

| Calling context / URL | Thread ID | Status | Start time | Finished | Duration |
|---|-----------|---------|-----------------------|-----------------------|----------|
| 1 CMS.Newsletter.ThreadEmailSender.Run
/KenticoCMS60_3/CMSModules/System/Debug/System_DebugThreads.aspx | 22 | Stopped | 8/25/2011 11:16:39 AM | 8/25/2011 11:16:39 AM | 0.016 |
| 2 CMS.EmailEngine.ThreadSender.Run
/KenticoCMS60_3/CMSModules/System/Debug/System_DebugThreads.aspx | 21 | Stopped | 8/25/2011 11:16:39 AM | 8/25/2011 11:16:39 AM | 0.156 |
| 3 CMS.Newsletter.ThreadEmailSender.Run
/KenticoCMS60_3/CMSModules/System/Debug/System_DebugCacheItems.aspx | 20 | Stopped | 8/25/2011 11:14:54 AM | 8/25/2011 11:14:54 AM | 0.000 |
| 4 CMS.EmailEngine.ThreadSender.Run
/KenticoCMS60_3/CMSModules/System/Debug/System_DebugCacheItems.aspx | 19 | Stopped | 8/25/2011 11:14:53 AM | 8/25/2011 11:14:54 AM | 0.188 |
| 5 CMS.Newsletter.ThreadEmailSender.Run
/KenticoCMS60_3/CMSSiteManager/trialversion.aspx?appexpires=35 | 12 | Stopped | 8/25/2011 11:13:49 AM | 8/25/2011 11:13:49 AM | 0.203 |
| 6 CMS.EmailEngine.ThreadSender.Run
/KenticoCMS60_3/CMSSiteManager/trialversion.aspx?appexpires=35 | 11 | Stopped | 8/25/2011 11:13:49 AM | 8/25/2011 11:13:49 AM | 0.219 |
| 7 CMS.SiteProvider.SearchTaskInfoProvider.Run
/KenticoCMS60_3/CMSDesk/default.aspx | 9 | Stopped | 8/25/2011 11:13:47 AM | 8/25/2011 11:13:47 AM | 0.078 |
| 8 CMS.EmailEngine.EmailInfoProvider.b__2
/KenticoCMS60_3/CMSDesk/default.aspx | 8 | Stopped | 8/25/2011 11:13:47 AM | 8/25/2011 11:13:47 AM | 0.063 |
| 9 CMS.Newsletter.EmailQueueManager.b__1
/KenticoCMS60_3/CMSDesk/default.aspx | 7 | Stopped | 8/25/2011 11:13:47 AM | 8/25/2011 11:13:47 AM | 0.047 |
| Version: 6.0 Build: 6.0.4253 | | | | | 0.969 |

The UI is split into two sections:

Running threads

In this section, you can see a list of all worker threads currently running in the system. The **Run testing thread** button can be used to launch a testing thread in order to verify that thread debugging works correctly.

You can perform the following actions with the listed threads:

-  **Cancel** - cancels execution of the thread (useful if the original window where the thread was started is already closed).
-  **View** - displays a pop-up window showing the current content of the thread log (in case that there is a log), as shown in the screenshot below.

Finished threads

In this section, you can see a list of the latest threads that have finished their activity in the recent past. By adding the following key into the *appSettings* section of your *web.config* file, you can limit the number of threads displayed in the list. If the key is not used, 20 threads are displayed by default.

```
<add key="CMSMaxFinishedThreadsLogged" value="10" />
```

7.6.3.4 Cache access

Cache access debugging can be turned on and configured either by adjusting certain settings in **Site Manager -> Settings -> System -> Debug**, or by adding certain keys into the *AppSettings* section of your *web.config* file. The following table lists and explains these settings and keys:

| Setting | Web.config key | Description |
|---|-------------------|---|
| Enable cache access debug | CMSDebugCache | Enables cache access debugging and the Cache access tab in Site Manager -> Administration -> System -> Debug . |
| Display cache access debug on live site | CMSDebugCacheLive | If enabled, cache access debug information is also displayed at the bottom of each live site page. This option requires cache access debugging to be enabled. |
| Debug cache access of UI pages | CMSDebugAllCaches | If enabled, access to data cached for pages of the administration interface (CMS Desk and Site Manager) will also be included in the cache access debug. This option requires cache access debugging to be enabled. |
| Log cache access to file | CMSLogCache | If enabled, cache access debug log is saved into the <i>logcache.log</i> file in the <i>~\App_Data</i> folder. This option does not require cache access debugging to |

| | | |
|-------------------------------|------------------------|--|
| | | be enabled. |
| Cache access debug log length | CMSDebugCacheLogLength | Sets the maximum length of the cache access debug log on the Debug -> Cache access tab, i.e. the number of requests for which debug information is preserved and displayed on the tab. If empty, value of the Default log length setting (or the CMSDebugEverythingLogLength key) is used. |
| Display stack information | CMSDebugCacheStack | If enabled, stack is tracked when debugging cache access and is displayed in the Context column. This information is only available in the debugging UI and on the live site, not in the debug log written into the <i>logcache.log</i> file. |

The screenshot shows the Kentico CMS Site Manager interface. The 'Settings' tab is active, and the 'Cache access' section is highlighted with a red box. The settings in this section are:

- Enable cache access debug:
- Display cache access debug on live site:
- Debug cache access of UI pages:
- Log cache access to file:
- Cache access debug log length:
- Display stack information:

It may happen that you specify different configuration in the settings and in the *web.config* file. In such cases, boolean settings (true/false) need to be enabled at least in one place (in *web.config* or in settings) in order to be enabled, while log lengths specified in **Site Manager -> Settings** have higher priority than log lengths specified in the *web.config*.

Here is a list of the keys for easy copy&paste into your *web.config*:

```
<add key="CMSDebugCache" value="true" />
<add key="CMSDebugCacheLive" value="true" />
<add key="CMSDebugAllCaches" value="true" />
<add key="CMSLogCache" value="true" />
<add key="CMSDebugCacheLogLength" value="10" />
<add key="CMSDebugCacheStack" value="true" />
```

Cache access debugging can also be enabled using the [general settings and keys](#).

User interface

On the **Debug -> Cache access** tab, you can see a log of requests that accessed the system cache.

For each request, you can see the URL and time when it was processed. The table below the URL always shows the type of **Access**, the accessed **Cache key**, its cache dependencies, the object type and size of cached **Data** and the **Context** from which the cache was accessed. If you enable the **Show complete context** option, complete context of the cache access, i.e. not only the method that accessed the cache item, but also the methods from which the first one was called, will be shown in the **Context** column.

Enabling the **Show complete context** check-box displays complete context (not only the topmost item) in the **Context** column. All dummy keys can be cleared from the cache using the **Clear cache** button. Clicking the **Clear cache log** button clears all records in the log.

The screenshot shows the Kentico Site Manager Administration interface. The left sidebar contains various administration tools like Avatars, Bad words, Badges, Banned IPs, Categories, E-mail queue, E-mail templates, Event log, Integration bus, Membership, Permissions, Recycle bin, Roles, Scheduled tasks, Smart search, SMTP servers, System, UI personalization, Users, and Web farm. The main content area is titled 'System' and has tabs for General, E-mail, Files, Deployment, and Debug. The 'Debug' tab is active, showing a 'Cache access' log. The log is filtered for the URL '/KenticoCMS60_3/getfile/8009a4a8-e6b4-49f2-b549-8bb232fe4272/pdf.aspx' (02:03:46). There are buttons for 'Show complete context', 'Clear cache', and 'Clear cache log'. The log contains two entries:

| Access | Cache key
Dependencies
Data | Context |
|--------|--|--|
| 1 ADD | getfile nodebyguid dotnetgroup en-us 8009a4a8-e6b4-49f2-b549-8bb232fe4272
filenode
filenode dotnetgroup
node dotnetgroup files/icons/pdf
CMS.WorkflowEngine.ContentDocument (242 B) | CMSPages_GetFile_Page_Load |
| 2 ADD | getfile dotnetgroup administrator en-us nodeguid=8009a4a8-e6b4-49f2-b549-8bb232fe4272
node dotnetgroup files/icons/pdf
attachment 2b930d5a-a2a2-45a8-8efd-d2d04c4c9693
CMS.UIControls.CMSOutputFile (368 B) | CMSPages_GetFile_Page_Load
Version: 6.0 Build: 6.0.4253 |

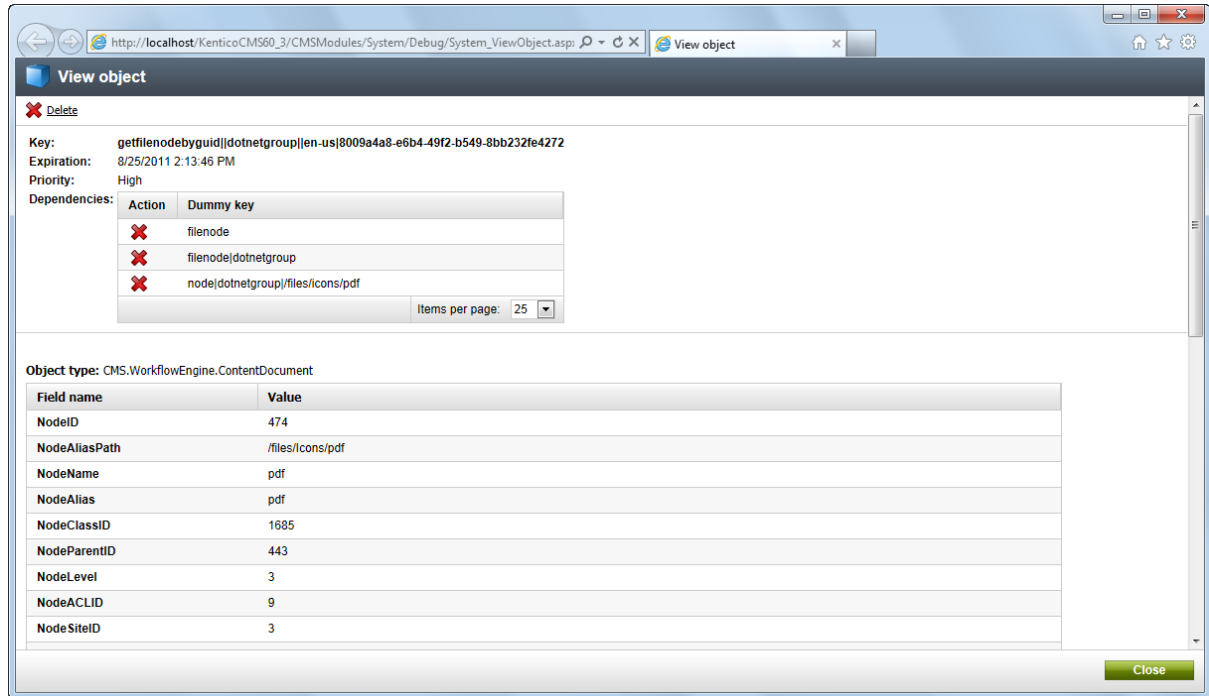

Below this, there is another log entry for the URL '/KenticoCMS60_3/Home.aspx' (02:03:28):

| Access | Cache key
Dependencies
Data | Context |
|--------|--|--|
| 1 ADD | pageinfo dotnetgroup home en-us home true
template 298
nodeid 424
pageinfo
CMS.PortalEngine.PageInfo (1.8 kB) | CMSApplicationModule.app_MapRequestHandler |
| 2 ADD | pageinfo dotnetgroup http://localhost/kentocms60_3/home.aspx en-us true true
template 298

CMS.PortalEngine.PageInfo (339 B) | CMSPortalManager.LoadContent
Version: 6.0 Build: 6.0.4253 |

If you click the **View object** (🔍) icon in a particular row, a pop-up window gets opened as in the screenshot below. There, you can see detailed information about the cached object:

- **Key** - the key under which the object is stored in the cache.
- **Expiration** - date and time when the cache item will expire (i.e. will be removed from the cache).
- **Priority** - priority of the cache item. The same as ASP.NET cache item priorities, while only *High* and *NotRemovable* are used in Kentico CMS.
- **Dependencies** - dummy keys on which the cache item is enabled.
- **Object type** - type of the cached object.

Finally, the table under the **Object type** value represents the actual data of the cached object. Displayed fields vary based on the currently displayed object type. The cache item can be cleared from cache using the **Delete** button in the top part of the window.

For more information about caching in Kentico CMS, please refer to [Development -> Caching and performance -> Caching options](#).

7.6.3.5 SQL queries

SQL query debugging can be turned on and configured either by adjusting certain settings in **Site Manager -> Settings -> System -> Debug**, or by adding certain keys into the *AppSettings* section of your *web.config* file. The following table lists and explains these settings and keys:

| Setting | Web.config key | Description |
|--------------------------------------|------------------------|---|
| Enable SQL query debug | CMSDebugSQLQueries | Enables SQL query debugging and the SQL queries tab in Site Manager -> Administration -> System -> Debug . |
| Display SQL query debug on live site | CMSDebugSQLQueriesLive | If enabled, SQL query debug information is also displayed at the bottom of each live site page. This option requires SQL query debugging to be enabled. |
| Debug SQL queries of UI pages | CMSDebugAllSQLQueries | If enabled, SQL queries called by pages of the administration interface (CMS Desk and Site Manager) will also be included in the SQL query debug. This option requires SQL query debugging to be enabled. |

| | | |
|----------------------------|-----------------------------|--|
| Log SQL queries to file | CMSLogSQLQueries | If enabled, SQL query debug log is saved into the <i>logsql.log</i> file in the <i>~App_Data</i> folder. This option does not require SQL query debugging to be enabled. |
| SQL query debug log length | CMSDebugSQLQueriesLogLength | Sets the maximum length of the SQL query debug log on the Debug -> SQL queries tab, i.e. the number of requests for which debug information is preserved and displayed on the tab. If empty, value of the Default log length setting (or the CMSDebugEverythingLogLength key) is used. |
| Debug SQL connections | CMSDebugSQLConnections | If enabled, SQL connection operations (new, open, close) are logged in the SQL query debug log. |
| Display stack information | CMSDebugSQLQueriesStack | If enabled, stack is tracked when debugging SQL queries and is displayed in the Context column. This information is only available in the debugging UI and on the live site, not in the debug log written into the <i>logsql.log</i> file. |

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The left sidebar shows a tree view of settings categories, with 'Debug' selected. The main content area displays the 'SQL queries' settings, which are highlighted with a red box. The settings include:

- Cache access debug log length: 10
- Display stack information:
- Enable SQL query debug:
- Display SQL query debug on live site:
- Debug SQL queries of UI pages:
- Log SQL queries to file:
- SQL query debug log length: 10
- Debug SQL connections:
- Display stack information:

It may happen that you specify different configuration in the settings and in the *web.config* file. In such cases, boolean settings (true/false) need to be enabled at least in one place (in *web.config* or in settings) in order to be enabled, while log lengths specified in **Site Manager -> Settings** have higher priority than log lengths specified in the *web.config*.

Here is a list of the keys for easy copy&paste into your *web.config*:

```
<add key="CMSDebugSQLQueries" value="true" />
<add key="CMSDebugSQLQueriesLive" value="true" />
<add key="CMSDebugAllSQLQueries" value="true" />
```

```
<add key="CMSLogSQLQueries" value="true" />
<add key="CMSDebugSQLQueriesLogLength" value="10" />
<add key="CMSDebugSQLConnections" value="true" />
<add key="CMSDebugSQLQueriesStack" value="true" />
```

SQL query debugging can also be enabled using the [general settings and keys](#).

User interface

On the **Debug -> SQL queries** tab, you can see a log of the SQL queries called when particular data is loaded. Each record contains the request used to access the given item and the time when it was loaded. Below it, you can find a table listing all SQL queries executed within the context of the request.

For each query, there are two lines in the table. The first line contains the exact text of the query and the second shows the number of loaded rows, columns in each row and the total size of the loaded data. The **Context** column shows the context where the query was called from. The last column of the table displays the exact duration of query execution. The last line of the table displays the total volume of data and loading time for all queries under the given request.

Enabling the **Show complete context** check-box displays complete context (not only the topmost item) in the **Context** column. Clicking the **Clear SQL log** button clears all records in this debug log.

| Table (1 [149], 832 B) | | |
| CloseConnection() | TreeProvider.SelectSingleNode | N/A |

7.6.3.6 IO

IO operation debugging can be turned on and configured either by adjusting certain settings in **Site Manager -> Settings -> System -> Debug**, or by adding certain keys into the *AppSettings* section of your *web.config* file. The following table lists and explains these settings and keys:

| Setting | Web.config key | Description |
|---|------------------------|---|
| Enable IO operation debug | CMSDebugFiles | Enables IO operation debugging and the IO tab in Site Manager -> Administration -> System -> Debug . |
| Display IO operation debug on live site | CMSDebugFilesLive | If enabled, IO operation debug information is also displayed at the bottom of each live site page. This option requires IO operation debugging to be enabled. |
| Debug IO operations of UI pages | CMSDebugAllFiles | If enabled, IO operations called by pages of the administration interface (CMS Desk and Site Manager) will also be included in the IO operation debug. This option requires IO operation debugging to be enabled. |
| Log IO operations to file | CMSLogFiles | If enabled, IO operation debug log is saved into the <i>logfiles.log</i> file in the <i>~\App_Data</i> folder. This option does not require IO operation debugging to be enabled. |
| IO operation debug log length | CMSDebugFilesLogLength | Sets the maximum length of the IO operation debug log on the Debug -> IO tab, i.e. the number of requests for which debug information is preserved and displayed on the tab. If empty, value of the Default log length setting (or the CMSDebugEverythingLogLevel key) is used. |
| Display stack information | CMSDebugFilesStack | If enabled, stack is tracked when debugging IO operations and is displayed in the Context column. This information is only available in the debugging UI and on the live site, not in the debug log written into the <i>logfiles.log</i> file. |

The screenshot shows the Kentico Site Manager interface. The 'Settings' tab is active, and the 'IO' section is highlighted with a red box. The settings in this section are:

| Setting | Help | Value |
|---|------|-------------------------------------|
| Enable IO operation debug | ? | <input type="checkbox"/> |
| Display IO operation debug on live site | ? | <input type="checkbox"/> |
| Debug IO operations of UI pages | ? | <input type="checkbox"/> |
| Log IO operations to file | ? | <input type="checkbox"/> |
| IO operation debug log length | ? | 10 |
| Display stack information | ? | <input checked="" type="checkbox"/> |

Below the 'IO' section, the 'Page ViewState' section is visible, with the setting 'Enable ViewState debug' set to .

It may happen that you specify different configuration in the settings and in the *web.config* file. In such cases, boolean settings (true/false) need to be enabled at least in one place (in *web.config* or in settings) in order to be enabled, while log lengths specified in **Site Manager -> Settings** have higher priority than log lengths specified in the *web.config*.

Here is a list of the keys for easy copy&paste into your *web.config*:

```
<add key="CMSDebugFiles" value="true" />
<add key="CMSDebugFilesLive" value="true" />
<add key="CMSDebugAllFiles" value="true" />
<add key="CMSLogFiles" value="true" />
<add key="CMSDebugFilesLogLength" value="10" />
<add key="CMSDebugFilesStack" value="true" />
```

IO operation debugging can also be enabled using the [general settings and keys](#).

User interface

On the **Debug -> IO** tab, you can see which file operations were carried out on each request. For each operation, you can see its type, size of transferred data, number of accesses and the path to the accessed file. In the **Context** column, you can see the context from which the file access operation was called.

Enabling the **Show complete context** check-box displays complete context (not only the topmost item) in the **Context** column. The log can be cleared using the **Clear log** button.

The screenshot shows the Kentico Site Manager Administration interface. The left sidebar contains various administration tools like Avatars, Bad words, Banned IPs, etc. The main content area is titled 'System' and has tabs for General, E-mail, Files, Deployment, and Debug. The 'Debug' tab is active, showing a list of log entries. Two entries are visible, both for the file path ~/App_Data/CMSModules/WebAnalytics/filedownloads_110903_1252.log. The first entry has an action of APPENDALLTEXT and a size of 46 B (1). The second entry has an action of APPENDALLTEXT and a size of 49 B (1). Both entries are associated with the context CMSPages_GetFile_Page_Load and version 6.0 Build: 6.0.4262.

7.6.3.7 Page ViewState

Page ViewState debugging can be turned on and configured either by adjusting certain settings in **Site Manager -> Settings -> System -> Debug**, or by adding certain keys into the *AppSettings* section of your *web.config* file. The following table lists and explains these settings and keys:

| Setting | Web.config key | Description |
|--------------------------------------|----------------------------|--|
| Enable ViewState debug | CMSDebugViewState | Enables ViewState debugging and the Page ViewState tab in Site Manager -> Administration -> System -> Debug . |
| Display ViewState debug on live site | CMSDebugViewStateLive | If enabled, ViewState debug information is also displayed at the bottom of each live site page. This option requires ViewState debugging to be enabled. |
| Debug ViewState of UI pages | CMSDebugAllViewState | If enabled, ViewState of administration interface pages (CMS Desk and Site Manager) will also be included in the ViewState debug. This option requires ViewState debugging to be enabled. |
| ViewState debug log length | CMSDebugViewStateLogLength | Sets the maximum length of the ViewState debug log on the Debug -> ViewState tab, i.e. the number of requests for which debug information is preserved and displayed on the tab. If empty, value of the Default log length setting (or the CMSDebugEverythingLogLength key) is used. |

The screenshot shows the Kentico Site Manager interface. The 'Settings' tab is active, and the 'Page ViewState' section is highlighted with a red box. The settings in this section are:

- Enable ViewState debug:
- Display ViewState debug on live site:
- Debug ViewState of UI pages:
- ViewState debug log length:

The 'Output' section below it has the following setting:

- Enable output debug:

It may happen that you specify different configuration in the settings and in the *web.config* file. In such cases, boolean settings (true/false) need to be enabled at least in one place (in *web.config* or in settings) in order to be enabled, while log lengths specified in **Site Manager -> Settings** have higher priority than log lengths specified in the *web.config*.

Here is a list of these keys for easy copy&paste into your *web.config*:

```
<add key="CMSDebugViewState" value="true" />
<add key="CMSDebugViewStateLive" value="true" />
<add key="CMSDebugAllViewStates" value="true" />
<add key="CMSDebugViewStateLogLength" value="10" />
```

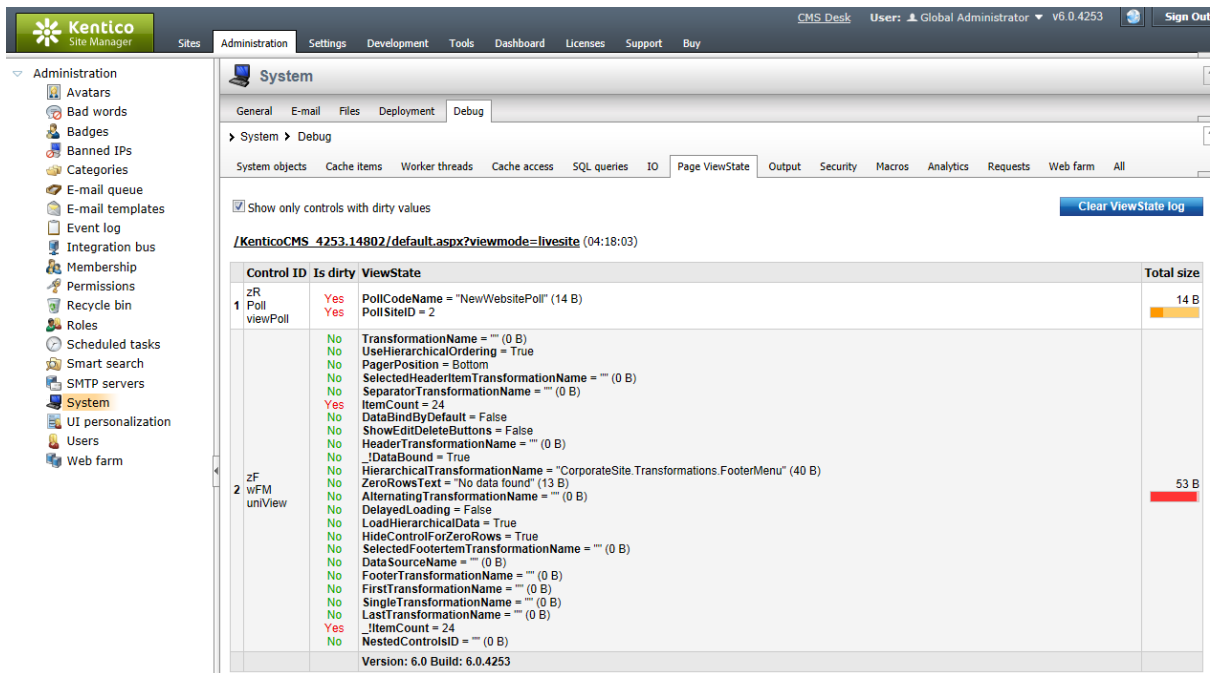

Page ViewState debugging can also be enabled using the [general settings and keys](#).

User interface

On the **Debug -> Page ViewState** tab, you can see the ViewState of particular controls on recently loaded pages. In the **Control ID** column, you can see the ID of each control on the requested page. The **Is dirty** column indicates if the item was added to the ViewState after the *Track ViewState()* method was called (typically occurs during *OnInit*). You can display only controls with such items by enabling the **Show only controls with dirty values** check-box above the grid. The **ViewState** column displays the control's ViewState data and the **Total size** column contains information about the total size of the control's ViewState data.

The log can be cleared using the **Clear ViewState log** button.

Please note: ViewState of the controls is retrieved using reflection. Therefore this debug may not work properly in a [medium trust environment](#) or other specific circumstances.

7.6.3.8 Output

Output debugging can be turned on and configured either by adjusting certain settings in **Site Manager -> Settings -> System -> Debug**, or by adding certain keys into the *AppSettings* section of your *web.config* file. The following table lists and explains these settings and keys:

| Setting | Web.config key | Description |
|--------------------------|----------------------|---|
| Enable output debug | CMSDebugOutput | Enables page output debugging and the Output tab in Site Manager -> Administration -> System -> Debug . |
| Debug output of UI pages | CMSDebugAllOutputs | If enabled, output of administration interface pages (CMS Desk and Site Manager) will also be included in the output debug. This option requires output debugging to be enabled. |
| Log output to file | CMSLogOutputToFile | If enabled, output debug log is saved into the <i>logOutput.log</i> file in the <i>~\App_Data</i> folder. This option does not require output debugging to be enabled. |
| Output debug log length | CMSDebugOutputToFile | Sets the maximum length of the output debug log on the Debug -> Output tab, i.e. the number of requests for which debug information is preserved and displayed on the tab. If empty, value of the Default log length setting (or the CMSDebugEverythingLogLevelLength key) is used. |

It may happen that you specify different configuration in the settings and in the *web.config* file. In such cases, boolean settings (true/false) need to be enabled at least in one place (in *web.config* or in settings) in order to be enabled, while log lengths specified in **Site Manager -> Settings** have higher priority than log lengths specified in the *web.config*.

Here is a list of the keys for easy copy&paste into your *web.config*:

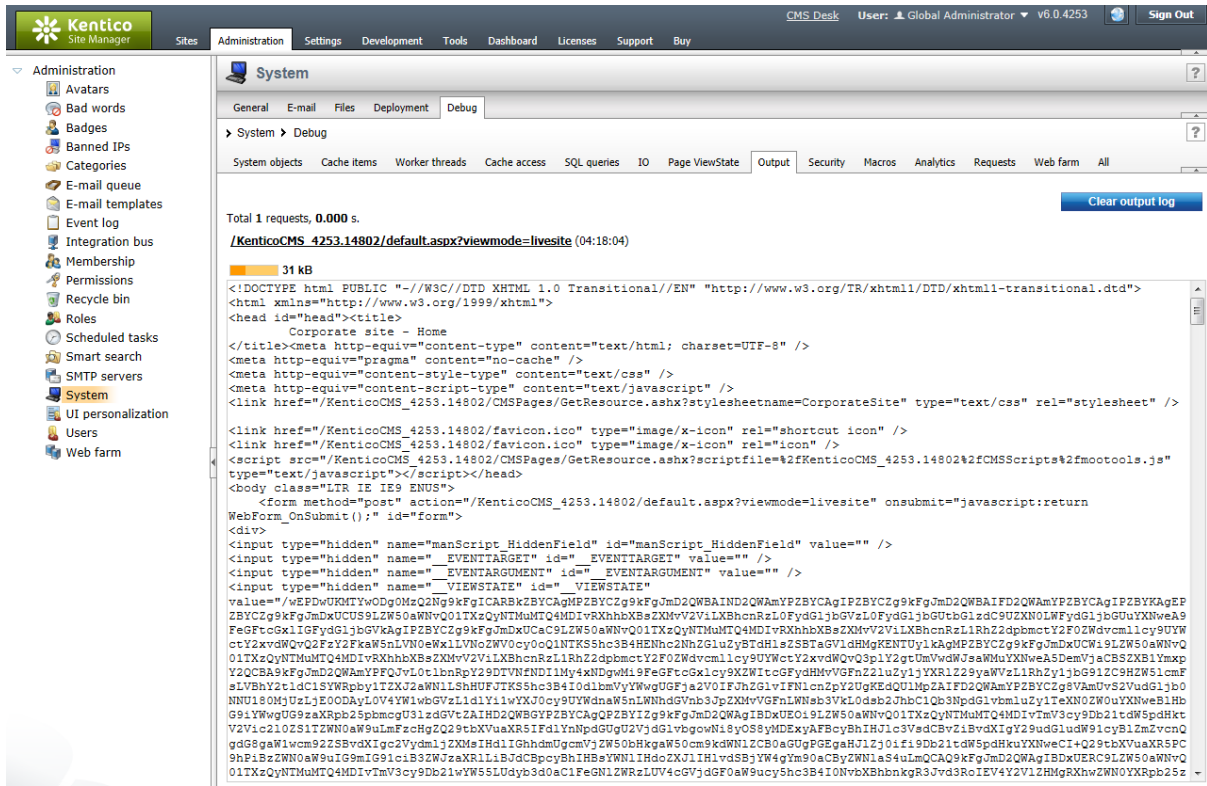

```
<add key="CMSDebugOutput" value="true" />
<add key="CMSDebugAllOutputs" value="true" />
<add key="CMSLogOutputToFile" value="true" />
<add key="CMSDebugOutputLogLength" value="10" />
```

Output debugging can also be enabled using the [general settings and keys](#).

User interface

On the **Debug -> Output** tab, you can see the exact output code of recently displayed pages. This is particularly useful in case of AJAX request, whose code cannot be viewed as part of the page source directly in the browser.

The log can be cleared using the **Clear output log** button.

7.6.3.9 Security

Security debugging can be turned on and configured either by adjusting certain settings in **Site Manager -> Settings -> System -> Debug**, or by adding certain keys into the *AppSettings* section of your *web.config* file. The following table lists and explains these settings and keys:

| Setting | Web.config key | Description |
|---------------------------------------|----------------------|--|
| Enable security debug | CMSDebugSecurity | Enables security operation debugging and the Security tab in Site Manager -> Administration -> System -> Debug . |
| Display security debug on live site | CMSDebugSecurityLive | If enabled, security operation debug information is also displayed at the bottom of each live site page. This option requires security debugging to be enabled. |
| Debug security operations of UI pages | CMSDebugAllSecurity | If enabled, security checks performed by pages of the administration interface (CMS Desk and Site Manager) will also be included in the security debug. This option requires security debugging to be enabled. |
| Log security operations to file | CMSLogSecurity | If enabled, security debug log is saved into the <i>logSecurity.log</i> file in the <i>~\App_Data</i> folder. This option does not require security debugging to be enabled. |

| | | |
|---------------------------|---------------------------|---|
| Security debug log length | CMSDebugSecurityLogLength | Sets the maximum length of the security debug log on the Debug -> Security tab, i.e. the number of requests for which debug information is preserved and displayed on the tab. If empty, value of the Default log length setting (or the CMSDebugEverythingLogLevel key) is used. |
| Display stack information | CMSDebugSecurityStack | If enabled, stack is tracked when debugging security and is displayed in the Context column. This information is only available in the debugging UI and on the live site, not in the debug log written into the <i>logSecurity.log</i> file. |

It may happen that you specify different configuration in the settings and in the *web.config* file. In such cases, boolean settings (true/false) need to be enabled at least in one place (in *web.config* or in settings) in order to be enabled, while log lengths specified in **Site Manager -> Settings** have higher priority than log lengths specified in the *web.config*.

Here is a list of the keys for easy copy&paste into your *web.config*:

```
<add key="CMSDebugSecurity" value="true" />
<add key="CMSDebugSecurityLive" value="true" />
<add key="CMSDebugAllSecurity" value="true" />
<add key="CMSLogSecurity" value="true" />
<add key="CMSDebugSecurityLogLength" value="10" />
<add key="CMSDebugSecurityStack" value="true" />
```

Security debugging can also be enabled using the [general settings and keys](#).

User interface

On the **Debug -> Security** tab, you can see which security checks were recently performed on the site. This is particularly useful if you want to quickly find out why some user is not able to access some section of the UI or gets the *Access denied* page displayed.

Enabling the **Show complete context** check-box displays complete context (not only the topmost item) in the **Context** column. The log can be cleared using the **Clear security log** button.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The left sidebar lists various administration options, with 'System' highlighted. The main content area is titled 'System' and has tabs for 'General', 'E-mail', 'Files', 'Deployment', and 'Debug'. Under the 'Debug' tab, there are sub-tabs for 'System objects', 'Cache items', 'Worker threads', 'Cache access', 'SQL queries', 'IO', 'Page ViewState', 'Output', 'Security', 'Macros', 'Analytics', 'Requests', 'Web farm', and 'All'. The 'Security' sub-tab is active, showing a table of security logs. The table has columns for 'User name', 'Operation', 'Result', 'Resource / Class / ID', 'Permission / UI element', 'Site', and 'Context'. The logs show several failed 'IsInRole' operations for the 'administrator' user. A 'Clear security log' button is visible in the top right of the log area.

| | User name | Operation | Result | Resource / Class / ID | Permission / UI element | Site | Context |
|---|---------------|-----------------------|--------|-----------------------|-------------------------|---------------|--|
| 1 | administrator | IsInRole | False | _notauthenticated_ | | CorporateSite | CMSPortalManager_LoadContent |
| 2 | administrator | IsGlobalAdministrator | True | | | | CMSPortalManager_LoadContent |
| 3 | administrator | IsGlobalAdministrator | True | | | | CMSModules_Polls_Controls_PollView_Page_Load |
| 4 | administrator | IsInRole | False | _notauthenticated_ | | CorporateSite | CMSAbstractWebPart_OnPreRender |
| 5 | administrator | IsInRole | False | _notauthenticated_ | | CorporateSite | CMSAbstractWebPart_Render |
| 6 | administrator | IsInRole | False | _notauthenticated_ | | CorporateSite | CMSAbstractWebPart_Render |
| 7 | administrator | IsInRole | False | _notauthenticated_ | | CorporateSite | CMSAbstractWebPart_Render |

Version: 6.0 Build: 6.0.4253

7.6.3.10 Macros

Macro debugging can be turned on and configured either by adjusting certain settings in **Site Manager -> Settings -> System -> Debug**, or by adding certain keys into the *AppSettings* section of your *web.config* file. The following table lists and explains these settings and keys:

| Setting | Web.config key | Description |
|-----------------------------|----------------|---|
| Enable macro debug | CMSDebugMacros | Enables macro debugging and the Macros tab in Site Manager -> Administration -> System -> Debug . |
| Enable detailed macro debug | N/A | <p>If enabled, the macro debug will additionally display the results of all sub-elements used within macro expressions. This allows you to check the exact data content of a macro's components during each step of the resolving process.</p> <p>Detailed macro debugging is highly recommended if you encounter problems with complex expressions. If disabled, only the final result of each macro will be shown in the debug.</p> <p>The detailed debug may also be enabled only for specific expressions by adding the !(debug) parameter to the given macro.</p> |

| | | |
|-----------------------------------|-------------------------|--|
| Display macro debug on live site | CMSDebugMacrosLive | If enabled, macro debug information is also displayed at the bottom of each live site page. This option requires macro debugging to be enabled. |
| Debug macros resolved on UI pages | CMSDebugAllMacros | If enabled, macros resolved on pages of the administration interface (CMS Desk and Site Manager) will also be included in the macro debug. This option requires macro debugging to be enabled. |
| Log macros to file | CMSLogMacros | If enabled, macro debug log is saved into the <i>logmacros.log</i> file in the <i>~\App_Data</i> folder. This option does not require macro debugging to be enabled. |
| Macro debug log length | CMSDebugMacrosLogLength | Sets the maximum length of the macro debug log on the Debug -> Macros tab, i.e. the number of requests for which debug information is preserved and displayed on the tab. If empty, value of the Default log length setting (or the CMSDebugEverythingLogLevel key) is used. |
| Display stack information | CMSDebugMacrosStack | If enabled, stack is tracked when debugging cache macros and is displayed in the Context column. This information is only available in the debugging UI and on the live site, not in the debug log written into the <i>logmacros.log</i> file. |

The screenshot shows the Kentico CMS 7.0 Settings interface. The left sidebar displays a tree view of settings categories, with 'Debug' highlighted under the 'System' category. The main content area shows the 'Debug' settings page, which includes a 'Save' button and a 'Reset these settings to default' link. The settings are organized into two sections: 'Debug' and 'Macros'. The 'Macros' section is highlighted with a red box and contains the following settings:

- Enable macro debug:
- Enable detailed macro debug:
- Display macro debug on live site:
- Debug macros resolved on UI pages:
- Log macros to file:
- Macro debug log length: 10
- Display stack information:

It may happen that you specify different configuration in the settings and in the *web.config* file. In such cases, boolean settings (true/false) need to be enabled at least in one place (in *web.config* or in settings) in order to be enabled, while log lengths specified in **Site Manager -> Settings** have higher priority than log lengths specified in the *web.config*.

Here is a list of these keys for easy copy&paste into your *web.config*:

```
<add key="CMSDebugMacros" value="true" />
<add key="CMSDebugMacrosLive" value="true" />
<add key="CMSDebugAllMacros" value="true" />
<add key="CMSLogMacros" value="true" />
<add key="CMSDebugMacrosLogLength" value="20" />
<add key="CMSDebugMacrosStack" value="true" />
```

Macro debugging can also be enabled using the [general settings and keys](#).

User interface

On the **Debug -> Macros** tab, you can see which macros were recently resolved. For each macro, the log displays the exact expression, the result (the value into which it was resolved) and the context from which it was called. If detailed macro debugging is enabled, the results will also be displayed for individual sub-elements that make up each macro expression. This is useful if you want to analyze how macros were processed.

Enabling the **Show complete context** check-box displays the complete context (not only the topmost item) in the **Context** column. The log can be cleared using the **Clear macro log** button.

The screenshot shows the Kentico Site Manager Administration interface. The left sidebar contains various administration options, with 'System' selected. The main content area is titled 'System' and has tabs for 'General', 'E-mail', 'Files', 'Deployment', 'Debug', and 'DB separation'. The 'Debug' tab is active, showing a sub-tab for 'Macros'. A 'Show complete context' checkbox is checked. A 'Clear macro log' button is located in the top right of the log area. The log displays the following data:

| Expression | Result | User | Context | Duration |
|---|---|---------------|---------------------------------------|----------|
| 1 {% prefix %} | Corporate site | | DocumentBase Load | 0.261 |
| > prefix | Corporate site | | | 0.110 |
| 2 {% pagetitle_orelse_name %} | Services | | DocumentBase Load | 0.001 |
| > pagetitle_orelse_name | Services | | | 0.000 |
| 3 {% MyComparisonMethod("test", "TEST") ? "Equal" : "Not Equal" %} | Not Equal | | CMSPagePlaceholder LoadRegionsContent | 0.023 |
| > MyComparisonMethod("test", "TEST") ? "Equal" : "Not Equal" | Not Equal | | | 0.009 |
| >> MyComparisonMethod("test", "TEST") | False | | | 0.008 |
| 4 {% date = CurrentDateTime.Year; if (date > 2000) (ResolveMacros ("
 Current year is (% date %), which is after 2000.
")) %} |
 Current year is , which is after 2000.
 | administrator | CMSPagePlaceholder LoadRegionsContent | 0.840 |
| > date = CurrentDateTime.Year | 2012 | | | 0.026 |
| >> CurrentDateTime.Year | 2012 | | | 0.013 |
| >>> CurrentDateTime | 5/31/2012 11:27:59 AM | | | 0.004 |
| > if (date > 2000) { | True | | | 0.000 |
| >> date > 2000 | True | | | 0.033 |
| >>> date | 2012 | | | 0.000 |

7.6.3.11 Analytics

Web analytics debugging can be turned on and configured either by adjusting certain settings in **Site Manager -> Settings -> System -> Debug**, or by adding certain keys into the *AppSettings* section of

your *web.config* file. The following table lists and explains these settings and keys:

| Setting | Web.config key | Description |
|--|-----------------------------|--|
| Enable web analytics debug | CMSDebugAnalytics | Enables web analytics debugging and the Analytics tab in Site Manager -> Administration -> System -> Debug . |
| Display web analytics debug on live site | CMSDebugAnalytics Live | If enabled, web analytics debug information is also displayed at the bottom of each live site page. This option requires web analytics debugging to be enabled. |
| Log web analytics to file | CMSLogAnalytics | If enabled, web analytics debug log is saved into the <i>loganalytics.log</i> file in the <i>~App_Data</i> folder. This option does not require web analytics debugging to be enabled. |
| Web analytics debug log length | CMSDebugAnalytics LogLength | Sets the maximum length of the web analytics debug log on the Debug -> Analytics tab, i.e. the number of requests for which debug information is preserved and displayed on the tab. If empty, value of the Default log length setting (or the CMSDebugEverythingLogLength key) is used. |
| Display stack information | CMSDebugAnalytics Stack | If enabled, stack is tracked when debugging web analytics and is displayed in the Context column. This information is only available in the debugging UI and on the live site, not in the debug log written into the <i>loganalytics.log</i> file. |

The screenshot shows the Kentico Site Manager Administration interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The left sidebar shows a tree view of settings categories: Content, URLs and SEO, Security & Membership, System (with sub-items: Performance, E-mails, Files, Health monitoring, Output filter, Search, Debug), On-line marketing, E-commerce, Community, Intranet & Collaboration, Versioning & Synchronization, Integration, and Cloud services. The main content area displays the 'Settings' page for the 'Analytics' section. The 'Enable web analytics debug' setting is highlighted with a red box. Other settings visible include 'Macro debug log length' (10), 'Display stack information' (checked), 'Log web analytics to file', 'Web analytics debug log length' (10), and 'Enable request debug'.

It may happen that you specify different configuration in the settings and in the *web.config* file. In such cases, boolean settings (true/false) need to be enabled at least in one place (in *web.config* or in

settings) in order to be enabled, while log lengths specified in **Site Manager -> Settings** have higher priority than log lengths specified in the `web.config`.

Here is a list of the keys for easy copy&paste into your `web.config`:

```
<add key="CMSDebugAnalytics" value="true" />
<add key="CMSDebugAnalyticsLive" value="true" />
<add key="CMSLogAnalytics" value="true" />
<add key="CMSDebugAnalyticsLogLength" value="10" />
<add key="CMSDebugAnalyticsStack" value="true" />
```

IO operation debugging can also be enabled using the [general settings and keys](#).

User interface

On the **Analytics** tab, you can see which statistics were logged by the Web analytics module for individual requests. For each logged item, you can see the code name of the logged operation, the object to which the operation relates, number of the performed operations and the name of the site where the operation was performed. In the **Context** column, you can see the context from which the operation was logged.

Enabling the **Show complete context** check-box displays complete context (not only the topmost item) in the **Context** column. The log can be cleared using the **Clear analytics log** button.

The screenshot shows the Kentico Site Manager Administration interface. The left sidebar contains various administration options like Avatars, Bad words, Badges, etc. The main content area is titled 'System' and has tabs for General, E-mail, Files, Deployment, and Debug. Under the 'Debug' tab, there are sub-tabs for System objects, Cache items, Worker threads, Cache access, SQL queries, IO, Page ViewState, Output, Security, Macros, Analytics, Requests, All, and Log files. The 'Analytics' sub-tab is active, showing a list of log entries. A 'Show complete context' checkbox is checked, and a 'Clear analytics log' button is present. The log entries are as follows:

| Code name | Object | Count | Site name | Context |
|-----------|---------------|-------|-----------|--|
| 1 | filedownloads | 1 | CorpSite | CMSPages_GetFile_Page_Load
Version: 6.0 Build: 6.0.4262 |
| 1 | filedownloads | 1 | CorpSite | CMSPages_GetFile_Page_Load
Version: 6.0 Build: 6.0.4262 |
| 1 | filedownloads | 1 | CorpSite | CMSPages_GetFile_Page_Load
Version: 6.0 Build: 6.0.4262 |

7.6.3.12 Requests

Request debugging can be turned on and configured either by adjusting certain settings in **Site Manager -> Settings -> System -> Debug**, or by adding certain keys into the `AppSettings` section of your `web.config` file. The following table lists and explains these settings and keys:

| Setting | Web.config key | Description |
|---------|----------------|-------------|
|---------|----------------|-------------|

| | | |
|------------------------------------|----------------------------|---|
| Enable request debug | CMSDebugRequests | Enables request debugging and the Requests tab in Site Manager -> Administration -> System -> Debug . |
| Display request debug on live site | CMSDebugRequests Live | If enabled, request debug information is also displayed at the bottom of each live site page. This option requires request debugging to be enabled. |
| Debug UI page requests | CMSDebugAllRequests | If enabled, administration interface (CMS Desk and Site Manager) page requests will also be included in the macro debug. This option requires request debugging to be enabled. |
| Log requests to file | CMSLogRequests | If enabled, request debug log is saved into the <i>logRequests.log</i> and <i>logRequestsUrls.log</i> files in the <i>~\App_Data</i> folder. The first file contains the full log, while the second one only lists requested URLs. This option does not require request debugging to be enabled. |
| Request debug log length | CMSDebugRequests LogLength | Sets the maximum length of the request debug log on the Debug -> Requests tab, i.e. the number of requests for which debug information is preserved and displayed on the tab. If empty, value of the Default log length setting (or the CMSDebugEverythingLogLength key) is used. |
| Display stack information | CMSDebugRequests Stack | If enabled, stack is tracked when debugging requests and is displayed in the Context column. This information is only available in the debugging UI and on the live site, not in the debug log written into the <i>logRequests.log</i> file. |

The screenshot shows the Kentico CMS 7.0 Administration interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The left sidebar shows a tree view of settings categories: Content, URLs and SEO, Security & Membership, System, Performance, E-mails, Files, Health monitoring, Output filter, Search, Debug, On-line marketing, E-commerce, Community, Intranet & Collaboration, Versioning & Synchronization, Integration, and Cloud services. The 'Debug' category is selected, and the 'Requests' section is highlighted with a red box. The 'Requests' section contains the following settings:

- Enable request debug:
- Display request debug on live site:
- Debug UI page requests:
- Log requests to file:
- Request debug log length:
- Display stack information:

Below the 'Requests' section, the 'Web farm' section is visible with the following settings:

- Enable web farm debug:
- Debug web farm operations of UI pages:

It may happen that you specify different configuration in the settings and in the *web.config* file. In such cases, boolean settings (true/false) need to be enabled at least in one place (in *web.config* or in settings) in order to be enabled, while log lengths specified in **Site Manager -> Settings** have higher priority than log lengths specified in the *web.config*.

Here is a list of the keys for easy copy&paste into your *web.config*:

```
<add key="CMSDebugRequests" value="true" />
<add key="CMSDebugRequestsLive" value="true" />
<add key="CMSDebugAllRequests" value="true" />
<add key="CMSLogRequests" value="true" />
<add key="CMSDebugRequestsLogLength" value="5" />
<add key="CMSDebugRequestsStack" value="true" />
```

Request debugging can also be enabled using the [general settings and keys](#).

User interface

On the **Debug -> Requests** tab, you can see the time each of the recent page requests took to process. You not only see the overall time, but also separate times of particular parts of each requests, along with other detailed information about the request.

This is particularly useful if your response time is too large and you need to figure out why. You can basically see whether the issue is outside the application or inside it by comparing the real response time and response time spent in the application, what data came with the request and from which context.

Enabling the **Show complete context** check-box displays complete context (not only the topmost item) in the **Context** column. The log can be cleared using the **Clear request log** button.

The screenshot shows the Kentico CMS 7.0 Site Manager interface. The left sidebar contains a navigation menu with categories like Administration, Avatars, Bad words, Badges, Banned IPs, Categories, E-mail queue, E-mail templates, Event log, Integration bus, Membership, Permissions, Recycle bin, Roles, Scheduled tasks, Smart search, SMTP servers, System (selected), UI personalization, Users, and Web farm. The main content area is titled 'System' and has tabs for General, E-mail, Files, Deployment, and Debug. Under the Debug tab, there are sub-tabs for System objects, Cache items, Worker threads, Cache access, SQL queries, IO, Page ViewState, Output, Security, Macros, Analytics, Requests (selected), Web farm, and All. A 'Clear requests log' button is visible. The main content shows a summary: 'Total 6 requests, 21.104 s.' and the URL: '/KenticoCMS_4253.14802/Images/arrow_examples.aspx?width=94&height=23&ext=.png (04:18:07)'. Below this is a table of requests:

| Method | Additional info | From first | Duration |
|------------------------------|--|------------|----------|
| 1 | BeginRequest | 0.000 | 0.000 |
| 2 | AuthorizeRequest | 0.000 | 0.011 |
| 3 | MapRequestHandler | 0.011 | 0.001 |
| 4 | RewriteURL /images/arrow_examples.aspx | 0.012 | 1.266 |
| 5 | AcquireRequestState | 1.277 | 0.000 |
| 6 | > OnPreInit | 1.277 | 0.004 |
| 7 | > OnInit | 1.281 | 0.000 |
| 8 | > OnLoad | 1.281 | 0.124 |
| 9 | > WriteBytes 2.6 kB | 1.405 | 0.001 |
| 10 | > CompleteRequest | 1.406 | 0.000 |
| 11 | > OnPreRender | 1.406 | 0.000 |
| 12 | > Render | 1.406 | 0.000 |
| 13 | > OnUnload | 1.406 | 0.000 |
| 14 | EndRequest 200 OK | 1.406 | 0.000 |
| 15 | FinishRequest | 1.406 | N/A |
| Version: 6.0 Build: 6.0.4253 | | 1.406 | |

Below the table, there are sections for 'Request cookies:' and 'Request information:'. The 'Request cookies:' section lists 8 cookies with their names and values. The 'Request information:' section lists 7 request details with their names and values.

7.6.3.13 Web farm

Web farm debugging can be turned on and configured either by adjusting certain settings in **Site Manager -> Settings -> System -> Debug**, or by adding certain keys into the *AppSettings* section of your *web.config* file. The following table lists and explains these settings and keys:

| Setting | Web.config key | Description |
|---------------------------------------|--------------------|---|
| Enable web farm debug | CMSDebugWebFarm | Enables request debugging and the Web farm tab in Site Manager -> Administration -> System -> Debug . |
| Debug web farm operations of UI pages | CMSDebugAllWebFarm | If enabled, operations performed via the administration interface (CMS Desk and Site Manager) will also be included in the web farm debug. This option requires web farm debugging to |

| | | |
|---------------------------------|------------------------------|--|
| | | be enabled. |
| Log web farm operations to file | CMSLogWebFarm | If enabled, web farm debug log is saved into the <i>logwebfarm.log</i> file in the <i>~\App_Data</i> folder. This option does not require web farm debugging to be enabled. |
| Web farm debug log length | CMSDebugWebFarm
LogLength | Sets the maximum length of the web farm debug log on the Debug -> Requests tab, i.e. the number of requests for which debug information is preserved and displayed on the tab. If empty, value of the Default log length setting (or the CMSDebugEverythingLogLength key) is used. |
| Display stack information | CMSDebugWebFarm
Stack | If enabled, stack is tracked when debugging web farm operations and is displayed in the Context column. This information is only available in the debugging UI and on the live site, not in the debug log written into the <i>logwebfarm.log</i> file. |

The screenshot shows the Kentico Site Manager interface. The 'Settings' tab is active, and the 'Web farm' section is highlighted with a red box. The settings in this section are:

- Enable web farm debug:
- Debug web farm operations of UI pages:
- Log web farm operations to file:
- Web farm debug log length: 10
- Display stack information:

The 'All' section below it has:

- Debug everything everywhere:

Please note that web farm debugging is only functional if web farms are enabled in the *web.config* and at least one server is defined (as described in [Modules -> Web farm synchronization -> Defining web farm server](#)).

It may happen that you specify different configuration in the settings and in the *web.config* file. In such cases, boolean settings (true/false) need to be enabled at least in one place (in *web.config* or in settings) in order to be enabled, while log lengths specified in **Site Manager -> Settings** have higher priority than log lengths specified in the *web.config*.

Here is a list of the keys for easy copy&paste into your *web.config*:

```
<add key="CMSDebugWebFarm" value="true" />
<add key="CMSDebugAllWebFarm" value="true" />
<add key="CMSLogWebFarm" value="true" />
<add key="CMSDebugWebFarmLogLength" value="20" />
<add key="CMSDebugWebFarmStack" value="true" />
```

Web farm debugging can also be enabled using the [general settings and keys](#).

User interface

On the **Debug -> Web farm** tab, you can see which web farm synchronization tasks were logged and which servers were notified about the changes. This is particularly useful if you want to find out if the web farm works effectively and synchronizes data correctly, or generally if you want to troubleshoot web-farm-related issues.

The following screenshot shows how the debug looks on the source server (the server where the data was modified). The bottom part displays the logged tasks, while the top part shows asynchronous notifications for other web farm servers.

The screenshot shows the Kentico CMS Administration interface. The left sidebar contains various administration options, with 'System' selected. The main content area is titled 'System' and has tabs for 'General', 'E-mail', 'Files', 'Deployment', and 'Debug'. The 'Debug' tab is active, showing a list of tasks. The top part of the debug area shows a notification for a task on a target server. The bottom part shows a task on the source server.

| Task type | Target | Data | Context |
|------------------|--|---|---|
| 1 NOTIFY | http://davids/5.0_Release/CMSPages/webfarmupdater.aspx | | Version: 6.0 Build: 6.0.4253 |
| 1 TOUCHCACHEITEM | Cache | cms.role all
cms.role byid 13
cms.role byname newrole
cms.role byguid 03b73d97-b937-4add-99d7-18709d7ad7bc | WebSyncHelperClass.CreateTask
CacheHelper.TouchKeys
AbstractInfo.TouchKeys
AbstractInfo.Insert
SynchronizedInfo.Insert
RoleInfoProvider.SetRoleInfoInternal
RoleInfoProvider.SetRoleInfo
CMSSiteManager_Administration_Roles_Controls_RoleEdit.btnOK_Click
Version: 6.0 Build: 6.0.4253 |

The second screenshot shows how the debug looks on the target server after it is notified about the modification. You can recognize the task by the *DO:* prefix, which indicates that the synchronization task was (is being) processed.

Enabling the **Show complete context** check-box displays complete context (not only the topmost item) in the **Context** column. The log can be cleared using the **Clear web farm log** button.

| Task type | Target | Data | Context |
|----------------------|--------|---|---|
| 1 DO: TOUCHCACHEITEM | Cache | cms.role all
cms.role byid 13
cms.role byname newrole
cms.role byguid 03b73d97-b937-4add-99d7-18709d7ad7bc | WebSyncHelper.ProcessMyTasks
CMSPages_WebFarmUpdater.Page_Load

Version: 6.0 Build: 6.0.4253 |

7.6.3.14 All

The **Debug -> All** tab is only displayed when at least two of the debugs that are not enabled by default (i.e. all except **System objects**, **Cache items** and **Worker threads**) are enabled, while the **Request** debug must be one of them.

This tab works as an aggregator of information logged by all enabled types of debugs. For each requests, it displays debug information from all enabled debugs. The information is listed in the order in which the respective action was processed within the request.

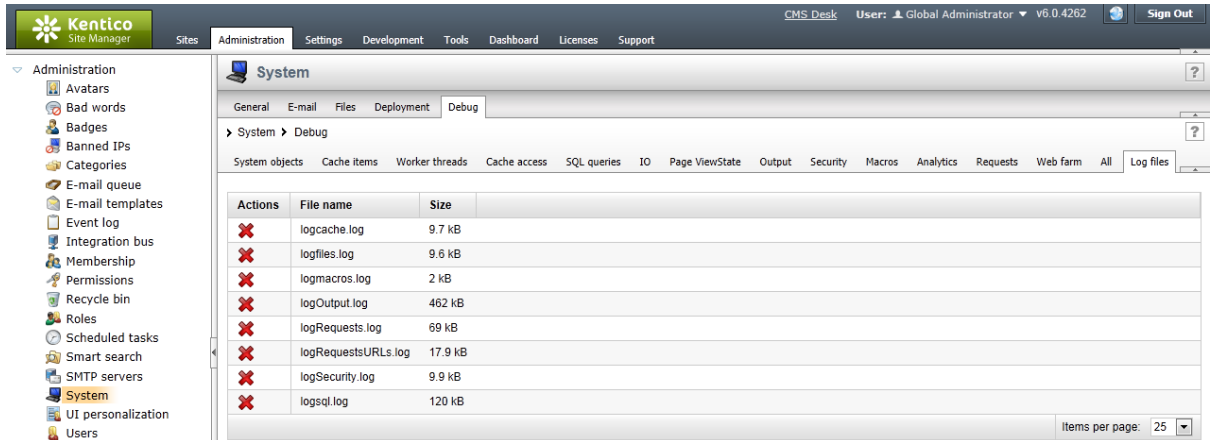

Enabling the **Show complete context** check-box displays complete context (not only the topmost item) in the **Context** column. The logged debug information can be cleared using the **Clear log** button.

| Type | Debug specific information | Result | Context | Total duration | Duration |
|------------|---|--------|---|----------------|----------|
| 0 Request | BeginRequest | | | 0.001 | N/A |
| 1 Request | AuthorizeRequest | | | 0.000 | N/A |
| 2 Request | MapRequestHandler | | | 0.000 | N/A |
| 3 Request | RewriteURL | | | 0.030 | N/A |
| 4 Request | AcquireRequestState | | | 0.024 | N/A |
| 5 Request | OnPreInit | | | 0.044 | N/A |
| 6 Security | IsGlobalAdministrator (administrator) | True | CMSPage_OnPreInit | N/A | N/A |
| 7 Request | OnInit | | | 0.000 | N/A |
| 8 Request | OnLoad | | | 0.038 | N/A |
| 9 Security | IsGlobalAdministrator (administrator) | True | SiteManagerPage_BasePage_Load | N/A | N/A |
| 10 Query | Proc_CMS_SqlResourceManager_GetStringByKey
@stringKey ("Administration-System.Header")
@cultureCode ("en-US")
75 B | | CMSModules_System_System_Header_Page_Load | N/A | 0.015 |

7.6.3.15 Log files

The **Debug -> Log files** tab is only displayed when logging of debug information into log files is enabled for at least one type of debug. This can be achieved either by adjusting certain settings or by adding certain keys into the *appSettings* section of your *web.config* file. Please see the topics about particular debugs above or the [General settings and keys for all debugs](#) topic below for more details.

This tab provides an overview of all log files stored in the `~\App_Data` folder. By clicking the **Delete** (✖) button, you can delete the respective file from the `App_Data` folder.

7.6.3.16 E-mails

E-mail debugging can help you resolve problems with newsletter, notification and other e-mails sent by Kentico CMS. To enable it, add the following keys to the `web.config` file of your web project:

```
<add key="CMSLogEmails" value="true" />
<add key="CMSDebugEmails" value="true" />
```

The **first key** enables you to log all the sent e-mails. You can find the logged e-mails in `<web root>/AppData/logemails.log`. The log contains each e-mail's recipient and subject. The following extract from the log shows 2 newsletters sent to 3 recipients each.

```
Rcpt: subscriber@localhost.local
Subject: Newsletter #1

Rcpt: subscriber2@localhost.local
Subject: Newsletter #1

Rcpt: subscriber3@localhost.local
Subject: Newsletter #1

Rcpt: subscriber@localhost.local
Subject: Newsletter #2

Rcpt: subscriber2@localhost.local
Subject: Newsletter #2

Rcpt: subscriber3@localhost.local
Subject: Newsletter #2
```

The **second key** enables you to log all the sent e-mails into event log without actually sending them to the recipients. This is helpful when you need to test the functionality but do not want the testing e-mails

to actually reach the recipient.

You can view the event log in **Site Manager -> Administration -> Event log**. The e-mails are logged as an **Information** type of event. The following picture shows a logged e-mail sent to three different recipients. The recipient's address is mentioned in the **Event code** column of the Event log.

| Actions | Type | Event time | Source | Event code | User name | IP address | Document name | Site | Machine name |
|---------|------|-----------------------|------------------|-----------------------------|-----------|------------|---------------|----------------|--------------|
| | I | 5/15/2012 10:21:16 AM | Newsletter issue | UPDATEOBJ | | ::1 | | Corporate Site | JAKUBC-PC |
| | I | 5/15/2012 10:21:15 AM | Mail | SUBSCRIBER3@LOCALHOST.LOCAL | | ::1 | | | JAKUBC-PC |
| | I | 5/15/2012 10:21:14 AM | Mail | SUBSCRIBER2@LOCALHOST.LOCAL | | ::1 | | | JAKUBC-PC |
| | I | 5/15/2012 10:21:13 AM | Mail | SUBSCRIBER@LOCALHOST.LOCAL | | ::1 | | | JAKUBC-PC |

Additionally, with the second key enabled, a **'Sending failed for <recipient's e-mail address>'** error is generated at random to simulate an error when sending an e-mail.

You can find more information on viewing logged events in [Developer's guide -> Modules -> Event log](#).

7.6.4 General settings and keys for all debugs

Apart from the settings and *web.config* keys for individual debugs listed in the topics above, you can use the following general settings and keys to configure debugging on a global level, i.e. to affect all the individual debugs. In **Site Manager -> Settings -> System -> Debug**, the global settings are located in two setting groups.

In the **General** group, you can find the following settings:

| Setting | Web.config key | Description |
|---------------------|----------------------|--|
| Disable debugging | CMSDisableDebug | Globally disables all debugs, regardless of individual debug settings. |
| Debug Import/Export | CMSDebugImportExport | If disabled, debug information is not logged for the Import/Export user interface. To optimize system performance, it is recommended to have this option disabled unless you really need to debug the Import/Export process. |
| Debug resources | CMSDebugResources | If false, all resource requests (<i>GetResource</i> and <i>GetCSS</i>) are ignored by all debugs. |
| Debug scheduler | CMSDebugScheduler | If false, all scheduler operations are excluded from all debugs. |

The screenshot shows the Kentico CMS 7.0 Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The 'Settings' tab is active, and the 'Debug' settings page is displayed. The left sidebar shows a tree view of settings categories, with 'Debug' selected. The main content area is titled 'Debug' and contains two sections: 'General' and 'Cache access'. The 'General' section has four settings, each with a green question mark icon and a checkbox: 'Disable debugging' (checkbox unchecked), 'Debug Import/Export' (checkbox unchecked), 'Debug resources' (checkbox unchecked), and 'Debug scheduler' (checkbox checked). The 'Cache access' section has three settings, each with a green question mark icon and a checkbox: 'Enable cache access debug' (checkbox unchecked), 'Display cache access debug on live site' (checkbox unchecked), and 'Debug cache access of UI pages' (checkbox unchecked).

In the **All** group, the following settings can be found:

| Setting | Web.config key | Description |
|------------------------------------|------------------------------|---|
| Debug everything everywhere | CMSDebugEverythingEverywhere | Enables all debugs, includes UI pages in all debugs and ensures that the debugs are displayed both in the Site Manager -> Administration -> System -> Debug interface and on the live site. |
| Enable all debugs | CMSDebugEverything | Enables all debugs and ensures that the corresponding tabs are displayed in Site Manager -> Administration -> System -> Debug . |
| Display all debugs on live site | CMSDebugEverythingLive | If enabled, debug information of all debug types is displayed at the bottom of each live site page. This only applies to debugs that are already enabled. |
| Include UI pages in all debugs | CMSDebugAllForEverything | If enabled, actions performed on UI pages are included in all debugs. This only applies to debugs that are already enabled. |
| Log everything to file | CMSLogEverythingToFile | Enables logging of all possible operations (including the Event log and E-mail sending log) into .log files stored in the <code>~/App_Data/</code> folder. |
| Default log length | CMSDebugEverythingLogLength | Sets the default maximum length of all debugs on the respective tabs in Site Manager -> Administration -> System -> Debug . This value is used if no log length is configured for the respective type of debug. |
| Display stack information in every | CMSDebugStackForEverything | If enabled, stack is tracked by all debugs and is displayed on the respective tabs in Site Manager -> |

debug Administration -> System -> Debug.

The screenshot shows the Kentico Site Manager Administration interface. The left sidebar contains a tree view of settings categories, with 'System' expanded to show 'Debug'. The main content area displays the 'Debug' settings page. The 'All' section is highlighted with a red box and contains the following settings:

- Debug everything everywhere:
- Enable all debugs:
- Display all debugs on live site:
- Include UI pages in all debugs:
- Log everything to file:
- Default log length: 10
- Display stack information in every debug:

Here is a list of the keys for easy copy&paste into your *web.config*:

```
<add key="CMSDisableDebug" value="true" />
<add key="CMSDebugStackForEverything" value="true" />
<add key="CMSDebugImportExport" value="true" />
<add key="CMSDebugResources" value="true" />

<add key="CMSDebugEverythingEverywhere" value="true" />
<add key="CMSDebugEverything" value="true" />
<add key="CMSDebugEverythingLive" value="true" />
<add key="CMSDebugAllForEverything" value="true" />
<add key="CMSLogEverythingToFile" value="true" />
<add key="CMSDebugEverythingLogLength" value="10" />
```

7.6.5 System error notifications

If you go to **Site Manager -> Settings -> System** and fill in an e-mail address into the **Error notification e-mail address**, notifications about internal errors in Kentico CMS system will be sent to this address whenever such an error occurs.

The e-mail address specified in the **No-reply e-mail address** field will be used as the sender ('From') e-mail address.

The screenshot shows the Kentico CMS 7.0 Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The 'Settings' tab is active, and the 'System' settings page is displayed. The left sidebar shows a tree view of settings categories, with 'System' selected. The main content area is titled 'System' and contains a 'Save' button and a link to 'Reset these settings to default'. Below this, a message states: 'These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.' The settings are organized into three sections: 'General', 'Scheduler', and 'E-mails'. The 'E-mails' section is highlighted with a red box and contains the following settings:

| Setting | Value |
|-----------------------------------|--------------------------|
| No-reply e-mail address | no-reply@localhost.local |
| Error notification e-mail address | admin@localhost.local |
| Send e-mail notifications from | no-reply@localhost.local |

7.7 Document types and transformations

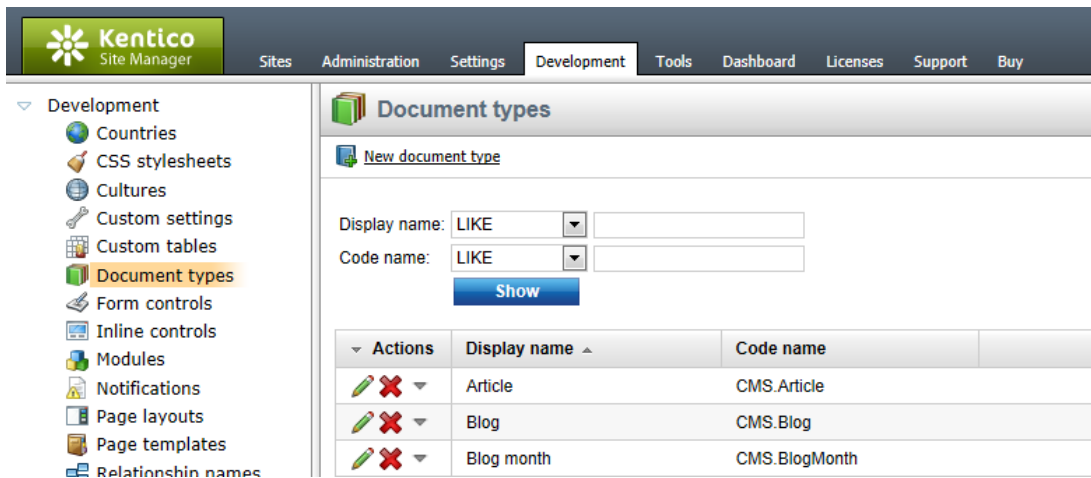

7.7.1 Overview

Each document in Kentico CMS is of some type. Each document type has its own:

- fields (data structure)
- editing form layout
- transformations (design)
- queries

and other settings.

Document types are fully customizable - you can add, modify and delete custom fields. The advantage of using custom document types is that you can define custom structure of documents and store content (data) separated from design. This can be done in **Site Manager -> Development -> Document types**.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The left sidebar shows a 'Development' menu with options like 'Countries', 'CSS stylesheets', 'Cultures', 'Custom settings', 'Custom tables', 'Document types' (highlighted), 'Form controls', 'Inline controls', 'Modules', 'Notifications', 'Page layouts', 'Page templates', and 'Relationship names'. The main content area is titled 'Document types' and contains a 'New document type' wizard. The wizard has two input fields: 'Display name' and 'Code name', both set to 'LIKE'. Below the fields is a 'Show' button. At the bottom, there is a table listing existing document types:

| Actions | Display name | Code name |
|---|--------------|---------------|
|   | Article | CMS.Article |
|   | Blog | CMS.Blog |
|   | Blog month | CMS.BlogMonth |

- To learn how to define a new document type, please refer to the [Defining a new document type](#) topic.
- To learn about document type properties, please refer to the [Document type properties](#) topic.
- To learn how to upload your own icons and associate them with document types, please refer to the [Uploading document type icons](#) topic.
- Transformations as used in Kentico CMS are described in the [Transformations](#) subchapter.

To see a practical example of creating a new document, please refer to the [Creating a new structured document](#) topic in the Content management -> Editing content section of this guide.

7.7.2 Defining a new document type

In this example, you will learn how to define a new custom document type.

1. Go to **Site Manager -> Development -> Document types** and click  **New document type**. You will be redirected to the New document type wizard. In the first step, enter the following values:

- **Document type display name:** Computer (this name will be displayed to users in the administration interface)
- **Document type code name:** custom.computer (*custom* is your namespace to distinguish your own document types from system types that use the *cms* namespace, *computer* is the document type). You will use this value in web part properties later.

Click **Next**.

The screenshot shows the 'New document type' wizard in the Kentico CMS 7.0 Site Manager. The interface includes a top navigation bar with 'Development' selected, and a left sidebar with various development tools. The main content area is titled 'New document type' and shows 'Step 1: General'. The instructions for this step are: 'Please enter document type display name (for users) and code name (it will be used in your code when necessary)'. The form contains two input fields: 'Document type display name' with the value 'Computer', and 'Document type code name' with the value 'custom.namespace.computer.document.type'. A 'Next >' button is located at the bottom right of the form.

2. In Step 2, you need to choose the name of the database table that will be used for storing computer details. You also need to enter the name of the primary key in this table. Enter the following values:

- **Table name:** CUSTOM_Computer
- **Primary key name:** ComputerID
- **Inherits fields from document type:** (none)

Click **Next**.

The screenshot shows the 'Data type' step of the 'New document type' wizard. The instructions are: 'Please choose document data type. If you choose a document type with custom attributes you will also need to supply names of the new database table and its primary key.' There are two radio button options: 'The document type has custom fields' (which is selected) and 'The document type is only a container without custom fields'. Under the selected option, there are three input fields: 'Table name' with the value 'custom_computer', 'Primary key name' with the value 'ComputerID', and 'Inherits fields from document type' with a dropdown menu set to '(none)'. A 'Next >' button is located at the bottom right of the form.

3. The wizard has created a new database table for computers. Now you need to define the fields of the document type (columns of the table). Use the **New attribute** (+) button to create the following fields. For each field, enter the values, click **Save** and repeat the procedure until you have all the listed fields defined.

- **Column name:** ComputerName
 - **Attribute type:** Text
 - **Attribute size:** 200
 - **Field caption:** Computer name
 - **Form control:** Text box
-
- **Column name:** ComputerProcessorType
 - **Attribute type:** Text
 - **Attribute size:** 200
 - **Field caption:** Processor type
 - **Form control:** Drop-down list
 - **Editing control settings -> Data source:** select *Options* and enter the following items into the text area, one per line:
Athlon;Athlon
Pentium XEON;Pentium XEON
Pentium Core 2 Duo;Pentium Core 2 Duo
-
- **Column name:** ComputerRamSize
 - **Attribute type:** Integer number
 - **Field caption:** RAM (MB)
 - **Form control:** Text box
-
- **Column name:** ComputerHddSize
 - **Attribute type:** Integer number
 - **Field caption:** HDD (GB)
 - **Form control:** Text box
-
- **Column name:** ComputerImage
 - **Attribute type:** File
 - **Allow empty value:** Enabled (check the box)
 - **Field caption:** Image
 - **Form control:** Upload file

Step 3
Fields

Please define custom attributes of the document type and their appearance in the editing form. You can define attributes, such as product number, product weight, press release text, etc.

ComputerID*
ComputerName*
ComputerProcessorType*
ComputerRamSize*
ComputerHddSize*
ComputerImage

Save

The changes were saved.

Database

Column name:

Attribute type:

Attribute size:

Allow empty value:

Display attribute in the editing form

Field appearance

Field caption:

Form control:

Field description:

Next >

Please note that you can also define system fields that will be displayed when editing documents of this type on the **Form** tab. This can be done by clicking the **New system attribute** (🌐) button. Using the **Group** drop-down list, you can then choose from the following two groups of system fields:

- **Document attributes** - offers the system fields of documents.
- **Node attributes** - offers the system fields of content tree nodes.

Document or node system fields will then be offered in the **Attribute name** drop-down list. If you leave the **Display attribute in the editing form** check-box checked, the field will be visible on the document **Form** tab.

Click **Next**.

Step 3
Fields
Please define custom attributes of the document type and their appearance in the editing form. You can define attributes, such as product number, product weight, press release text, etc.

| ComputerName | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="text"/> |
| ComputerProcessorType | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="text"/> |
| ComputerRamSize | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text"/> |
| ComputerHddSize | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text"/> |

Next >

8. The wizard has finished the configuration of the new document type. It has automatically created not only the database table, but also the SQL queries for SELECT, INSERT, UPDATE and DELETE operations and default transformations.

Click **Finish**. Congratulations, you have learned how to define a new document type.

Step 8

The wizard has finished

The setup has finished the following steps:

- › The new document type was created.
- › The new editing form was created.
- › The document types were added among allowed child types of the new document type.
- › The sites were selected where this document type can be used.
- › The default queries were created.
- › The default ASCX transformations were created.
- › The default permission names were created.
- › The default icon was created.
- › Document smart search specification was created.

Finish**How the content is stored**

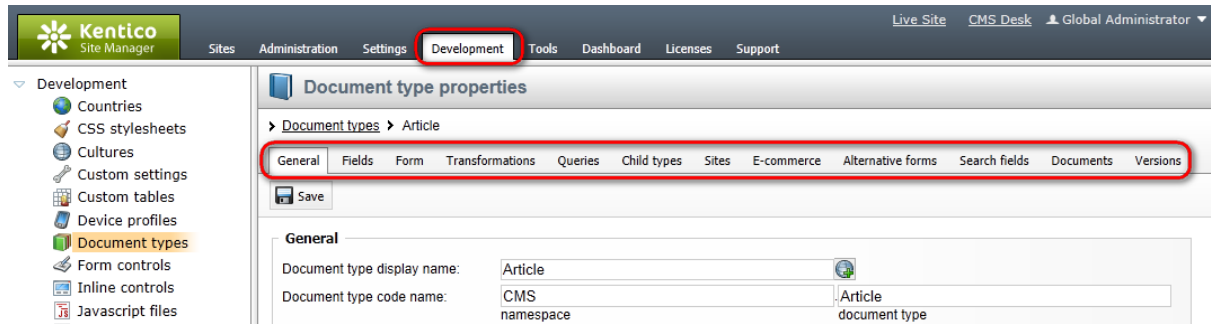

As you already know, the new document type *Computer* has its own database table for its specific fields. Each document is stored in three tables: *CMS_TREE* (tree structure), *CMS_Document* (document properties, metadata and content defined on the Page tab) and the custom table - in this case *CUSTOM_Computer*.

The system automatically ensures all operations are performed correctly on these tables. The advantage of this storage is that it is very fast and you can easily write standard SQL SELECT queries to retrieve data from the repository (i.e. from the Microsoft SQL Server database).

7.7.3 Document type properties

Document type properties can be accessed in **Site Manager -> Development -> Document types -> Edit (✎) Document type**.

The Document types properties user interface [consists](#) of the following tabs: [General](#), [Fields](#), [Form](#), [Transformations](#), [Queries](#), [Child types](#), [Sites](#), [E-commerce](#), [Alternative forms](#), [Search fields](#), [Documents](#) and [Versions](#).

General tab

The general properties of a document type define its basic characteristics as shown below:

| General | |
|-----------------------------------|---|
| Document type display name | The name of the document type displayed in the administration and content editing interface. |
| Document type code name | Sets a namespace prefix and unique name that serves as an identifier for the document type, for example in selectors or the API. |
| Table name | Displays the name of the database table used to store coupled data for documents of this type, i.e. the content of its specific fields. |
| Inherit fields from document type | If a document type is selected and saved, the definitions of its fields will be loaded and added to the current document type. These fields can be viewed and modified on the Fields tab. |
| Document type icons | Allows you to upload custom icons that will be used to represent the document type in various parts of the system. |
| New document settings | |
| New page | URL of the page that will be used when creating new documents of this type. |
| Show template selection | Indicates if users will be required to select a page template when creating a new document of this type. |
| Root page template category | May be used to limit the page template options available for documents of this type to a specific sub-section of the template catalog. When creating new documents of the given type, users can only choose from the templates located under the specified category or in its child categories. |
| Default page template | Sets the page template used by default when the document is created. If no page template is specified, new documents will inherit the template of their parent by default. |
| Editing pages settings | |

| | |
|---|--|
| (these should only be specified if you do not wish to use the system's default editing pages) | |
| Editing page | URL of the editing page that will be used when the document is displayed in editing mode via the Page tab. |
| Editing form | URL of the editing page that will be used when the document is displayed in editing mode on the Form tab. |
| Preview page | URL of the page that will be used when the document is displayed in preview mode. |
| List page | URL of the editing page that will be used when the document is displayed in list mode. |
| Advanced settings | |
| Use publish from/publish to | Indicates if the Publish from/to fields should be offered on the Form tab for documents of this type. These may be used to schedule the page represented by the document to be published on the live site on a specific date and time, or shown only during a limited time interval. |
| Behaves as Page (menu item) type | Indicates if the document type should behave similar to the default <i>Page (menu item)</i> document type. The default view mode for such a document type is the Page tab. Viewer web parts are automatically set to display child documents if the path is not configured and the document does not inherit its parent template by default. |

Fields tab

The **Fields** tab contains a field editor that allows you to manage the data fields (columns) of the document type. Using the tab, you can add a **New attribute** (+), **New system attribute** (🌐) or **New category** (📁) and you can **Save** (💾), **Delete** (✖), **Move Up** (↑) and **Move Down** (↓) the fields. You can also define which fields should be used as the source for the default name and alias of new documents of this type. This can be done via the drop-down lists below the field listbox.

For a practical example of the use of the **Fields** tab, please refer to the [File Management -> Document attachments -> Example: Grouped attachment](#) topic in the **Content management** section of this guide.

Please note

If a document type is inherited from another document type, the inherited fields are grayed out and must be edited in the parent type. Any changes made to the fields in the parent type are automatically reflected in the child type.

Form tab

The **Form** tab allows you to create a custom form layout that will be used for adding and editing data items. You can use the WYSIWYG editor and you can also insert a field label, input, validation label and submit button. This functionality can be enabled by checking the **Use custom form layout** checkbox. Please note that if no custom layout is available, the default layout will be used.

More details about the use of the **Form** tab can be found in [Forms -> Defining custom form layout](#) in the **Modules** section or in [Custom fields visibility -> Use in custom form layout](#) in the **Development -> Membership, permissions and security** section of this guide.

The screenshot shows the 'Document type properties' dialog for an 'Article' document type. The 'Form' tab is selected and highlighted with a red circle. Below the tabs, there is a 'Save' button and a checked checkbox labeled 'Use custom form layout', also highlighted with a red circle. A blue button labeled 'Generate table layout' is positioned below the checkbox. The main area contains a rich text editor toolbar with options for Source, Bold, Italic, Underline, text color, background color, bulleted list, numbered list, link, unlink, table, table border, undo, redo, and print. Below the toolbar are dropdown menus for Styles, Format, Font, and Size, along with color and font size pickers. To the right, under 'Available fields:', a list of fields is shown: ArticleName, ArticleTeaserText, ArticleTeaserImage, ArticleText, Publish from, and Publish to. At the bottom right, there are four blue buttons: 'Insert label', 'Insert input', 'Insert validation label', and 'Insert submit button'.

Transformations tab

On the **Transformations** tab, you can see the list of all available transformations added to the given document type. New transformations can be added using **New transformation** or **New hierarchical transformation**. The transformations can also be **Edited** or **Deleted** here.

More information about transformations can be found in this chapter in the [Transformations](#), [Adding custom functions to transformations](#), [Writing transformations](#) and [Hierarchical transformations](#) topics.

| | update |

Child types tab

The **Child types** tab allows you to select document types (child document types) that can be placed under documents of the given type. And vice versa, you can define under which document types (parent document types) documents of the given document type can be placed.

Sites tab

The **Sites** tab enables you to select sites where the given document type can be used. If you need to add a site, click the **Add sites** button and select it from the list of available sites. To remove a site, check the checkbox next to the site you would like to remove and click the **Remove selected** button.

E-commerce tab

The **E-commerce** tab allows you to specify whether the current document type should be offered as a product type or section type.

Document's relation to product

- **Document type represents a product type** - indicates if the document type represents a [product type](#).
- **Document type represents a product section** - indicates if the document type represents a [product section](#).

Fields mapping

The section is available only if the currently edited document type is set to represent a product type. You can optionally select fields here that will be automatically populated with values from the specified [SKU](#) fields.

New product creation

The section is available only if the currently edited document type is set to represent a product type.

- **Default department** - can be used to specify a [department](#) where, by default, [products](#) created on the basis of the given product type belong.
- **This document type represents** - can be used to choose default [representation](#) for the product.
- **Create SKU automatically when a new document of this type is created** - indicates if an SKU

should be created automatically when a new document of this type is created.

The screenshot shows the 'Document type properties' interface for an 'Article' document type. The 'E-commerce' tab is selected and highlighted with a red circle. Below the tabs, there is a 'Save' button and a section titled 'Document's relation to product' with two unchecked checkboxes: 'Document type represents a product type' and 'Document type represents a product section'.

Alternative forms

The **Alternative forms** tab allows management of alternative forms for the selected document type. New forms can be created using the **Create new form**. You can also **Edit** () or **Delete** () the existing alternative forms listed in the table.

More information about alternative forms can be found in the [Alternative forms](#) chapter in the **Modules** section of this guide.

The screenshot shows the 'Document type properties' interface for an 'Article' document type, with the 'Alternative forms' tab selected and highlighted with a red circle. Below the tabs, there is a 'Create new form' button and a table listing existing forms.

| Actions | Display name ^ | Code name | Hides new fields |
|---------|----------------|-----------|------------------|
| | Form 1 | Form_1 | No |
| | Form 2 | Form_2 | Yes |
| | Form 3 | Form_3 | Yes |

Search fields

On the **Search fields** tab, you can define how data stored in the document type will be indexed by the **Smart search** module. In the top part, you can specify how documents of the given type will be displayed in search results. Lines of the table in the bottom part of the tab represent document fields defined on the [Fields](#) tab, while columns correspond to **Smart search** properties. Please note that you can use the **Set automatically** link to have the table configured automatically.

For more details on how the content of documents of this document type and of the whole website is searched, please refer to the [Smart search](#) chapter.

7.7.4 Uploading document type icons

Kentico CMS allows you to upload your own icons and associate them with document types. This can be useful if you create custom document types or if you want particular document types to be more easily recognizable in various parts of the CMS.

Please note

When importing and upgrading your custom document types using an export package, the associated icons are also included in this package.

1. If you need to add your own icon to a particular document type, go to **Site Manager -> Development -> Document types -> Edit (pencil icon) Document type** and in the **Document type properties** user interface switch to the **General** tab. You should see a page similar to the one depicted in the following screenshot:

2. Click one of the **Upload** buttons and select a **.png image** from your local or network file system. Its size will be changed automatically. Click **OK**. From now on, this image will be associated with the given document type.

The smaller document type icons (16x16) are used in various parts of Kentico CMS, e.g. in the content tree in **CMS Desk -> Content**:

The larger document type icons (48x48) are used in the [Insert link](#) webpage dialog on the **Tiles** and **Thumbnails** tabs:

Please note

You can associate just one image file with a document type. However, the same icon will be used in the **Insert link** dialog and elsewhere in the CMS.

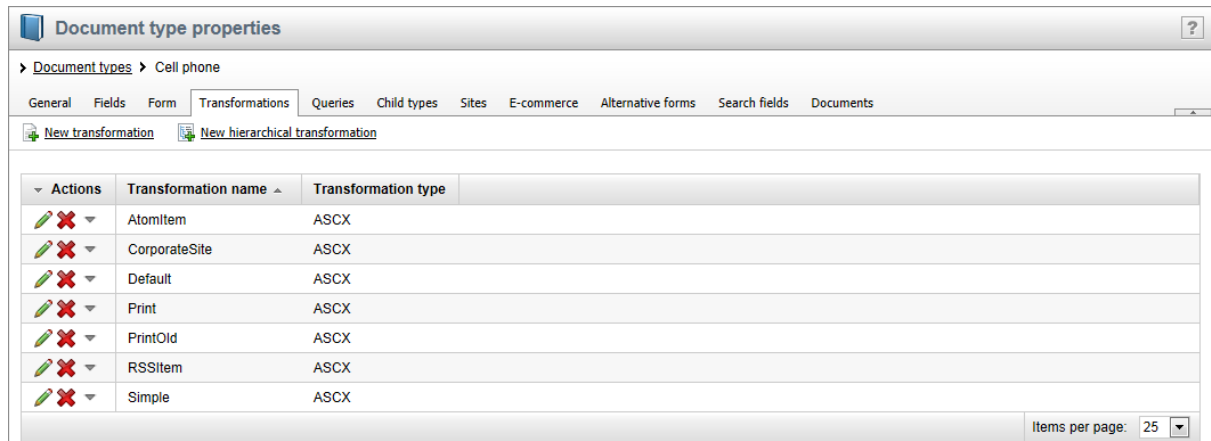

7.7.5 Transformations

7.7.5.1 Overview

Transformations are pieces of code that determine how Kentico CMS documents, or certain parts of them, are rendered by listing web parts and controls. They take raw data from the Kentico CMS database and transform it into the form you wish it to appear in. This makes them a crucial tool when displaying documents and document related data on the pages of your website.

Transformations can be accessed in **Site Manager -> Development -> Document types -> Edit** (✎)

a **document type**, on the **Transformations** tab.

- To learn about the functionality of transformations and to see examples of their code, please refer to the [Transformations](#) topic.
- To see an example of writing transformations for a particular document type, please refer to the [Writing transformations](#) topic.
- To learn how to display documents in a hierarchical structure, please refer to the [Hierarchical transformations](#) topic.
- To learn how to add context menus to web parts displaying users or groups, please refer to the [Context menus in transformations](#) topic.
- To learn how to add your own functions to transformations, please refer to the [Adding custom functions to transformations](#) topic.
- Transformations may also be applied to documents (and other data) loaded through macro expressions. Please see the [Transformations in macro expressions](#) topic for details and examples.

7.7.5.2 Transformations

The functionality of transformations is very similar to that of templates used by standard ASP.NET list controls such as the Repeater. The main difference is that our transformations are stored separately in the database and can easily be used repeatedly. They can be assigned to listing web parts or controls through the appropriate **Transformation** properties. The use of transformations is supported by all web parts that can display document data, as well as by those listing controls that are designed to work directly with Kentico CMS documents.

There are several different approaches that you can use when writing transformations. You can select one of the following transformation types, which determines how the system renders the transformation's code:

- **ASCX** - with this option, the code of the transformation supports ASCX markup, i.e. the same syntax that you would use to edit a standard web form or user control, including inline code, embedded controls, standard ASP.NET data binding expressions and special methods designed for use in transformations. You can access the fields of the transformed document through standard data binding expressions in format: `<%# Eval("ColumnName") %>`
- **Text/XML** - the system processes the code only as basic HTML. This means that any ASCX markup, such as controls or inline code, are not functional when the transformation is rendered. You may use Kentico CMS [Macro expressions](#) and methods to insert dynamic values into the content. Expressions in the following format allow you to easily get the values of the given document's fields:

{%ColumnName%}

- **HTML** - works the same way as the **Text/XML** option, but editing is done through the [WYSIWYG editor](#). The rendered output of HTML code will be shown inside the editor.
- **XSLT** - this option can be selected for transformations that use XSL elements to render the data. The code must be in valid XML format.
- **jQuery** - these transformations provide a way to define the jQuery templates used by the [Chat](#) module.

For security reasons, the code of ASCX type transformations may only be edited by users who have the **Edit ASCX code** [permission](#) for the **Design** module. This permission can only be assigned by global administrators.

Since text-based transformations (**Text/XML** or **HTML** types) are only processed as basic HTML, they cannot be used to compromise the security of the website. Another advantage of these transformation types is that they do not need to be compiled, which means they may be used and modified even if the Virtual path provider is not available, such as in a precompiled or medium trust environment.

Transformations are categorized under the document types that they are supposed to display. They can be managed in the Kentico CMS administration interface at **Site Manager -> Development -> Document types -> ... Edit document type ... -> Transformations**. Some document types do not represent an object but serve only as a container for transformations and queries.

The full name used to identify transformations uses the following format: **<document type code name>.<transformation name>**

The sample sites include many transformations for all document types and you can modify them or write new transformations to suit any of your requirements.

Example

The code of the **CorporateSite.Transformations.ProductList** ASCX transformation, which is used to display lists of products on the sample Corporate Site, looks like this:

```
<%@ Register Src="~/CMSModules/Ecommerce/Controls/ProductOptions/
ShoppingCartItemSelector.ascx" TagName="CartItemSelector" TagPrefix="uc1" %>
<div class="ProductPreview">
  <div class="ProductBox">
    <div class="ProductImage">
      <a href="<%# GetDocumentUrl() %>" style="display:block;">
<%# EcommerceFunctions.GetProductImage(Eval("SKUImagePath"), 180, Eval
("SKUName")) %>
      </a>
    </div>
    <a href="<%# GetDocumentUrl() %>">
      <span class="ProductTitle textContent">
        <%# HTMLEncode(ResHelper.LocalizeString(Convert.ToString(Eval
("SKUName")))) %>
      </span>
    </a>
```

```

    <div class="ProductFooter">
      <div class="productPrice"><%# GetSKUFormattedPrice(true, false) %></div>
    <uc1:CartItemSelector id="cartItemSelector" runat="server"
    SKUID='<%# ValidationHelper.GetInteger(Eval("SKUID"), 0) %>'
    SKUEnabled='<%# ValidationHelper.GetBoolean(Eval("SKUEnabled"), false) %>'
    AddToCartImageButton="btn_addToShoppingCart.png" ImageFolder="~/App_Themes/
    CorporateSite/Images/" />
    </div>
  </div>
</div>

```

When this transformation is assigned to a listing web part or control that has products (SKUs) in its data source, the output HTML code of individual products contains the values returned by the methods and data binding expressions, like in the following example (please note that a part of the code is omitted to save space):

```

<div class="ProductPreview">
  <div class="ProductBox">
    <div class="ProductImage">
      <a href="/KenticoCMS/Products/Laptops-and-Tablets/Apple-iPad-2.aspx"
      style="display:block;">
      
      </a>
    </div>
    <a href="/KenticoCMS/Products/Laptops-and-Tablets/Apple-iPad-2.aspx">
      <span class="ProductTitle textContent">
        Apple iPad 2
      </span>
    </a>
    <div class="ProductFooter">
      <div class="productPrice">$510.99</div>
      ...
    </div>
  </div>
</div>

```

The final output of this product on the website then looks like this:

Adding CSS styles to transformations

The CSS classes used in the transformation code can either be defined in the stylesheets used by the website and individual pages, or added directly to the transformation object. To do this:

1. Edit the transformation on its **General** tab.
2. Click [Add CSS styles](#) below the code editor.
3. The **CSS styles** field appears, where you can add any required CSS classes.

The screenshot shows the 'Document type properties' dialog for a 'ProductList' transformation. The 'Transformation' section is expanded, showing the 'Transformation type' set to 'ASCX'. The code editor contains the following code:

```
<%% Control Language="C#" AutoEventWireup="true" Inherits="CMS.Controls.CMSAbstractTransformation" %>
<%% Register TagPrefix="cci" Namespace="CMS.Controls" Assembly="CMS.Controls" %>
<%% Register Src="~/CMSModules/Ecommerce/Controls/ProductOptions/ShoppingCartItemSelector.ascx" TagName="CartItemSelector" %>
<div class="ProductPreview">
  <div class="ProductBox">
    ##editbuttons##
    <div class="ProductImage">
      <a href="<%%# GetDocumentUrl() %>" style="display:block;">
        <%%# EcommerceFunctions.GetProductImage(Eval("SKUImagePath"), 180, Eval("SKUName")) %>
      </a>
    </div>
    <a href="<%%# GetDocumentUrl() %>">
      <span class="ProductTitle textContent">
        <%%# HTMLEncode(ResHelper.LocalizeString(Convert.ToString(Eval("SKUName")))) %>
      </span>
    </a>
    <div class="ProductFooter">
      <div class="productPrice"><%%# GetSKUFormattedPrice(true, false) %></div><uc1:CartItemSelector id="cartItemSelector"
        SKUName="<%%# SKUName %>" SKUEnabled="
        <%%# ValidationHelper.GetBoolean(Eval("SKUEnabled"), false) %>" AddToCartImageButton="~/App_Themes/CMS/
    </div>
  </div>
</div>
```

The 'Add CSS styles' button is highlighted with a red circle at the bottom left of the dialog.

4. Click **Save**.

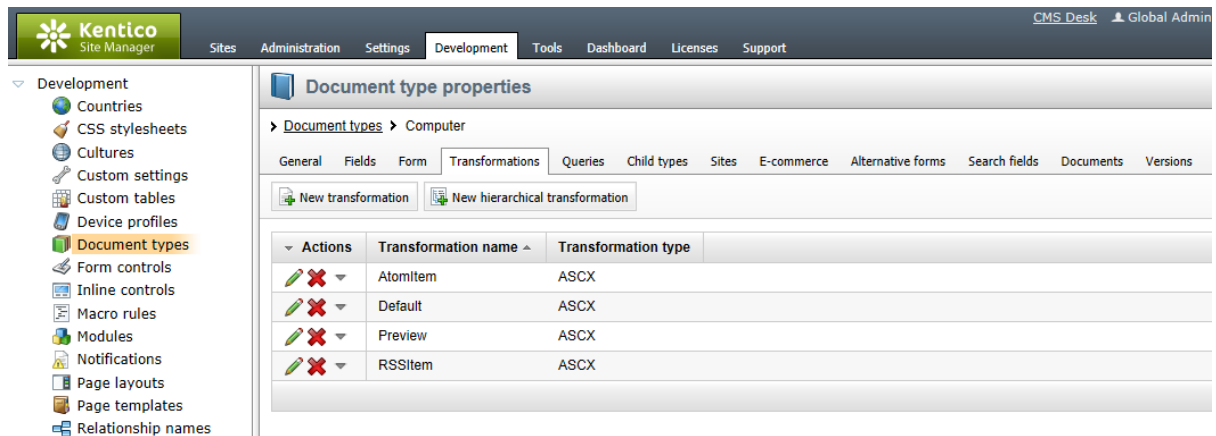

If the styles require any additional files (such as images), you can add them on the **Theme** tab.

For more information about page component CSS styles, see the [Development -> CSS stylesheets and design -> CSS for page components](#) topic.

7.7.5.3 Writing transformations

In this topic, you will learn how to write transformations for the Computer document type created according to the instructions in the [Defining a new document type](#) topic.

Typically, transformations are stored under the document type they are meant to display. Go to **Site Manager -> Development -> Document types**, edit () the **Computer** document type and open its **Transformations** tab. This is the main management interface for the transformations of the given document type.

The document type creation wizard has automatically generated several default transformations.

Preparing the source documents

Before you can use the transformations, you first need to add some computer documents to the website.

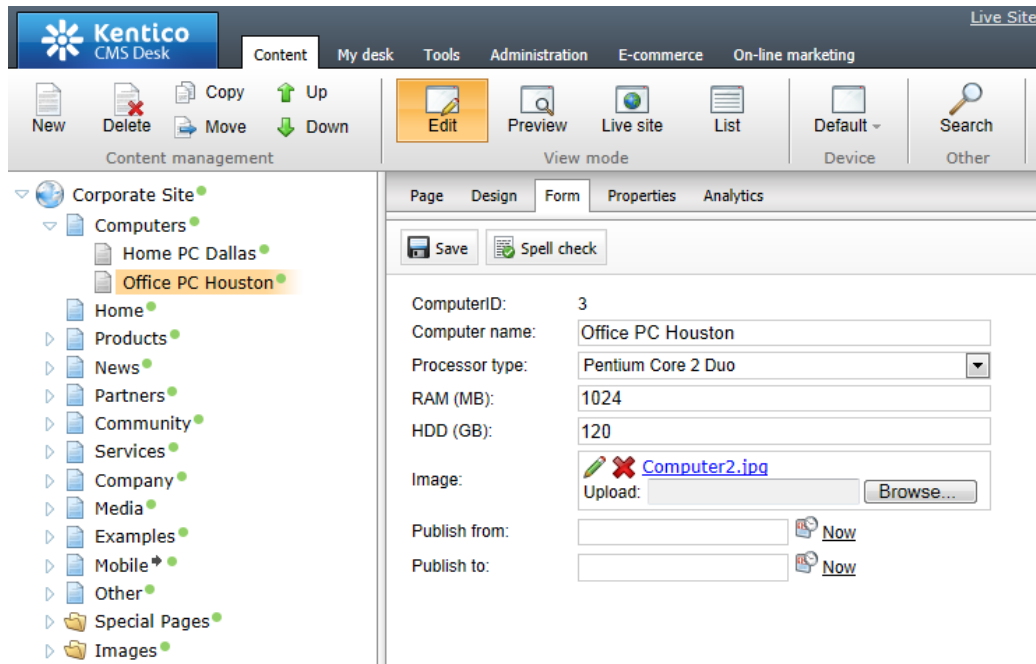

1. Go to **CMS Desk -> Content**, select the root of the site and click **New**.
2. Choose the **Page (menu item)** document type.
3. Type in *Computers* as the **Page name** and select the **Create a blank page** template option. Click **Save** to create the page.
4. Switch to the **Design** tab of the new page and add a **Listing and viewers -> Datalist** web part into *zoneA*.
5. Set the following property values for the Datalist web part:
 - **Document types:** *custom.computer*; you can choose the document type from a list by clicking the **Select** button.
 - **Transformation:** *custom.computer.preview*; to easily choose from a list of available transformations, click **Select**, choose the *Computer* document type in the dialog and then click on the required transformation.
 - **Selected item transformation:** *custom.computer.default*
6. Click **OK** to insert the web part. It will be used to display the data of computer documents on the page according to the specified transformations. For now, the page is empty, because there are no documents of the *custom.computer* type on the website.
7. Click **New** on the main CMS Desk toolbar with the *Computers* page selected and choose the **Computer** document type. This opens an editing form with the fields of the computer document type.
8. Enter the following values:
 - **Computer name:** Home PC Dallas
 - **Processor type:** Athlon
 - **RAM (MB):** 2048

- **HDD (GB):** 160
- **Image:** Upload an image from your local disk using the *Browse* button (you can find sample images in the <Kentico CMS setup directory>\CodeSamples\SampleWebTemplate\Computer_Images folder)

9. Click  **Save and create another** and enter the following values for the second computer document:

- **Computer name:** Office PC Houston
- **Processor type:** Pentium Core 2 Duo
- **RAM (MB):** 4096
- **HDD (GB):** 200
- **Image:** Upload another image.

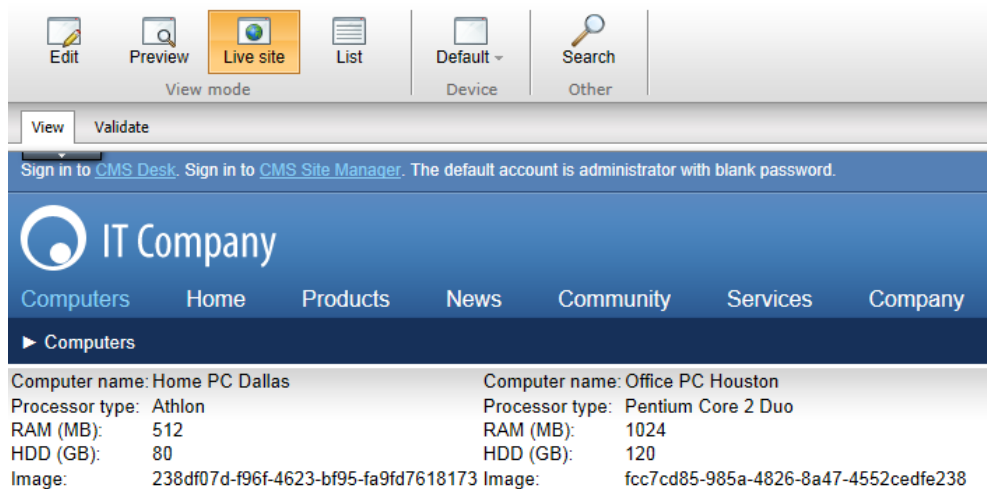

Click  **Save**.

The screenshot displays the Kentico CMS Desk interface. The left sidebar shows a tree view with 'Corporate Site' expanded, and 'Computers' selected. Under 'Computers', 'Office PC Houston' is highlighted. The main content area shows the 'Form' view of the document configuration. The fields are as follows:

| | |
|-----------------|--|
| ComputerID: | 3 |
| Computer name: | Office PC Houston |
| Processor type: | Pentium Core 2 Duo |
| RAM (MB): | 1024 |
| HDD (GB): | 120 |
| Image: | <input type="button" value="Upload"/>  Computer2.jpg <input type="button" value="Browse..."/> |
| Publish from: | <input type="text"/> <input type="button" value="Now"/> |
| Publish to: | <input type="text"/> <input type="button" value="Now"/> |

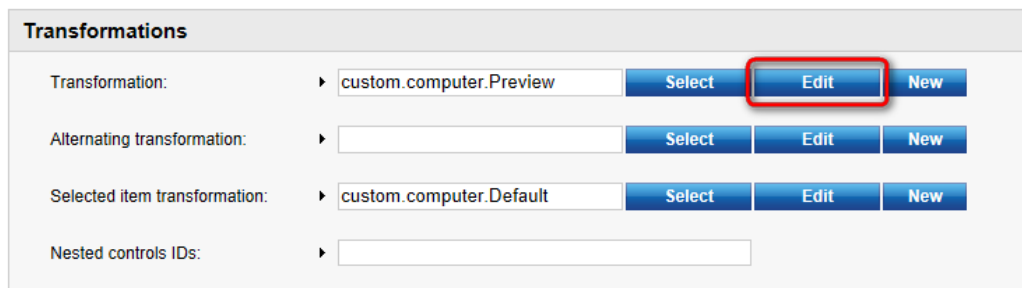

Select the **Computers** page again and view it in **Live site** mode. The data of the two computer documents will be displayed as shown below:

Editing the transformations

The format of the data on the *Computers* page is determined by the automatically generated default transformation. You can fully customize the data format by modifying the code of the transformations through the main interface in Site manager. CMS Desk also allows you to edit transformations, which is more convenient in many cases.

1. Return to **Edit** mode and open the **Design** tab of the *Computers* page.
2. **Configure** (⚙️) the Datalist web part, scroll down to the **Transformation** property and click the **Edit** button.

The editing dialog of the *custom.computer.Preview* transformation opens (the same dialog that you would get when editing the transformation in Site Manager). The Datalist web part uses this transformation for displaying computers in list mode.

3. Delete the default code and enter the following instead:

```
<div style="text-align:center;padding: 8px;margin: 4px;border: 1px solid #CCCCCC">
  <h2>
    <a href="<%# GetDocumentUrl() %>"><%# Eval("ComputerName") %></a>
  </h2>
  <%# GetImage("ComputerImage", 120) %>
```

```
</div>
```

Because this is an **ASCX** type transformation, the code is similar to standard ItemTemplates that you may already be familiar with from using ASP.NET Repeater or DataList controls. It combines HTML with ASP.NET commands and data binding expressions. You may also use built-in methods that simplify various tasks. For more information about the available transformation methods, click the [?](#) Transformation examples link above the code editor.

Note the code used to create the link to specific documents. It consists of a standard HTML link tag and inserts the appropriate URL and link text dynamically:

```
<a href="<%# GetDocumentUrl() %>"><%# Eval("ComputerName") %></a>
```

You can generate an image tag containing the file uploaded into the given document's **ComputerImage** field using the **GetImage** method. The sample code calls the method with a parameter that ensures automatic server-side resizing of the image's longest side to 120 pixels:

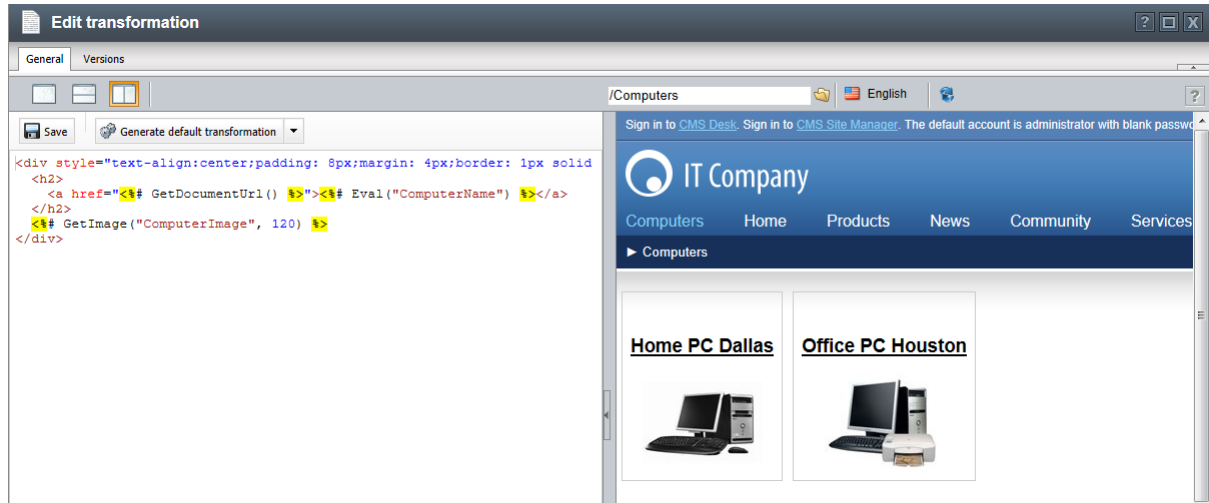

```
<%# GetImage("ComputerImage", 120) %>
```

When writing ASCX transformations, you often need to specify the names of data fields as parameters of the *Eval* data binding expression or other methods, such as *ComputerName* and *ComputerImage* in the example above. You can either type the names manually, or press the **CTRL + SPACE** key combination to access a list of available document fields and related objects.

By clicking on an item in the list or selecting it and pressing enter, you can insert it to the current cursor position in the code. The specific fields of the given document type are prioritized at the top.

4. Click **Save** to apply the changes in the code.

5. Click the  **Preview** button to see how the new transformation affects the page. This opens a split view that allows you to check the appearance of the web part directly while editing the transformation code. The computer documents should now be displayed as shown below.

Next, define the transformation used for viewing the details of computer documents.

6. Close the **Edit transformation** dialog and click the **Edit** button next to the *custom.computer.Default* transformation specified in the **Selected item transformation** property of the Datalist web part. Remove the original code and enter the following:

```
<h1># Eval("ComputerName") %></h1>

<table>
<tr>
<td>
Processor:
</td>
<td>
# Eval("ComputerProcessorType") %>
</td>
</tr>

<tr>
<td>
RAM (MB):
</td>
<td>
# Eval("ComputerRamSize") %>
</td>
</tr>

<tr>
<td>
HDD (GB):
</td>
<td>
```

```

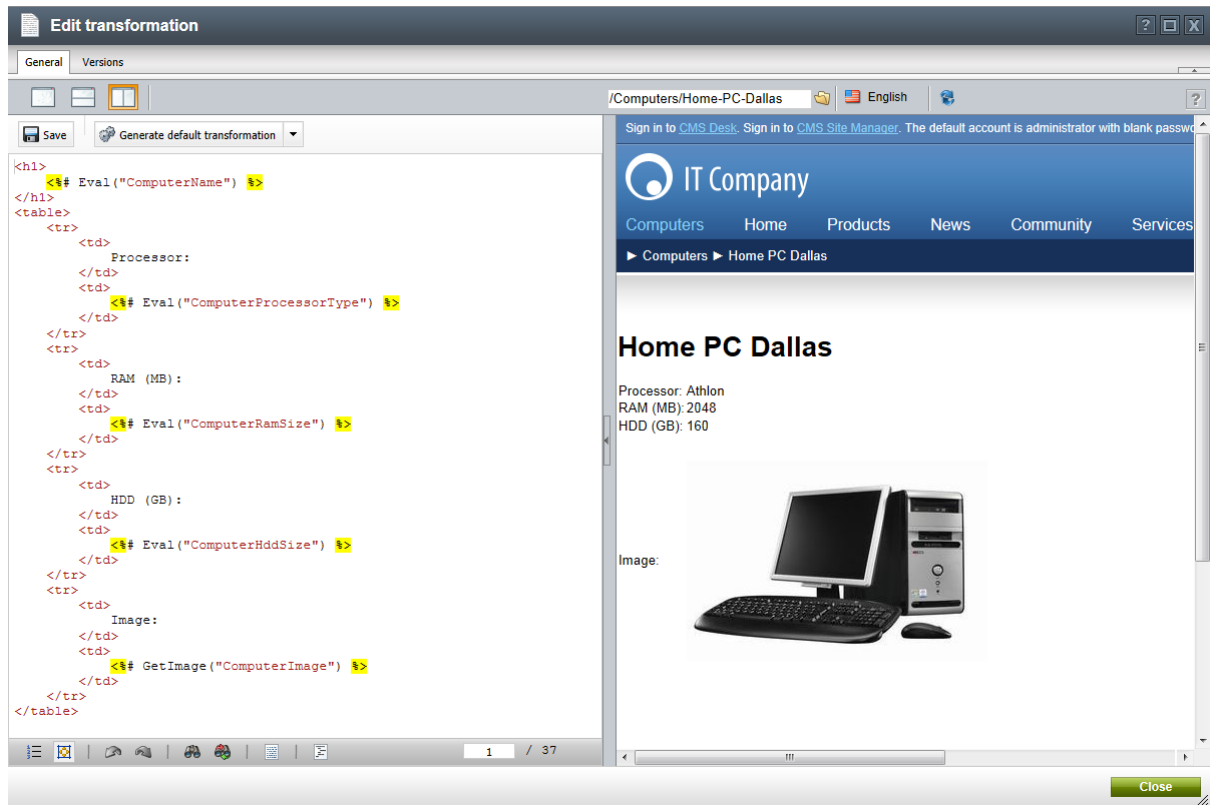

<%# Eval("ComputerHddSize") %>
</td>
</tr>

<tr>
<td>
Image:
</td>
<td>
<%# GetImage("ComputerImage") %>
</td>
</tr>
</table>

```

7. Click  **Save**.

The web part applies the *Selected item transformation* when one of the displayed documents is the currently active page, e.g. when a visitor clicks on the link in the titles of the computers on the **Computers** page. To see how the detail view looks like for a specific computer document, enter `/Computers/Home-PC-Dallas` into the path textbox on the preview toolbar and **Refresh** () the page section.

The screenshot shows the 'Edit transformation' dialog in Kentico CMS. The left pane is a code editor with the following HTML code:

```

<h1>
<%# Eval("ComputerName") %>
</h1>
<table>
<tr>
<td>
Processor:
</td>
<td>
<%# Eval("ComputerProcessorType") %>
</td>
</tr>
<tr>
<td>
RAM (MB):
</td>
<td>
<%# Eval("ComputerRamSize") %>
</td>
</tr>
<tr>
<td>
HDD (GB):
</td>
<td>
<%# Eval("ComputerHddSize") %>
</td>
</tr>
<tr>
<td>
Image:
</td>
<td>
<%# GetImage("ComputerImage") %>
</td>
</tr>
</table>

```

The right pane shows a live preview of the page at `/Computers/Home-PC-Dallas`. The page features a blue header for 'IT Company' with navigation links: Computers, Home, Products, News, Community, Services. A breadcrumb trail shows 'Computers > Home PC Dallas'. The main content area displays 'Home PC Dallas' with the following specifications:

- Processor: Athlon
- RAM (MB): 2048
- HDD (GB): 160

Below the specifications is an image placeholder labeled 'Image:' with a picture of a desktop computer system.

If you close the configuration dialogs and view the *Computers* page on the live site, you will see that both the list of computers and the detail pages of individual computer documents are rendered according to the new data format.

You have learned how to write *ASCX* transformations for displaying the content of structured documents. Other types of transformations may be used in the same way, only with different transformation code syntax.

Please note: If you wish to use *XSLT* transformations, it is necessary to display the data through the [XSLT viewer](#) or [Universal document viewer](#) web parts (or **CMSViewer** server control), otherwise the transformation will not work.

Transformations for multilingual websites

In some cases, you may need to display different text in transformations based on the currently selected language. If you are using the built-in multilingual support, you can achieve this by creating a separate transformation for each language, using the appropriate culture code as a suffix in the transformation name.

Example:

English (default language) transformation code name: *cms.news.detail*

French transformation code name: *cms.news.detail_fr-fr*

When a user switches the content culture to French, web parts and controls automatically load the French version of the transformation.

7.7.5.4 Hierarchical transformations

Hierarchical transformations are special types of transformation that can be used to display documents (and other types of appropriately organized data) in a hierarchical structure. These transformations can affect multiple document types and may be customized differently for every level of the hierarchy (e.g. levels of the document content tree). Currently, they are meant to be used by the following web parts from the **Listings and viewers** category:

- [Hierarchical viewer](#)
- [Universal viewer](#)
- [Universal viewer with custom query](#)

As well as the following Kentico CMS controls:

- [UniView](#)
- [BasicUniView](#)
- [CMSUniView](#)
- [QueryUniView](#)

They can be managed in the same way as standard transformations by editing a document type on its **Transformations** tab. However, a hierarchical transformation is not directly defined by code. Instead, it serves as a container for a number of standard transformations, which are then applied to the appropriate parts of the source data when it is rendered. A proper hierarchical transformations can be composed of many sub-transformations that define its layout and the content or format of the displayed items.

The screenshot shows the 'Document type properties' window for 'Job opening' under 'HierarchicalJobsCareer (Hierarchical)'. The 'Transformations' tab is active, displaying a list of sub-transformations. The 'Add transformation' section is visible above the list.

| Actions | Type | Document types | Level | Transformation name |
|---------|-----------------------------|----------------|-------|-----------------------------|
| | Header item transformation | All | All | CMS.Menuitem.ListItemHeader |
| | Footer item transformation | All | All | CMS.Menuitem.ListItemFooter |
| | Item transformation | CMS.Job | All | CMS.Job.Preview |
| | Current item transformation | CMS.Job | All | CMS.Job.Default |
| | Item transformation | CMS.Menuitem | All | CMS.Menuitem.ListItem |
| | Item transformation | CMS.Office | All | CMS.Office.Simple |
| | Current item transformation | CMS.Office | All | CMS.Office.Default |

You can **Add** () , **Edit** () and **Delete** () these sub-transformations. The delete action does not remove the actual transformation from the system (only from the given hierarchical transformation). The purpose of each transformation depends on its individual settings, which can be configured when it is added or later via the edit action.

The screenshot shows the 'Edit transformation' dialog in the 'Document type properties' window. The 'Transformations' tab is active, and the 'List of transformations' section is selected. The dialog allows configuring a sub-transformation.

Transformation type:

Document types:

Level:

Transformation name:

A **Transformation type** can be selected for each sub-transformation from among the following options:

- **Item transformation** - applied to all displayed items that are not covered by a specialized transformation type (e.g. alternating items, first items etc.).
- **Alternating item transformation** - applied to items that have an even position in the listing order. Every level in the hierarchy has its own separate alternation pattern.
- **First item transformation** - applied to the first item on every level in the hierarchy. Only works for levels that contain more than one item.
- **Last item transformation** - applied to the last item on every level. Only works for levels that contain more than one item.

- **Header transformation** - rendered at the beginning of every level (before the first item on the level). These transformations provide a convenient way to visually separate or style individual levels.
- **Footer transformation** - rendered at the end of every level (after the last item on the level). Can be used to close encapsulating elements from the *Header*.
- **Single item transformation** - applied in cases where there is only one item on a level in the hierarchy.
- **Separator transformation** - rendered between items on the same level. It is not placed between items on different hierarchy levels (i.e. between a parent item and its child).
- **Current item transformation** - applied to the currently selected item (i.e. the document that is being viewed). Please note that it is always necessary to specify a *Document type* (or types) for this kind of transformation.

If there are multiple transformations of different types included in the hierarchical transformation, more than one may be applicable to a single item. In these cases, the item will be displayed using the transformation type with the highest priority, according to the following order:

1. Current item (top priority)
2. First/Last/Single item
3. Alternating item
4. Item

It is also possible to restrict which **Document types** should be affected by the given transformation. You can specify multiple document types by entering their code names separated by semicolons, e.g. *CMS.News;CMS.Article*. Leaving this field empty means that the transformation will be applied to all document types. Transformations that are dedicated to specific document types have a greater priority than those set to include all types. The field has no effect for *Header*, *Footer* or *Separator* transformation types.

The **Level** field sets the level in the hierarchy from which the transformation should be applied. For example, if 2 is entered, the transformation will affect items on the third level (the number of the first level in the hierarchy is 0) and will also be **inherited** by all levels below it. Leaving an empty value or entering -1 specifies all levels. Levels are always counted from the start of the particular data hierarchy that is being displayed. In the case of documents, this means that level 0 represents the first level under the selected path, not the root of the entire website.

Breaking level inheritance

Please note that you can override the level inheritance by adding another transformation for a lower level (it must use the same transformation type and affect the same document types).

Finally, it is necessary to set the actual transformation in the **Transformation name** field and it will be used for the defined purpose. Please refer to the [Transformations](#) topic to learn what options are available when creating or editing standard transformations.

By adding transformations as components and configuring their fields according to the descriptions above, you can create complex hierarchical transformations suitable for displaying any kind of hierarchical data.

You can find an example of a *Universal viewer* web part using a hierarchical transformation on the Corporate Site sample website in the **Examples -> Web Parts -> Listings and viewers -> Documents**

-> **Universal viewer** section of the content tree.

The screenshot shows a web page for 'IT Company' with a navigation menu. The 'Web Parts' section is active, showing a list of web parts. The 'Universal viewer' web part is displayed, showing a list of 'Offices' and 'Careers'. The 'Offices' section lists 'Prague office' and 'Sydney office'. The 'Careers' section lists 'QA manager' and 'Sales manager'.

Data requirements for hierarchical transformations

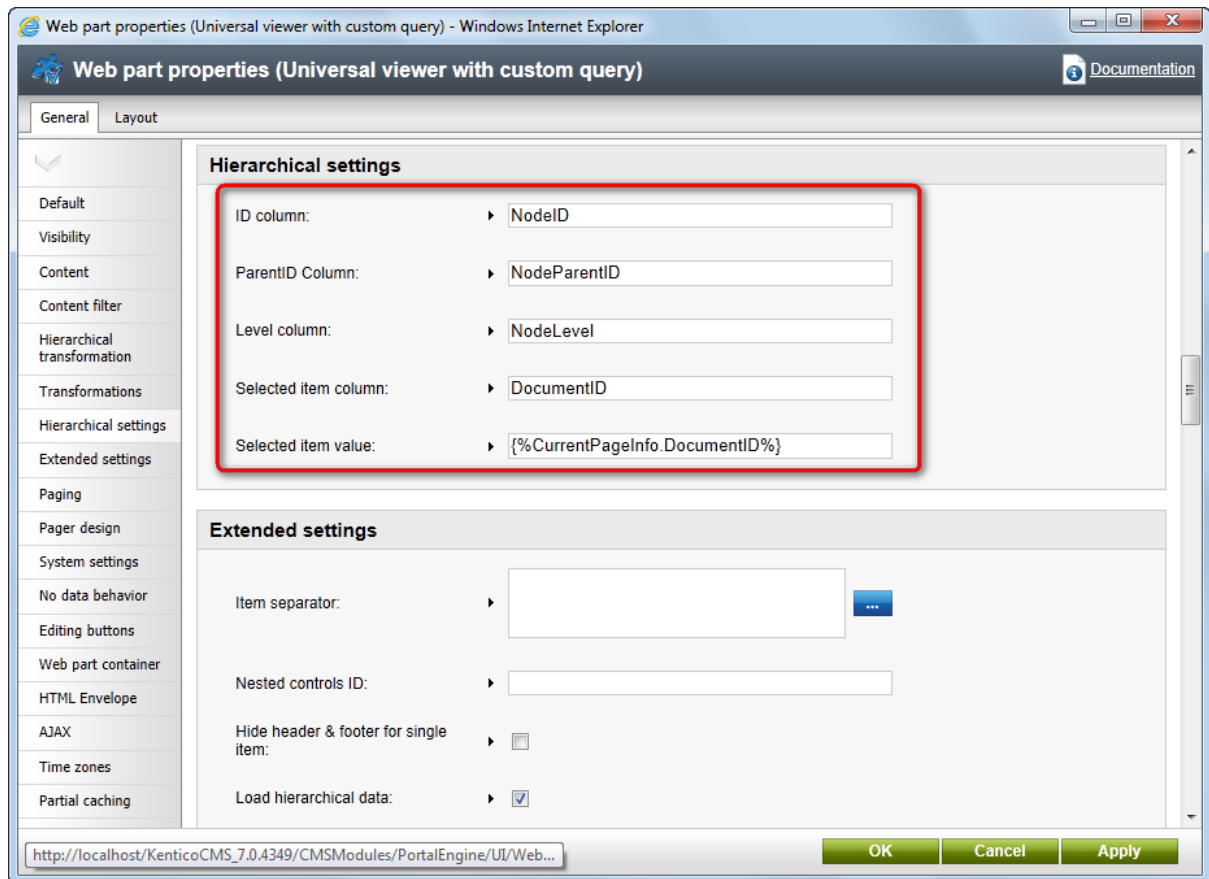

If you wish to use a hierarchical transformation, the source data must be organized in the appropriate hierarchical format. This can be ensured by enabling the **Load hierarchical data** property, which is available for all supported web parts and controls. Please note that paging is not possible in this scenario, because the separation of data into pages would break the hierarchy.

Additionally, all records in the source data need to contain a value that determines their level in the hierarchy and must be connected through parent-child relationships. If any parent records are missing from the used data (for example due to content filtering, WHERE conditions etc.), the disconnected parts of the hierarchy will not be displayed. The most common example of a suitable type of hierarchical data are documents in the Kentico CMS content tree.

However, the *Universal viewer with a custom query* web part (or *QueryUniView* control) may also be used to load other types of data from the database, as long as they meet the given requirements. In this case, you need to specify how the data retrieved by the query should be organized into a hierarchy via the properties in the **Hierarchical settings** section:

The **ID column** and **ParentID column** properties are used to set up the parent-child relationships of the data. The *ID column* needs to be a unique identifier for records. The value of a record's *parentID column* must match the ID of the item that should serve as its parent in the hierarchy (it should never be *null* for any of the items in the data source). Then, the name of the column whose value determines what level an item belongs to needs to be entered into the **Level column** property.

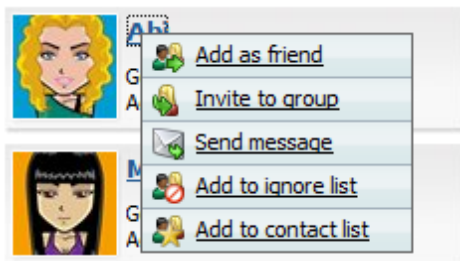

If you also wish to set up special behavior for the displayed items that reflects some type of selection made by the current user, you can enter the name of a column into the **Selected item column** property (the values of this column must be unique for every record to ensure correct functionality). Typically, you will then need to insert a [Macro expression](#) as the **Selected item value** in order to dynamically retrieve the appropriate value from the current context. The item whose value in the specified column matches the result of the macro will be treated as the currently selected item.

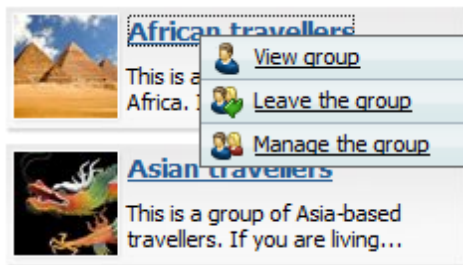

7.7.5.5 Context menus in transformations

When writing transformations for a web part displaying **Users** or **Groups**, you can enclose the transformation in a menu container control, which ensures displaying context menus after right-clicking on a user or group. You can see a live example of these context menus on the sample **Community Starter site**:

In the screenshot below, you can see the context menu displayed when you right-click one of the users listed in the **Members** section:

The following screenshot shows the context menu displayed when you right-click one of the groups listed in the **Groups** section:

How is this achieved? As you can see when you view the transformation code used in the **Users viewer** or **Groups viewer** web parts, you need to have enclosed your transformation in the **cms:usermenucontainer** or **cms:groupmenucontainer** control:

Users

```
<cms:usermenucontainer runat="server" ID="userMenuElem" MenuID="userContextMenu"
Parameter='<%# Eval("UserID").ToString() %>' ContextMenuCssClass="UserContextMenu"
>
... transformation code ...
</cms:usermenucontainer>
```

Groups

```
<cms:groupmenucontainer runat="server" ID="groupMenuElem"
MenuID="groupContextMenu" Parameter='<%# Eval("GroupID").ToString() %>'
ContextMenuCssClass="UserContextMenu" >
... transformation code ...
</cms:groupmenucontainer>
```

Please note

It is only possible to add controls into transformations that use the **ASCX** type. This means that the context menu controls will not be rendered correctly by the other transformation types.

Modifying context menu design

The default controls used for context menus are stored in **<web project>\CMSAdminControls\ContextMenus:**

- **GroupContextMenu.ascx**
- **UserContextMenu.ascx**

These two controls are used automatically for the Group or User context menus. If you want to modify the design of the context menus, you can edit these controls in Visual Studio.

You can also develop your custom controls for this purpose. In this case, you need to include the **MenuControlPath** parameter in the `cms:usermenucontainer` or `cms:groupmenucontainer` controls in the transformation and set its value to the path to your control:

```
<cms:groupmenucontainer runat="server" ID="groupMenuElem"
MenuID="groupContextMenu" Parameter="<%# Eval("GroupID").ToString() %>"
ContextMenuCssClass="UserContextMenu"
MenuControlPath="~/CMSAdminControls\ContextMenus\MyGroupContextMenu.ascx" >

... transformation code ...

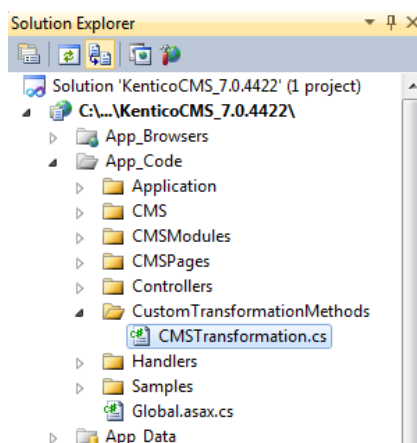

</cms:groupmenucontainer>
```

7.7.5.6 Adding custom functions to transformations

In many cases, you may need to add custom logic into your transformations. This can be achieved by implementing custom methods and calling them in the transformation code. Using this approach, you can process field values, display data in a specific format, add custom conditions etc.

The following example demonstrates how to create a custom method that trims text values to a specified number of characters, and shows how to use it in an ASCX transformation:

1. Open your Kentico CMS web project in Visual Studio. Create a new folder under the **App_Code** folder (or **Old_App_Code** if you installed the project as a web application) and name it *CustomTransformationMethods*.
2. Right click the folder and select **Add New Item**. Choose to add a new **Class** called **CMSTransformation.cs**. Please note that transformation methods must be developed in C# at this time.

3. Remove the default content of the class (apart from the basic references) and enter the following code instead:

[C#]

```

namespace CMS.Controls
{
    /// <summary>
    /// Extends the CMSTransformation partial class.
    /// </summary>
    public partial class CMSTransformation
    {

        /// <summary>
        /// Trims text values to the specified length.
        /// </summary>
        /// <param name="txtValue">Original text to be trimmed</param>
        /// <param name="leftChars">Number of characters to be returned</param>
        public string CustomTrimText(object txtValue, int leftChars)
        {
            // Checks that text is not null.
            if (txtValue == null | txtValue == DBNull.Value)
            {
                return "";
            }
            else
            {
                string txt = (string)txtValue;

                // Returns a substring if the text is longer than specified.
                if (txt.Length <= leftChars)
                {
                    return txt;
                }
                else
                {
                    return txt.Substring(0, leftChars) + "...";
                }
            }
        }
    }
}

```

As shown above, you can extend the **CMSTransformation** partial class in the **App_Code** folder, and then add the definitions of the methods that you wish to call in your transformations.

Save the changes made to the file. **Build** the project if it is installed as a web application.

4. Now open the **Site Manager** administration interface, go to **Development -> Document types** and **Edit** (✎) the **Corporate site - Transformations** document type. Select the **Transformations** tab, edit the **NewsList** transformation and change line 5 of its code to the following:

```

..
<p><%# CustomTrimText(Eval("NewsSummary"), 50) %><br /><br />

```

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The left sidebar lists various development tools, with 'Document types' highlighted. The main content area is titled 'Document type properties' and shows the configuration for 'NewsList'. The 'General' tab is active, displaying the transformation name 'NewsList' and the transformation type 'ASCX'. The transformation code is visible in the editor, with a red circle highlighting the line: `<p><# CustomTrimText(Eval("NewsSummary"), 50) #>
</p>`.

Click **Save** to confirm the modification.

5. To check the result, click the **Preview** button, enter `/News` into the path textbox on the toolbar and **Refresh** (🔄) the page section. In the preview of the news page that uses the transformation, you can see the text of the summaries truncated to the first 50 characters:

The screenshot shows the Kentico CMS editor interface. On the left, the code editor displays the following HTML code:

```
<div class="listBoxWithTeaser">
<div class="teaser"><# IfEmpty (Eval ("NewsTeaser"), "<a href=\"".
<div class="description">
<a class="header bold" href="<# GetDocumentUrl () #>"><# Eval ("
<p><# CustomTrimText (Eval ("NewsSummary"), 50) #><br /><br />
<span class="black bold"><# GetUserFullName (Eval<int> {"NodeOwne
</p>
</div>
<div class="clear"></div>
</div>
```

On the right, the preview shows a list of news items:

In this topic, you have learned how to write your own methods for ASCX transformations. If you wish to add custom functionality to a **Text** transformation, you may implement a custom macro method for this purpose as described in [Development -> Macro expressions -> Registering custom macro methods](#).

7.7.5.7 Transformations in macro expressions

In addition to being used by web parts and controls, transformations of the **Text/XML** or **HTML** type may also be applied to documents and other objects retrieved via [Macro expressions](#).

This can be particularly useful if you need to display dynamically loaded data in content that is based on text and HTML, where it is not possible to add listing web parts or controls. Typical examples include the [E-mail templates](#) on which system e-mails are based, and [Newsletter templates](#). Of course, this technique may be used in all locations where macro resolving is supported.

The functionality described above is achieved by calling the following method within your macro expression:

ApplyTransformation (String transformationName)

The parameter must match the full name of the transformation that you wish to use. An overload with three parameters is also available, which allows you to place additional transformations before and after the displayed data:

ApplyTransformation (String transformationName, String contentBeforeTransformationName, String contentAfterTransformationName)

This method can be called for collections of objects that implement the *IEnumerable* interface or for single instances of an object. When such a macro expression is resolved, it returns the objects in the given collection, formatted into output code according to the given transformation.

Security considerations

Macros are saved with a security signature, which is used to check access permissions for the data collections specified in the expression. The signature depends on the user who entered and saved the given macro expression, not the user viewing the resolved result.

This means that macro expressions will not be resolved if their author does not have permissions to access the given data. Please refer to the [Macro security](#) topic to learn more.

Examples

Start by creating a new **Page (menu item)** document on your website to prepare an environment where you can easily try out the examples below. You can choose the **Create a blank page** option when selecting the page template. On the **Design** tab, add (+) a **Text & Images -> Editable text** web part into the zone on the page. You can now insert the macro expressions described below into the editable region on the **Page** tab of the document and they will be resolved on the live version of the page.

Please keep in mind that this scenario is intended primarily for demonstration purposes. The recommended way to display data on standard website pages is using listing web parts or controls, which provide support for transformations through the appropriate properties.

Displaying the current user

First it is necessary to create the desired transformation. Go to **Site Manager -> Development -> Document types**, edit (✎) the **Root** document type and open its **Transformations** tab. Click  **New transformation** and enter the following data:

- **Transformation name:** *UsersInText*
- **Transformation type:** *Text / XML*
- **Code:**

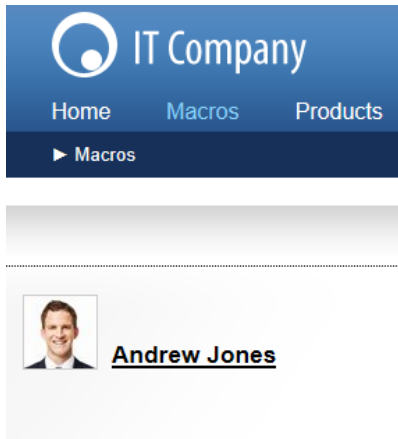

```
<div class="member">
  <a href="{% GetMemberProfileUrl(UserName) %}">
    {% GetUserAvatarImage(UserAvatarID, UserID, FullName, 52, 0, 0) %}
  </a>
<div class="memberInfo">
<p>
  <h3>
    <a href="{% GetMemberProfileUrl(UserName) %}">
      {% FullName %}
    </a>
  </h3>
</p>
</div>
</div>
```

Click  **Save**.

Now open CMS Desk and go to the **Page** tab of the previously created document. Enter the following expression into the editable region and  **Save** the page.

```
{%CurrentUser.ApplyTransformation("CMS.Root.UsersInText")%}
```

This expression retrieves an object containing the data of the user currently viewing the page, which is then formatted according to the specified transformation. You can view the page on the live site to see how the macro is resolved.

Displaying documents from the content tree

First, use the approach described in the previous example to create a new transformation named *NewsInText*. Remember to set the type to *Text / XML* and enter the following code:

```
<div class="description">
  <a class="header bold" href="{% GetDocumentUrl() %}">
    {% NewsTitle %}
  </a>
  <p>
    {% NewsSummary %}
    <br />
  </p>
</div>
```

Switch to the sample document in CMS Desk and insert the following macro expression on the **Page** tab:

```
{%Documents[" /News "].Children.WithAllData.ApplyTransformation
 ("CMS.Root.NewsInText")%}
```

In the expression above, the document under the */News* path is selected from the **Documents** collection. Through its **Children** property, we then access a collection containing all child documents. Using the **WithAllData** property ensures that the retrieved document objects include their coupled data,

i.e. the specific fields defined for the given document type.

The macro will be resolved as shown below.

Home Macros Products News Community Services Company Media

► Macros

New Consulting Services)

We are proud to announce that the range of services we provide was extended by web development consulting. The most e development department have been promoted to consultants and are here to help you with your web development projects.

Apple iPad 2 In Stock)

Today, we have good news for all fans of the awesome Apple iPad. We are glad to announce that its new version, Apple iP reasonable pricing policy, providing the lowest price currently available on the Web.

Company Growth Exceeds Expectations)

Our company growth has reached astonishing 256% in the last financial year. It is not only thanks to the excellent and devot faithful customers. Therefore, we would like to thank you for your loyalty and state a promise that we will keep to the high st:

Community Website Section)

As a result of our continuous effort to improve our services, we have recently introduced the [Community](#) section of our webs information about the company from various communication channels and express your opinions and thoughts yourselves.

Retrieving and displaying site objects

In this example, it is necessary to create three separate *Text / XML* transformations:

- **ProductTableHeader**

```
<table border="2" cellpadding="3">
  <tr>
    <td width="200"><b>Product name</b></td>
    <td width="100"><b>Price</b></td>
  </tr>
```

- **ProductTableRow**

```
<tr>
  <td>{% SKUName %}</td>
  <td>{% SKUPrice %}</td>
</tr>
```

- **ProductTableFooter**

```
</table>
```

This time, copy the following macro into the editable region on the **Page** tab:

```
{%SiteObjects.SKUs.Where("SKUdepartmentID = 4").OrderBy("SKUPrice")
.ApplyTransformation("CMS.Root.ProductTableRow", "CMS.Root.ProductTableHeader",
"CMS.Root.ProductTableFooter")%}
```

Product objects (SKUs) are retrieved from the **SiteObjects** collection. The **Where** macro method is then used to filter the collection according to a standard SQL condition specified as the parameter. In this case, only products from the Smartphones department are loaded. The **OrderBy** method sorts the objects according to the values in their **SKUPrice** field. The **Where** and **OrderBy** methods may be applied to all types of collections, including documents.

The **ApplyTransformation** method is called with additional parameters to add the header and footer transformations before and after the main data items. This ensures that the transformations are combined to achieve the desired result:

| Product name | Price |
|---------------------------------|--------|
| Apple iPhone 3GS | 424.99 |
| BlackBerry Torch 9800 | 459.99 |
| Motorola Atrix 4G | 529.98 |
| Samsung Google Nexus S | 599.99 |
| Apple iPhone 4 with inscription | 759.99 |
| HTC Sensation | 799.99 |

7.8 Editing code in the UI

7.8.1 Code editor overview

The interface of Kentico CMS contains areas where various types of code can be entered to define certain aspects of the website's appearance or behavior. These code fields use an editor that provides syntax highlighting support and other features to help website developers easily write and maintain sections of code.

Highlighting ensures that text elements are displayed in different colors depending on the syntax of the given language. This greatly improves the readability of the code and makes it easier to spot and avoid mistakes. All languages commonly used for web development are supported, including HTML, ASPX markup, CSS, JavaScript, SQL, XML and C#. Each language has its own set of highlighting rules used to format the code.

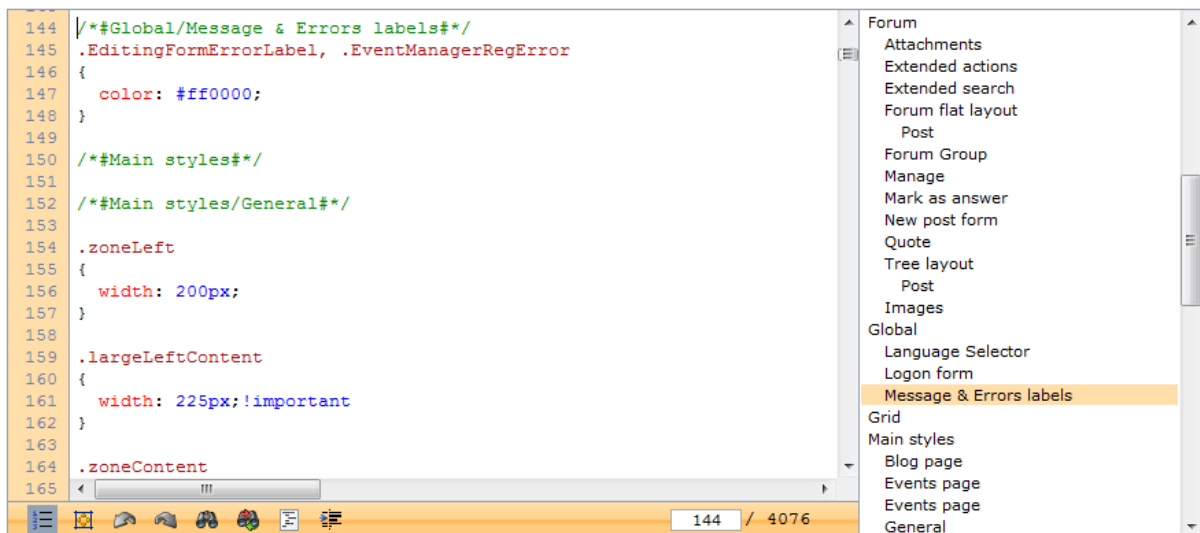

Syntax highlighting customization

It is possible to modify the way languages are displayed in the code editor, including font properties, the colors applied to various syntax tokens and styles in general.

To do this, simply open the **CMSAdminControls/CodeMirror/css** folder under your web project and edit the stylesheet of the language that you wish to customize, e.g. **sqlcolors.css** to change the styles applied to SQL code.

In addition to syntax highlighting, the editor also provides other types of functionality.

The following buttons are located on the toolbar below the code editing area:

- **Show/hide line numbers** - enables or disables the panel displaying line numbers on the left of the editing region.
- **Toggle fit-to-window mode** - toggles the editor between its normal size and an expanded one covering the entire window (frame) in which it is placed.
- **Show hide/bookmarks** - enables or disables the bookmark panel on the side of the editor. Only available for CSS code by default.
- **Undo (CTRL+Z)** - removes the last change made to the code in the editor, restoring it to its previous state. The history of changes is saved, so this action can be used multiple times.
- **Redo (CTRL+Y)** - reverses one previously made **Undo** action every time it is used.
- **Search** - opens a dialog that allows the code in the editor to be searched for a word or phrase. You can select if the search should be case sensitive and the direction of the search.
- **Replace** - opens a dialog that can be used to find a word or phrase and replace it with the entered text. Either all occurrences in the code can be replaced at once or processed one by one.
- **Edit source** - opens a resizable dialog where the code can be edited without syntax highlighting or any other advanced functionality.
- **Indent all** - sets the indentation of all code in the editor according to the conventions of the given language.

The right side of the bottom toolbar contains a **line counter** displaying the number of the line where the cursor is currently positioned. A number can be manually entered here, which allows users to jump directly to the specified line.

The panel on the right is an alphabetical list of bookmarks that can be used to jump to marked sections in the code. Bookmarks are inserted using code blocks (regions) following the syntax of the currently edited language, e.g. `/* #<bookmark name># */` for CSS. By default, the bookmarks panel is only displayed when editing [CSS stylesheets](#).

Global code editor settings

The behavior of the code editor may be configured by adding the following keys into the **/configuration/appSettings** section of your project's `web.config` file:

- **CMSEnableSyntaxHighlighting** - globally enables or disables the advanced editor and syntax highlighting support for all code fields in the user interface. This can be used to turn off the editor if it is causing performance issues or other problems. The default value is `true`.
- **CMSEnableSyntaxHighlighting.<Language>** - can be used to disable the advanced editor and syntax highlighting support for fields that display code in a specific language. Replace the `<Language>` string with the name of the language that you wish to disable. The following language options are available: `Text`, `HTML`, `CSS`, `JavaScript`, `XML`, `CSharp`, `SQL`, `HTMLMixed`, `ASPNET`, `CMSSharp`. All languages are enabled by default.
- **CMSShowLineNumbers** - if set to `true`, the line number panel will be displayed in the editor by default when the page is loaded. Please note that some fields in the user interface are not affected by this setting. The default value is `false`.

Sample key values:

```
<add key="CMSEnableSyntaxHighlighting" value="false" />
<add key="CMSEnableSyntaxHighlighting.CSS" value="false" />
<add key="CMSShowLineNumbers" value="true" />
```

Customization of individual editors

Internally, the functionality of the code editor is provided by the **ExtendedTextArea** server control from the **CMS.ExtendedControls** namespace. If you wish to customize the code editor used for a specific field, you must locate the corresponding control in the code of the Kentico CMS user interface and configure its properties. This way you can switch between the advanced editor and a simple text area, define the language syntax according to which highlighting will be performed, hide the button toolbar, enable the bookmarks panel and much more. Information about the properties of the control can be found in the [Kentico CMS API Reference](#).

The editor is also integrated into the **Large text area (Input type) Form control**, which can be used if you wish to create a custom field somewhere in the UI, which will be used to enter a certain type of code.

7.8.2 Design preview

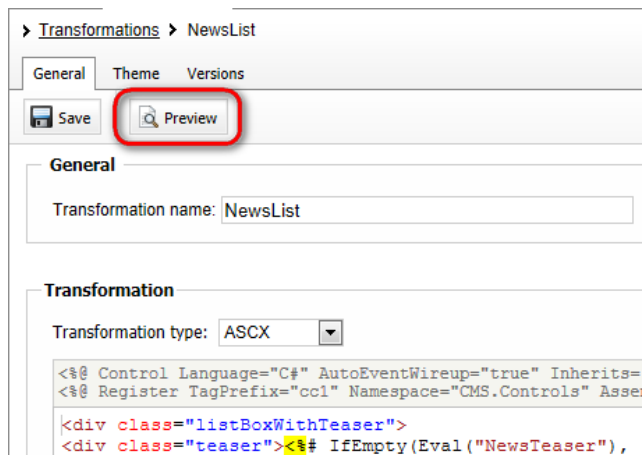

The administration interface provides a convenient way to edit the code of web design components side-by-side with a view of the results on the actual website. This allows designers to quickly check how changes affect pages without having to leave the editing interface or switch between browser tabs.

This preview functionality is available for all objects in Kentico CMS that influence the design or

appearance of the site's pages, including:

- [Transformations](#)
- [CSS stylesheets](#)
- [Page layouts](#)
- [Web part containers](#)
- [Web part layouts](#)

To access the preview mode, click the  **Preview** button in the header above the given code editor.

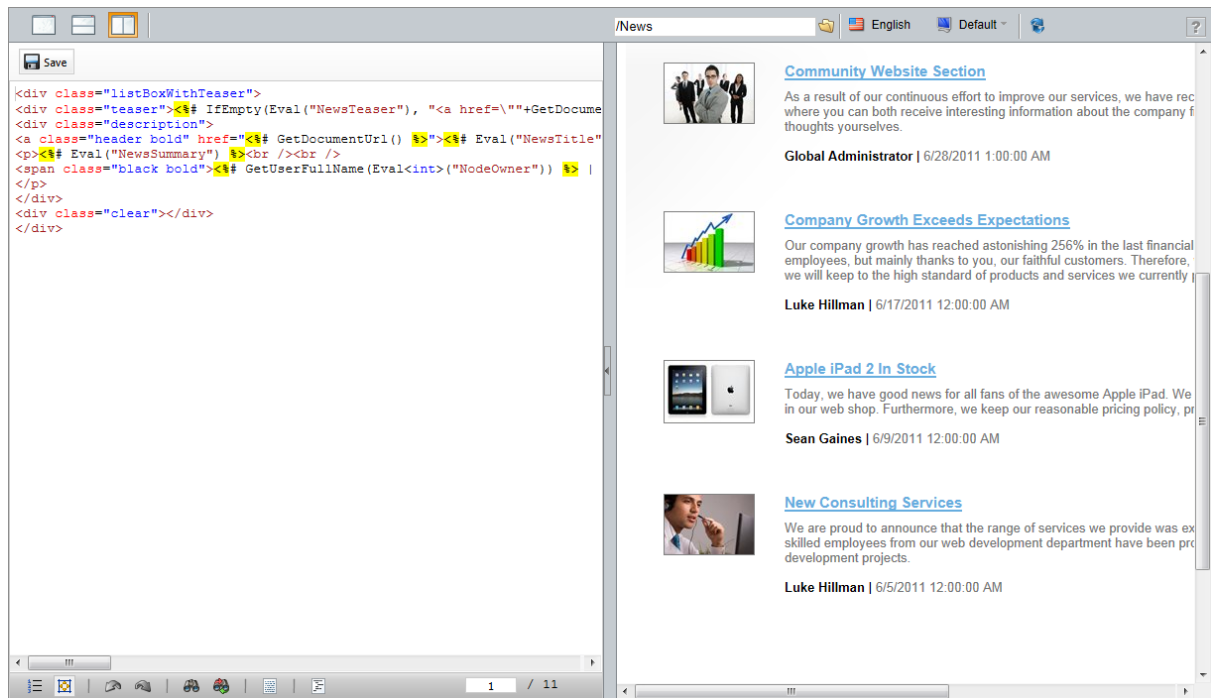

The preview interface is divided into two parts: an editing area where you can modify the code or other fields of the given object and a section displaying a live site view of a selected page.

The following options are available on the preview toolbar:

- **Close preview** - returns to the standard editing form without a preview section.
- **Horizontal layout** - splits the area horizontally. The top section contains the editing area (i.e. the code), and the preview of the page is displayed in the bottom half.
- **Vertical layout** - splits the area vertically, with the editing area on the left and the page preview on the right.

This allows you to choose the layout that best fits the dimensions of the previewed page and the edited code.

By default, the code editor automatically expands to completely cover the first section. The other fields on the form can be accessed by minimizing the editor using the **Toggle fit-to-window mode** () button on the toolbar below the code. Saving () the editing form automatically refreshes the page preview.

Setting the preview page

It is important to view an appropriate page where you can see the effects of the changes made in the code. For example, when editing a transformation, you need to select a page containing a web part that uses the given transformation to display data.

To configure the page in the preview section:

1. Select a document via the path selector on the toolbar. You have two options:
 - Click the **Select** () button to choose a document from the content tree.
 - Specify a page by manually entering its alias path into the textbox. In this case, you then need to click **Refresh** () to reload the page in the preview section.

When editing a design component from CMS Desk, the preview section automatically preloads the currently selected document.

2. On [multilingual websites](#), switch to the appropriate culture version of the selected Section document using the language selector on the toolbar.
3. If your website is configured to display different content for specific [device profiles](#), choose the preferred profile for the preview. When previewing content for a specific device profile, you can also click  **Rotate device** to rotate the preview 90 degrees.

The section displaying the page works like the **Preview** mode of CMS Desk, which means that the

specified document does not actually need to be published on the live site. You may also preview documents that are scheduled to be published in the future or are currently in an unapproved [Workflow](#) step.

7.9 E-mail templates

7.9.1 E-mail templates

Kentico CMS sends automatic system e-mails for various purposes, such as workflow notifications. The content of these e-mails is determined by templates according to the type of a given e-mail. Many modules and features of Kentico CMS send e-mails based on predefined templates that are included in the default installation.

There are two types of e-mail templates: global and site-specific. If a site-specific template of a certain type is not defined, the respective global template is used by the site instead. All e-mail templates can be modified in **Site Manager -> Administration -> E-mail templates** and the templates of a given site may also be accessed in **CMS Desk -> Administration -> E-mail templates**. Editing templates allows you to alter the e-mails sent by the system to match the required design and/or language.

An e-mail template has the following properties:

| | |
|--------------------|--|
| Display name | The name of the template displayed in the user interface. |
| Code name | The name of the template used in code. |
| E-mail type | Identifies the type of functionality to which the template is related. This can be used to categorize and filter e-mail templates. |
| From | E-mail address that will be used as the sender (From) address of the e-mail. |
| Cc | E-mail addresses of copy recipients. |
| Bcc | E-mail addresses of blind copy recipients. These will get a copy of the e-mail, but won't see the addresses of other recipients in the mail. |
| Subject | Subject of the e-mail. |
| HTML version | Defines the content that is used for the template when sending e-mails in HTML format. The preferred format can be selected using the Site Manager -> Settings -> System -> E-mails -> E-mail format setting. |
| Plain text version | Plain text version of the e-mail template. |

Example of the HTML version of a template:

```
<html>
  <head>
  </head>
  <body style="font-size: 12px; font-family: arial">
```

```

    <p>
        This is an automatic notification sent by Kentico CMS. The following
        document is waiting for your approval. Please sign in to Kentico CMS Desk and
        approve it.
    </p>
    <p>
        <strong>Document:</strong> <a href="{%DocumentEditUrl%}">{%documentname%}</
a> {% ifEmpty(DocumentPreviewUrl, "", "(

```

Please note that e-mail template properties may contain [macro expressions](#), such as those marked in the code above, that are resolved (merged) when the e-mail is sent. The use of macros is necessary to ensure that individual e-mails contain information relevant to the situation that caused them to be sent. In some cases, you may wish to display the data loaded via a macro in a specific format. This can be done by applying transformations as described in the [Transformations in macro expressions](#) topic.

It is possible to attach files to an e-mail template through the  **Attachments** button in the header of the template editing page. When e-mails based on the given template are sent out, the attachments will be included. Clicking the button opens a dialog where the attachments can be managed.

7.10 Form controls

7.10.1 Overview

Form controls provide the interface for various editing forms that allow users to input data into Kentico CMS, both in the administration interface and on the live site. Each control represents a single field by displaying a certain form element, like a text box or area for user input, a group of radio buttons, an object selector etc.

The image shows a user profile form with the following fields and controls:

- Full name:
- Email:
- Nickname:
- Signature:
- Messaging notification e-mail:
- Time zone:
- Avatar:
[Select pre-defined avatar](#)
- Gender: Male Female
- Date of birth:

All form controls are registered as objects in the system and may be configured in various ways. More information can be found in the [Managing form controls](#) topic.

The controls can be placed into all editing forms that are based on the Kentico CMS form engine, which includes the following:

- [Document type](#) editing forms (Form tab)
- [Web part](#) and [Widget](#) properties
- Editing forms of [System table](#) objects
- Editing forms of [Custom tables](#)
- [On-line forms](#)
- [Alternative forms](#) for the objects mentioned above
- [Custom website settings](#)
- [Report parameters](#)
- [Macro rule parameters](#)

These forms are defined through a special field editor interface as described in the [Assigning form controls to fields](#) topic.

From a website development point of view, form controls are implemented as standard user controls (.ascx files) that inherit from the **CMS.FormControls.FormEngineUserControl** class.

Even though the built-in set of controls covers most standard types of form functionality, it is also possible to customize existing controls or create completely new ones to match any specific requirements. Please refer to the [Developing form controls](#) topic for additional information and an example of how to create a custom form control, register it in the system and insert it into a form.

7.10.2 Managing form controls

You can view the catalog of available form controls in **Site Manager -> Development -> Form controls** and register new ones as necessary. When edited, form controls have the following properties available on the **General** tab:

- **Display name** - sets the name of the form control displayed in the administration interface, e.g. when selecting a control in the field editor.
- **Code name** - sets the name of the control that is used as its unique identifier, for example in the API.
- **Type** - allows the selection of a category under which the form control will be placed. The type can be used to filter form controls.
- **File name** - contains the relative path to the .ascx file that implements the form control, for example: `~/CMSFormControls/Basic/TextBoxControl.ascx`
- **Description** - may be used to enter a text description of the control or comments for other administrators.
- **High priority** - when selecting a form control in the field editor, controls with high priority are offered at the top of the list and highlighted using a colored background. This option should only be enabled for those controls that are most commonly used.

The screenshot displays the 'Form control properties' dialog in the Kentico CMS 7.0 Administration interface. The 'General' tab is selected, and the 'Form controls' category is chosen in the left-hand navigation pane. The 'Text box' control is being edited. The 'General' section includes fields for 'Display name' (Text box), 'Code name' (TextBoxControl), 'Type' (Input), and 'File name' (~/CMSFormControls/Basic/TextBc). A 'Description' text area and a 'High priority' checkbox (checked) are also present. The 'Control scope' section is expanded, showing 'Use control for' and 'Show control in' sections. The 'Use control for' section lists attribute types with checkboxes: Text (checked), Long text, Decimal, Integer (checked), Long integer, Visibility, Date-time, Boolean, Unique identifier (GUID) (checked), File, and Document attachments. The 'Show control in' section lists where the control should be available: Document types, Custom tables, System tables, Reports, Controls and web parts, and Forms (checked). The 'Default data type' is set to 'Text' and the 'Column size' is 500.

The properties under the **Use control for** section determine for which attribute types the form control should be available. Possible attribute types for fields include standard data types (Text, Long text, Decimal, Integer, Long integer, Boolean, Date-time), as well as the following special options:

- **Visibility** - this attribute type is used for controls that modify the visibility options of other fields. Please see the [Development -> Membership, permissions and security -> Custom field visibility](#)

chapter for more details.

- **Unique identifier (GUID)** - attributes of this type are 32-character strings used as globally unique identifiers for objects.
- **File** - used for fields that provide file management.
- **Document attachments** - this attribute type is used for fields that allow the management of document attachments.

The **Show control in** section is used to specify in which types of forms the control can be used i.e. where in the user interface it can be selected. The following options are available:

- **Document types** - allows use in document type fields, which can be edited in *Site Manager* -> *Development* -> *Document types*. The actual form is displayed when editing a document on the *Form* tab in *CMS Desk* -> *Content* -> *Edit*.
- **Custom tables** - allows the control in custom table fields, which can be edited in *Site Manager* -> *Development* -> *Custom tables*. The corresponding data editing form can be found in *CMS Desk* -> *Tools* -> *Custom tables*.
- **System tables** - allows use in system table fields, which can be edited in *Site Manager* -> *Development* -> *System tables*. The editing forms of system objects are located in various sections of the administration interface or on the live site, depending on the specific object.
- **Reports** - if checked, the control may be used to provide the interface for entering report parameters, which can be defined when editing a report in *CMS Desk* -> *Tools* -> *Reporting*. The reporting parameter form is displayed when a report is viewed in the interface or published on the live site.
- **Controls and web parts** - allows the control to be used for the properties of web parts and widgets, as defined in *Site Manager* -> *Development* -> *Web parts/Widgets*. This editing form provides the configuration dialog of individual web parts or widget instances.
- **Forms** - if checked, the control may be used to represent the fields of on-line forms, which can be edited in *CMS Desk* -> *Tools* -> *Forms*. The *High priority* flag of the form control also needs to be enabled if you wish to have it offered in the form field editor's *simple* mode. If you allow a form control for forms, you also need to enter the following default values that will be used if the field is edited in simple mode:
 - **Default data type** - the data type of the field that will be used by default when a user chooses to create a new field of this type.
 - **Column size** - only applies to the *Text* data type. This sets the maximum size of the database column used to store the field, which also limits the maximum number of characters that may be entered into the field.

The **Properties** tab is used to define parameters for the specific form control. Further information can be found in the [Form control parameters](#) topic.

Form control inheritance

When creating a new form control, it is possible to inherit from an existing control rather than starting from scratch. Inherited controls work the same way as their parent, but it is possible to change their general settings (i.e. set where they can be used) and assign different default values for their parameters. This allows you to create specialized controls based on general ones. Such controls can be particularly useful for users who work with the field editor in simple mode.

For example, imagine that you need to define a reusable drop-down list with a specific set of options. This is a typical scenario that can easily be achieved by creating an inherited form control. You could use the general *Drop-down list* form control as the parent and then simply set the required options through the default values of the parameters available on the **Properties** tab.

New form control

> Form controls > New form control

Create a new form control
 Inherit from an existing form control

Save

Display name: Specialized selector

Code name: (automatic)

Type: Input

Inherit from: Drop-down list

Inherited form controls use the same source file as their parent, so they do not have a **File name** property. Instead, you simply select the parent when creating the inherited control.

7.10.3 Assigning form controls to fields

To allow users to interact with the fields in an editing form, it is necessary to select an appropriate form control for each displayed field. This can be done through the field editor of the given form, specifically using the **Form control** property in the **Field appearance** section.

Save

Database

Column name: ItemText

Attribute type: Text

Attribute size: 400

Allow empty value:

Default value:

Translate field:

Display attribute in the editing form

Field appearance

Field caption: Item text

Form control: Text box

Field description:

Input style:

Control CSS class:

Quick links:
[Database](#)
[Field appearance](#)
[Editing control settings](#)
[Validation](#)
[CSS styles](#)

As you can see, the high priority form controls are highlighted and offered first in the selection list. If there are too many form control options and you cannot find the one that you need directly in the drop-down, you can assign it via the full selection dialog opened by clicking the (*more items ...*) option.

Please keep in mind that the selection options are limited by the scope settings of individual form controls. This means that different controls will be offered based on the type of form that is being edited and the **Attribute type** selected for the current field.

Default form control selection

You can use the settings in **Site Manager -> Settings -> System -> Form engine** to choose which form controls should be offered as the default option when adding new fields in the field editor. A separate setting is available for each data type (Attribute type) that can be assigned to a field.

These settings are global and affect all sites in the system.

In addition to the choice of a form control, the field editor provides many configuration options for individual fields as described in the table below. Please note that not all settings may be available depending on the selected **Attribute type** and the field editor may also have other options related to the specific object type for which the form is being defined.

| Database | |
|---------------------------------------|--|
| Column name | Sets the name used for the database column storing the values of the field. It also serves as an identifier for the field. |
| Attribute type | Determines the data type of the value that the field will contain. |
| Attribute size | Sets the maximum amount of characters that can be entered into the field. Only available if the Attribute type is set to <i>Text</i> . |
| Allow empty value | If enabled, the field will allow empty values. If disabled, it will not be possible to save the form unless there is a value entered in the given field. |
| Default value | The default value of the field that will be pre-filled when the form is loaded. |
| Translate field | Indicates if the field should be included when using translation services with the objects for which the form is defined.

Only available if the selected Attribute type is <i>Text</i> or <i>Long text</i> . |
| Display attribute in the editing form | Indicates if the given field should be shown in the form to users. This can be disabled for fields that store internal or system values. |
| Field appearance | |

| | |
|---|---|
| Field caption | Sets the text displayed in the editing form next to the field. |
| Form control | As described in the text above, this field selects the form control that will be used to interact with the given field in the editing form. |
| Field description | Tooltip which will be displayed if a user hovers over the field. |
| Editing control settings | |
| The settings in this section provide a way to configure the parameters defined for the selected Form control . Please see the Form control parameters topic to learn more. | |
| Validation | |
| Regular expression | This regular expression will be used by the field's validator to determine which values are acceptable. Only available if the selected Attribute type is <i>Text</i> or <i>Long text</i> . |
| Min/Max length | Sets the minimum/maximum length for entered values. Only available if the selected Attribute type is <i>Text</i> or <i>Long text</i> . |
| Min/Max value | Sets the minimum/maximum value that can be entered. Only available if the selected Attribute type is numerical. |
| From/To | Can be used to specify a time interval into which the entered value must belong. Only available if the selected Attribute type is <i>Date and time</i> . |
| Error message | Error message displayed if a user enters invalid input into the field and attempts to save the editing form. |
| CSS styles | |
| Caption style | Used to set CSS styles for the caption of the given field. |
| Input style | Used to set CSS styles for the input entered into the field. |
| Control CSS class | Name of the CSS class used to style the field. |
| Field advanced settings | |
| Visible condition | <p>May be used to enter a macro condition that must be fulfilled in order for the specific field to be visible in the editing form. The condition is dynamically resolved when the form is loaded.</p> <p>You can write any condition according to your specific requirements. For details about available macro options and syntax, please refer to the Development -> Macro expressions chapter of the Developer's Guide.</p> <p>If you wish to create a condition that depends on the state of the other fields in the form, you can access them in the macro expression using the corresponding Column name. The data of the fields may then be retrieved through the following properties:</p> |

| | |
|--------------------------|--|
| | <ul style="list-style-type: none"> • Value - returns the current value of the field. For example, <i>FirstName.Value</i> is resolved into the value entered into the <i>FirstName</i> field. • Visible - returns a true value if the given field is currently visible in the form. • Enabled - true if the field is currently enabled, i.e. its value can be edited. • Info.<field setting> - may be used to access various settings configured for the field, for example: <i>FirstName.Info.AllowEmpty</i> |
| Enabled condition | <p>Allows you to enter a macro condition that determines when the field should be enabled. If this condition is resolved as false, the field will be visible, but it will not be possible to edit its value.</p> <p>You can use the same macro options as described above for the Visible condition property.</p> |
| Has depending fields | <p>If enabled, the editing form will be refreshed via autopostback whenever the value of the given field is changed. This means that other fields can be dynamically updated according to the current value of the field.</p> <p>Please note that the actual logic of the dependencies needs to be implemented in the code of the used form controls.</p> |
| Depends on another field | <p>This option must be enabled if you wish to have the behavior of the field dynamically changed according to the value of some other field.</p> |

Forms may also contain categories, which allow you to group multiple fields together. Using categories is recommended in large forms to make orientation easier for users. Each category will include those fields that are positioned below it in the field editor. Categories can be created by clicking the **New category** (📁) button.

The following settings are available when creating or editing a category:

| Category | |
|----------------------|---|
| Category name | Sets the name of the category that will be displayed in the editing form. |
| Collapsible | If enabled, users will be able to collapse and expand the content of the category. |
| Collapsed by default | If enabled, the category will initially be collapsed when the form is loaded. |
| Visible | If disabled, the category and all of the fields it contains will be hidden in the form. |
| Visible condition | May be used to enter a macro condition that must be fulfilled in order for the category to be visible. You can use the same |

macro options as described above for the **Visible condition** property of fields.

7.10.4 Form control parameters

It is possible to define parameters for form controls that can be used to further specify the behavior or appearance of the generated form fields. Parameters can greatly increase the flexibility of a form control, since they provide additional configuration options for individual fields that use the control. This allows you to reuse the same control without having to develop a new one for every small difference in functionality or design.

To access the parameters of a form control, edit (✎) the given control in **Site Manager -> Development -> Form controls** and switch to the **Properties** tab. Here, you can manage the fields that represent individual parameters.

The screenshot shows the 'Form control properties' dialog box with the 'Properties' tab selected. On the left, a list of parameters is shown, with 'Width' highlighted. On the right, the configuration options for the 'Width' parameter are displayed:

- Database:** Column name: Width, Attribute type: Integer number, Attribute size: (empty), Allow empty value: , Default value: (empty)
- Display attribute in the editing form
- Field appearance:** Field caption: Width (px), Form control: Text box, Field description: Sets the width of the editor area.
- Editing control settings:** Watermark: (empty)

As you may have noticed, the parameters themselves are created through a field editor and the form used to edit their values is based on the standard form engine. The editing interface for every parameter is provided by a selected form control, which means you can create completely custom parameters according to your own requirements.

The defined parameters are then displayed when the given form control is selected in the field editor of an object. You can view and configure them under the **Editing control settings** section of the given field.

The screenshot shows the 'Document type properties' window for a 'News' document type. The 'Fields' tab is selected, and the 'NewsSummary*' field is chosen. The 'Editing control settings' section is highlighted with a red box, containing the following parameters:

- Width (px): 300
- Height (px): 100
- Maximum text length (without HTML tags): 300
- CSS stylesheet: Corporate Site
- Toolbar set: (empty)
- Toolbar location: (empty)
- Starting path: (empty)
- Media dialog configuration: [Configure](#)

Below this, the 'Validation' section includes:

- Spell-check this field:
- Regular expression: (empty)
- Min length: (empty)
- Max length: (empty)
- Error message: (empty)

There are two possible modes for this group of settings: *Advanced* and *Simplified*. You can switch between them using the corresponding link in the given section of the field editor. Simplified mode only offers the parameters that have the **Display in simple mode** option enabled (on the **Properties** tab of the given form control under the **Field advanced settings** section).

The parameter values entered here will be applied to the given field.

Warning!

Removing or modifying the parameters of the built-in form controls may cause the system to behave incorrectly in some cases, since the controls are used in various parts of the Kentico CMS interface.

We recommend implementing a new form control or inheriting from an existing example if you wish to create a custom field.

Parameters of inherited form controls

When editing an inherited form control on the **Properties** tab, the parameters are automatically loaded from the parent control. The configuration of the parameters cannot be modified, it is only possible to change their default values. This allows you to create specialized form controls that may easily be used in the field editor without any configuration of their **Editing control settings**.

To modify the default value of a parameter, uncheck the **Inherited** box next to it and then make the necessary changes. Otherwise, the default value set for the given property in the parent control will be used.

The screenshot shows the 'Form control properties' dialog for an 'Avatar type selector'. The 'Properties' tab is selected. A 'Save' button is visible. Under the 'General' section, the 'Data source' is a dropdown menu containing three items: 'avatar;Avatar', 'gravatar;Gravatar', and 'userchoice;User can choose'. To the right of the dropdown are two 'Inherited' checkboxes: 'LongText' (unchecked) and 'Boolean' (checked). Below the dropdown is an 'Allow edit value' checkbox, which is unchecked.

An inherited form control may only override the default value for parameters that have the **Display attribute in the editing form** option enabled in the definition of the parent control.

Handling parameters in the code of custom form controls

In order to be reflected by the field in the resulting form, each parameter must be processed in the code of the form control. The following methods can be used to access the value of a parameter:

- `GetValue("<ParameterName>")`
- `SetValue("<ParameterName>", Object value)`

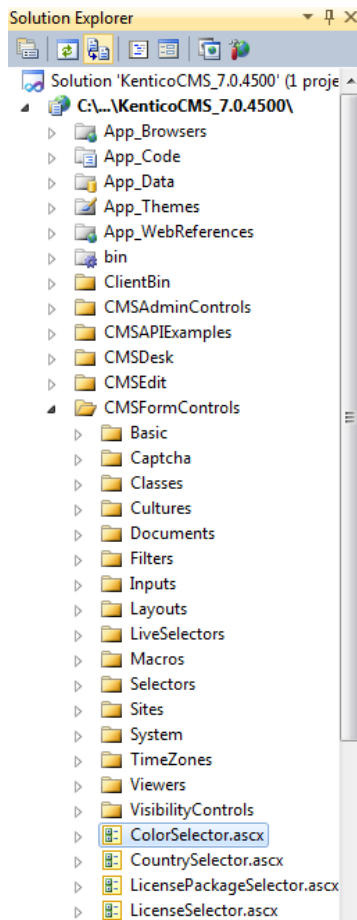

Replace the `<ParameterName>` expression with the **Column name** of the parameter that you wish to get or set. These two methods are inherited from the **FormEngineUserControl** class, so they are available for every form control. For easy storage and usability, it is recommended to define a separate property for every parameter (as a member of the control's class). Once you have the value of the parameter, you can implement code that modifies the control accordingly.

For more details, please see the example in the [Developing form controls](#) topic, which demonstrates how a parameter can be added to a form control and handled in the code.

7.10.5 Developing form controls

The following example shows how to create a form control that will allow users to choose a color from a drop-down list. The example is relatively simple, but the same basic approach can be used to create any type of custom form control or modify an existing one.

1. Open your web project in Visual Studio (or Visual Web Developer) using the **WebProject.sln** file or via **File -> Open -> Web site** in Visual Studio.
2. Right-click the **CMSFormControls** folder and choose **Add New Item**. Choose to create a new **Web User Control** and call it `ColorSelector.ascx`.

This folder (or a sub-folder under it) should always be used to store the source files of custom form controls, since it ensures that registered form controls are exported correctly along with the site.

3. Edit the new control on the **Design** tab. Drag and drop a standard **DropDownList** control onto the form from the Toolbox:

4. Edit the properties of the DropDownList and change its **ID** to *drpColor*.

5. Switch to the code behind and add a reference to the following namespace:

[C#]

```
using CMS.FormControls;  
using CMS.GlobalHelper;
```

[VB.NET]

```
Imports CMS.FormControls
Imports CMS.GlobalHelper
```

6. Next, modify the class definition according to the following:

[C#]

```
public partial class CMSFormControls_ColorSelector : System.Web.UI.UserControl

to

public partial class CMSFormControls_ColorSelector : FormEngineUserControl
```

[VB.NET]

```
Partial Class CMSFormControls_ColorSelector
    Inherits System.Web.UI.UserControl

to

Partial Class CMSFormControls_ColorSelector
    Inherits FormEngineUserControl
```

This ensures that our form control inherits from the **CMS.FormControls.FormEngineUserControl** class and can use its standard properties.

7. Now add the following members into the class:

[C#]

```
/// <summary>
/// Gets or sets the value entered into the field, a hexadecimal color code in
/// this case.
/// </summary>
public override Object Value
{
    get
    {
        return drpColor.SelectedValue;
    }
    set
    {
        // Ensure drop down list options
        EnsureItems();
        drpColor.SelectedValue = System.Convert.ToString(value);
    }
}
```

```
/// <summary>
/// Property used to access the Width parameter of the form control.
/// </summary>
public int SelectorWidth
{
    get
    {
        return ValidationHelper.GetInteger(GetValue("SelectorWidth"), 0);
    }
    set
    {
        SetValue("SelectorWidth", value);
    }
}

/// <summary>
/// Returns an array of values of any other fields returned by the control.
/// </summary>
/// <returns>It returns an array where the first dimension is the attribute name
and the second is its value.</returns>
public override object[,] GetOtherValues()
{
    object[,] array = new object[1, 2];
    array[0, 0] = "ProductColor";
    array[0, 1] = drpColor.SelectedItem.Text;
    return array;
}

/// <summary>
/// Returns true if a color is selected. Otherwise, it returns false and displays
an error message.
/// </summary>
public override bool IsValid()
{
    if ((string)Value != "")
    {
        return true;
    }
    else
    {
        // Set form control validation error message.
        this.ValidationErrorMessage = "Please choose a color.";
        return false;
    }
}

/// <summary>
/// Sets up the internal DropDownList control.
/// </summary>
protected void EnsureItems()
{
    // Applies the width specified through the parameter of the form control if it
is valid.
    if (SelectorWidth > 0)
    {
        drpColor.Width = SelectorWidth;
    }
}
```

```

    if (drpColor.Items.Count == 0)
    {
        drpColor.Items.Add(new ListItem("(select color)", ""));
        drpColor.Items.Add(new ListItem("Red", "#FF0000"));
        drpColor.Items.Add(new ListItem("Green", "#00FF00"));
        drpColor.Items.Add(new ListItem("Blue", "#0000FF"));
    }
}

/// <summary>
/// Handler for the Load event of the control.
/// </summary>
protected void Page_Load(object sender, EventArgs e)
{
    // Ensure drop-down list options
    EnsureItems();
}

```

[VB.NET]

```

''' <summary>
''' Gets or sets the value entered into the field, a hexadecimal color code in
this case.
''' </summary>
Public Overrides Property Value() As Object
    Get
        Return drpColor.SelectedValue
    End Get
    Set(ByVal value As Object)
        EnsureItems()
        drpColor.SelectedValue = System.Convert.ToString(value)
    End Set
End Property

''' <summary>
''' Property used to access the Width parameter of the form control.
''' </summary>
Public Property SelectorWidth() As Integer
    Get
        Return ValidationHelper.GetInteger(GetValue("SelectorWidth"), 0)
    End Get
    Set(ByVal value As Integer)
        SetValue("SelectorWidth", value)
    End Set
End Property

''' <summary>
''' Sets values for any other fields (attributes) of the object in which the form
control is used.
''' </summary>
''' <returns>Returns an array where the first dimension is the field's column name
and the second is its value.</returns>
Public Overrides Function GetOtherValues() As Object(,)
    Dim arr(0, 1) As Object
    arr(0, 0) = "ProductColor"
    arr(0, 1) = drpColor.SelectedItem.Text

```

```
Return arr
End Function

''' <summary>
''' Returns true if a color is selected. Otherwise, it returns false and displays
an error message.
''' </summary>
Public Overrides Function IsValid() As Boolean
    If CType(Value, String) <> "" Then
        Return True
    Else
        ' Set form control validation error message.
        Me.ValidationErrors.Add("Please choose a color.")
        Return False
    End If
End Function

''' <summary>
''' Sets up the internal DropDownList control.
''' </summary>
Public Sub EnsureItems()
    ' Applies the width specified through the parameter of the form control if it
is valid.
    If SelectorWidth > 0 Then
        drpColor.Width = SelectorWidth
    End If

    If drpColor.Items.Count = 0 Then
        drpColor.Items.Add(New ListItem("(select color)", ""))
        drpColor.Items.Add(New ListItem("Red", "#FF0000"))
        drpColor.Items.Add(New ListItem("Green", "#00FF00"))
        drpColor.Items.Add(New ListItem("Blue", "#0000FF"))
    End If
End Sub

''' <summary>
''' Handler for the Load event of the control.
''' </summary>
Protected Sub Page_Load(ByVal sender As Object, ByVal e As System.EventArgs)
Handles Me.Load
    ' Ensure drop down list options
    EnsureItems()
End Sub
```

The above code overrides three members inherited from the **FormEngineUserControl** class that are most commonly used when developing form controls:

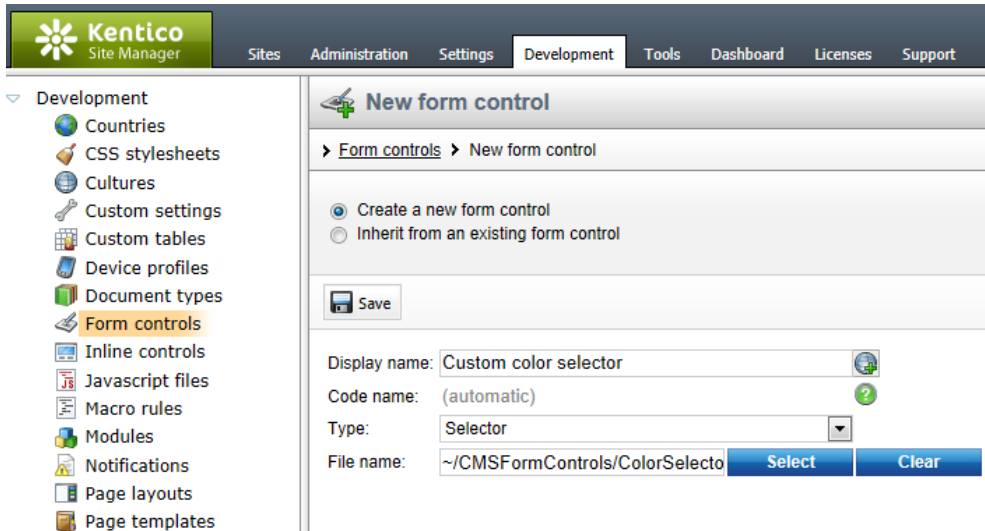

- **Value** - it is necessary to override this property for every form control. It is used to get and set the value of the field provided by the control.
- **GetOtherValues()** - this method is used to set values for other fields of the object in which the form control is used. It must return a two dimensional array containing the names of the fields (columns) and their assigned values. Typically used for multi-field form controls that need to store data in multiple database columns, but only occupy a single field in the form.
- **IsValid()** - this method is used to implement validation for the values entered into the field. It must return *true* or *false* depending on the result of the validation.

Also notice that a **SelectorWidth** property was defined for the form control. It serves as a way to access the value of a parameter that will be defined for the form control later in the example. This property is used in the **EnsureItems()** method to set the width of the internal drop-down list .

Remember to save the changes to both code files and **Build** your project if it is installed as a web application.

8. Go to **Site Manager -> Development -> Form controls** where you can register the new form control in the system. Click the  **New form control** button, select the **Create a new form control** option and enter the following values:

- **Display name:** Custom color selector
- **Code name:** Leave the *(automatic)* option
- **Type:** Selector
- **File name:** ~/CMSFormControls/ColorSelector.ascx (you can use the **Select** button to choose the file)

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The left sidebar shows a tree view under 'Development' with categories like 'Countries', 'CSS stylesheets', 'Cultures', 'Custom settings', 'Custom tables', 'Device profiles', 'Document types', 'Form controls' (highlighted), 'Inline controls', 'Javascript files', 'Macro rules', 'Modules', 'Notifications', 'Page layouts', and 'Page templates'. The main content area is titled 'New form control' and contains the following options and fields:

- Navigation: > [Form controls](#) > New form control
- Options:
 - Create a new form control
 - Inherit from an existing form control
- Buttons: Save
- Fields:
 - Display name: Custom color selector
 - Code name: (automatic)
 - Type: Selector
 - File name: ~/CMSFormControls/ColorSelecto
- Buttons: Select, Clear

Click  **Save** and the form control will be created.

9. You will be redirected to the control's **General** tab. Here, check the **Use control for - Text** and **Show control in - Document types** boxes and click  **Save** again.

Form control properties

> Form controls > Custom color selector

General Properties

Save

General

Display name: Custom color selector

Code name: Custom_color_selector

Type: Selector

File name: ~/CMSFormControls/ColorSelecto **Select** **Clear**

Description:

High priority:

Control scope

Use control for:

- Text
- Long text
- Decimal
- Integer
- Long integer
- Visibility
- Date-time
- Boolean
- Unique identifier (GUID)
- File
- Document attachments

Show control in:

- Document types
- Custom tables
- System tables
- Reports
- Controls and web parts
- Forms

Default data type: Text

Column size: 0

10. Switch to the **Properties** tab where parameters can be defined for the form control. Use the **New attribute** (+) action and set the following values for the parameter:

- **Column name:** SelectorWidth
- **Attribute type:** Integer number
- **Allow empty value:** true (checked)
- **Display attribute in editing form:** true
- **Field caption:** Drop-down list width
- **Form control:** Text box

When finished, click **Save**.

Form control: Text box

Field description:

Editing control settings

Watermark Advanced

Text:

Quick links:
[Database](#)
[Field appearance](#)
[Editing control settings](#)
[Validation](#)
[CSS styles](#)

This parameter will allow users to specify the width of the color selector directly from the administration interface whenever they add this control to a form. The code of the form control already ensures that the value is properly applied.

11. Now we will test this control by placing it onto a document editing form. Go to **Site Manager -> Development -> Document types** and edit (✎) the **Product** document type. Select the **Fields** tab to access the field editor for this document type. Add two new fields using the **New attribute** (+) action. Set the following properties for the fields:

- **Column name:** ProductColor
- **Attribute type:** Text
- **Attribute size:** 100
- **Display attribute in editing form:** false

This field will store the name of the color selected for the product. It will not be available in the editing form, its value will be set automatically by the **GetOtherValues()** method of the **ColorSelector.ascx** control (notice that the *Column name* matches the name used in the code of the method).

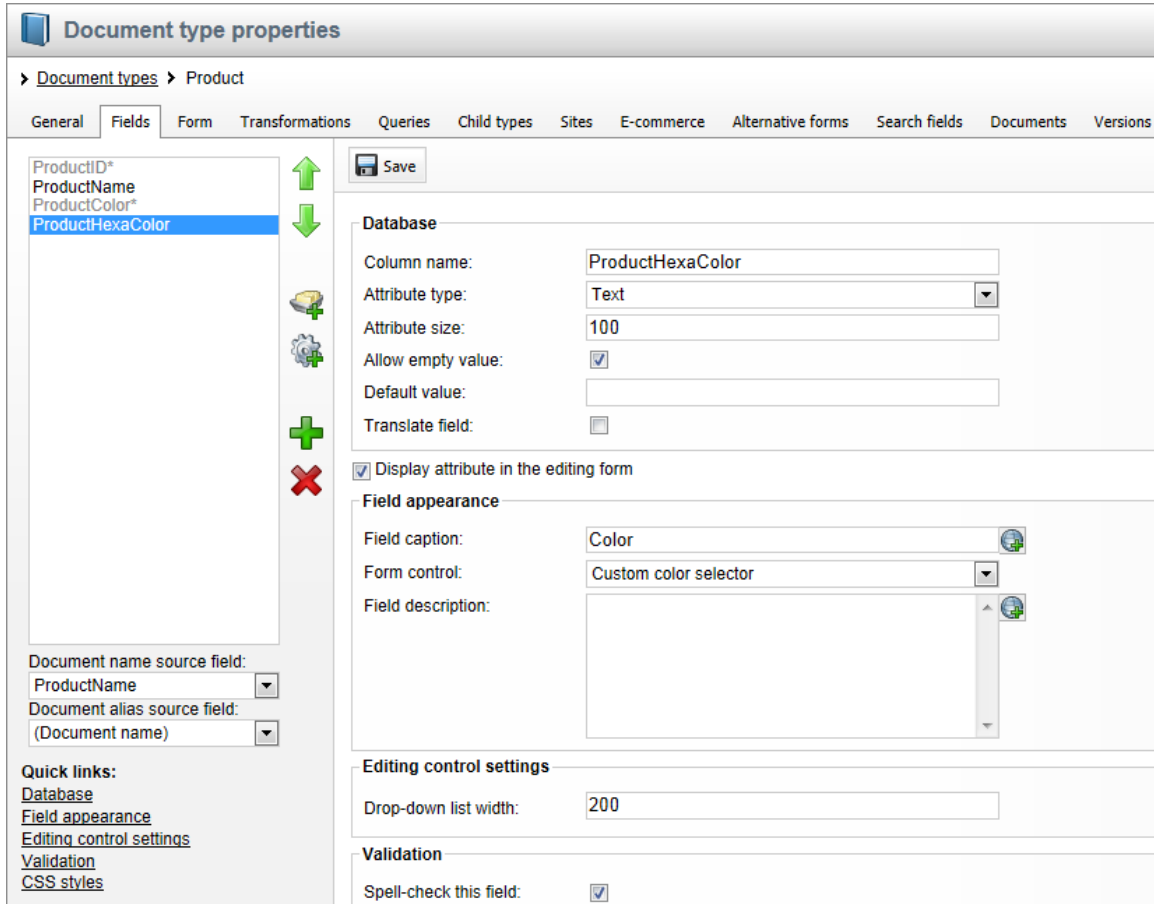

Click **Save** and create the next field:

- **Column name:** ProductHexaColor
- **Attribute type:** Text
- **Attribute size:** 100
- **Allow empty value:** true (checked)
- **Display attribute in editing form:** true
- **Field caption:** Color
- **Form control:** Custom color selector

This field will store the hexadecimal code of the selected color. In the code of the form control, this value is handled through the **Value** property. The field will be displayed in the document's editing form according to the design of the custom form control.

Notice that the **Editing control settings** section of this field contains the **Drop-down list width** field. This is the **SelectorWidth** parameter defined for the form control in the previous step. Try to specify the width of the selector by entering some number, for example **200**.

Click  **Save** again.

The screenshot shows the 'Document type properties' dialog for the 'Product' document type. The 'Fields' tab is active, and the 'ProductHexaColor' field is selected in the left-hand list. The right-hand pane shows the configuration for this field, organized into several sections:

- Database:** Column name: ProductHexaColor; Attribute type: Text; Attribute size: 100; Allow empty value: ; Default value: ; Translate field:
- Display attribute in the editing form
- Field appearance:** Field caption: Color; Form control: Custom color selector; Field description: (empty text area)
- Editing control settings:** Drop-down list width: 200
- Validation:** Spell-check this field:

At the bottom left, there are 'Quick links' for Database, Field appearance, Editing control settings, Validation, and CSS styles. Below the field list, there are dropdowns for 'Document name source field' (set to ProductName) and 'Document alias source field' (set to (Document name)).

12. Go to **CMS Desk -> Content** and create a new document of the **Product** document type under the **Products** section. For the purposes of this example, choose the **Do not create an SKU** option in the **SKU binding** section. The document's editing form will contain the new form control as shown below:

As you can see, the document field can be managed using the custom form control. The width of the displayed drop-down list will match the value that you entered into the form control's parameter. If you do not choose any color, the validation error message defined in the code of the form control will be displayed.

By implementing custom form controls as shown in this example, it is possible to create editing forms with almost unlimited flexibility, both in the administration interface and on the live site.

Getting and setting values of other fields using the API

The data of the current form can be accessed through the **Form** property of the form control inherited from the **FormEngineUserControl** class.

You can retrieve the values entered into other fields using the following method:

- **Form.GetFieldValue(string columnName)** - returns an object containing the value of the specified field.

For example, the following code could be used to get the value of the **ProductName** field from the current form (*New product* is returned if the field is empty):

[C#]

```
string productName = CMS.GlobalHelper.ValidationHelper.GetString(
    Form.GetFieldValue("ProductName"), "New product");
```

To set the value of a field, you can use the following approach:

- **Form.Data.SetValue(string columnName, object value)** - sets a value for the specified field.

To modify the value of a field **before the form is saved**, you need to place the code inside the **IsValid** method of your form control.

7.11 Inline controls

7.11.1 Overview

Inline controls are user controls (ASCX) that can be placed into the text of editable regions using a special expression in format `%%control:MyUserControl%%`, where *MyUserControl* is the name of the inline control. The system dynamically loads the controls when the page is displayed on the live site.

The controls may contain any functionality, such as "polls", "latest news", "mortgage calculator", "travel destination search", etc. The advantage of inline controls is that any content editor can place them anywhere into the text without programming knowledge.

How to insert inline controls into text

Inline controls can be inserted into text using the **Insert inline control** () button on the [WYSIWYG editor](#) toolbar. If the text is not edited in the WYSIWYG editor, you can insert inline controls by typing the `%%control:MyUserControl%%` expressions manually. Only controls that have been registered in the system and assigned to the currently edited site can be inserted. This can be done at **Site Manager -> Development -> Inline controls**.

The inline control may also have a single parameter. In this case, you must use one of the following expression formats:

- `%%control:BizFormControl?form1%%`
- `{^BizFormControl|form1^}`
- `{^BizFormControl|{(formname)form1^}`

To learn how to create a new inline control and add it to the system, please see the [How to develop inline controls](#) topic.

Important!

Inline controls are obsolete and can no longer be added using the WYSIWYG editor toolbar by default. It is recommended to implement your custom controls as [Widgets](#) and insert them into text using the **Insert/Edit widget** () button. Further details can be found in the [Inline widgets](#) topic.

This approach offers several advantages, such as increased flexibility, an unlimited amount of parameters for the controls, and a more user-friendly configuration dialog.

For the purposes of backward compatibility, existing inline controls are still resolved correctly. If you wish to use inline controls via the WYSIWYG editor, you can enable

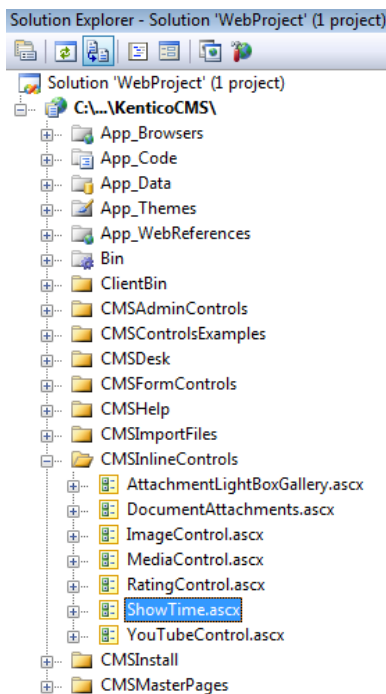

this functionality by adding the following key into the **configuration/appSettings** section of your web.config file:

```
<add key="CMSEnableInlineControls" value="true" />
```

7.11.2 How to develop inline controls

This topic will show you an example of inline control development. We will create a simple control that will display the current time when a button is clicked.

1. Open the web project in Visual Studio (or Visual Web Developer) using the **WebProject.sln** file or using **File -> Open -> Web Site...** in Visual Studio.
2. Right-click the **CMSInlineControls** folder and choose **Add New Item**. Choose to create a new **Web User Control** and call it **ShowTime.ascx**.

3. Switch to the **Design** tab and drag and drop a **Label** control and a **Button** control onto the form:

4. Double-click the Button control and enter the following code into the **Button1_Click** method. It will ensure the displaying of the current date and time by the label control.

[C#]

```
Label1.Text = DateTime.Now.ToString();
```

[VB.NET]

```
Label1.Text = DateTime.Now.ToString()
```

5. Change the following line:

[C#]

```
public partial class CMSInlineControls_ShowTime : System.Web.UI.UserControl  
  
to  
  
public partial class CMSInlineControls_ShowTime :  
CMS.ExtendedControls.InlineUserControl
```

[VB.NET]

```
Partial Class CMSInlineControls_ShowTime  
    Inherits System.Web.UI.UserControl  
  
to  
  
Partial Class CMSInlineControls_ShowTime  
    Inherits CMS.ExtendedControls.InlineUserControl
```

What you did

You have changed the user control so that it inherits from the **InlineUserControl** class. It allows you to access the parameter of the control in the next step.

6. Add the following code to the **Page_Load** method of the control:

[C#]

```
Button1.Text = this.Parameter;
```

[VB.NET]

(The **Page_Load** method is not generated by default in VB.NET)

```
Protected Sub Page_Load(ByVal sender As Object, ByVal e As System.EventArgs)
```

```
Handles Me.Load  
    Button1.Text = Parameter  
End Sub
```

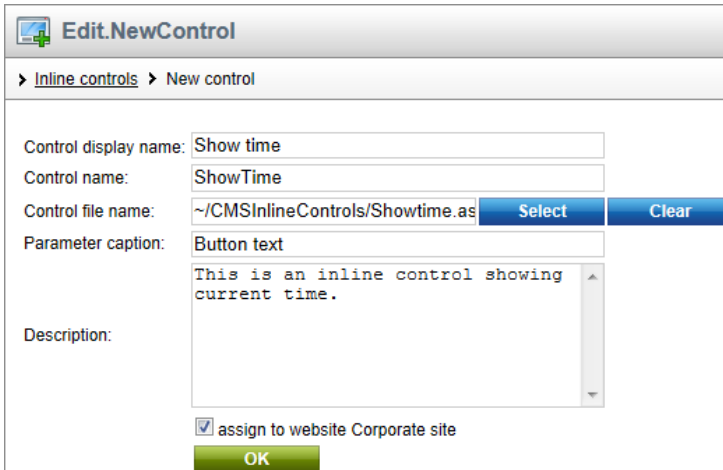

What you did

This code sets the Button1 caption based on the parameter of the inline control.

7. Save the changes.

8. Go to **CMS Site Manager -> Development -> Inline controls**. Click  **New control** and enter in the following values:

- **Control display name:** Show time
- **Control name:** ShowTime (the name of the user control without the extension)
- **Control file name:** ~/CMSInlineControls/ShowTime.ascx
- **Parameter caption:** Button text

Edit.NewControl

> Inline controls > New control

Control display name:

Control name:

Control file name:

Parameter caption:

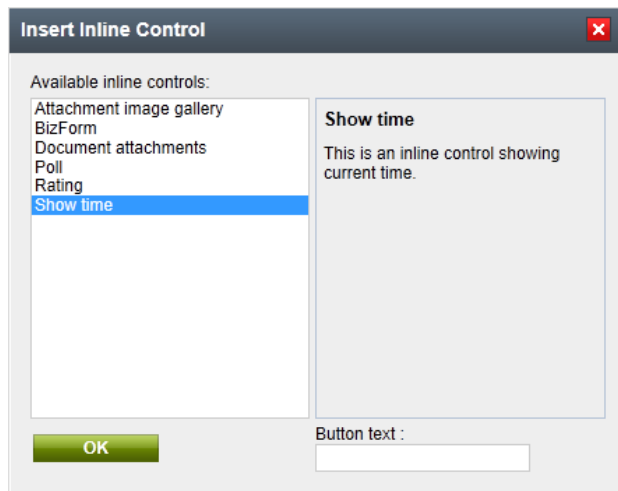

Description:

assign to website Corporate site

Click **OK**.

9. Now click the **Sites** tab and check the boxes for all sites where content editors should be able to insert this control. Click **OK**.

10. Go to CMS Desk, edit some page with editable regions and click the **Insert Inline Control** () button. Select the control and set the **Button text** value to *Show time*. Click **OK**. The special expression is now inserted into the text.

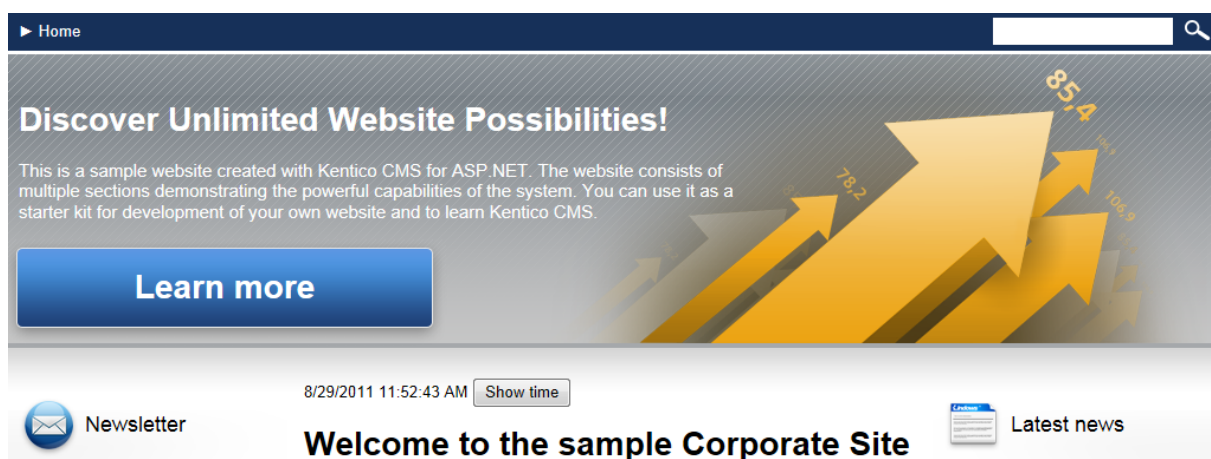

Please note

Due to the fact that in-line controls are obsolete, the **Insert Inline Control** (📄) button is only available in the toolbar after adding the following key into the **configuration/appSettings** section of your web.config file:

```
<add key="CMSEnableInlineControls" value="true" />
```

11. Click **Save** to save changes and click **Live site** to see the live version of the page. The user control is now displayed inside your text. The button has the caption you have specified. When you click the button, the label displays the current date and time:

7.12 Macro expressions

7.12.1 Overview

Macros are strings that are automatically resolved into their value equivalents. They represent a powerful option that can often eliminate writing custom .NET code.

There are several types of macros, all of which are listed and explained in the [Types of macros](#) topic. The most powerful are **context macros**, using which you can achieve most of the results achievable by using all other types of macros. Context macros can contain advanced expressions written in the K# language, whose syntax and features are described in the [K# syntax](#) topic. Methods that can be used in K# are listed and described in the [Available macro methods](#) topic. [Macro parameters](#) known from older versions of Kentico CMS are still functional and available, even though the same results can now usually be achieved through macro methods.

The user interface of Kentico CMS has several built-in features which facilitate entering of macro expressions. These are explained in the [Entering macro expressions](#) topic.

One of the ways to leverage macros is defining dynamic conditions for various types of functionality. There are several features available that make it easier to build such conditions. It is even possible to prepare components that allow users to work with conditions without any knowledge of the macro syntax. Please see the [Macro conditions](#) topic to learn more.

When certain macros are resolved, security checks are performed to verify that the user who entered the expression has permissions to read the resolved data. These checks are covered in the [Macro security](#) topic.

The default functionality of the macro engine can be enhanced by your custom code. It is possible to define custom macro methods and use them in macro expressions along with the default ones. The process of creating such methods is described in the [Registering custom macro methods](#) topic. Additionally, macro expressions can be resolved in your custom code using the API, and it is even possible to customize macro resolvers. This is described in the [Resolving macros using the API](#) topic.

For performance reasons, the system also provides a way to cache the values of resolved macros, so that certain macros do not need to be resolved repeatedly. More information on this can be found in the [Macro result caching](#) topic.

7.12.2 Types of macros

The macro type is determined by the character at the beginning and end of the macro. Macros look like:

```
{<type character><expression><parameters><type character>}
```

Where the **type character** can be one of the following:

- [% - Context \(data\) macro](#)
- [\\$ - Localization macro](#)
- [? - QueryString macro](#)
- [@ - Cookie macro](#)
- [^ - Control macro](#)
- [& - Path macro](#)
- [# - Custom macro](#)
- [~ - Substitution macro](#)

Macros of the same type can be nested using the "index parentheses" syntax, e.g. `{{(1)%FullName|default|((2)%Username%(2))%(1)}`. Click particular macro types in the listing above to get redirected to their detailed explanation.

Context (data) macros

This type of macros evaluates data based on current context. These macros can be used for example to parametrize web parts' parameters with current document or user values. These macros can be used in combination with the K# language. For more information on its syntax and possibilities, please refer to the [K# syntax](#) and [Available macro methods](#) topics.

The format of the macro is `{%ColumnName%}` and the value is replaced with the appropriate value of the column based on current context. You can use all column names from **current site** data, **current user** data and **current document** data.

Example: `"Welcome {%FullName%}"` will be resolved as `"Welcome Global administrator"` when the administrator is the current user.

There are also data macros with selectors to precisely identify the source of the data, these macros look like `{%CurrentDocument.DocumentName%}` and can be used for accurate determination of the data source. Availability of the selectors depends on the context where the macros are evaluated.

Localization macros

These macros are usually used on multilingual websites to help localize system strings. There are two types of localization macros:

Basic

Basic localization macros are entered in format `{String.key$}`. Alternatively, you can enter them as context macros in the `{% GetResourceString("resourcestring.key") %}` format. The system uses the `ResHelper.GetString("string.key")` method and replaces the macro with the appropriate language version of the given resource string.

Example: `"The weather is {General.OK$}"` is resolved as `"The weather is OK"`.

In-place localization

You can include the string and its localized equivalents directly within the macro. Such macros are entered in format `{$=Default string|cs-cz=Czech string|de-de=German string$}`. They either return a localized string for the current language, or the default (first) string if a matching localized value is not available.

Example: `"The weather is {$=OK|cs-cz=dobre|de-de=gut$}"` is resolved into `"The weather is dobre"` in the Czech culture, `"The weather is gut"` in the German culture and `"The weather is OK"` in any other culture.

QueryString macros

These macros evaluate querystring parameters information. These macros can be used for example to dynamically parameterize the controls by the querystring parameters.

The macros are entered in the `{?querystring_key?}` format. Alternatively, you can also enter them as data macros like the following: `{%QueryString.querystring_key%}`. The macro is replaced by the querystring parameter value.

Example: “Current node ID: `{?nodeid?}`” will be resolved as “Current node ID: 10” for a URL like “default.aspx?nodeid=10”

Cookie macros

These macros evaluate the values of the current user's browser cookies. For example, these macros can be used to parametrize web parts using client-based persistent values like styles or user options.

The macro is entered in format `{@cookie_name@}`. Alternatively, you can also enter them as data macros like the following: `{%Cookies.cookie_name%}`. The macro is replaced by the given cookie's value.

Example: “Current style: `{@StyleCookie@}`” will be resolved as “Current style: Red” if the `StyleCookie` value is set to “Red”

Control macros

These macros are resolved into inline controls, which can be used to place dynamic content into editable text regions and HTML layouts. The macros are specified in format `{^BizFormControl^}` and can (usually must) contain parameters for the control using standard parameterized macro syntax, such as `{^BizFormControl{(FormName)ContactForm^}`. The parameters will be used to initialize the control when the macro is resolved.

Path macros

These macros are entered in the `{&path&}` format. Alternatively, you can also enter them as data macros like the following: `{%Path.path%}`. They can be used to resolve current document *Alias path* the same way as the *Path* property of controls. The macro is replaced by the resolved path.

Example: WhereCondition: `NodeAliasPath LIKE {&../%&}`. In this case, the macro is resolved as the path of the parent document and results in selecting all siblings of the current document and their child documents. This macro is intended mostly for including the document structure context into the controls WHERE condition, but can be used for many more purposes.

See [Appendix A - Path expressions](#) for more details on how paths can be entered.

Custom macros

Custom macros allow you to define your own macro expressions. Their basic format is: `{#Expression#}`. Alternatively, you can also enter custom macros as data macros with the *Custom.* prefix: `{%Custom.Expression%}`.

Defining custom macros

When a custom macro needs to be resolved, the system calls the methods registered as handlers for the **MacroResolver.OnResolveCustomMacro** event. To create a new custom macro, you must

implement a handler method that ensures the resolving of individual expressions into the appropriate results.

1. Open your web project in Visual Studio and add a new class into the **App_Code** folder (or **Old_App_Code** if the project is installed as a web application). For example, name the class **CustomMacroLoader.cs**.

2. Edit the class and add the following references:

[C#]

```
using CMS.SettingsProvider;
using CMS.GlobalHelper;
```

3. Delete the default class declaration and its content. Instead, extend the **CMSModuleLoader** partial class and define a new attribute:

[C#]

```
[CustomMacroLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Attribute class ensuring the registration of macro handlers.
    /// </summary>
    private class CustomMacroLoader : CMSLoaderAttribute
    {
        ...
    }
}
```

4. Enter the following code into the **CustomMacroLoader** attribute class:

[C#]

```
/// <summary>
/// Called automatically when the application starts.
/// </summary>
public override void Init()
{
    // Assigns a custom macro resolving handler.
    MacroResolver.OnResolveCustomMacro += MacroResolver_OnResolveCustomMacro;
}

/// <summary>
/// Resolves custom macros.
/// </summary>
/// <param name="sender">Sender</param>
/// <param name="e">Event arguments representing the resolved macro</param>
```

```
private void MacroResolver_OnResolveCustomMacro(object sender, MacroEventArgs e)
{
    // Checks that the macro is not resolved yet.
    if (!e.Match)
    {
        // Defines the return values of specific custom macro expressions.
        switch (e.Expression.ToLower())
        {
            // Handles the {#CustomExpression#} macro.
            case "customexpression":
                e.Match = true;
                e.Result = "Resolved expression";
                break;
        }
    }
}
```

- The override of the **Init** method registers the *MacroResolver_OnResolveCustomMacro* method as a handler for the *OnResolveCustomMacro* event.
- The **MacroResolver_OnResolveCustomMacro** method defines the return value of the custom expression. The sample code only assigns a string constant as the macro result, but you may add any required API logic to set the value dynamically. You can create any number of custom macros by adding further cases into the switch statement.

The system now recognizes the *{#CustomExpression#}* macro and resolves it into the *Resolved expression* string.

Substitution macros

Substitution macros are entered in format *{~expression~}*. They are similar to [Custom macros](#). The difference is that the system resolves substitution macros **in page output code**, i.e. the page's final code before it is sent to the browser for rendering. The main advantage of substitution macros is that they are resolved on each request, even for pages that use [full-page caching](#).

Defining substitution macros

When a substitution macro needs to be resolved, the system calls the methods registered as handlers for the **OutputFilter.OnResolveSubstitution** event. To create a new substitution macro, you must implement a handler method that ensures the resolving of individual expressions into the appropriate results.

1. Open your web project in Visual Studio and add a new class into the **App_Code** folder (or **Old_App_Code** if the project is installed as a web application). For example, name the class **CustomMacroLoader.cs**.
2. Edit the class and add the following references:

[C#]

```
using CMS.SettingsProvider;
```

```
using CMS.GlobalHelper;
using CMS.CMSOutputFilter;
using CMS.OutputFilter;
```

3. Delete the default class declaration and its content. Instead, extend the **CMSModuleLoader** partial class and define a new attribute:

[C#]

```
[CustomMacroLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Attribute class ensuring the registration of macro handlers.
    /// </summary>
    private class CustomMacroLoader : CMSLoaderAttribute
    {
        ...
    }
}
```

4. Enter the following code into the **CustomMacroLoader** attribute class:

[C#]

```
/// <summary>
/// Called automatically when the application starts.
/// </summary>
public override void Init()
{
    // Assigns a substitution macro resolving handler.
    OutputFilter.OnResolveSubstitution += OutputFilter_OnResolveSubstitution;
}

/// <summary>
/// Resolves output substitution macros.
/// </summary>
/// <param name="sender">Sender</param>
/// <param name="e">Event arguments representing the resolved macro</param>
private void OutputFilter_OnResolveSubstitution(object sender,
SubstitutionEventArgs e)
{
    // Checks that the macro is not resolved yet.
    if (!e.Match)
    {
        // Defines the return values of specific substitution macros.
        switch (e.Expression.ToLower())
        {
            // Handles the {~CustomSubstitution~} macro.
            case "customsubstitution":
```

```
e.Match = true;
e.Result = "Resolved substitution";
break;
    }
}
}
```

- The override of the **Init** method registers the *OutputFilter_OnResolveSubstitution* method as a handler for the *OnResolveSubstitution* event.
- The **OutputFilter_OnResolveSubstitution** method defines the return value of the custom expression. The sample code only assigns a string constant as the substitution result, but you may add any required API logic to set the value dynamically. You can create any number of substitution macros by adding further cases into the switch statement.

The system now recognizes the *{~CustomSubstitution~}* macro and resolves it into the *Resolved substitution* string.

7.12.3 K# syntax

The syntax of data macros is very similar to syntax of the **C#** language — that is why the name **K#** was given to the macro language. The following text summarizes the main specifics and features of the language and provides examples of how individual features can be used:

Basic features

- K# is **case-insensitive**. This means that upper- or lower-case letters are handled equally in the macro expressions.
- K# supports **variable declarations**. The scope where declared variables can be used spans from the point of their declaration towards the end of the whole text where the macro is used (e.g. an e-mail template, transformation, etc.).

```
// returns "12"
{% x = 5; x + 7 %}
```

- K# supports **compound expressions**. These are expressions consisting of multiple sub-expressions separated by semicolons, where the result returned by the macro is the result of the last sub-expression.

```
// returns "10"
{% x = 5; y = 3; x += 2; x + y %}
```

- K# supports **suffix method calls**.

```
// returns "TEST"
{% "test".ToUpper() %}
```

- K# supports **infix method calls**.

```
// returns "TEST"  
{% ToUpper("test") %}
```

- K# supports **indexing**. The following is a list of indexable objects:

- DataRow, DataRowView, DataRowContainer (returns value at given index)
- DataTableContainer (returns row at given index)
- DataSetContainer (returns table at given index)
- String (returns char at given index)
- IList
- IEnumerable

```
//returns "e"  
{% "hello"[1] %}  
  
// returns value of the FirstName column from the DataRow  
{% dataRow["FirstName"] %}
```

- K# supports **lambda expressions**, which are ad-hoc declarations of in-line functions that can be used in your macro expressions. The scope where declared lambda expressions can be used span from the point of their declaration towards the end of the whole text where the macro is used (e.g. an e-mail template, transformation, etc.).

```
// returns "6"  
{% myMul = ((x, y) => x * y); myMul(2,3) %}  
  
// returns "4"  
{% mySucc = (x => x + 1); mySucc(3) %}
```

- K# supports **comments in macro expression text**. You can use one-line, multi-line and in-line comments.

```
{%  
  
// this is a one line comment, it spans across one single line initiated by two  
forwardslashes  
  
/*  
this is a multi-line comment, it can span across any number of lines  
it begins with the forwardslash-asterisk sequence and ends with the asterisk-  
forwardslash sequence  
*/  
  
x = 5; y = 3; /* this is an in-line comment nested in the middle of an expression  
*/ x+= 2; x + y
```

```
% }
```

Flow control commands

K# supports the following types of flow control commands:

- **Ternary operators** for returning of conditional output written in the following format: *<condition> ? <expressions 1> : <expressions 2>*. In case of a true condition, return value of *<expressions 1>* is returned. In case of a false condition, return value of *<expressions 2>* is returned.

```
// returns "The second parameter is grater."
{% GreaterThan(1,2) ? "The first parameter is greater." : "The second parameter is greater." %}
```

- The **if** flow control command written in format: *if (<condition>) {<expressions>}*. In case of a true condition, return value of *<expressions>* is returned. In case of a false condition, null is returned.

```
// returns "z is lesser than 3"
{% z = 1; if (z<3) {"z is lesser than 3"} %}
```

- The **if-else** flow control command written in format: *if (<condition>) {<expressions 1>} else {<expressions 2>}*. In case of a true condition, return value of *<expressions 1>* is returned. In case of a false condition, return value of *<expressions 2>* is returned.

```
// returns "z is greater than 3"
{% z = 5; if (z<3) {"z is lesser than 3"} else {"z is greater than 3"} %}
```

- The **for** iteration command written in format: *for (<init_expression>; <condition>; <incr_expression>) {<expressions>}*. The command itself has a return value. It returns a concatenated list of return values of *<expressions>* from each iteration of the loop.

```
// returns "5"
{% z = 0; for (i = 0; i < 5; i++) { z += 1 }; z %}

// returns "12345"
{% z = 0; for (i = 0; i < 5; i++) { z += 1 } %}
```

- The **foreach** iterator written in format: *foreach (<variable> in <enumerable>) {<expressions>}*. The command itself has a return value. It returns a concatenated list of return values of *<expressions>* from each iteration of the loop.

```
// returns "HELLO"
{% z = ""; foreach (x in "hello") {z += x.toupper()}; z %}
```

```
// returns "H HE HEL HELL HELLO"
{% z = ""; foreach (x in "hello") {z += x.toupper();}
```

- The **while** loop command written in format: *while* (<condition>) {<expressions>}. The command itself has a return value. It returns a concatenated list of return values of <expressions> from each iteration of the loop.

```
// returns "10"
{% z = 1; while (z<10) {++z}; z %}

// returns "2345678910"
{% z = 1; while (z<10) {++z} %}
```

- The **break** command in loops. This command terminates the nearest enclosing loop in which it appears.

```
// returns "12345"
{% z = 0; while (z < 10) {if (z > 4) {break}; ++z} %}
```

- The **continue** command in loops. This command passes control to the next iteration of the closest enclosing loop in which it appears.

```
// returns "01245"
{% for (i=0; i<=5 ; i++) {if (i == 3) {continue}; i} %}
```

- The **return** command in loops. The command returns current value of the provided expression as final result of the macro in which it appears and terminates its further processing. If no expression is provided, it returns the current console output (see below for more details on console output).

```
// returns "3"
{% i = 0; while (i < 10) {i++; if (i>2) {return i;}} %}

// returns "012"
{% i = 0; while (i < 10) {print(i++); if (i > 2) {return;}} %}
```

Open conditions and loops

When defining conditions or loops through the commands described above, it is possible to leave the body of the loop/condition open and have it closed later in another macro expression. This allows you to apply the command to text content or HTML code placed between the macro expressions, for example:

```
{% date = CurrentDateTime; if (date.Year > 2011) { %}  
The current date is: {%date%}. The registration period has ended.  
{% } %}
```

As you can see, additional macro expressions may also be nested inside open loops or conditions. This technique can be particularly useful in macro-based [transformations](#) or various types of templates.

Console output

- K# supports **console output** using the *print(<expressions>)* or *println(<expressions>)* syntax. This is useful if you want to output current values during loop iterations without the need to declare a variable where values would be stored in each iteration and returned in the end. Console output has higher priority than standard output of an expression, as you can see in the example below.

```
// returns "2345678910", the "ignore" string at the end is ignored as console  
output has higher priority  
{% z = 1; while (z < 10) {print(++z)}; "ignored" %}
```

Overloaded operators

- The + operator can be used in the following ways:

Double (Double leftOperand)+(Double rightOperand)

Takes two numbers as operands and returns their sum as Double.

DateTime (DateTime leftOperand)+(TimeSpan rightOperand)

Takes a DateTime and a TimeSpan as operands, adds the TimeSpan to the DateTime and returns the result as DateTime.

TimeSpan (TimeSpan leftOperand)+(TimeSpan rightOperand)

Takes two TimeSpans as operands and returns their sum as TimeSpan.

String (String leftOperand)+(String rightOperand)

Takes two Strings as operands and returns their concatenation as String. A String concatenation is also performed if none of the operand type combinations above are detected (e.g. if you provide a DateTime together with a String, you will get a concatenation of their String representations).

- The - operator can be used in the following ways:

Double (Double leftOperand)-(Double rightOperand)

Takes two numbers as arguments, subtracts the second one from the first one and returns the result as a Double value.

DateTime (DateTime leftOperand)-(TimeSpan rightOperand)

Subtracts a TimeSpan entered as right operand from a DateTime entered as left operand and returns the result as DateTime.

TimeSpan (DateTime leftOperand)-(DateTime rightOperand)

Subtracts a DateTime entered as right operand from a DateTime entered as left operand and returns the result as TimeSpan.

TimeSpan (TimeSpan leftOperand)-(TimeSpan rightOperand)

Subtracts a TimeSpan entered as right operand from a TimeSpan entered as left operand and returns the result as TimeSpan.

Differences from C# syntax

- To perform the modulus operation (computing the remainder after division of two integer operands), use the **mod** operator or the **Modulo (Int32 left, Int32 right)** macro method. You **cannot** use the % operator for this purpose.

```
// returns "1"  
{% x = 5; x mod 2 %}
```

- The % character provides a way to enter percentage values. It converts the associated number to a double equivalent (i.e. multiplies the number by 0.01).

```
// returns "0.3"  
{% 30% %}
```

7.12.4 Available macro methods

You can use a large variety of methods in your macro expressions. This topic lists all methods intended specifically for use in Kentico CMS macro expressions that are members of the *GlobalHelper.MacroMethods.cs*. They are listed in the following categories according to the type of functionality they provide:

- [Boolean methods](#)
- [Comparison methods](#)
- [Conversion methods](#)
- [Data manipulation methods](#)
- [DateTime methods](#)
- [GlobalHelper methods](#)
- [Mathematical methods](#)
- [Membership methods](#)
- [String methods](#)
- [Transformation methods](#)
- [Other methods](#)

Boolean methods**Boolean (Boolean left) && (Boolean right)**

Returns logical product of given parameters.

Boolean left: Left operand.

Boolean right: Right operand.

Boolean (Boolean left) || (Boolean right)

Returns logical addition of given parameters.

Boolean left: Left operand.

Boolean right: Right operand.

Boolean Not (Boolean value)**Boolean ! (Boolean value)**

Returns logical negation of the provided value.

Boolean value: Value to negate.

Boolean And (Boolean left, Boolean right)

Returns logical product of given parameters.

Boolean left: Left operand.

Boolean right: Right operand.

Boolean Or (Boolean left, Boolean right)

Returns logical addition of given parameters.

Boolean left: Left operand.

Boolean right: Right operand.

Int32 LogicalAnd (Int32 left, Int32 right)**Int32 (Int32 left) & (Int32 right)**

Returns bit logical product of given parameters.

Int32 left: Left operand.

Int32 right: Right operand.

Int32 LogicalOr (Int32 left, Int32 right)**Int32 (Int32 left) | (Int32 right)**

Returns bit logical addition of given parameters.

Int32 left: Left operand.

Int32 right: Right operand.

Int32 LogicalXor (Int32 left, Int32 right)**Int32 (Int32 left) ^ (Int32 right)**

Returns bit logical exclusive addition of given parameters.

Int32 left: Left operand.

Int32 right: Right operand.

Int32 LeftShift (Int32 left, Int32 right)**Int32 (Int32 left) << (Int32 right)**

Shifts its first operand left by the number of bits specified by its second operand.

Int32 left: Left operand.

Int32 right: Right operand.

Int32 RightShift (Int32 left, Int32 right)**Int32 (Int32 left) >> (Int32 right)**

Shifts its first operand right by the number of bits specified by its second operand.

Int32 left: Left operand.

Int32 right: Right operand.

Comparison methods

Boolean GreaterThan(Double left, Double right)

Boolean (Double left) > (Double right)

Returns true if the first parameter is greater than second. The method also accepts DateTime values as operands.

Double left: Left operand.

Double right: Right operand.

Boolean LowerThan(Double left, Double right)

Boolean (Double left) < (Double right)

Returns true if the first parameter is lower than second. The method also accepts DateTime values as operands.

Double left: Left operand.

Double right: Right operand.

Boolean GreaterThanOrEqual(Double left, Double right)

Boolean (Double left) >= (Double right)

Returns true if the first parameter is greater than or equal to second. The method also accepts DateTime values as operands.

Double left: Left operand.

Double right: Right operand.

Boolean LowerThanOrEqual(Double left, Double right)

Boolean (Double left) <= (Double right)

Returns true if the first parameter is lower than or equal to second. The method also accepts DateTime values as operands.

Double left: Left operand.

Double right: Right operand.

Boolean Equals(Object left, Object right)

Boolean (Object left) == (Object right)

Returns true if the first parameter is equal to the second. The method also accepts DateTime values as operands.

Object left: Left operand.

Object right: Right operand.

Boolean NotEquals(Object left, Object right)

Boolean (Object left) != (Object right)

Returns true if first parameter is not equal to the second.

Object left: Left operand.

Object right: Right operand.

Conversion methods

Int32 ToInt(Object value, Int32 defaultValue)

Converts value to int, if it is not possible, returns default value. This method is overloaded, while the *Int32 defaultValue* parameter is optional.

Object value: Object to convert.

Int32 defaultValue: Default value.

Boolean ToBool(Object value, Boolean defaultValue)

Converts value to bool, if it is not possible, returns default value. This method is overloaded, while the *Boolean defaultValue* parameter is optional.

Object value: Object to convert.

Boolean defaultValue: Default value.

Double ToDouble(Object value, Double defaultValue, String culture)

Converts value to double, if it is not possible, returns default value. This method is overloaded, while the *Double defaultValue* and *String culture* parameters are optional.

Object value: Object to convert.

Double defaultValue: Default value.

String culture: Culture to use.

Guid ToGuid(Object value, Guid defaultValue)

Converts value to Guid, if it is not possible, returns default value. This method is overloaded, while the *Guid defaultValue* parameter is optional.

Object value: Object to convert.

Guid defaultValue: Default value.

DateTime ToDateTime(Object value, DateTime defaultValue, String culture)

Converts value to DateTime, if it is not possible, returns default value. This method is overloaded, while the *DateTime defaultValue* and *String culture* parameter are optional.

Object value: Object to convert.

DateTime defaultValue: Default value.

String culture: Culture to use.

DateTime FromOADate(Double value)

Converts double representation of DateTime (OLE Automation Date) to DateTime.

Double value: OADate double representation to convert.

TimeSpan ToTimeSpan(Object value)

Parses the provided string value and converts it to TimeSpan.

Data manipulation methods

Object GetValue(ISimpleDataContainer container, String column)

Gets value of the specified column from the object.

ISimpleDataContainer container: Data container.

String column: Column name.

Object GetProperty(IHierarchicalObject collection, String property)

Gets value of the specified property from the object.

IHierarchicalObject collection: DataContainer.

String property: Property name.

Object GetItem(IEnumerable collection, Int32 index)

Gets the item stored at the specified index from the collection.

IEnumerable collection: Collection.

Int32 index: Index of the item.

AbstractObjectCollection OrderBy(AbstractObjectCollection collection, String orderBy)

Applies an Order by clause to the collection.

AbstractObjectCollection collection: Collection to order.

String orderBy: ORDER BY column(s).

AbstractObjectCollection Where(AbstractObjectCollection collection, String where)

Can be used to filter the objects in a collection by applying a Where condition.

AbstractObjectCollection collection: Collection to filter.

String where: WHERE condition.

AbstractObjectCollection TopN(AbstractObjectCollection collection, Int32 parameters)

Limits how many objects should be included in the collection.

AbstractObjectCollection collection: Collection to filter.

Int32 parameters: TOP N parameter.

AbstractObjectCollection Columns(AbstractObjectCollection collection, String columns)

Specifies which object data columns should be included in the collection.

AbstractObjectCollection collection: Collection to filter.

String columns: Columns parameter.

InfoObjectCollection Filter(InfoObjectCollection collection, String condition)

Returns the collection filtered by given condition.

InfoObjectCollection collection: Collection of items.

String condition: Filtering macro condition to evaluate for each item.

TreeNodeCollection ClassNames(TreeNodeCollection collection, String classNames)

Filters a collection of tree nodes (documents) to only include the specified document types.

TreeNodeCollection collection: Collection of documents.

String classNames: A list of document types that should be returned in the filtered collection (specified by their code names and separated by semicolons).

ArrayList List(Object items)

Creates an ArrayList from given list of items.

Object items: List of items to add.

Boolean InList(Object object, IEnumerable collection)

Returns true if specified object exists within the given collection.

Object object: Object which should be checked for existence within the collection.

IEnumerable collection: Collection of items.

Boolean Exists(InfoObjectCollection collection, String condition)

Returns true if there is at least one object in the collection which matches given condition.

InfoObjectCollection collection: Collection of items.

String condition: Filtering macro condition to evaluate for each item.

Object Cache(Object expression, Int32 cacheMinutes, Boolean condition, String cacheItemName, String cacheItemNameParts, CMSCacheDependency cacheDependency)

Evaluates the given expression and puts it to the cache. The expression is evaluated only when not found in cache.

Object expression: Expression to be evaluated and cached.

Int32 cacheMinutes: Cache minutes

Boolean condition: Cache condition

String cacheItemName: Cache item name.

String cacheItemNameParts: Cache item name parts.

CMSCacheDependency cacheDependency: Cache dependency object (use GetCacheDependency method to get the object).

CMSCacheDependency GetCacheDependency(String dependencies)

Returns CacheDependency object created from given string.

String dependencies: Cache dependency strings.

DateTime methods**DateTime AddMilliseconds(DateTime datetime, Int32 milliseconds)**

Adds the specified number of milliseconds to the specified base DateTime value.

DateTime datetime: Base DateTime value to which the milliseconds should be added.

Int32 milliseconds: Number of milliseconds to be added to the base DateTime value.

DateTime AddSeconds(DateTime datetime, Int32 seconds)

Adds the specified number of seconds to the specified base DateTime value.

DateTime datetime: Base DateTime value to which the seconds should be added.

Int32 seconds: Number of seconds to be added to the base DateTime value.

DateTime AddMinutes(DateTime datetime, Int32 minutes)

Adds the specified number of minutes to the specified base DateTime value.

DateTime datetime: Base DateTime value to which the minutes should be added.

Int32 minutes: Number of minutes to be added to the base DateTime value.

DateTime AddHours(DateTime datetime, Int32 hours)

Adds the specified number of hours to the specified base DateTime value.

DateTime datetime: Base DateTime value to which the hours should be added.

Int32 hours: Number of hours to be added to the base DateTime value.

DateTime AddDays(DateTime datetime, Int32 days)

Adds the specified number of days to the specified base DateTime value.

DateTime datetime: Base DateTime value to which the days should be added.

Int32 days: Number of days to be added to the base DateTime value.

DateTime AddWeeks(DateTime datetime, Int32 weeks)

Adds the specified number of weeks to the specified base DateTime value.

DateTime datetime: Base DateTime value to which the weeks should be added.

Int32 weeks: Number of weeks to be added to the base DateTime value.

DateTime AddMonths(DateTime datetime, Int32 months)

Adds the specified number of months to the specified base DateTime value.

DateTime datetime: Base DateTime value to which the months should be added.

Int32 months: Number of months to be added to the base DateTime value.

DateTime AddYears(DateTime datetime, Int32 years)

Adds the specified number of years to the specified base DateTime value.

DateTime datetime: Base DateTime value to which the years should be added.

Int32 years: Number of years to be added to the base DateTime value.

GlobalHelper methods**String UriEncode (String url)**

Encodes the URL.

String url: URL to be encoded.

String ResolveBBCode (String text)

Resolves BB code in the provided string.

String text: Text to be resolved.

String JSEscape (String text)

Escapes the string for usage in JavaScript to avoid XSS.

String text: Text to be processed.

String SQLEscape (String text)

Escapes the string for usage in SQL to avoid SQL injection. Single quotes are replaced by two single quotes.

String text: Text to be processed.

String StripTags (String text)

Removes all HTML tags from the provided string.

String text: Text to be processed.

String ResolveUrl (String url)

Resolves the URL.

String url: URL to be resolved.

String UnresolveUrl (String url)

Unresolves the URL.

String url: URL to be unresolved.

String MapPath (String path)

Maps the virtual path to the disk.

String path: Virtual path.

String LimitLength (String text, Int32 length)

Limits the length of the string to specified number of characters.

String text: Text to be processed.

Int32 length: Length of the result.

String RegexReplace (String text, String regex, String replacement)

Replaces the string using regular expressions.

String text: Text to be processed.

String regex: Regular expression.

String replacement: Replacement string.

String GetMatch (String text, String regex)

Matches the string provided in the first parameter to the regular expression and returns the match.

String text: Text to be processed.

String regex: Regular expression.

Boolean Matches (String text, String regex)

Matches the string provided in the first parameter to the regular expression and returns true if the it matches, false if not.

String text: Text to be processed.

String regex: Regular expression.

String Localize (String inputText, String culture)

Localizes given text (resolves localization macros). This method is overloaded, while the *String culture* parameter is optional.

String inputText: Text to be localized.

String culture: Required culture of the translation.

String GetString (String resourceStringKey, String culture)

Translates given resource string. This method is overloaded, while the *String culture* parameter is optional.

String resourceStringKey: Name of the resource string.

String culture: Target culture of the translation.

Mathematical methods

The following methods are only offered under the **Math** namespace by [macro autocompletion](#) (type e.g. *Math.Add(2,3)*). However, if you enter them manually without the namespace, they are functional as well.

Double Multiply (Double[] parameters)

Double (Double parameters) * (Double parameter) * ...

Returns product of the parameters.

Double[] parameters: List of numbers to multiply.

Double parameter: Number to multiply.

Double Divide (Double left, Double right)

Double (Double left) / (Double right)

Divides two number values.

Double left: Left operand.

Double right: Right operand.

Double Percent (Double percent)

Double (Double percent) %

Returns the 0.01 multiple of the first argument.

Double percent: Number of percent (number to be multiplied by 0.01).

Int32 Modulo (Int32 left, Int32 right)

Int32 mod (Int32 left, Int32 right)

Returns modulo of two values.

Int32 left: Left operand.

Int32 right: Right operand.

Double Max (Double[] parameters)

Returns maximum from given numbers.

Double parameters: List of numbers.

Double Min (Double[] parameters)

Returns minimum from given numbers.

Double parameters: List of numbers.

Double Abs (Double number)

Returns the absolute value of a specified number.

Double number: Number to do the operation on.

Double Acos (Double number)

Returns the angle whose cosine is the specified number.
Double number: Number to do the operation on.

Double Asin (Double number)

Returns the angle whose sine is the specified number.
Double number: Number to do the operation on.

Double Atan (Double number)

Returns the angle whose tangent is the specified number.
Double number: Number to do the operation on.

Double Ceiling (Double number)

Returns the smallest whole number greater than or equal to the specified number.
Double number: Number to do the operation on.

Double Cos (Double number)

Returns the cosine of the specified angle.
Double number: Number to do the operation on.

Double Cosh (Double number)

Returns the hyperbolic cosine of the specified angle.
Double number: Number to do the operation on.

Double Exp (Double number)

Returns e raised to the specified power.
Double number: Number to do the operation on.

Double Floor (Double number)

Returns the largest whole number less than or equal to the specified number.
Double number: Number to do the operation on.

Double Log (Double number)

Returns the logarithm of the specified number.
Double number: Number to do the operation on.

Double Log10 (Double number)

Returns the base 10 logarithm of the specified number.
Double number: Number to do the operation on.

Double Pow (Double base, Double exp)

Returns a specified number raised to the specified power.
Double base: Base.
Double exp: Exponent.

Double Round (Double number)

Returns the nearest whole number to the specified number.
Double number: Number to do the operation on.

Double Sign (Double number)

Returns a value indicating the sign of a number.
Double number: Number to do the operation on.

Double Sin (Double number)

Returns the sine of the specified angle.

Double number: Number to do the operation on.

Double Sinh (Double number)

Returns the hyperbolic sine of the specified angle.

Double number: Number to do the operation on.

Double Sqrt (Double number)

Returns the square root of a specified number.

Double number: Number to do the operation on.

Double Tan (Double number)

Returns the tangent of the specified angle.

Double number: Number to do the operation on.

Double Tanh (Double number)

Returns the hyperbolic tangent of the specified angle.

Double number: Number to do the operation on.

Int32 ~ (Int32 number)

Returns a bitwise complement.

Int32 number: Number to do the operation on.

Boolean IsOdd (Int32 number)

Returns true if the given number is odd.

Int32 number: Number to do the operation on.

Boolean IsEven (Int32 number)

Returns true if the given number is even.

Int32 number: Number to do the operation on.

Double Average(InfoObjectCollection collection, String columnName)

Returns an average of all collection items over specified column.

InfoObjectCollection collection: Collection of items.

String columnName: Name of the column.

Double Sum(InfoObjectCollection collection, String columnName)

Returns a sum of all collection items over specified column.

InfoObjectCollection collection: Collection of items.

String columnName: Name of the column.

Int32 GetRandomInt(Int32 minValue, Int32 maxValue, Int32 seed)

Returns a random integer within a specified range.

Int32 minValue: The inclusive lower bound of the number.

Int32 maxValue: The inclusive upper bound of the number.

Int32 seed: Seed for the pseudorandom generator - default is system time.

Double GetRandomDouble(Int32 minValue, Int32 maxValue, Int32 seed)

Returns a random double within a specified range.

Int32 minValue: The inclusive lower bound of the number.

Int32 maxValue: The inclusive upper bound of the number.

Int32 seed: Seed for the pseudorandom generator - default is system time.

Membership methods

Boolean IsInRole(Object User, String userRole)

Returns true if user is in role.

Object User: User info object

String userRole: Name of the role to test whether user is in.

Boolean HasMembership(Object User, String userMembership)

Returns true if user is in membership.

Object User: User info object

String userMembership: Name of the membership to test whether user is in.

Boolean IsInGroup(Object User, String userGroup)

Returns true if user is in group.

Object User: User info object

String userGroup: Name of the group to test whether user is in.

String methods

String ToLower (String text)

Converts the string to lower case letters.

String text: Text to convert.

String ToUpper (String text)

Converts the string to upper case letters.

String text: Text to convert.

Boolean EndsWith (String text, String findText)

Determines whether the end of the first string matches the second string.

String text: Text to check.

String findText: Text to find.

Boolean StartsWith (String text, String findText)

Determines whether the beginning of the first string matches the second string.

String text: Text to check.

String findText: Text to find.

String Substring (String text, Int32 index, Int32 length)

Retrieves a substring from the base string. The method is overloaded, while the *Int32 length* parameter is optional.

String text: Base text.

Int32 index: The index of the start of the substring.

Int32 length: The number of characters in the substring.

String[] Split (String text, String delimiters)

Identifies the substrings in this instance that are delimited by one or more characters specified in an array, then places the substrings into a string array.

String text: String to split.

String delimiters: Delimiters string. Each character of this string will be taken as a delimiter.

String Join (IEnumerable list, String separator)

Concatenates a specified separator string between each element of a specified string array, yielding a

single concatenated string.
IEnumerable list: IEnumerable to be joined.
String separator: Separator string.

Boolean Contains (String text, String search)

Returns a value indicating whether the string specified in the second parameter occurs within the string specified in the first one.

String text: Text to search in.
String search: Text to search.

String Trim (String text, String charsToTrim)

Removes all occurrences of white space characters from the beginning and end of the string specified in the first parameter. The method is overloaded, while the *String charsToTrim* parameter is optional.

String text: Text to be trimmed.
String charsToTrim: String divided to individual characters which are then trimmed.

String TrimEnd (String text, String charsToTrim)

Removes all occurrences of a set of characters specified in an array from the end of the string specified in the first parameter. The method is overloaded, while the *String charsToTrim* parameter is optional.

String text: Text to be trimmed.
String charsToTrim: String divided to individual characters which are then trimmed.

String TrimStart (String text, String charsToTrim)

Removes all occurrences of a set of characters specified in an array from the beginning of the string specified in the first parameter. The method is overloaded, while the *String charsToTrim* parameter is optional.

String text: Text to be trimmed.
String charsToTrim: String divided to individual characters which are then trimmed.

String Replace (String text, String replace, String replacement)

Replaces all occurrences of a specified Unicode character or string in the string specified in the first parameter with another specified Unicode character or string specified in the third parameter.

String text: Base text.
String replace: Text to be replaced.
String replacement: Replacement text.

String Remove (String text, Int32 position, Int32 length)

Deletes a specified number of characters from the string specified in the first parameter, beginning at the specified position.

String text: Base text.
Int32 position: The position in the base text where to begin deleting characters.
Int32 length: The number of characters to delete.

String PadLeft (String text, Int32 length, String paddingString)

Left-aligns the characters in the string, padding on the right with a specified Unicode character, for a specified total length. This method is overloaded, while the *String paddingString* parameter is optional.

String text: Base text.
Int32 length: The number of characters in the resulting string, equal to the number of original characters plus any additional padding characters.
String paddingString: A Unicode padding character (if not specified, space is used).

String PadRight (String text, Int32 length, String paddingString)

Right-aligns the characters in this string, padding on the left with a specified Unicode character, for a

specified total length. This method is overloaded, while the *String paddingString* parameter is optional.
String text: Base text.
Int32 length: The number of characters in the resulting string, equal to the number of original characters plus any additional padding characters.
String paddingString: A Unicode padding character (if not specified, space is used).

Int32 IndexOf (String text, Object searchFor)

Reports the index of the first occurrence of a string within this instance.
String text: Base text.
Object searchFor: The string to seek.

Int32 LastIndexOf (String text, Object searchFor)

Reports the index position of the last occurrence of a specified Unicode character or string within the string specified in the first parameter.
String text: Base text.
Object searchFor: The string to seek.

String Format (Object formattedObject, String format)

Formats given value to requested format.
Object formattedObject: Object to format.
String format: Formatting string.

String LoremIpsum (Int32 length)

Generates Lorem Ipsum text of given length. This method is overloaded, while the *Int32 length* parameter is optional. If the parameter is not used, the returned text is 1002 characters long (including white spaces).
Int32 length: Length of the text.

Transformation methods

String ApplyTransformation (IEnumerable collection, String transformationName)

Applies the specified transformation to list of items.
IEnumerable collection: Collection of items.
String transformationName: Transformation name.

String Transform (IEnumerable parameters, String transformationText)

Applies ad-hoc text transformation to the provided list of items.
IEnumerable parameters: Collection of items.
String transformationText: Text of the transformation.

For more information and practical examples demonstrating how the *ApplyTransformation* method can be used, please refer to the [Transformations in macro expressions](#) topic.

In addition to the methods mentioned above, you can also use all methods usable in transformation text. The methods are listed and described in [Context Help -> General -> Methods in transformations](#). These methods are only offered under the **Transformation** namespace by [macro autocompletion](#) (type e.g. *Transformation.Eval(DocumentName)*) when entered elsewhere than in transformation text. However, if you enter them manually without the namespace, they will be functional as well.

Other methods

void LogToDebug (params object[] valuesToLog)

Logs values of provided parameters into the [macro debug](#) in *Site Manager -> Administration -> System -> Debug -> Macros*.

params object[] valuesToLog: Array of parameters whose values will be logged into the macro debug.

7.12.5 Macro parameters

It is possible to create macros with parameters to get better or specific functionality, especially for data (context) macros. Each parameter of a macro is separated with the "|" character located after the macro expression. You can use multiple macro parameters.

Examples: `{%SKUPrice|(culture)en-us%}`, `{%SKUPrice|(culture)en-us|(format){0:f1}%}`

The "|" character can be escaped using the "\|" sequence, e.g. `{%SKUPrice|(default)N\|A%}` will display "N|A", i.e. the "|A" sequence will not be interpreted as a new parameter.

Please note

The same results that can be achieved using macro parameters can be achieved through [macro methods](#). Macro parameters are still functional due to backward compatibility with previous versions of Kentico CMS, but they are now obsolete and using macro methods is recommended instead.

Currently available parameters are:

- **|(culture)<code>** - specifies culture that should be used for the macro result.
- **|(format)<format>** – formats the macro result according to the provided formatting string.
- **|(default)<value>** or **|<value>** - saying what should be returned when the macro returns an empty value.
- **|(encode)<true/false>** – processes the macro result result with *HTMLHelper.HTMLEncode*.
- **|(urlencode)<true/false>** – processes the result with *HttpUtility.UrlEncode*.
- **|(tolower)<true>** – converts the macro result to lowercase.
- **|(toupper)<true>** – converts the macro result to uppercase.
- **|(toint)<default value>** – converts the macro result to integer, if not successful, uses the default value.
- **|(tobool)<default value>** – converts the macro result to Boolean.
- **|(toguid)<default value>** – converts the macro result to GUID.
- **|(todouble)<default value>** – converts the macro result to Double.
- **|(todatetime)<default value>** – converts the macro result to DateTime.

- **|{resolvebbcode}<true/false>** – resolves the BB code in the result of the macro.
- **|{equals}<value>** – returns *true* if the resolved value matches the given value, otherwise returns *false*.
- **|{notequals}<value>** - returns *false* if the resolved value matches the given value, otherwise returns *true*.
- **|{truevalue}<value>** – output settings for the positive output of comparison.
- **|{falsevalue}<value>** – output settings for the negative output of comparison.
- **|{add}<number>** - adds the provided number to the macro result.
- **|{multiply}<number>** - multiplies the macro result by the specified number.
- **|{divide}<number>** - divides the macro result by the specified number.
- **|{sin}** - returns sinus of the macro result.
- **|{cos}** - returns cosinus of the macro result.
- **|{tan}** - returns tangens of the macro result.
- **|{sqrt}** - returns square root of the macro result.
- **|{pow}<number>** - returns the *<number>*-th power of the macro result.
- **|{startswith}<string>** - returns *true* if the macro result starts with the specified string.
- **|{endswith}<string>** - returns *true* if the macro result ends with the specified string.
- **|{contains}<string>** - returns *true* if the macro result contains the specified string.
- **|{not}** - returns logical negation of the macro result.
- **|{append}<string>** - appends the specified string to the macro result.
- **|{prepend}<string>** - prepends the specified string to the macro result.
- **|{trim}<chars>** - removes all characters contained in the *<chars>* string from the beginning and end of the macro result if they are present there.
- **|{trimend}<chars>** - removes all characters contained in the *<chars>* string from the end of the macro result if they are present there.
- **|{trimstart}<chars>** - removes all characters contained in the *<chars>* string from the beginning of the macro result if they are present there.
- **|{padleft}<totalwidth>(with)<char>** - returns the macro result with the beginning of the string padded with the *<char>* character to the total length of *<totalwidth>*.

- **|{padright}<totalwidth>(with)<char>** - returns the macro result with its end padded with the *<char>* character to the total length of *<totalwidth>*.
- **|{substring}<start>;<length>** - returns a *<length>*-long substring of the macro result beginning on the *<start>* index.
- **|{replace}<src>(with)<dest>** - replaces all occurrences of the *<scr>* string in the macro result with the *<dest>* string.
- **|{matches}<regex>** - returns true if the macro result matches the provided regular expression.
- **|{getmatch}<regex>** - returns match of the provided regular expression from the macro result.
- **|{regexreplace}<regex>(with)<dest>** - replaces matches of the provided regular expression in the macro result with the *<dest>* string.
- **|{striptags}** - strips the macro result of HTML tags.
- **|{limitlength}<length>** - limits length of the macro result to the specified number of characters.
- **|{resolveurl}** - resolves the URL returned by the macro expression.
- **|{unresolveurl}** - unresolves the URL returned by the macro expression.
- **|{mappath}** - maps the virtual path returned by the macro expression to a disk path.
- **|{lowerthan}<number>** - returns *true* if the macro result is lower than the provided number.
- **|{greaterthan}<number>** - returns *true* if the macro result is greater than the provided number.
- **|{jsecape}** - escapes the macro result for usage in JavaScript to avoid XSS.
- **|{sqlscape}** - escapes the macro result for usage in SQL to avoid SQL injection (single quote characters are replaced by two single quotes).
- **|{resolve}** - resolves macros again in the result of the macro expression.
- **|{casesensitive}** - by default, string comparison is performed as case insensitive, unless it is switched to case sensitive by adding the *<add key="CMSMacrosCaseSensitiveComparison" value="true">* key to the *appSettings* section of the *web.config* file. You can use this parameter to switch string compariton to case sensitive. You can also use the **|{casesensitive>false** and **|{casesensitive>true** notation to turn case sensitive string comparison on or off when the opposite default way of comparison is configured.
- **|{debug}** - indicates that detailed debugging should be used for the given macro expression. Detailed debugging may also be enabled globally for all macros through the *Site Manager -> Settings -> System -> Debug -> Enable detailed macro debug* setting. Please see the [Development -> Debugging and system information](#) chapter for additional information.

Disabling resolving of macro parameters

It is possible to disable resolving of macro parameters. This can be done by adding the following key to

the appSettings section of your project's *web.config* file:

```
<add key="CMSDisableMacroParameters" value="true" />
```

With this key added, macro parameters will be ignored, so that e.g. `{%"HELLO"|(tolower)%}` will be resolved as *HELLO* and not as *hello*.

7.12.6 Entering macro expressions

This topic provides a summary of features that facilitate entering of macro expressions in various parts of the system. These features include:

- [Macro autocompletion](#)
- [Macro selection control](#)
- [Insert macro WYSIWYG editor dialog](#)
- [Edit value dialog in web part properties](#)
- [Macro condition editor](#)

Click the feature name in the list above learn more about it.

Macro autocompletion

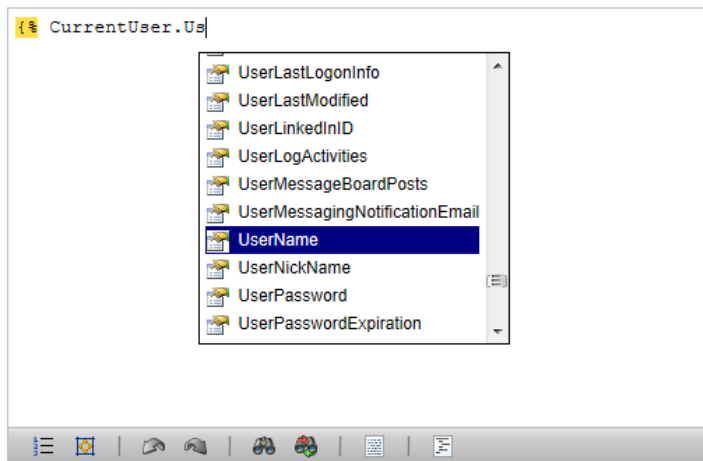

Automatic completion of macro expressions is available when writing macro expressions in all dedicated macro editors, as well as the following places:

- **E-mail templates**
- **Macro-based transformations**

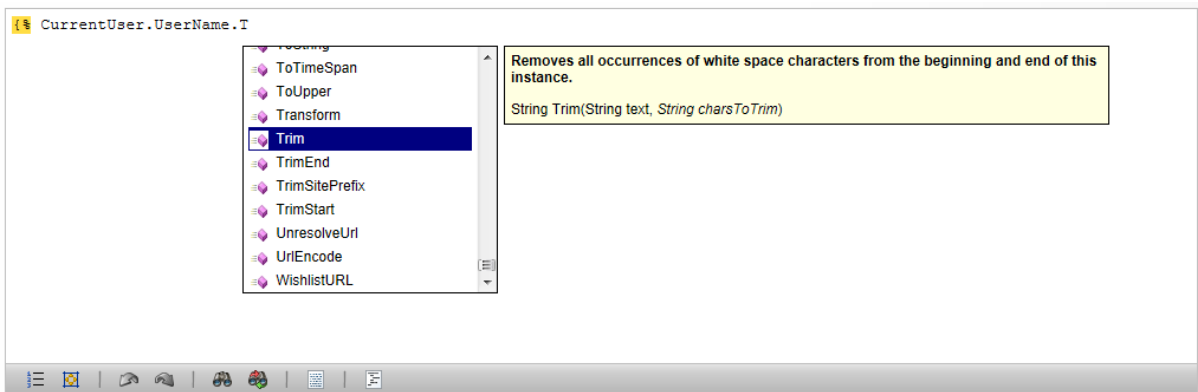

This feature is similar to IntelliSense in Visual Studio — as you type, a box with methods or properties that begin with the letters you wrote is displayed above or below the cursor. Only those methods and properties that are relevant in the current context are displayed in the box. The methods and properties are listed in alphabetical order and you can navigate through them using the up and down arrows or the mouse. Once you select the appropriate one, press the Enter, space or dot key to insert it into the text.

The box with available methods and properties is also displayed when adding further parts of expressions using the dot-suffix notation.

If a macro method is selected from the drop-down list, its description and signature (containing the return type and parameter types) is displayed in a tooltip next to the drop-down list. As some methods are overloaded, i.e. they can accept different numbers of parameters, parameters present in all overloads are displayed in standard letters (as "String text" in the screenshot below), while additional parameters present only in certain overloads are displayed in italics (as *String charsToTrim* in the screenshot below).

If the macro is being added within a particular type of context, for example an e-mail template belonging to a specific module, the related objects and properties will be prioritized. This means that the most frequently needed items can be accessed at the top of the autocomplete box, separated by a horizontal line.

```

</tr>
</table>

```

Macro selection control

Another feature that makes entering of macro expressions easier is the macro selection control.

It is present in the following locations:

- **E-commerce invoice templates**
- **E-mail templates**
- **Web part properties**

The control can be used in two different ways. The first one is simply typing the macro text into the text box, where macro autocompletion is available.

 

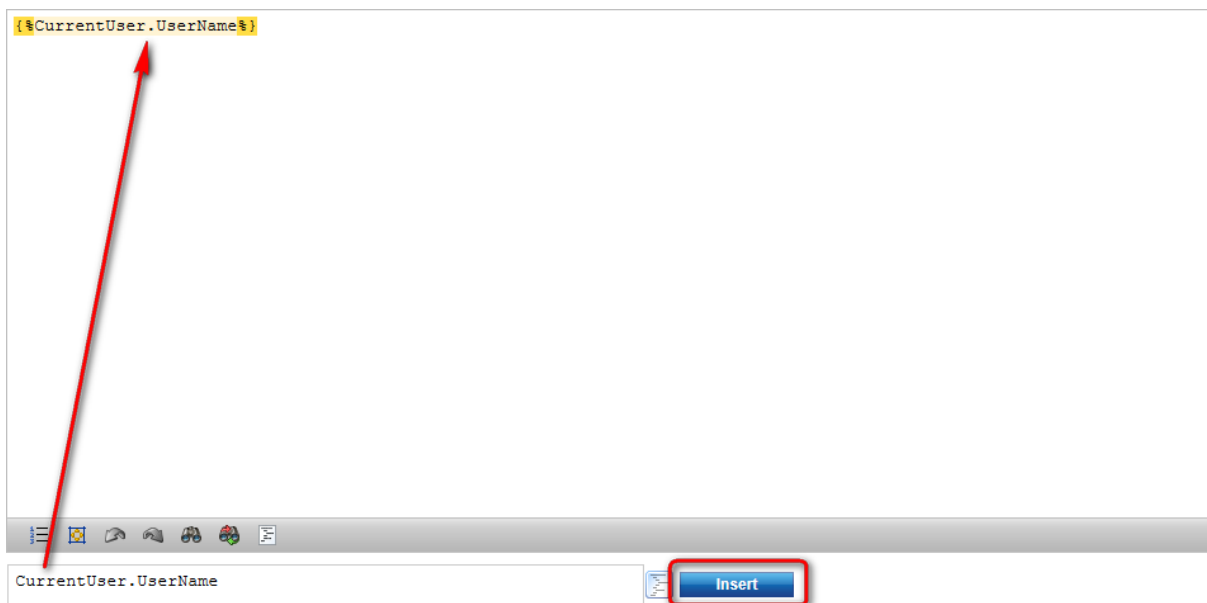

- UserName
- UserNickName
- UserPassword
- UserPasswordFormat
- UserPasswordRequestHash
- UserPhone
- UserPicture
- UserPosition
- UserPreferences
- UserRegistrationInfo

The other option is to select the required macro by clicking the **Show/hide macro object tree** () button. After doing so, an object tree is opened above the text box, letting you choose objects or their properties from the current context. Like with the autocompletion feature, certain objects may be prioritized and offered in a separate tree at the top (**Context specific objects**). Clicking an object or its property automatically enters the corresponding macro expression into the text box.

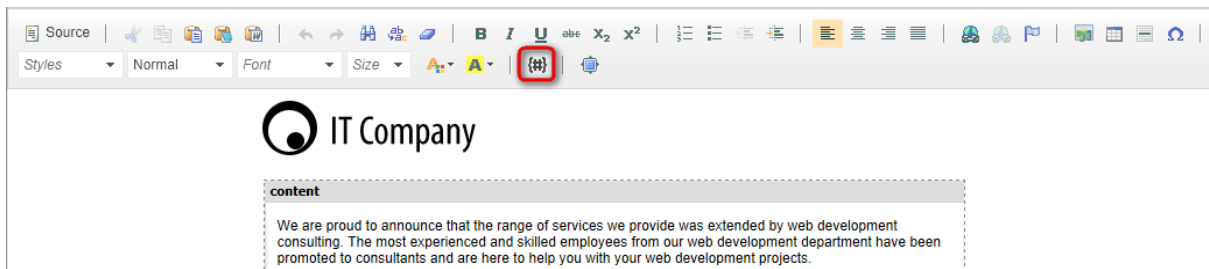

When you have the required expression in the text box, click the **Insert** button to paste it into the current position in the edited text. The expression will be pasted, enclosed within the `{%%}` data macro parentheses.

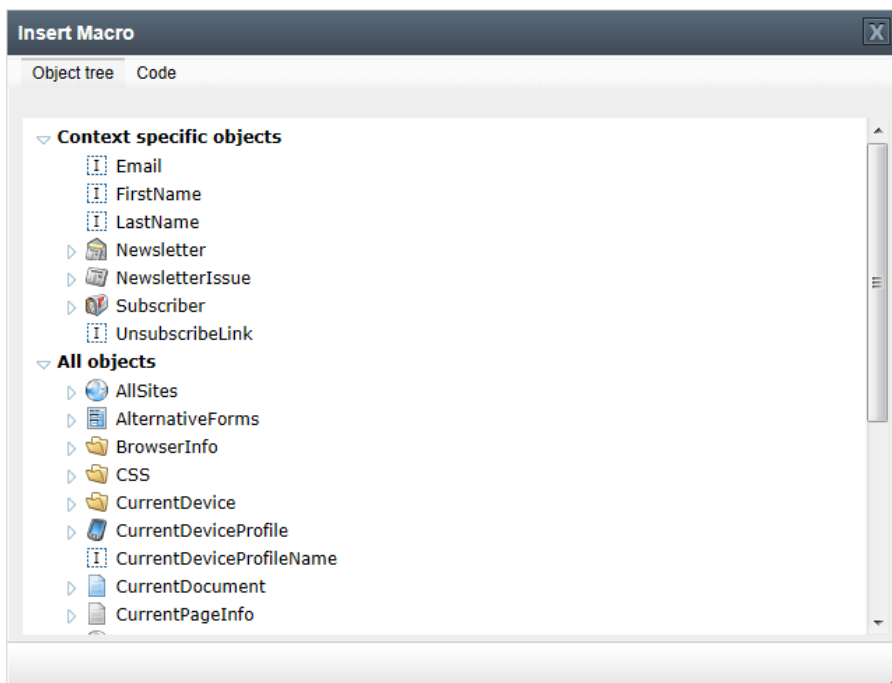

Insert macro WYSIWYG editor dialog

Macros may also be easily added into any content areas where the [WYSIWYG editor](#) is provided, such as when editing documents in CMS Desk on the *Page* tab or writing the content of newsletters. In this case, macro functionality can be accessed by clicking the **Insert macro** (🔗) button on the editor's toolbar.

This opens a dialog with an object tree that works the same way as described above for the Macro selection control. Clicking on an item in the tree inserts the appropriate macro at the current position of the cursor in the edited area.

If you wish to write the macro expression directly (with autocompletion support), you can do so by switching to the **Code** tab of the dialog and clicking the **Insert macro** button when done.

Edit value dialog in web part properties

Macro expressions can be used in the values of web part properties. You may enter any required macros directly into the content of properties that allow you to specify text values. Additionally, all properties provide the  button highlighted in the screenshot below.

Web part properties (Static text)

General

Default

Web part control ID*:

Web part title:

Visibility

Visible:

Hide on subpages:

Show for document types:

Display to roles:

Content

Text:

Refresh content

If clicked, the **Edit value** dialog pops up and lets you enter a macro that will determine the value of the property dynamically. In the dialog, you can use both macro autocompletion and the macro selection control described above. This option allows you to use macros even for properties that do not otherwise allow text input, such as checkboxes or lists of options.

Edit value

{% CurrentUser.UserIsGlobalAdministrator %}

For example, the `{% CurrentUser.UserIsGlobalAdministrator %}` macro shown above returns a true or

false value depending on if the current user is a global administrator. When added into the **Visible** property, this ensures that the given web part is only displayed to global administrators.

SQL injection protection in web part properties

Some web part properties are secured against SQL injection attacks, which may affect how macros are resolved in specific cases. By default, this is applied to macros entered into the **WhereCondition** and **OrderBy** web part properties.

If the macro returns a string value that contains single quote characters ('), they will be escaped and replaced by two single quotes ("). This may cause an SQL syntax error if you are using the macro to dynamically insert a part of a query, such as a WHERE clause.

It is possible to disable single quote escaping for a specific macro expression by adding the **handlesqlinjection** parameter and setting its value to *false*:

```
{% ... {(handlesqlinjection>false) %}
```

To disable SQL escaping globally for all properties of a specific type of web part, edit its code behind file (e.g. `~/CMSWebParts/Viewers/Documents/cmsrepeater.ascx.cs` for the **Repeater** web part) and add the following line of code into the **SetupControl()** method:

[C#]

```
this.SQLProperties = "";
```

The **SQLProperties** property is inherited from the **CMSAbstractWebPart** base class by all web parts, but you can override its value to set which properties should be protected.

If you wish to enable SQL escaping for additional web part properties, you can enter their names into the value separated by semicolons, for example:

```
this.SQLProperties = "wherecondition;orderby;sqlquery";
```

Please note that disabling SQL protection may create a **security vulnerability** if the macro resolves its value according to data that can be modified by the website's users, such as in the case of QueryString macros.

7.12.7 Macro conditions

Macro conditions add a large degree of flexibility to various types of functionality in the system. Each condition is defined by a macro expression that returns a boolean value (true or false). Whenever the condition is evaluated, the specified macro is resolved according to the currently available context data and its return value determines whether the condition is fulfilled or not. For example, such conditions

may be used to dynamically set when a certain action should be performed, under which circumstances an item should be visible and so on.

Conditions are available for the following types of objects:

- **Content personalization variants**
- **Dynamic contact groups**
- **Web analytics campaigns**
- **Scheduled tasks**
- **Report subscriptions**
- **Fields and categories in the field editor**
- **Workflow scopes and advanced workflow steps**
- **Automation process triggers**

The interface used to enter these conditions is provided by a special *Macro condition editor*.

Contact group properties

> Contact groups > Original prospective clients

General Contacts Accounts

Save

Display name: Original prospective clients

Code name: OriginalProspectiveClients

Description: This group contains the first recorded segment of contacts who are still marked as prospective clients.

Dynamic condition:

Macro condition: {OriginalProspectiveClients}

Schedule rebuild:

It is not necessary to enclose the expression between the standard macro parentheses — the entire content of the condition is automatically processed as a [context macro](#). You can also leverage [Macro autocompletion](#) support when typing in condition fields. Clicking the **Clear condition** (🗑️) action deletes the current condition.

The editor itself can be accessed in a separate dialog, opened by clicking the edit icon (✎) next to the respective condition field. There are several different approaches that may be used to define conditions, as described in the sections below.

Macro rules

In some cases, macro conditions may need to be created by non-technical users without any knowledge of K# macro syntax. For this reason, the condition editor provides a way to build conditions simply by adding and configuring predefined components called *Macro rules*. Each macro rule is implemented by a standard macro expression, which is wrapped into a user friendly, text-based interface.

Macro rules need to be prepared in advance before they may be used in conditions. Many different types of rules are included by default, but you can also define any additional ones that your users might need.

There are several categories of macro rules, which can be managed in different sections of the administration interface. The rules from each category are offered when designing the corresponding types of conditions, as described in the following table:

| Rule category | Description |
|-------------------|--|
| Global | Global rules may be used for all conditions in any part of the system.

They can be defined in Site Manager -> Development -> Macro rules . |
| Workflow | Offered when adding conditions to Workflow scopes or advanced workflow steps.

Workflow rules may be managed in Site Manager -> Development -> Workflows -> Macro rules . |
| On-line marketing | On-line marketing rules can be selected when building conditions for the following items: <ul style="list-style-type: none"> • Content personalization variants • Dynamic contact groups • Campaigns They may be defined in CMS Desk -> On-line marketing -> Configuration -> Macro rules . |
| Reporting | These rules are available when specifying conditions for Report subscriptions .

To add reporting macro rules, go to CMS Desk -> Tools -> Reporting , select any report category in the tree and choose the Macro rules tab. |

 **Macro rules**

 New macro rule

Display name: LIKE

Condition: LIKE

| Actions | Display name | Condition |
|---|--|--|
|   | Current city is one of specified cities | {_is}AnalyticsContext.CurrentGeoLocation.City.EqualsAny("{cities}".Split(",")) |
|   | Current country is one of specified countries | {_is}AnalyticsContext.CurrentGeoLocation.CountryCode.EqualsAny("{countries}".Split(",")) |
|   | Current date/time is in range | {_is}CurrentDateTime.Between(ToDateTime("{date1}"), ToDateTime("{date2}")) |
|   | Current day of the week is one of specified days | {_is}CurrentDateTime.DayOfWeek.EqualsAny("{days}".Split(",")) |
|   | Current day time is in range | {_is}CurrentDateTime.TimeOfDay.Between(ToTimeSpan({time1}), ToTimeSpan({time2})) |
|   | Current device is mobile | CurrentDevice.IsMobile |

When creating a new macro rule or editing () an existing one on the **General** tab, the following options can be specified:

- **Display name** - sets the name of the macro rule displayed to users. This name is shown to users in the list of available macro rules, so it should also serve as a basic description.
- **Name** - sets the name used as an identifier for the rule (for example in the API).
- **Description** - may be used to enter a description for the rule. This text is displayed to users as a tooltip when they hover over the rule in the list of available options.
- **User text** - defines the text clause displayed when the rule is inserted into a macro condition. It should accurately describe the requirements that must be fulfilled in order for the rule to be true.
- **Condition** - this is where the actual condition represented by the rule needs to be defined using standard context macro code (K#). The entered macro expression is resolved whenever the rule is evaluated, and its return value determines whether the rule is true or false. Autocompletion support is provided when writing in this field.
- **Requires context** - this property should be enabled if the rule's condition needs to access context data (information about the current user, the currently viewed page etc.) in order to work correctly. Doing so ensures that the rule will only be offered for conditions that have the context available when they are resolved. For example, the context is accessible when evaluating the conditions of content personalization variants on the website's page, but not when the system is building dynamic contact groups.

General Parameters

Save

General

Display name: Current date/time is in range

Name: Current_date_time_is_in_range

Description:

Rule data

User text: Current date/time {_is} between {date1} and {date

Condition: {_is}CurrentDateTime.Between(ToDateT

Requires context:

The functionality of a macro rule can be modified through parameters. After a user adds the rule to a condition, they can configure its exact behavior by setting the values of its parameters. This makes rules more flexible and allows them to be used for various different scenarios. For example, in a macro rule that requires the current user to be a member of a role, the exact role could be determined by a parameter.

Parameters can be created by editing the rule on its **Parameters** tab. Each parameter is defined as a field with a certain data type and various other settings. The interface shown to users when editing the parameter's value is provided by a selected [Form control](#).

The screenshot shows the 'Macro rule properties' dialog box with the 'Parameters' tab selected. On the left, a list of parameters includes 'date1', 'date2', and '_is'. The 'date1' parameter is highlighted. To the right of the list are several icons: a green up arrow, a green down arrow, a green plus sign, a green plus sign with a plus sign, and a red X. The 'Database' section contains the following fields: 'Column name' (text box with 'date1'), 'Attribute type' (dropdown menu with 'Date and time'), 'Attribute size' (text box), 'Allow empty value' (checkbox checked), and 'Default value' (text box with a 'Now' button). Below this is a checked checkbox 'Display attribute in the editing form'. The 'Field appearance' section contains: 'Field caption' (text box with 'select date'), 'Form control' (dropdown menu with 'Calendar'), and 'Field description' (text box). A 'Save' button is located at the top right of the dialog.

Once the required parameter fields are prepared, it is necessary to add them into the rule's text clause and condition code back on the **General** tab. To place a parameter into the **User text**, enter its *Column name* enclosed in curly brackets, for example *{role}*. Also use the same format to insert parameters into the appropriate position in the rule's **Condition** code. When the condition is being resolved, the parameter expressions are replaced by the values specified by users for the given occurrence of the rule.

There are several predefined parameters that may be used to add commonly required functionality to macro rules:

- **{_is}**, **{_has}**, **{_was}**, **{_will}**, **{_perfectum}** - these provide an easy way to negate a rule's condition. Several variants with different wording are available, so you can use the one that matches the text of the particular rule. They allow users to choose between a positive and negative option, e.g. *is* or *is not*. If the negative option is selected, the parameter is resolved into the K# negation operator "!" in the condition code. With the positive option, it returns an empty string.
- **{_any}** - useful for rules where a list of items needs to be specified through another parameter. It allows users to switch between two options that determine how the item list will be processed — *any* (at least one of the items must meet the given condition) or *all* (the condition must be fulfilled for all items in the list). When resolved, the parameter returns either a *false* (any) or *true* (all) value. In the condition code, the parameter can be inserted as an additional argument of macro methods that work with object lists, which automatically ensures the required functionality. For example:
`CurrentUser.IsInRole("{roles}", {_any})`

When one of these parameters is entered into the **User text** field of a rule and saved, the corresponding definition with the appropriate form control and default values is automatically created on the **Parameters** tab of the given rule.

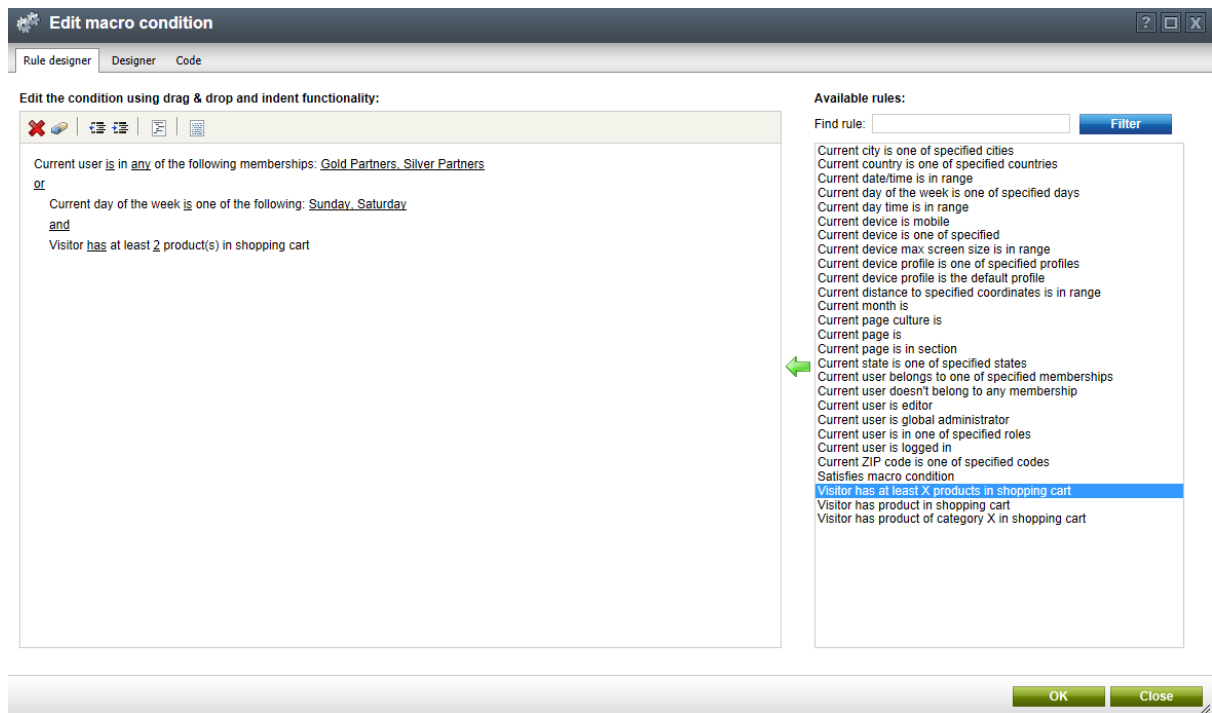

Adding macro rules to conditions

When creating a condition via the macro condition editor, you can work with macro rules on the **Rule designer** tab.

All rules prepared for the type of condition that is being edited are listed under the **Available rules** section. To add a rule to the condition, select it in the list and use the **Add rule** (➔) button. This inserts the given rule clause into the main designer area, where it is displayed as a text description of the corresponding requirements.

If multiple rules clauses are present in the condition, logical operators are automatically added between them. The **and** operator means that the combination of two rules will only be true if both of them are also true. If **or** is placed between two rules, the result will be true if at least one of them is fulfilled. You can switch between these two options by clicking on individual operators. The final result of the condition is calculated based on the used operators.

Any parameters in the text of the added rules are underlined. Clicking on a parameter opens a separate dialog where the user can set its value.

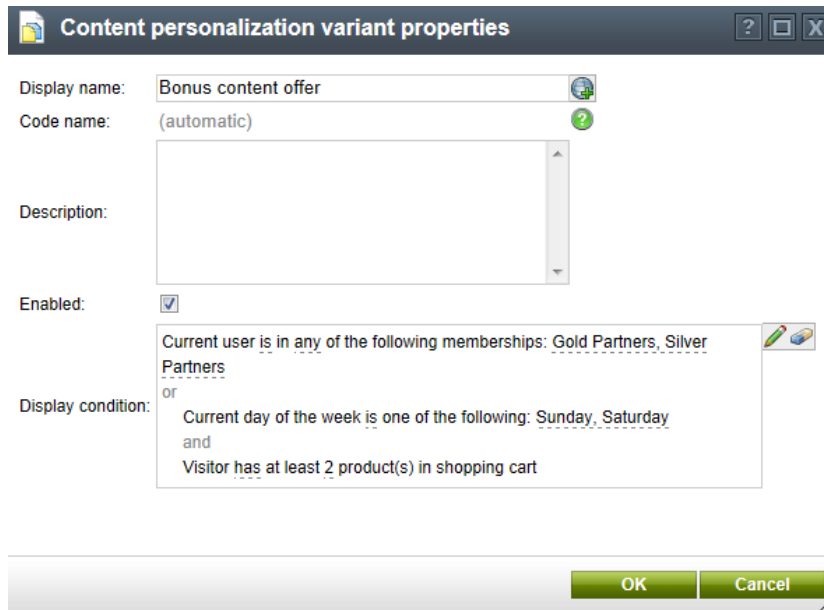

You can select a rule clause in the designer simply by clicking on it (outside of any underlined parameter text). The rules may be managed through the actions available in the header of the designer area:

- **✖ Delete** - removes the currently selected macro rule clause.
- **🗑 Clear all rules** - removes all rules from the condition.
- **☰ Unindent** - this action decreases the indentation of the selected macro rule. Indentation in the rule designer provides a way to group together macro rules and set the precedence of the logical operators between them. The rules on the level with the largest indentation are evaluated first. The result is then passed to the level above, and this continues until the final result of the condition is known.
- **☰ Indent** - increases the indentation level of the selected macro rule.
- **☑ Auto indent** - changes the indentation of all rules in the condition according to standard operator priorities.

-  **View condition in K#** - allows you to view the K# code of the overall condition defined through the macro rules.

It is also possible to change the order of the rules by dragging them to a different position in the designer area.

Once all required rules are added, you can insert the result into the edited condition field by clicking **OK**.

Content personalization variant properties

Display condition:

Designing macro conditions directly

In addition to the Rule designer, the macro condition editor also offers other ways to create conditions that are directly based on writing K# code. This approach offers much more flexibility and does not need any predefined components. However, it requires users to have at least basic understanding of the macro syntax and programming principles.

The **Designer** mode of the editor provides a graphical interface that makes it easier to build complex conditions. It allows you to divide the condition into individual expressions and groups of expressions, which can then be managed as separate elements. The overall condition is defined by combining these sub-elements as necessary.

You can add elements into the designer using the actions in the headers of groups or the main area:

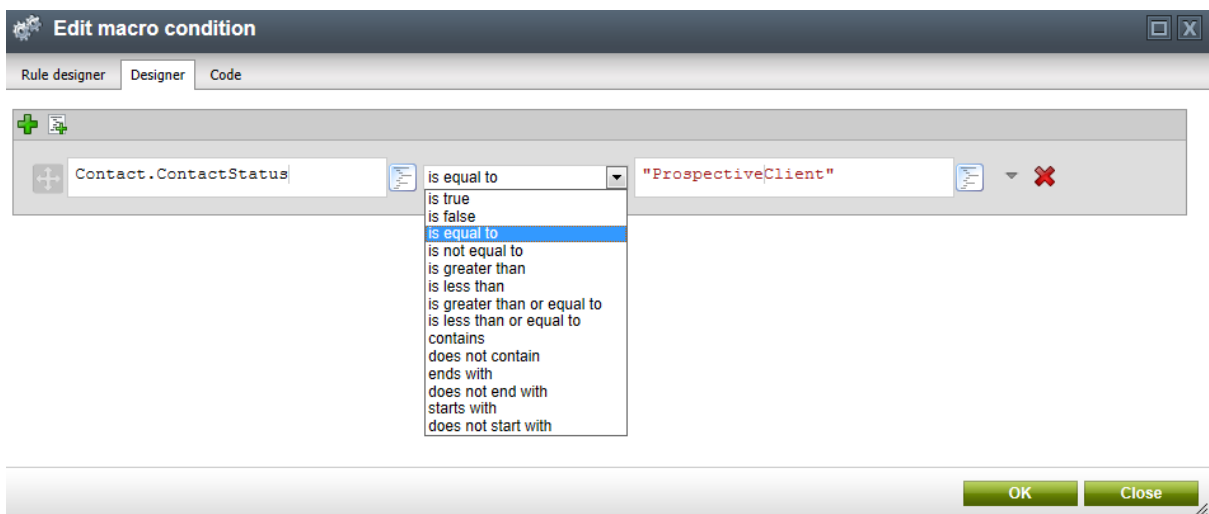

-  **Add expression** - adds a new macro expression into the group.
-  **Add group** - adds a new sub-group under the given group.

Expressions are composed of two [macro selection controls](#) with a relation drop-down list between them. You can either input context macro code or static values into these fields. Macro autocompletion and the **Show/hide macro object tree** (🔍) button are available for easier macro specification.

Each expression must always return a boolean result (true or false). Through the relation drop-down list, you can specify the operator that will be used to evaluate the values on the left and right of the expression. The following operator options are available:

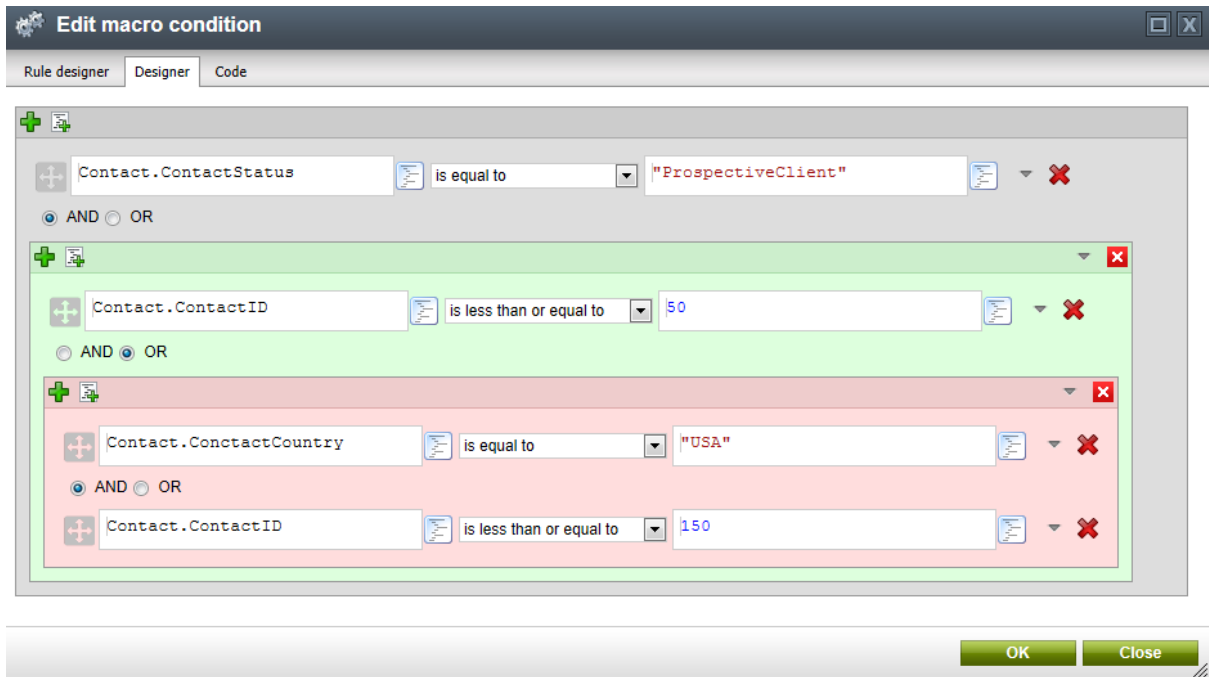

- **is true, is false** - these options may be used to evaluate macro expressions that already return a boolean value. Only one macro field is displayed in this case, as there is no need to compare two values.
- **is equal to (==), is not equal to (!=)** - determine whether the values returned by the expressions on the left and right are equal.
- **greater than (>), less than (<), greater than or equal (>=), lesser than or equal (<=)** - allow you to compare numeric values returned by the expressions on the left and right.
- **contains, ends with, starts with** (and **does not** equivalents) - these operators allow you to compare text-based (string) values in various ways.

By adding groups, you can organize expressions and set precedence. Groups in the macro designer are the equivalent of parentheses. Each group of expressions is evaluated separately before being combined with the remaining elements.

Expressions and groups are added together using logical conjunction (**AND**) or logical disjunction (**OR**). You can choose which of these you wish to use by selecting the corresponding radio button between

any two elements. The final result of the condition is determined by the total combined value of all expressions and groups.

Existing expressions or groups can be removed from the condition using the following action icons:

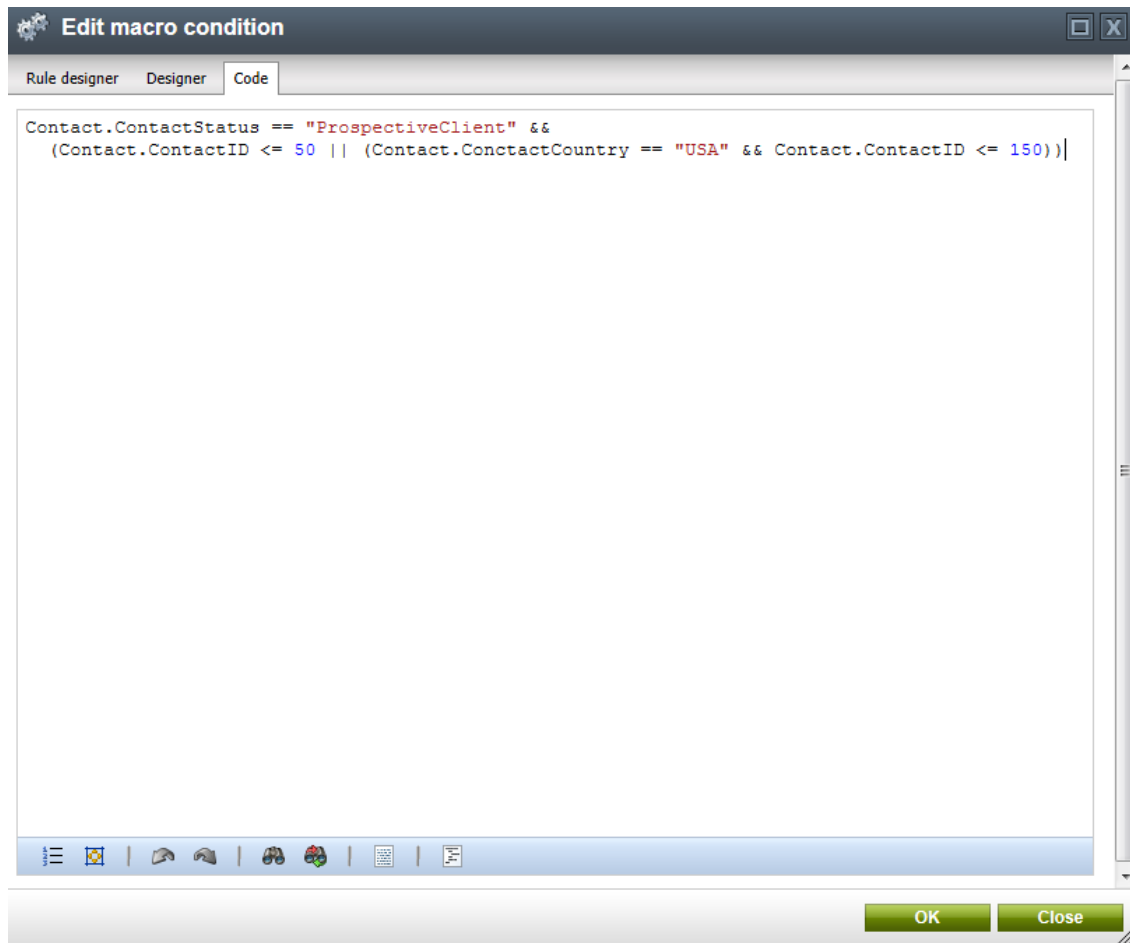

- **Remove group** - removes the whole group, including all expressions and sub-groups that it contains.
- **Remove expression** - removes the given macro expression.

You can also change the order and position of elements using the actions available in the context menus that can be opened by clicking the respective icons:

- **Move up** - moves the macro expression or group up before the one above it.
- **Move down** - moves the macro expression or group down after the one below it.
- **Move to parent** - moves the macro expression or group from its current group to the parent group.

Items can also be moved simply by dragging them into the desired location. Groups need to be picked up by their header row, expressions need to be dragged using the cross icon.

If necessary, the overall macro code of the defined condition can be reviewed or directly modified by switching to the **Code** tab.

Finally, when you finish specifying the condition on either the **Designer** or **Code** tab, click **OK** to insert it. In this case, the resulting macro code will be displayed in the condition field.

Macro condition: `Contact.ContactStatus == "ProspectiveClient" && (Contact.ContactID <= 50 || (Contact.ContactCountry == "USA" && Contact.ContactID <= 150))`

Incompatibility with the rule designer

Please note that the system is not capable of converting general macro code to macro rules. Because of this, making any changes to the condition on the **Designer** or **Code** tab deletes the content of the **Rule designer**.

7.12.8 Macro security

Whenever a user saves a macro expression, the system automatically adds a security signature. The signature contains the user name of the macro's author and a hash of the given expression. To improve security, the hash function used when creating macro signatures appends a salt to the input (a sequence of additional characters). The salt value depends on the [configuration](#) of the application's environment, so the signatures are in most cases not valid when deploying macros to other instances of

Kentico CMS.

You can recognize signed macro expressions by the # character, which the system automatically inserts before the closing %} parentheses when saving the text containing the macro.

```
{% CurrentUser.Children["cms_category"][0].CategoryName #%}
```

If the execution of the macro requires any [permissions](#), the system resolves the macro only if the **user specified by the signature** has the appropriate permissions.

Permissions are only checked when resolving macro expressions that:

- access an *InfoObject* through another *InfoObject* (i.e. access an encapsulated object), for example: `{% CurrentDocument.DocumentPageTemplate %}`
- access an *InfoObjectCollection*, for example: `{% CurrentUser.Children["cms_category"][0].CategoryName %}`

The system carries out a security check for each access to any collection, not just for the final macro result.

Note

Unsuccessful security checks prevent the system from resolving macros. If you encounter such problems, you can view the [event log](#) or the [macro debug log](#), which provide information about performed security checks and their results.

Disabling the security signature for specific macros

If you manually add the @ character before the closing %} sequence of a macro, the system does not add a signature.

```
{% CurrentDocument.DocumentName @%}
```

These macros do not store the user name of the author or the security hash, so the internal length of the expression does not exceed the visible number of characters. This allows you to safely use macros in fields with a limited character count.

Unsigned macros are always evaluated with the permissions of a public user.

Configuring the hash salt for macro signatures

The system appends a [salt](#) to the input of the hash function that creates macro signatures.

The default salt is the application's main database connection string (the exact **CMSCONNECTIONSTRING** value set in the web.config file). However, **we strongly recommend using a custom salt**.

A custom salt provides the following benefits:

- Stability (you do not need to re-sign macros if your connection string changes)
- You can use the same salt for other instances of Kentico CMS, which makes deployment easier and allows [content staging](#) of macros

The best option is to set the hash salt value before you start creating content for your website. Changing the salt causes all current hash values to become invalid (including macro signatures).

To set a custom hash salt value for your application, add the **CMSHashStringSalt** key to the *appSettings* section of your web.config file. You can use any string as the value, but the salt should be random and at least 16 characters long. For example, a randomly generated [GUID](#) is a strong salt:

```
<add key="CMSHashStringSalt" value="e68b9ad6-a461-4707-8e3e-ece73f03dd02" />
```

Warning

In addition to macro signatures, the system uses the **CMSHashStringSalt** value for other hash functions. Changing the hash salt on a website that already has defined content may break dialog links and images on your website.

If you encounter such problems, you need to re-save the given content (the system then creates the hashes using the new salt).

Re-signing existing macros *[Only available after applying [hotfix 7.0.9](#) or newer]*

If the hash salt value used by your application changes, the security signatures of existing macro expressions become invalid. This may lead to problems with unresolved macros, for example when:

- The connection string of your application has changed, e.g., when moving to a different server or after setting a new database password.
- You are using [Content staging](#) to transfer data containing macros to an instance of Kentico CMS with a different connection string.
- You have set a new custom salt via the **CMSHashStringSalt** web.config key.

You can repair invalid macro signatures by re-signing all macros using a new hash salt:

1. Go to **Site Manager -> Administration -> System -> Macros**.

2. Fill in the **Old salt** field.

- If you leave the **Sign all macros** option *disabled*, the system attempts to re-sign macros based on the data in the original signatures. As a result, only macros that have a valid signature under the old salt are re-signed and the user names of the macro authors remain unchanged. You need to enter the old salt that was used to generate the security hash of the existing macro expressions in the system.

- By default, the old salt is the value of the application's previous connection string in format:
Persist Security Info=False;database=DBName;server=ServerName;user id=DBUser;password=pwd;Current Language=English;Connection Timeout=240;
 - If your application uses a custom hash salt, enter the original value of the **CMSHashStringSalt** web.config key.
 - If you *enable* **Sign all macros**, the macro re-signing process skips the signature integrity check and creates new signatures for all macros. This includes macros that are unsigned or have invalid signatures. The new signatures use the name of the user who started the re-signing procedure. You do not need to enter the old salt value in this case.
3. Type in the **New salt** that will be used to re-sign the macros.
- By default, the field automatically loads the current application's hash salt value. To enter a different value, disable the **Use current salt** option.

Important!

In order for the system to correctly validate macro signatures, the new hash salt value must match the current salt of the application (the connection string or **CMSHashStringSalt** key value).

Only set a different value than the current salt if you are planning to change the connection string or custom salt.

4. Click **Update macro signatures**.

The system replaces the security signature in all occurrences of macros based on the new salt.

7.12.9 Registering custom macro methods

In addition to the macro methods available by default, you can also define your own custom methods. Users can then call these methods in their macro expressions.

Code samples

The Kentico CMS installation includes code examples of custom macro method registration that you can add directly to your web project. To access these samples:

1. Open your Kentico CMS installation directory (by default *C:\Program Files\KenticoCMS\<version>*).
2. Expand the *CodeSamples\App_Code Samples* sub-directory.
3. Copy the **Samples** folder into the **App_Code** folder of your web project.

Web application installations

If your Kentico CMS project was installed in the web application format, copy the

samples into the **Old_App_Code** folder instead.

You must also manually include the sample class files into the project:

1. Open your application in Visual Studio.
2. Click **Show all files** at the top of the Solution Explorer.
3. Expand the *Old_App_Code* folder, right-click the new **Samples** sub-folder and select **Include in Project**.

You can find the macro method examples in the following classes:

- **Samples/Classes/CustomMacroMethods.cs** - class containing the sample macro methods.
- **Samples/Modules/SampleMacroModule.cs** - initializes the custom method registration.

Creating custom macro methods

1. Open your web project in Visual Studio and add a new class into the **App_Code** folder (or **Old_App_Code** if the project is installed as a web application). For example, name the class **CustomMacroMethods.cs**.

2. Edit the class and add the following references:

[C#]

```
using CMS.SettingsProvider;  
using CMS.GlobalHelper;
```

3. Implement all overloads of your custom method, so that it performs the required functionality and returns the correct value.

[C#]

```
/// <summary>  
/// Appends "default" to the specified string.  
/// </summary>  
public static string MyMethod(string param1)  
{  
    return MyMethod(param1, "default");  
}  
  
/// <summary>  
/// Concatenates two strings.  
/// </summary>  
public static string MyMethod(string param1, string param2)  
{  
    return param1 + " " + param2;  
}
```

4. Create a wrapper suitable for registration as a macro method. The signature and return type of the wrapper method must be exactly the same as shown in the following code:

[C#]

```
/// <summary>
/// Wrapper for MyMethod suitable for registration as a macro method.
/// </summary>
/// <param name="parameters">Parameters of the method</param>
public static object MyMethod(params object[] parameters)
{
    switch (parameters.Length)
    {
        case 1:
            // Overload with one parameter
            return MyMethod(ValidationHelper.GetString(parameters[0], ""));

        case 2:
            // Overload with two parameters
            return MyMethod(ValidationHelper.GetString(parameters[0], ""),
                ValidationHelper.GetString(parameters[1], ""));

        default:
            // No other overload is supported
            throw new NotSupportedException();
    }
}
```

5. (Optional) Add another method with an additional *MacroResolver* parameter:

[C#]

```
public static object MyComparisonMethod(MacroResolver resolver, params object[]
parameters)
{
    switch (parameters.Length)
    {
        case 2:
            // Compares the string parameters. Ignores case if the resolver is not
            case sensitive.
            return ValidationHelper.GetString(parameters[0], "").EqualsCSafe
(ValidationHelper.GetString(parameters[1], ""),
!resolver.IsCaseSensitiveComparison);

        default:
            throw new NotSupportedException();
    }
}
```

The parameter allows you to access the macro resolver used for the context in which the method was called. The sample method above checks if the resolver is case sensitive and then compares the string parameters accordingly.

6. Add a registration method for your custom macro methods:

[C#]

```

public static void RegisterMethods()
{
    // Registers MyMethod with two parameter overloads.
    MacroMethod myMethod = new MacroMethod("MyMethod", MyMethod)
    {
        Comment = "Returns a concatenation of two strings.",
        Type = typeof(string),
        AllowedTypes = new List<Type>() { typeof(string) },
        MinimumParameters = 1
    };
    myMethod.AddParameter("param1", typeof(string), "First string to
concatenate.");
    myMethod.AddParameter("param2", typeof(string), "Second string to
concatenate.");
    MacroMethods.RegisterMethod(myMethod);

    // Registers a code snippet for MyMethod.
    MacroMethod myMethodSnippet = new MacroMethod("MyMethodSnippet", MyMethod)
    {
        Comment = "Calls MyMethod for the current user's name in lower case.",
        Type = typeof(string),
        AllowedTypes = new List<Type>() { typeof(string) },
        Snippet = "MyMethod(ToLower(CurrentDocument.DocumentName), |);"
    };
    MacroMethods.RegisterMethod(myMethodSnippet);

    // Registers MyComparisonMethod, which uses a resolver object parameter.
    MacroMethod myComparisonMethod = new MacroMethod("MyComparisonMethod",
MyComparisonMethod)
    {
        Comment = "Compares two strings according to resolver
IsCaseSensitiveComparison setting.",
        Type = typeof(string),
        AllowedTypes = new List<Type>() { typeof(string) },
        MinimumParameters = 2
    };
    myComparisonMethod.AddParameter("param1", typeof(string), "First string to
compare.");
    myComparisonMethod.AddParameter("param2", typeof(string), "Second string to
compare.");
    MacroMethods.RegisterMethod(myComparisonMethod);
}

```

Register each macro method through the following steps:

- a. Prepare a **CMS.GlobalHelper.MacroMethod** object representing the custom macro method.
 - The first parameter of the MacroMethod constructor sets the name used for the method in macro expressions.
 - The second parameter specifies the method delegate (wrapper method) containing the definition in the code.
- b. Specify the following basic properties:

| Property | Description |
|----------|-------------|
|----------|-------------|

| | |
|--------------------|--|
| Comment | Comment displayed for the method in the macro autocompletion . |
| Type | The return type of the method. |
| Allowed types | List of object types for which the method can be called. Set to <i>null</i> for all types to be allowed. If unspecified, the method is applicable to objects of the type specified for the first parameter. |
| Minimum parameters | The minimum number of parameters that must be entered when calling the method (minimum overload). |
| Snippet (optional) | Allows you to define methods with a code snippet. Users can insert the snippet by pressing the TAB key when they have the method selected in the macro autocompletion. Use the pipe character " " to determine the cursor position after the insertion of the snippet. |

c. Define the method's parameters one-by-one through the **AddParameter** method of the *MacroMethod* object. You must specify the name, data type and comment text of each parameter. When the system needs to resolve the custom method in a macro expression, it passes the values of these parameters to the parameter array of the wrapper method.

d. Register the method by calling **MacroMethods.RegisterMethod(MacroMethod methodName)**.

Initializing the custom method registration

To complete the registration, you also need to ensure that the system calls the *RegisterMethods* method of the *CustomMacroMethods* class created in the previous section.

1. Create another class in the **App_Code** folder (or **Old_App_Code** if the project is installed as a web application). For example, name the class **MacroMethodLoader.cs**.

2. Edit the class and add the following reference:

[C#]

```
using CMS.SettingsProvider;
```

3. Delete the default class declaration and its content. Instead, extend the **CMSModuleLoader** partial class and define a new attribute inheriting from *CMS.SettingsProvider.CMSLoaderAttribute*:

[C#]

```
[MacroMethodLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Attribute class ensuring the registration of custom macro methods.
    /// </summary>
    private class MacroMethodLoader : CMSLoaderAttribute
    {
        /// <summary>
```

```

    /// Called automatically when the application starts.
    /// </summary>
    public override void Init()
    {
        // Calls the registration method.
        CustomMacroMethods.RegisterMethods();
    }
}

```

When the CMS application starts, it automatically executes the override of the **Init** method, which registers your custom methods.

Result

Your methods are now ready to be used in macro expressions. Open any macro code editor in the Kentico CMS interface and enter a macro with a string data type. The autocompletion box offers the new methods.

The second parameter in the **MyMethod** signature (*String param2*) is displayed in italic letters. This means that the method is overloaded and the parameter is optional.

You can also select the *MyMethodSnippet* method and press the TAB key to insert the defined code snippet.

7.12.10 Resolving macros using the API

If you need to resolve text containing macro expressions in your custom code, you can do so by using the following code:

[C#]

```
string CMS.CMSHelper.CMSContext.CurrentResolver.ResolveMacros(string inputText)
```

As you can see, macros are processed by calling the *ResolveMacros* static method of an appropriate resolver object, typically of the *CMS.CMSHelper.ContextResolver* class.

If you wish to add custom functionality to the resolving process, you can create a new resolver, load additional data into it and then use it to resolve the macro expression text. This is shown in the following example:

[C#]

```
using CMS.SiteProvider;
using CMS.CMSHelper;

private void CustomResolverExample()
{
    string resolvedText = "";

    // Create child resolver of ContextResolver
    ContextResolver resolver = CMSContext.CurrentResolver.CreateContextChild();

    // Fill the resolver with custom data
    resolver.SetNamedSourceData("MyUser", UserInfoProvider.GetUserInfo
("administrator"));
    resolver.SourceParameters = new object[,] { { "MySimpleValue", "RESOLVED
Simple value!" }, { "MySecondSimpleValue", "RESOLVED Second simple value!" } };

    // Use the resolver to resolve macros in text
    resolvedText = resolver.ResolveMacros("The name of my user is (in upper case):
{% MyUser.UserName.ToUpper() %}. First eight characters of the first simple value:
{% MySimpleValue.Substring(0, 8) %}");
}
```

There are several ways to register new items into macro resolvers. The **SetNameSourceData** method adds a single new macro, with the first parameter specifying the name of the macro and the second one providing the object that will be returned when the macro is resolved. The **SourceParameters** property may be used to add multiple pairs of this type simultaneously through a two dimensional array of objects.

Alternatively, you can define the value of a macro using a callback:

[C#]

```
using CMS.CMSHelper;
using CMS.GlobalHelper;

private object MyPropertyEvaluator(MacroResolver resolver)
{
    return "Macro return value";
}

private void CustomResolverExample()
{
    string resolvedText = "";

    ContextResolver resolver = CMSContext.CurrentResolver.CreateContextChild();
```

```
// Fill the resolver with custom data
resolver.SetNamedSourceDataCallback("MyProperty", MyPropertyEvaluator);

// Use the resolver to resolve macros in text
resolvedText = resolver.ResolveMacros("Example: {% MyProperty %}");
}
```

This approach allows you to implement a separate method that will return the macro's value instead of having to specify an object directly. The example above is only meant as a demonstration of the basic principles. The method can be as complex as required.

Please note that the callback is executed for every occurrence of the custom macro in an expression. If the evaluator method contains any computationally intensive logic, it is recommended to optimize performance by implementing a [caching mechanism](#) for the result.

Resolving localization macros

If you only need to resolve a localization macro, you may use the following static method instead:

```
string CMS.GlobalHelper.ResHelper.LocalizeString(string inputText)
```

Adding custom macros to the global resolver

The techniques described above may also be used to define additional macro properties for existing resolvers. Macro resolvers are organized in a hierarchy that allows child resolvers to inherit all macro options defined for their parent. You can create a child resolver by calling the *CreateContextChild()* method of an existing resolver, as shown in the examples above.

The following step-by-step example demonstrates how custom macros can be added to the global resolver, i.e. the parent of all other resolvers. By adding data items into the global resolver, you can create new macros that will be available in all parts of the system.

1. Open your web project in Visual Studio, expand the **App_Code** folder (or **Old_App_Code** if you installed the project as a web application) and add a new class called **GlobalResolverExtender.cs**.
2. Edit the class and add the following references:

[C#]

```
using CMS.SettingsProvider;
using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.SiteProvider;
```

3. Next, delete the default class declaration and its content. Instead extend the **CMSModuleLoader** partial class and define an attribute for it as shown below:

[C#]

```
[GlobalResolverExtender]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Module registration
    /// </summary>
    private class GlobalResolverExtenderAttribute : CMSLoaderAttribute
    {
        ...
    }
}
```

4. Then enter the following code into the **GlobalResolverExtenderAttribute** class:

[C#]

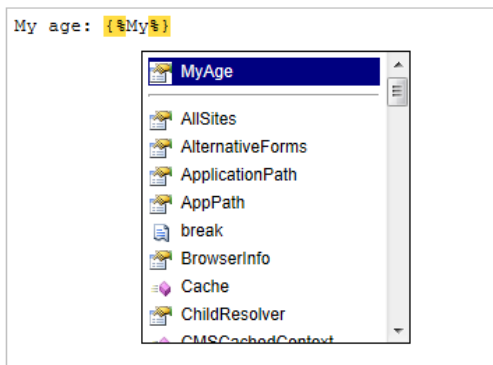

```
/// <summary>
/// Called automatically when the application starts
/// </summary>
public override void Init()
{
    ContextResolver.GlobalResolver.SetNamedSourceDataCallback("MyAge",
MyAgeEvaluator);
}

private object MyAgeEvaluator(MacroResolver resolver)
{
    System.DateTime dateOfBirth =
CMSContext.CurrentUser.UserSettings.UserDateOfBirth;
    System.DateTime now = DateTime.Now;

    int age = now.Year - dateOfBirth.Year;
    if (dateOfBirth > now.AddYears(-age))
    {
        age--;
    }
    return age;
}
```

The code in the override of the **Init()** method (executed automatically when the application starts) is used to add the **MyAge** macro property into the global resolver. The value of this macro is retrieved via callback by the private **MyAgeEvaluator** method.

5. **Save** the file and **Build** the project if it is installed as a web application. You can now try entering the `{% MyAge %}` expression in any part of the system where macros are supported. It will automatically be offered in the autocomplete box, as well as the object tree provided by the macro selection control.

As you can see, the custom property is displayed in the high priority section at the top of the list. By default, all items registered through the *SetNameSourceData* or *SetNameSourceDataCallback* methods are prioritized. If you wish to add a property with normal priority, you can use an overload of the methods that includes the *isPrioritized* boolean parameter and set it as *false*. For example:

[C#]

```
ContextResolver.GlobalResolver.SetNamedSourceDataCallback("MyAge",
MyAgeEvaluator, false);
```

7.12.11 Macro result caching

It is possible to cache macro results so that certain expressions don't have to be evaluated repeatedly. This is possible by enclosing the expression into the **Cache** method. The method has the following signature:

- **Object Cache(Object expression, Int32 cacheMinutes, Boolean condition, String cacheItemName, String cacheItemNameParts, CMSCacheDependency cacheDependency)**

The method is overloaded and only the first parameter is mandatory — the rest of the parameters are optional. The parameters determine the following:

- *string macroExpression*: Macro expression (without encapsulating character sequences, e.g. *{% %}*) to be evaluated and cached.
- *Int32 cacheMinutes*: Number of minutes for which the value will be cached.
- *Boolean condition*: Boolean expression whose value determines if the macro expression should be cached.
- *String cacheItemName*: Name of the cache item under which the value will be stored in the cache.
- *String cacheItemNameParts*: Any number of parameters whose values will be concatenated (together with the *cacheItemName* parameter value) and used as the name of the cache item.
- *CMSCacheDependency cacheDependency*: Cache dependency (use the *GetCacheDependency* method to get the object).

The following example demonstrates how it can be used to cache a simple *"test_string".ToUpper()* expression.

```
{% Cache("test_string".ToUpper()) %}
```

When the macro is first evaluated, it is resolved as TEST_STRING and the result is stored in cache. In the screenshot below, you can see the respective [cache access debug](#) record for this operation.

| | Access | Cache key
Dependencies
Data |
|---|--------|--|
| 1 | ADD | administrator en-us toupper("test_string")
"TEST_STRING" (11 B) |

On each subsequent resolving, the expression is not resolved again and its value is taken from cache.

| | Access | Cache key
Dependencies
Data |
|---|--------|--|
| 1 | GET | administrator en-us toupper("test_string")
"TEST_STRING" (11 B) |

The following example shows how the method can be used with the optional parameters to specify the cache item name, time period for which the value will be cached and a cache dependency.

```
{% Cache("test_string".ToUpper(), 5, true, "mykey", GetCacheDependency
("mydependency")) %}
```

In this case, the cache access debug record looks as in the following screenshot.

| | Access | Cache key
Dependencies
Data |
|---|--------|---|
| 1 | ADD | mykey
mydependency
"TEST_STRING" (11 B) |

7.13 Membership, permissions and security

7.13.1 Security model overview

Kentico CMS provides a flexible security model that allows you to configure granular access permissions for content and modules.

The security model consists of:

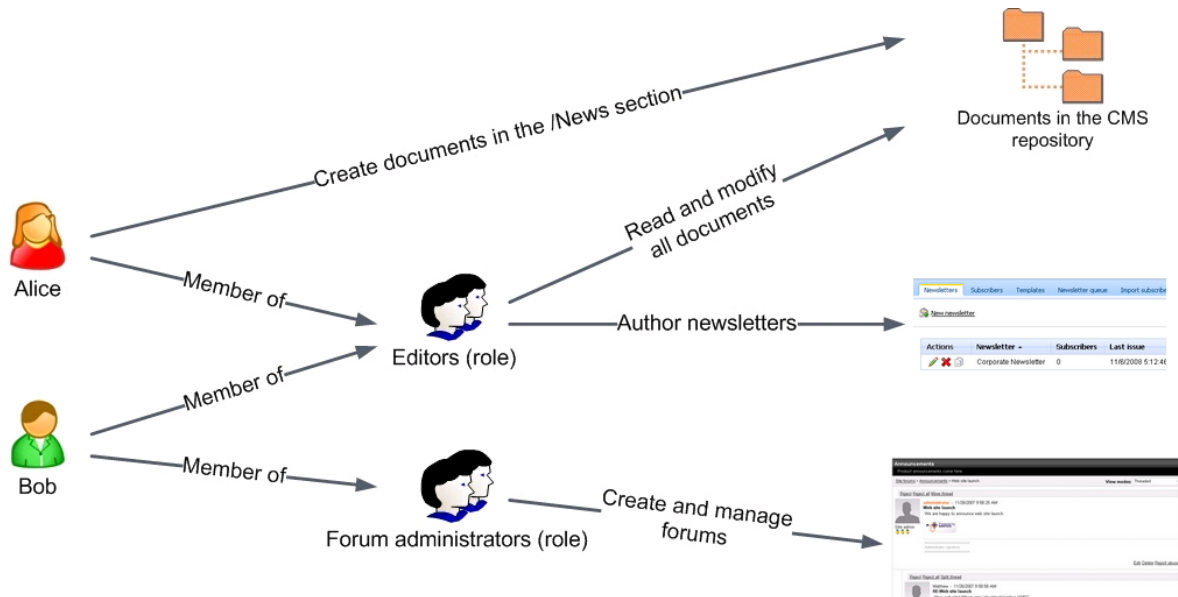

- [users](#) (shared among websites)
- [roles](#) (defined for particular websites or globally for all sites in the system)
- [memberships](#) (collections of roles that can be assigned to users)
- [module permissions](#)
- [document permissions](#)
- [UI personalization](#)

Users, roles and permissions can be managed on two levels:

- In **Site Manager -> Administration**, where global administrators can configure the data of all sites and define global objects.
- In **CMS Desk -> Administration**, where local administrators can edit only data related to the current website (the current website is recognized by the current domain).

Relationships between users, roles and permissions

The following figure shows how users are assigned to roles and how permissions for documents and modules are granted to users and roles:

Users can be members of any number of roles. Permissions for particular documents in the CMS repository can be granted to them. If you want to grant permissions for some module to a user, you need to make the user a member of a role and grant the permissions to the role (i.e. permissions for modules cannot be granted to users directly).

Roles in Kentico CMS are fully customizable. It means you're not limited to a predefined set of roles. Instead, you can define your own roles with custom sets of permissions.

If a user is a member of multiple roles, their **permissions for modules** are calculated as a sum of all permissions granted to all roles.

If **permissions for documents** in the CMS repository are granted to both a user and their roles, document permissions are calculated as a sum of all permissions granted to the user and to all roles. If a user or some of their roles are **denied to make some action** (such as modify document), then the result is always "denied" for the given permission, even if some of the roles are allowed to perform the action.

7.13.2 User management

A user can be a member of any number of roles and can be assigned to any number of websites.

There are two important attributes of every user account:

- **Is editor** - the user can access **CMS Desk** and the [On-site editing](#) interface. The attribute does not grant any particular permissions — it only differentiates between site editors and registered users who are limited to the live website. This provides an extra security layer. Users who are editors can access the editing interface of all sites to which they are assigned on the **Sites** tab.
- **Is global administrator** - the user is authorized to access all sections of the system and perform any operations, regardless of permissions or other settings. Global administrators are the only users who can use the **Site Manager** interface.

Global administrators

Global administrators are the only users allowed to manage site settings and all development tools. Their permissions cannot be denied or limited – they have access to all features and data.

Local administrators cannot modify global administrator accounts.

Default user accounts

The following default user accounts are available:

- **Administrator** – global administrator user with full permissions.
- **Public** – user that represents an anonymous visitor of the site.

Creating a new user

New user accounts are typically created when a user goes through [registration](#) on the live site. However, you can also create accounts manually in **Site manager -> Administration -> Users** or **CMS Desk -> Administration -> Users**. Click  **New user** and enter the following properties into the displayed form:

- **User name** - the user's user name (login). By default, it must be unique across all websites in the system.
- **Full name** - user's full name (first name, middle name and last name).
- **E-mail** - user's e-mail address.
- **Enabled** - indicates if the user account is enabled and the user can sign in.
- **Is editor** - indicates if the user is allowed to sign in to CMS Desk and access the On-site editing interface. This is used to differentiate between users who are only allowed to visit member areas of the website and content editors.
- **Password** - user's password.
- **Confirm password** - user's password again for confirmation.

User passwords

It is highly recommended to set a safe password for every user account to ensure the security of your website. Global administrators can monitor the list of users for accounts that have empty passwords, which will be marked with a warning icon (⚠).

You can add a password manually by editing the given users, specifically on the **Password** tab.

The system can be configured to require users to enter passwords matching specific strength requirements. For more information, please see the [Password management -> Password strength policy](#) topic.

Editing user properties

You can edit user properties in **Site manager -> Administration -> Users** -> click the **Edit** (✎) icon of the chosen the user.

General properties

The following properties can be set on the **General** tab:

- **User name** - the user's user name (login). By default, it must be unique across all websites in the system.
- **Full name** - user's full name (first name, middle name and last name).
- **First name** - user's first name.
- **Middle name** - user's middle name.
- **Last name** - user's last name.
- **E-mail** - user's e-mail address.

- **Enabled** - indicates if the user account is enabled and the user can sign in.
- **Is editor** - indicates if the user is allowed to sign in to CMS Desk and access the On-site editing interface. This is used to differentiate between users who are only allowed to visit member areas of the website and content editors.
- **Is global administrator** - indicates if the user is a global administrator. Global administrators have full permissions for all features and data across the system and are not affected by permission settings for particular modules.
- **Is external user** - this attribute is used when you are using an integration with an external user database.
- **Is domain user** - indicates if the user was imported from Active Directory.
- **Is hidden** - if true, the user is not visible on the site (e.g. on-line user monitoring, repeaters displaying users, etc.).
- **Disable site manager** - this option is available only when editing a global administrator, but not when a global administrator is editing their own account. If enabled, the user will still be designated as a global administrator, but will not be able to access the Site Manager interface, i.e. will only be allowed to perform actions in CMS Desk.

- **Preferred content culture** - preferred culture in which the content is displayed to the user.
- **Preferred user interface culture** - preferred culture in which the users wants to see the user interface (CMS Desk and Site Manager).

- **Created** - date and time when the user account was created.
- **Last logon** - date and time when the user last logged in.
- **Last logon information** - information about the IP address and browser user agent of the user's last logon.

- **Starting alias path** - the starting alias path of the content tree in CMS Desk -> Content; if you specify this value, the user is not allowed to browse other sections of the website in the content tree; please note that this feature is only intended for better usability and it doesn't ensure security control - if you need to establish access rights for a given user, grant appropriate document permissions (Properties -> Security) to them

You can also view the following information and perform related actions:

- **Invalid logon attempts** - number of unsuccessful attempts to log in with a wrong password. You can reset the value to zero and unlock the user's account by clicking the **Reset & enable** button.
- **Password expires in** - number of days left until the user's password expires. You can reset the validity to the maximum value by clicking **Extend validity & enable**.

User impersonation

Global administrators have the option of using the  **Log in as this user** button displayed at the top of the **General** tab. This allows them to sign in as the currently edited user and view the website or CMS Desk interface from their perspective. When this action is performed, the administrator will be redirected depending on the type of the impersonated user:

- **Editor** - if impersonating an editor (a user with the **Is editor** option enabled), you will be redirected to CMS Desk.
- **Standard user** - if impersonating a standard user, you will be redirected to the title page of the live site.

It is not possible to impersonate other global administrators.

User impersonation may also be performed from anywhere in the administration interface by opening the context menu located on the main header of **CMS Desk** or **Site Manager** and selecting  **Impersonate**.

When clicked, a dialog containing a list of all users under the current site is displayed, where you can select which specific user should be impersonated.

Actions carried out while impersonating a user are logged in **Site Manager -> Administration -> Event log** under a user name in format `<user name> (<original user name>)`, where the original user is the administrator using the impersonate function.

When impersonating an editor in CMS Desk, you can return to the original global administrator at any time by selecting the  **Cancel impersonation** option available in the same context menu.

Password

Here you can change the user's password:

- **Password** - user's password.

- **Confirm password** - user's password again for confirmation.

You can either enter a new password directly, or have the system generate a new one. The tab also provides the option to send an automatic notification e-mail to the given user containing the new password.

This tab is hidden if the edited user is authenticated using either an external user database or Active Directory, i.e., if the user has the **Is external user** property enabled on the **General** tab of the user editing interface or if **Is domain user** is enabled and the application is configured to use [Windows authentication](#).

Settings

On the **Settings** tab, you can edit the following properties of the user:

- **User nick name** - nick name of the user used in website forums, on the user's profile, etc.
- **User picture** - user's avatar image; this image will be used in forums and on user's profile; you can either upload an image or select a pre-defined avatar
- **User signature** - user's signature that will be used below the user's forum posts
- **Description** - optional text describing the user
- **URL referrer** - URL from that the user came to the site when they performed registration
- **Campaign** - if the given user arrived on the website through a campaign before registering, this field will store the name of that campaign. Please see the [Modules -> Web analytics -> Campaigns](#) chapter for details.
- **Messaging notification e-mail** - notifications about new messages received in the messaging module will be sent to this e-mail address

- **Time zone** - user's time zone; if set, this time zone will be used where applicable instead of the site time zone
- **Badge** - user's badge; depends on the number of gained activity points

- **User activity points** - number of user's activity points; these points are gained for forum posts, message board posts, blog posts and blog post comments
- **Live ID** - user's Live ID token; this is a hexadecimal number that the user is identified by when logging-in via Windows Live ID
- **Facebook user ID** - user's Facebook user ID; it is used when the user is logging in via Facebook Connect
- **OpenID** - user's OpenID; it is used when the user is logging in via OpenID
- **LinkedIn ID** - user's LinkedIn ID; it is used when the user is logging in via LinkedIn authentication

- **Activation date** - date of the user's account activation
- **Activated by user** - user who activated this user's account
- **Registration info** - user's IP and browser agent detected on registration

- **Gender** - user's gender
- **Date of birth** - user's date of birth

- **Skype account** - user's Skype account
- **Instant messenger** - user's instant messenger; format of values of the field is not strictly required, you may use any string of characters according to your specific needs (e.g. *ICQ: 123456789*)
- **Phone number** - user's phone number; the number may be entered in any format, no validation is applied

- **Log activities** - indicates if on-line marketing activities should be logged for this user
 - **Waiting for approval** - if checked, the user account is not active yet and is waiting for an administrator's approval
 - **Show splash screen** - determines if splash screen should be displayed to the user when accessing Kentico CMS administration interface
 - **Show web part toolbar** - determines whether the web part toolbar should be displayed for the given user when editing documents in CMS Desk on the *Content* -> *Edit* -> *Design* tab. This is only relevant for users who have the *Design web site* permission
 - **Web part toolbar position** - if the web part toolbar is enabled for the user, the choice made here sets its location on the Design tab
-
- **Forum posts** - number of user's forum posts
 - **Forum comments** - number of user's forum comments
 - **Blog comments** - number of user's blog comments
 - **Message board posts** - number of user's message board posts

Custom Fields

Here you can edit the custom fields added to the user profile. The custom fields can be defined in **Site Manager** -> **Development** -> **System tables** -> **User**.

Sites

Here you can specify the sites into which the user can sign in using their user name and password credentials. To assign the user to a site, simply click the **Add sites** button, check the appropriate boxes in the displayed dialog and click **OK** to save the changes.

Please note

The sites assigned here only limit access to the **CMS Desk** interface. Logging in on the live site is possible even for users who are not assigned to the given site.

This is intended to allow the separation of access privileges for content editors responsible for different websites.

Roles

Here you can manage the roles to which the edited user is assigned. Depending on the permissions available for individual roles, the user will be authorized to perform various actions on the website or in the administration interface. Please refer to the [Role management](#) topic for further information about roles.

Departments

Here you can specify the E-commerce module departments in which the user is authorized to manage products.

Notifications

On this tab, you can see a list of all notification subscriptions of the currently edited user. You can **Delete** (✖) subscriptions in the list, which unsubscribes the user from receiving notifications.

Categories

This tab displays a list of the user's custom categories. Each of the categories can be edited (✎) or deleted (✖).

By clicking the **New category**, you can create a new category that will behave the same way as if it was created by the user in **CMS Desk -> Edit -> Properties -> Categories**.

The following details will be required when creating a new category:

- **Display name** - name of the category displayed in the user interface
- **Code name** - name of the category used in website code

Friends

On this tab, you can manage the currently edited user's friends.

Subscriptions

On this tab, you can manage the user's subscriptions to newsletters, blog posts (comment notifications), message boards, forums and reports.

Languages

On this tab, you can specify which cultural versions of documents can be edited by the user. You have the following options:

- **User can edit all languages** - if selected, the currently edited user can edit documents in all language versions of all sites in the system
- **User can edit following languages** - if selected, you can specify which language versions can be edited by the user by checking the check-boxes in the list of language versions; this can be set separately for each site in the system using the **Select site** drop-down list

Memberships

Here you can manage special types of website membership assigned to the edited user. Each membership represents a collection of roles. When a membership is assigned to a user, it automatically authorizes that user to perform any actions allowed for all contained roles. Please refer to [Memberships](#) to learn more.

7.13.3 Role management

Roles are objects that define authorization options for users, i.e. which actions they are allowed to perform on the website and within the Kentico CMS administration interface. Roles provide an interface that maps [permissions](#) to users in a way that can easily be reused. Each role can be assigned to any amount of users and vice versa, a user can be a member of an unlimited number of roles.

The management interface for roles can be found in the **Administration -> Roles** section, both in **CMS**

Desk and Site Manager.

The screenshot shows the Kentico Site Manager Administration interface. The left sidebar contains a navigation menu with categories like Administration, Users, and System. The main content area is titled 'Roles' and shows a site context of 'E-commerce site'. A 'New role' button is present. Below it, a form allows setting a 'Role name' to 'LIKE'. A table lists existing roles with edit and delete icons.

| Actions | Role name |
|---------|---------------------------------|
| | Authenticated users |
| | CMS Basic users |
| | CMS Community administrators |
| | CMS Designers |
| | CMS Desk Administrators |
| | CMS E-commerce Account Managers |
| | CMS E-commerce Administrators |
| | CMS E-commerce Editors |
| | CMS Editors |
| | CMS Readers |

Roles can either be assigned to a specific site or defined as global objects that are available for all sites. In **CMS Desk**, only roles that belong under the current site can be managed. When in **Site Manager**, you can select the site context using the **Site** drop-down list at the top of the page. To access the list of all global roles in the system, choose the (*global*) option. Using global roles can save a lot of time when working with a large number of sites that require similar types of authorization options. Please note that global roles may only be assigned to users by global administrators.

It is possible to edit () or delete () the roles displayed in the list. New roles can be created for the selected site (or globally) by clicking **New role**. You can specify the following properties when adding a new role:

- **Role display name** - sets a name for the role displayed to users in the administration interface.
- **Role code name** - sets a name that serves as an identifier for the role.
- **Role description** - can be used to enter an optional text description for the role.
- **Is domain role** - indicates if the role was imported from Active Directory.

Code names of global roles

Code names are only checked for uniqueness within the context of individual sites, which means that it is possible for a global role to have the same code name as a site-specific role.

If you need to specify a global role using its code name in your custom website code or via the API, you can add the period character (".") as a prefix. This ensures that only the global role will be selected and any site roles with the same code name will be

ignored (for example `.Content_admin`).

Editing a role

There are four tabs available when editing (✎) a role:

General

On this tab you can edit the same properties that were specified when the role was created.

Users

Here you can add or remove users to/from the currently edited role. These users will be authorized to perform actions according to the permissions granted to the role on the **Permissions** tab. Roles can either be assigned to users permanently or only until a specified date and time.

Role properties

Roles > CMS Editors

General Users Memberships Permissions UI personalization

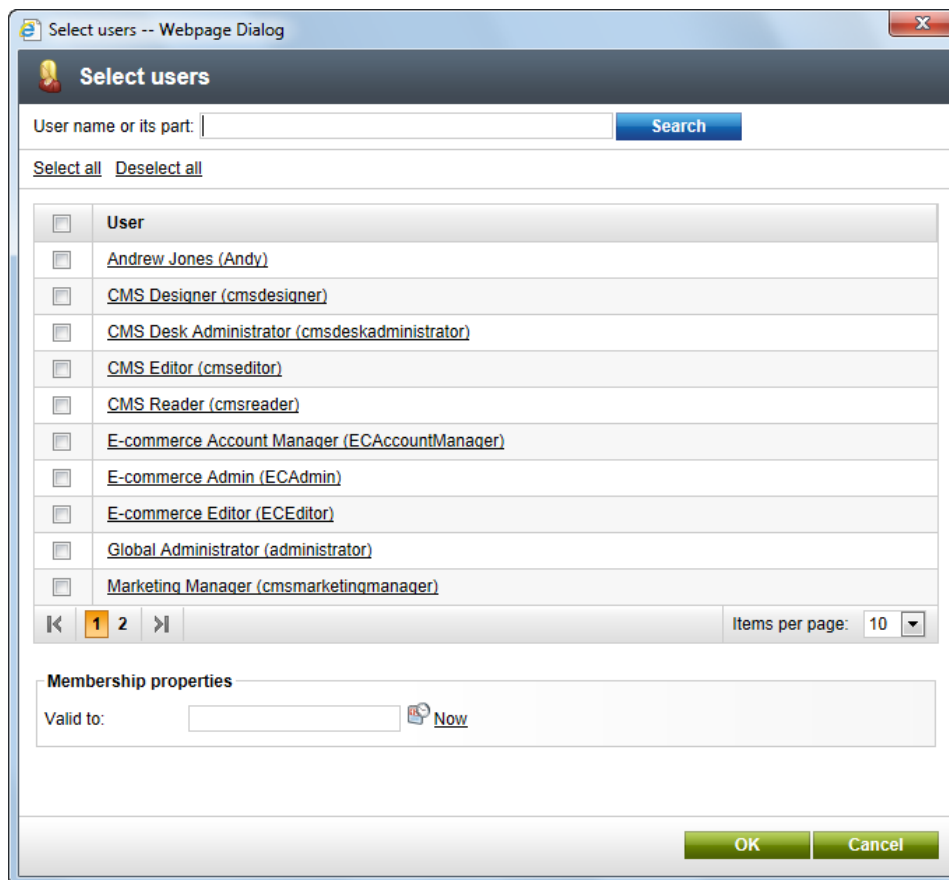

Following users are assigned to the role:

The changes were saved.

| <input type="checkbox"/> | Action | User | Valid to |
|--------------------------|--------|--------------------------------------|----------|
| <input type="checkbox"/> | | Andrew Jones (Andy) | |
| <input type="checkbox"/> | | E-commerce Editor (ECEditor) | |
| <input type="checkbox"/> | | Global Administrator (administrator) | |

Remove selected Add users

If you wish to add users, click the **Add users** button and check the boxes next to the appropriate users in the displayed selection dialog.

Only users who are assigned to the same site as the role can be chosen (global roles may be assigned to all users in the system). You can enter a name or its part into the textbox above the list and click **Search** to quickly find any user. The **Valid to** field at the bottom of the dialog can be used to assign users to the role for a limited time only. The  **Calendar** button can be clicked to easily select the exact date and time when the role should expire for the user. If this field is left empty, the users will be assigned to the role for an unlimited time period. Click **OK** to apply any changes.

The  **Change validity** action that is available for every listed user may be used to prolong or shorten the time interval for which the user should be assigned to the role. This way you can set an expiration date or reactivate expired roles for users.

Users can be removed from the role at any time using the checkboxes in the list together with the **Remove selected** button.

Permissions

On this tab you can configure which permissions should be assigned to the given role. If you wish to add permissions, select the type of the permission that you wish to assign using the two drop-down lists. Once this is done, individual permissions for the specified module or document type will be displayed below and can be enabled by checking the corresponding boxes.

UI Personalization

From the this tab, you can choose which parts of the CMS Desk interface will be displayed to members

of the given role. You can also change the settings of the [WYSIWYG](#) Editor for this particular role.

Individual interface elements can be configured from the **Dialogs** sub-tab. This is where you can select a module from the **Module** drop-down list and then enable or disable the visibility of individual dialogs by checking the corresponding boxes. Only dialogs that are checked will be displayed to users assigned to the given role. You can easily reach nested dialogs by clicking the  **Expand all** and  **Collapse all** links, respectively. You can also expand and collapse dialogs on different levels of the dialogs tree. If you would like to adjust WYSIWYG Editor settings for the given role, switch to the **Editor** tab. You can make adjustments in a similar way as with dialogs.

For more information, please see the [UI personalization](#) chapter.

7.13.4 Username customization

If you want to customize the way usernames are displayed in the administration interface, you can do it by modifying the **GetFormattedUsername** method in `~/AppCode/CMS/Functions.cs`. The method has four overrides and is used to retrieve usernames in the whole administration interface.

Example: Usernames are displayed in the `<full name> (<user name>)` (e.g. *Abigail Woodwarth (Abi)*) format in some parts of the system, e.g. in document **Properties -> General -> Owner**. The following code example shows how you can modify the method to get usernames in format `<user name> [<full name>]` (e.g. *Abi [Abigail Woodwarth]*):

[C#]

```
public static string GetFormattedUserName(string username, string fullname, bool
isLiveSite)
{
    if (!String.IsNullOrEmpty(DataHelper.GetNotEmpty(fullname, "").Trim()))
    {
        return String.Format("{1} [{0}]", fullname, username);
    }
    else
    {
        return username;
    }
}
```

7.13.5 Permissions

7.13.5.1 Permissions overview

Permissions provide a way how you can control access to particular sections of the Kentico CMS administration interface (modules), documents in the content tree and [custom tables](#).

Permissions for roles

In addition to global roles defined for all sites in the system, every website has its own set of roles. Permissions are assigned to these roles, which means that every website can use a different configuration of role permissions as necessary. Permissions for roles can be configured in the **Administration -> Permissions** section of both **CMS Desk** and **Site Manager**. The difference between the two locations is that in CMS Desk, permissions can only be configured for roles belonging under the

currently edited website, while in **Site Manager**, you can configure permissions for all sites in the system or for global roles by selecting a site from the **Site** drop-down.

Based on the selection made by the first **Permission for** drop-down list, you can choose from the following three types of permissions:

- **Modules** - permissions for specified actions in Kentico CMS modules. You can find details on particular permissions in documentation of respective [modules](#).
- **Document types** - permissions applied to all documents of a particular type. These permissions represent one level of the three-level document permissions hierarchy, as described in the [Document permissions](#) topic.
- **Custom tables** - permissions for the custom tables module, see [Modules -> Custom tables -> Security](#) for more info.

Then you need to select the appropriate module, document type or custom table from the second drop-down list and grant the permissions to roles using the check-boxes:

- - the permission is granted to the role.
- - the permission is not granted to the role.

The screenshot shows the Kentico Site Manager Administration interface. The 'Permissions' section is active, displaying a form for configuring permissions for the 'Corporate Site'. The 'Permissions for' dropdown is set to 'Module' and 'Content'. Below the form is a table showing permissions for various roles. The table has the following structure:

| Role | Read | Modify | Check in any document | Create | Delete | Manage workflow |
|------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Designers | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |

When performing this task in **CMS Desk -> Administration -> Permissions** while you are not a global administrator, you may come across the following grayed-out check boxes:

- - the permission is granted to the role, and only a global administrator can change it.
- - the permission is not granted to the role, and only a global administrator can change it.

These grayed-out check-boxes are also accompanied by the icon in the header row of the table, indicating that the permission can only be granted to roles by the global administrator, as can be seen in the screenshot below.

| Role | Design web site | Destroy transformations | Destroy CSS stylesheets |
|------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Designers | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Editors | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

Permission reports for users

As permissions are assigned to roles, not directly to users, it is possible to display a permission report for each website user. This can be achieved by selecting the user from the **Report for user** drop-down list. After doing so, a sum of all permissions granted to the user's roles is displayed in the first line, highlighted in green color. Roles where the selected user is a member will be highlighted in yellow color. If you enable the **Show only this user's roles** check-box, only the yellow roles will be displayed in the matrix.

| Role | Read | Modify | Check in any document | Create | Delete | Manage workflow |
|---------------------|-------------------------------------|-------------------------------------|--------------------------|-------------------------------------|-------------------------------------|--------------------------|
| Andrew Jones (Andy) | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

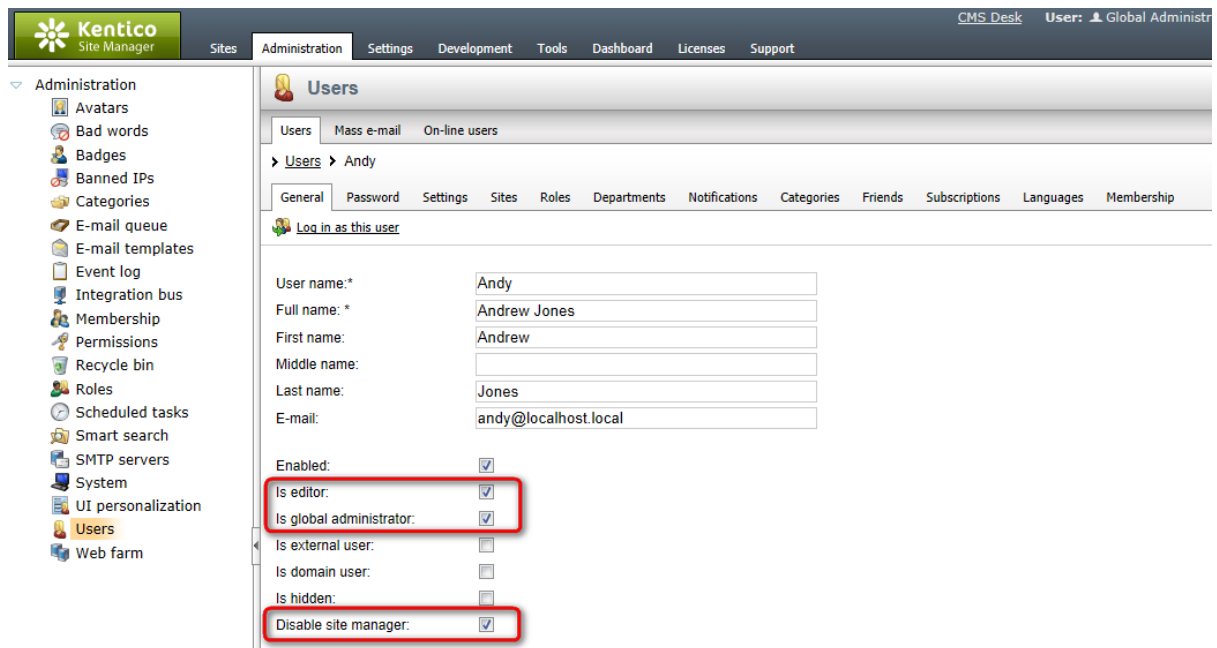

Permission-related settings for users

When editing (✎) a user in **Administration -> Users**, you can enable the following two options. These options have impact on permission checking and provide an extra security layer:

- **Is global administrator** - the user is authorized to perform all operations and their access cannot be denied by permissions or otherwise limited. Global administrators are the only users who can use the Site Manager interface.
- **Is editor** - the user can access CMS Desk and the [On-site editing](#) interface. This attribute does not

grant any particular permissions — it only differentiates between site editors and registered users who are limited to the live website. Users who are editors can access the editing interface of all sites to which they are assigned on the **Sites** tab.

- **Disable site manager** - this option is only available for users who are designated as global administrators. If enabled, the user will have unrestricted access to all actions in CMS Desk like all global administrators, but will be unable to use the Site Manager interface. This combination of options can be used to authorize users as administrators for specific sites without having to worry about setting individual permissions. Administrators cannot change the value of this property for their own account.

7.13.5.2 Document permissions

7.13.5.2.1 Document permissions

Permissions for access to Kentico CMS documents can be configured at three levels of the three-level permissions hierarchy. Click the links in the **Document permission level** column to learn more about each of them.

| Document permission level | Granted to | Applied to | Configurable in |
|---|---------------------|---|--|
| Permissions for all content | roles | all documents | CMS Desk / Site Manager -> Administration -> Permissions |
| Document type permissions | roles | all documents of one particular document type | CMS Desk / Site Manager -> Administration -> Permissions |
| Document-level permissions | roles or individual | one particular document | CMS Desk -> Content -> Edit -> Properties -> Security |

| | | | |
|--|-------|--|--|
| | users | | |
|--|-------|--|--|

Permissions from these three levels are merged together when checking if a user is permitted to perform an action with a document. For example, to read a *CMS.News* document, a user must have the *Read* permission on at least one of the three levels: either on document-level, or for the *CMS.News* document type, or for all content.

There is also one special setting that allows hiding of documents in the content tree depending on document permissions granted to the current user. See the [Hiding documents in the content tree based on permissions](#) topic for more information on this possibility.

In the [Document permissions internals and API](#) sub-chapter, you can find information about database tables and classes that are used for document permissions, as well as several examples of how permissions can be logged and managed using Kentico CMS API.

7.13.5.2.2 Permissions for all content

In **Site Manager -> Administration -> Permissions**, you can find a special permission matrix for controlling access to all documents within the content tree. It is the **Module -> Content** permission matrix. The following global permissions can be granted to particular roles:

| | |
|-----------------------|---|
| Browse tree | Allows members of the role to view the document content tree in CMS Desk (not necessarily the actual document content — that is determined by the <i>Read</i> permission). For users without this permission, the system blocks the entire Content tab (except for users who belong to roles with the Browse tree permission for the <i>CMS.Root</i> document type or for the given website's <i>Root</i> document on the document level).

Users also need this permission to perform document management actions through the On-site editing interface. |
| Read | Allows members of the role to view the content and settings of documents in the CMS Desk content tree. Additionally, users require this permission to access the on-site editing interface. |
| Modify | Allows members of the role to modify any document in the content tree. Note that for approving or rejecting documents within a workflow, the Manage workflow permission is sufficient. |
| Check in any document | Authorizes members of the role to perform the Check-in and Undo check-out actions on the Properties -> Versions tab of a document's editing interface. |
| Create | Allows members of the role to create documents of any document type in the content tree. |
| Delete | Allows members of the role to delete any document in the content tree. |
| Manage workflow | Allows members of the role to approve or reject any document at any workflow step. Note that the Modify permission is not necessary for approving or rejecting documents. |
| Destroy | Allows members of the role to destroy (delete without the <i>Undo</i> option) any document. |

| | |
|------------------------|---|
| Modify permissions | Allows members of the role to manage document-level permissions of any document in CMS Desk -> Content -> Edit -> Properties -> Security . |
| Submit for translation | Allows members of the role to create new language versions of documents using Translation services . |

Permissions

Site: Corporate Site

Permissions for: Module Content

Report for user: (none) Show only this user's roles

| Role | Browse tree | Read | Modify | Check in any document | Create | Delete | Manage workflow | Destroy | Modify permissions | Submit for translation |
|------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

| CMS Readers | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Facebook users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Gold Partners | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| LinkedIn users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Live ID users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Marketing Manager | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Not authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

7.13.5.2.3 Document type permissions

Document type permissions allow control of access to all documents of a particular document type. These permissions are assigned to roles in the **Administration -> Permissions** section of both **Site Manager** and **CMS Desk**. In this section, you have to choose *Document type* from the first **Permissions for** drop-down list and then choose the required document type from the second one. You can grant the following document type permissions to particular roles:

| | |
|-----------------|---|
| Read | Allows members of the role to view any document of this type. |
| Modify | Allows members of the role to edit any document of this type. |
| Create | Allows members of the role to create documents of this type. With this permission, users must also have the Create document-level permission on the parent document under which they want the new document to be created. |
| Create anywhere | Allows members of the role to create documents of this type anywhere in the content tree, without the need to have the Create document-level permission on the parent document under which they want the new document to be created. |
| Delete | Allows members of the role to delete any document of this type. |
| Destroy | Allows members of the role to destroy (delete without the <i>Undo</i> option) |

| | |
|--------------------|--|
| | any document of this type. |
| Browse tree | Allows members of the role to see documents found under documents of this type in the content tree. |
| Modify permissions | Allows members of the role to manage document-level permissions of all document of this type in CMS Desk -> Content -> Edit -> Properties -> Security . |

The screenshot shows the 'Permissions' configuration page in the Kentico CMS Administration interface. The 'Site' dropdown is set to 'Corporate site'. The 'Permissions for' dropdown is set to 'Document type'. The 'Report for user' dropdown is set to '(none)'. A table below lists various roles and their permissions for actions like Read, Modify, Create, Create Anywhere, Delete, Destroy, Browse Tree, and Modify Permissions.

| Role | Read | Modify | Create | Create Anywhere | Delete | Destroy | Browse Tree | Modify Permissions |
|------------------------------|-------------------------------------|-------------------------------------|--------------------------|--------------------------|-------------------------------------|-------------------------------------|--------------------------|--------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Designers | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Editors | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Readers | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Facebook users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Gold Partners | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| LinkedIn users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Live ID users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Marketing Manager | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Not authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| OpenID users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Silver Partners | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

7.13.5.2.4 Document-level permissions

You can manage document-level permissions (i.e. permissions for a particular document or a particular website section) in **CMS Desk -> Content -> Edit -> Properties -> Security**. Select the appropriate user or role in the left box. If the user or role is not available in the box, you may need to add them using the **Add users** or **Add roles** button. Now you can choose if the permissions should be allowed or denied:

- **Allow** - the action will be allowed to the user or role.
- **Deny** - the action will not be allowed even if the user or role has the permission assigned on a global level. I.e. the *Deny* option overrides settings for this permission on the other two levels.

The following permissions can be allowed or denied:

| | |
|--------------|--|
| Full control | Allows the user or members of the role to perform any action with this document. |
| Read | Allows the user or members of the role to view this document. |

| | |
|--------------------|--|
| Create | Allows the user or members of the role to create new documents under this document. |
| Modify | Allows the user or members of the role to edit this document. |
| Delete | Allows the user or members of the role to delete this document. |
| Destroy | Allows the user or members of the role to destroy (delete without the <i>Undo</i> option) this document. |
| Browse tree | Allows the user or members of the role to see documents found under this document in the content tree. |
| Modify permissions | Allows the user or members of the role to manage document-level permissions of this document in CMS Desk -> Content -> Edit -> Properties -> Security . |

The screenshot shows the Kentico CMS Desk interface. The 'Security' tab is selected in the left-hand navigation pane. The main content area displays the 'Permissions' dialog box. The dialog box contains the following information:

- Permissions:** This document inherits permissions from the parent document. [Change permission inheritance...](#)
- Users and Roles:**
 - Global Administrator (administrator)
 - Andrew Jones (Admin)
 - CMS Editor (cmseditor)
- Access rights:**

| | Allow | Deny |
|--------------------|-------------------------------------|--------------------------|
| Full control | <input type="checkbox"/> | <input type="checkbox"/> |
| Read | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Modify | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Create | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Delete | <input type="checkbox"/> | <input type="checkbox"/> |
| Destroy | <input type="checkbox"/> | <input type="checkbox"/> |
| Browse tree | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Modify permissions | <input type="checkbox"/> | <input type="checkbox"/> |

Buttons at the bottom of the dialog box include 'Add users', 'Add roles', 'Remove', and 'OK'.

Permission inheritance

You will typically need to set up permissions for site sections rather than for particular documents. In this case, you can grant permissions for the section's parent document and inherit them by all child documents.

Example

Consider a website structure like this:

- Root
 - Home
 - News
 - Products
 - Category 1
 - Category 2

You may want to grant the following permissions to the users:

| | | |
|---------------|---|--|
| JohnS | Marketing manager
John can manage all content. | Grant the Full control permission on the root to the user or grant permissions for the CMS Content module to some of this user's roles. |
| MarkJ | Product manager
Mark can manage only the documents in the /Products section. | Grant the Browse tree permission on the root to the user so that they can browse the Products section.

Grant the Read, Modify, Create, Delete, Destroy and Browse tree permissions on the /Products document to the user. These permissions are inherited by all child documents under the /Products section.

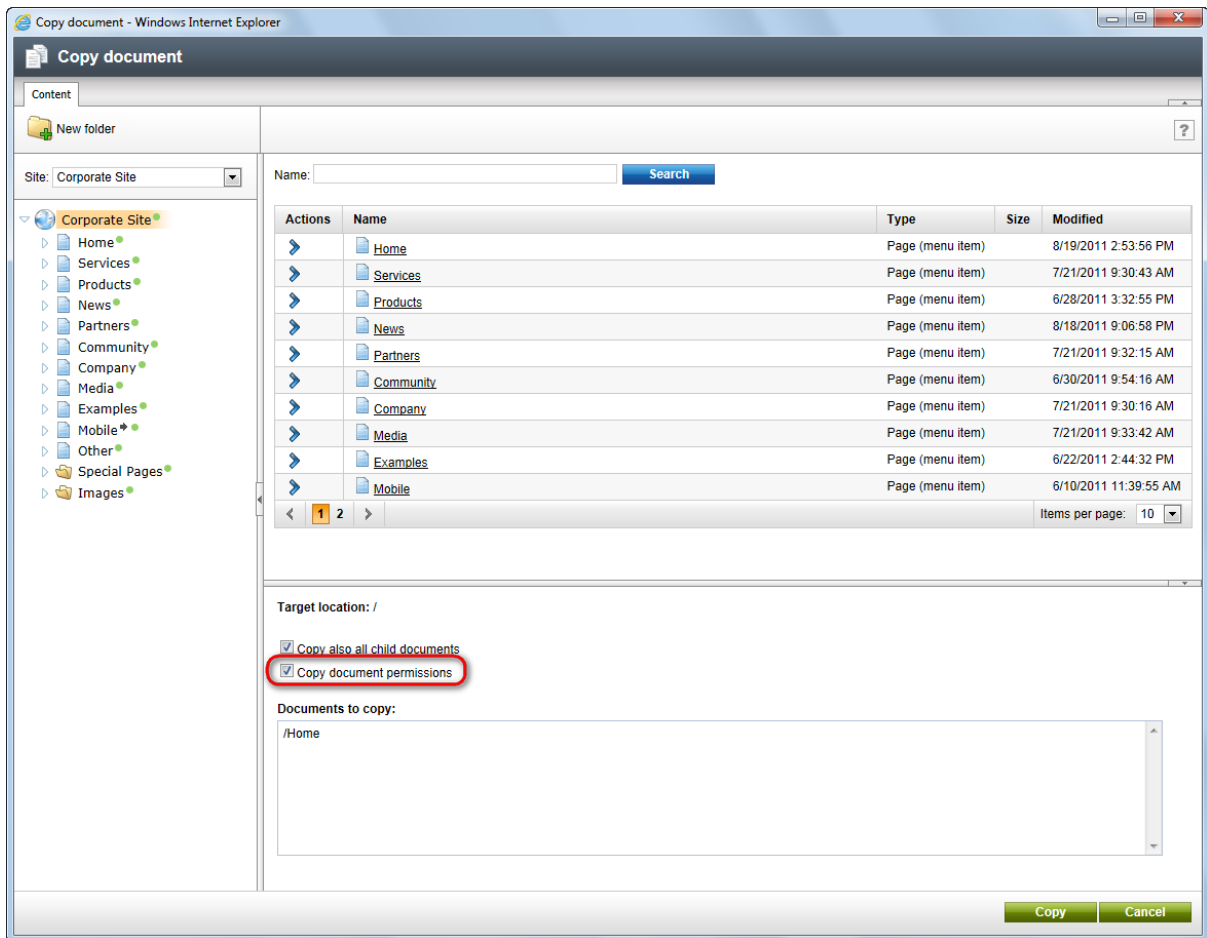

Please note that if you click the /Products/Category 1 document, the Browse tree permission is grayed and disabled. It means that this permission is inherited and cannot be removed - you can only deny the permission (unless you break inheritance - see below). |
| AliceM | Copy writer
Alice can modify the copy of all documents, but Mark prefers to manage the copy of the /Products section by himself only. | Grant the Read, Modify, Create, Delete and Browse tree permissions for the root to the user.

Go to the /Products document and deny the Modify, Create, Delete permissions to the user so that Alice cannot modify the copy in the /Products section. |

Please note: It's recommended that you configure local permissions for roles and then only assign users to the appropriate roles. In this example, you would first create roles "Marketing manager", "Product manager" and "Copy writer" and then configure their permissions.

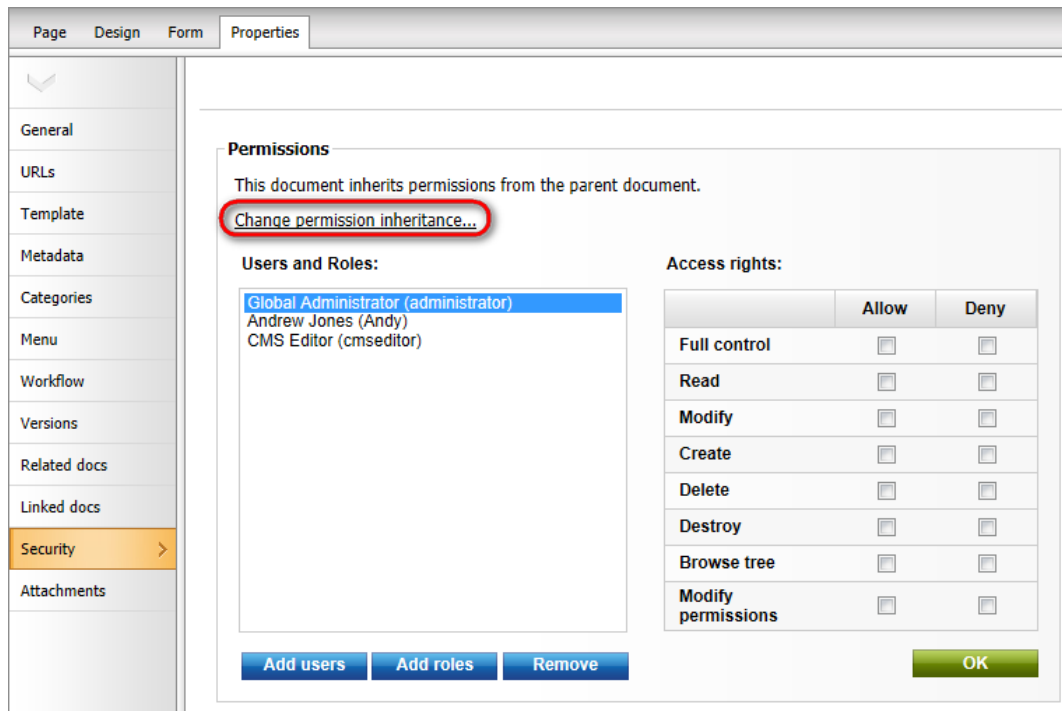

Copying permissions along with documents

If you copy, move or link a document, its permissions can be transferred along with it. You only need to enable the **Copy/Preserve document permissions** option in the **Copy/move/link document** dialog. This applies only to permissions configured for the particular document - parent or inherited permissions are not transferred. If you leave the option disabled, the copy will inherit permissions from its parent in the target location.

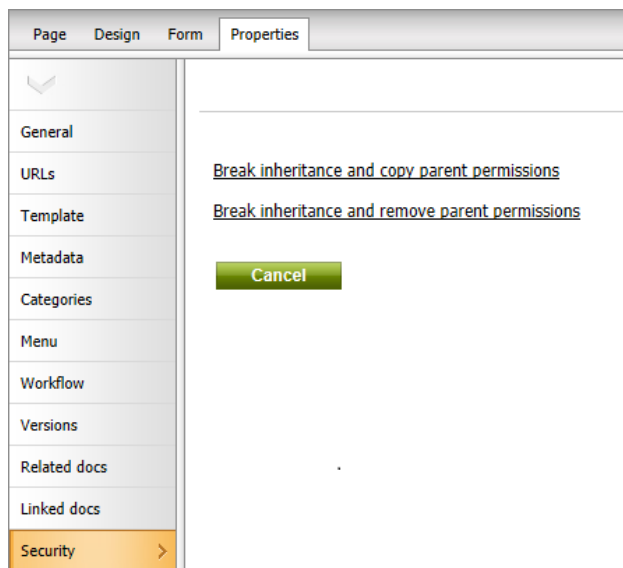

Changing permission inheritance

In case you need to break permission inheritance and configure different permissions for some site section, you need to click **Change permission inheritance...** link in the **Security** dialog.

If permissions are inherited by the current document, the following two options will be offered:

- **Break inheritance and copy parent permissions** - breaks inheritance and adds parent permissions to the document, while original permissions configured for the document are preserved.
- **Break inheritance and remove parent permissions** - breaks inheritance and removes all permissions inherited from the parent, while additional permissions configured for the document are preserved.

If you decide to inherit the permissions from the parent again, click the **Change permission inheritance...** link again. This time, the following two options will be offered:

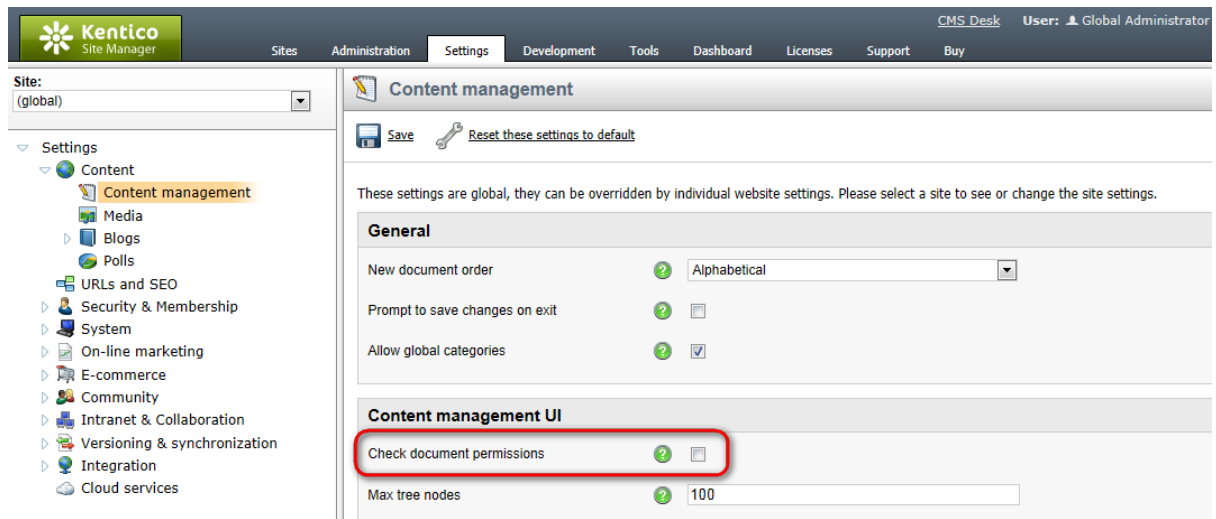

- **Restore inheritance to parent document permissions (current document only)** - makes the current document inherit permissions of the parent document.
- **Recursively restore inheritance to parent document permissions (current and all child documents)** - makes the current document and all its child documents inherit permissions of the parent document, while only documents which do not inherit parent permissions are affected by this action.

7.13.5.2.5 Hiding documents in the content tree based on permissions

If you enable the **Check document permissions** option in **Site Manager -> Settings -> Content -> Content management**, each user will only be able to see the documents for which they have the **Read** permission assigned on any of the three levels. This applies in **CMS Desk -> Content**, in document listings and in various dialogs where the content tree is displayed.

If a user has the **Read** permission for a child document but not for its parent, the child document is not displayed as well. In case that a user doesn't have the **Read** permissions for any document at all, a message is displayed instead of the content tree, saying that you have insufficient permissions to see the root document.

7.13.5.2.6 Document permissions internals and API

7.13.5.2.6.1 Overview

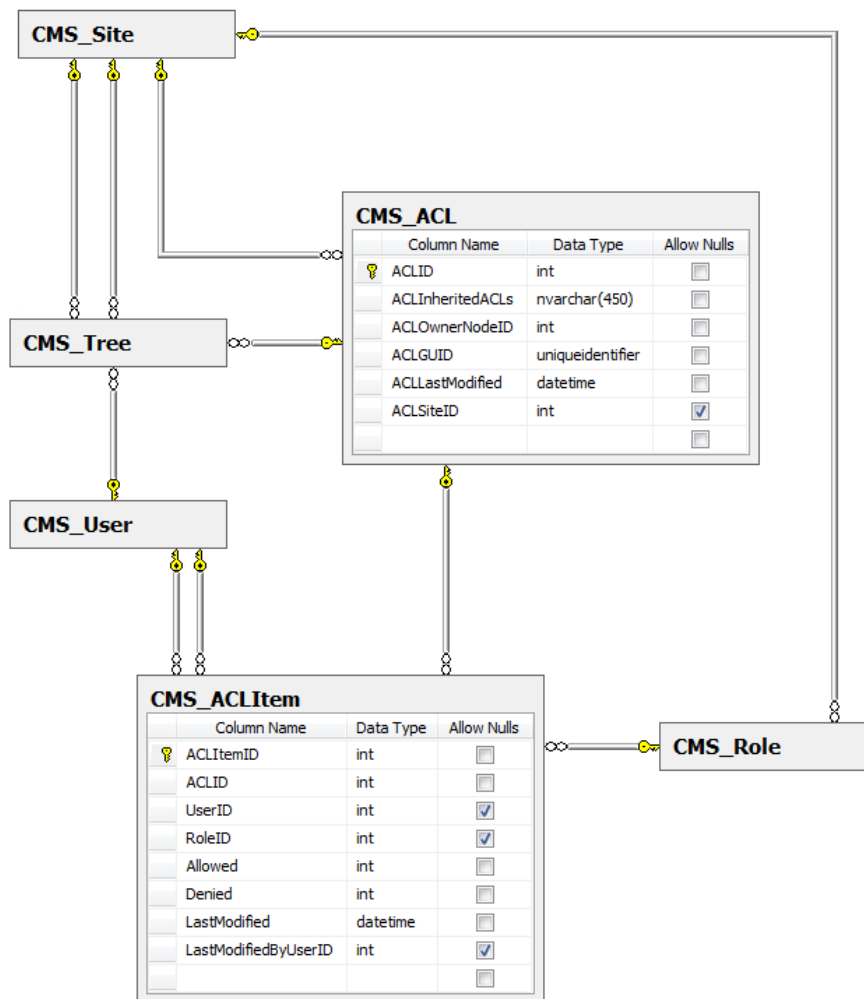

In this chapter, you will learn which [database tables](#) and [API classes](#) are used for managing document-level permissions. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the used classes, please refer to [Kentico CMS API Reference](#).

7.13.5.2.6.2 Database tables

The following database tables are used to store document level permissions:

- **CMS_ACL** - contains records representing ACLs (access control lists), i.e. document level permission matrices of single documents.
- **CMS_ACLItem** - contains records representing document level permission settings for individual users or roles within particular ACLs.

7.13.5.2.6.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes used for document permissions can be found in the **CMS.DocumentEngine** namespace.

CMS_ACL table API:

- **AcIInfo** - represents one document level permission matrix.
- **AcIProvider** - provides management functionality for document level permission.

7.13.5.2.6.4 API examples

These topics show examples of how the document permissions API can be used:

- [Preparing document structure](#)
- [Settings document level permissions](#)
- [Managing permission inheritance](#)
- [Checking permissions](#)

**Please note**

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Documents\Security\Default.aspx.cs**.

The document permissions API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.CMSHelper;
using CMS.GlobalHelper;
using CMS.SettingsProvider;
using CMS.SiteProvider;
using CMS.DocumentEngine;
using CMS.UIControls;
```

The following example is not directly related to document permissions. It only prepares a sample document structure used by the API examples on the following pages.

```
private bool CreateDocumentStructure()
{
    // Create new instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get default culture code
    string culture = SettingsKeyProvider.GetStringValue
(CMSContext.CurrentSiteName + ".CMSDefaultCultureCode");

    // Get parent node
    TreeNode parentNode = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/",
culture);

    if (parentNode != null)
    {
        // Create the API Example document
    }
}
```

```
TreeNode newNode = TreeNode.New("CMS.MenuItem", tree);

newNode.DocumentName = "API Example";
newNode.DocumentCulture = culture;

newNode.Insert(parentNode);

parentNode = newNode;

// Create the API Example subpage
newNode = TreeNode.New("CMS.MenuItem", tree);

newNode.DocumentName = "API Example subpage";
newNode.DocumentCulture = culture;

newNode.Insert(parentNode);

return true;
}

return false;
}
```

The following example deletes the sample document structure created by the API example above.

```
private bool DeleteDocumentStructure()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get default culture code
    string culture = SettingsKeyProvider.GetStringValue
(CMSContext.CurrentSiteName + ".CMSDefaultCultureCode");

    // Get the API Example document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", culture);

    if (node != null)
    {
        // Delete the document and all child documents
        node.DeleteAllCultures();
    }

    return true;
}
```

The following example grants the **Modify permissions** permission to the **CMSEditor** user on document level for a single document.

```
private bool SetUserPermissions()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get default culture code
    string culture = SettingsKeyProvider.GetStringValue
(CMSContext.CurrentSiteName + ".CMSDefaultCultureCode");

    // Get the API Example document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example", culture);

    if (node != null)
    {
        // Get the user
        UserInfo user = UserInfoProvider.GetUserInfo("CMSEditor");

        if (user != null)
        {
            // Prepare allowed / denied permissions
            int allowed = 0;
            int denied = 0;
            allowed += Convert.ToInt32(Math.Pow(2, Convert.ToInt32
(NodePermissionsEnum.ModifyPermissions)));

            // Create an instance of ACL provider
            AclProvider acl = new AclProvider(tree);

            // Set user permissions
            acl.SetUserPermissions(node, allowed, denied, user);

            return true;
        }
    }

    return false;
}
```

The following example grants the **Modify** permission to the **CMSEditor** role on document level for a single document.

```
private bool SetRolePermissions()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get default culture code
    string culture = SettingsKeyProvider.GetStringValue
(CMSContext.CurrentSiteName + ".CMSDefaultCultureCode");

    // Get the API Example document
```

```
TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-Example", culture);

if (node != null)
{
    // Get the role ID
    RoleInfo role = RoleInfoProvider.GetRoleInfo("CMSEditor", CMSContext.CurrentSiteName);

    if (role != null)
    {
        // Prepare allowed / denied permissions
        int allowed = 0;
        int denied = 0;
        allowed += Convert.ToInt32(Math.Pow(2, Convert.ToInt32(NodePermissionsEnum.Modify)));

        // Create an instance of ACL provider
        AclProvider acl = new AclProvider(tree);

        // Set role permissions
        acl.SetRolePermissions(node, allowed, denied, role.RoleID);

        return true;
    }
}

return false;
}
```

The following example removes all document level permissions granted to both users and roles on document level for a single document.

```
private bool DeletePermissions()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get default culture code
    string culture = SettingsKeyProvider.GetStringValue(CMSContext.CurrentSiteName + ".CMSDefaultCultureCode");

    // Get the API Example document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-Example", culture);

    if (node != null)
    {
        // Create an instance of ACL provider
        AclProvider acl = new AclProvider(tree);

        // Get ID of ACL used on API Example document
    }
}
```

```
        int nodeACLID = ValidationHelper.GetInteger(node.GetValue("NodeACLID"),
0);

        // Delete all ACL items
        acl.ClearACLItems(nodeACLID);

        return true;
    }

    return false;
}
```

The following example breaks permission inheritance on document level of a single document.

```
private bool BreakPermissionInheritance()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get default culture code
    string culture = SettingsKeyProvider.GetStringValue
(CMSContext.CurrentSiteName + ".CMSDefaultCultureCode");

    // Get the API Example document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example/API-Example-subpage", culture);

    if (node != null)
    {
        // Create an instance of ACL provider
        AclProvider acl = new AclProvider(tree);

        // Break permission inheritance (without copying parent permissions)
        bool copyParentPermissions = false;
        acl.BreakInheritance(node, copyParentPermissions);

        return true;
    }

    return false;
}
```

The following example restores permission inheritance on document level of a single document.

```
private bool RestorePermissionInheritance()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get default culture code
```

```
string culture = SettingsKeyProvider.GetStringValue
(CMSContext.CurrentSiteName + ".CMSDefaultCultureCode");

// Get the API Example document
TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
Example/API-Example-subpage", culture);

if (node != null)
{
    // Create an instance of ACL provider
    AclProvider acl = new AclProvider(tree);

    // Restore permission inheritance
    acl.RestoreInheritance(node);

    return true;
}

return false;
}
```

The following example checks if the **CMSEditor** user has the **Read** permission for the **Content** module.

```
private bool CheckContentModulePermissions()
{
    // Get the user
    UserInfo user = UserInfoProvider.GetUserInfo("CMSEditor");

    if (user != null)
    {
        // Check permissions and perform an action according to the result
        if (UserInfoProvider.IsAuthorizedPerResource("CMS.Content", "Read",
CMSContext.CurrentSiteName, user))
        {
            apiCheckContentModulePermissions.InfoMessage = "User 'CMSEditor' is
allowed to read module 'Content'.";
        }
        else
        {
            apiCheckContentModulePermissions.InfoMessage = "User 'CMSEditor' is
not allowed to read module 'Content'.";
        }

        return true;
    }

    return false;
}
```

The following example checks if the **CMSEditor** user has the **Read** permission for the **CMS.MenuItem**

document type.

```
private bool CheckDocTypePermissions()
{
    // Get the user
    UserInfo user = UserInfoProvider.GetUserInfo("CMSEditor");

    if (user != null)
    {
        // Check permissions and perform an action according to the result
        if (UserInfoProvider.IsAuthorizedPerClass("CMS.MenuItem", "Read",
        CMSContext.CurrentSiteName, user))
        {
            apiCheckDocTypePermissions.InfoMessage = "User 'CMSEditor' is allowed
            to read document type 'MenuItem'.";
        }
        else
        {
            apiCheckDocTypePermissions.InfoMessage = "User 'CMSEditor' is not
            allowed to read document type 'MenuItem'.";
        }

        return true;
    }

    return false;
}
```

The following example checks if the **CMSEditor** user has the **Read** permission on document level for a single document.

```
private bool CheckDocumentPermissions()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get default culture code
    string culture = SettingsKeyProvider.GetStringValue
    (CMSContext.CurrentSiteName + ".CMSDefaultCultureCode");

    // Get the API Example document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/API-
    Example", culture);

    if (node != null)
    {
        // Get the user
        UserInfo user = UserInfoProvider.GetUserInfo("CMSEditor");

        if (user != null)
        {
```

```
        // Check permissions and perform an action according to the result
        if (TreeSecurityProvider.IsAuthorizedPerNode(node,
NodePermissionsEnum.ModifyPermissions, user) == AuthorizationResultEnum.Allowed)
        {
            apiCheckDocumentPermissions.InfoMessage = "User 'CMSEditor' is
allowed to modify permissions for document 'API Example'.";
        }
        else
        {
            apiCheckDocumentPermissions.InfoMessage = "User 'CMSEditor' is not
allowed to modify permissions for document 'API Example'.";
        }

        return true;
    }
}

return false;
}
```

The following example gets multiple document into a DataSet, filters the documents depending on if the **Modify permissions** permission was granted to the **CMS Editor** user on their document level, and breaks permission inheritance of the filtered documents.

```
private bool FilterDataSet()
{
    // Create an instance of the Tree provider
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Set the parameters for getting documents
    string siteName = CMSContext.CurrentSiteName;
    string aliasPath = "/%";
    string culture = SettingsKeyProvider.GetStringValue
(CMSContext.CurrentSiteName + ".CMSDefaultCultureCode");
    bool combineWithDefaultCulture = true;

    // Get data set with documents
    DataSet documents = tree.SelectNodes(siteName, aliasPath, culture,
combineWithDefaultCulture);

    // Get the user
    UserInfo user = UserInfoProvider.GetUserInfo("CMSEditor");

    if (user != null)
    {
        // Filter the data set by the user permissions
        TreeSecurityProvider.FilterDataSetByPermissions(documents,
NodePermissionsEnum.ModifyPermissions, user);

        if (!DataHelper.DataSourceIsEmpty(documents))
        {
            // Create an instance of ACL provider

```

```
AclProvider acl = new AclProvider(tree);

// Loop through filtered documents
foreach (DataRow documentRow in documents.Tables[0].Rows)
{
    // Create a new Tree node from the data row
    TreeNode node = TreeNode.New(documentRow, "CMS.MenuItem", tree);

    // Break permission inheritance (with copying parent permissions)
    acl.BreakInheritance(node, true);
}

// Data set filtered successfully - permission inheritance broken for
filtered items
apiFilterDataSet.InfoMessage = "Data set with all documents filtered
successfully by permission 'Modify permissions' for user 'CMSEditor'. Permission
inheritance broken for filtered items.";
}
else
{
    // Data set filtered successfully - no items left in data set
    apiFilterDataSet.InfoMessage = "Data set with all documents filtered
successfully by permission 'Modify permissions' for user 'CMSEditor'. No items
left in data set.";
}

return true;
}

return false;
}
```

7.13.5.3 Design permissions

The Design permission matrix is used to set up important permissions related to the design of page templates and their components.

To access the matrix in **Site manager**:

1. Navigate to **Administration -> Permissions**.
2. In the **Site** drop-down list, choose the site you want to configure the permissions, e.g., for Corporate site.
3. Choose **Module** in the first and **Design** in the second **Permissions for** drop-down list.

You can also choose for which user you want a [permission report to be shown](#) by using the **Report for user** drop-down list.

In **CMS Desk**, you can access the matrix for a given site by going to **Administration -> Permissions**.

The screenshot shows the Kentico Site Manager Administration interface. The 'Permissions' page is active, displaying a table of roles and their permissions for the 'Design' module. The table has columns for 'Role' and various permissions: 'Wireframing', 'Design web site', 'Edit ASCX code', 'Edit SQL code', 'Destroy transformations', 'Destroy CSS stylesheets', 'Destroy page layouts', and 'Destroy page templates'. The 'Design' module is selected in the 'Permissions for:' dropdown. The 'Report for user:' dropdown is set to '(none)'. The 'Show only this user's roles' checkbox is unchecked. The table shows that 'Authenticated users', 'CMS Basic users', 'CMS Community administrators', 'CMS Designers', 'CMS Desk Administrators', 'CMS Editors', 'CMS Readers', 'Everyone', 'Facebook users', 'Gold Partners', 'LinkedIn users', and 'Live ID users' all have the 'Design' module permissions checked.

You can assign the following permissions to members of the specified roles:

| | |
|-----------------------------|---|
| Wireframing | Allows users to edit the content of wireframe schematics in CMS Desk - > Content on the Wireframe tab and create new wireframe documents. Users without this permission can view wireframes, but are not allowed to make any modifications. |
| Design website | Allows users to edit documents on the Design tab of CMS Desk . Note that even though the changes on the Design tab are made on a specific website, this may also affect other sites in the system if they use the same shared page template.

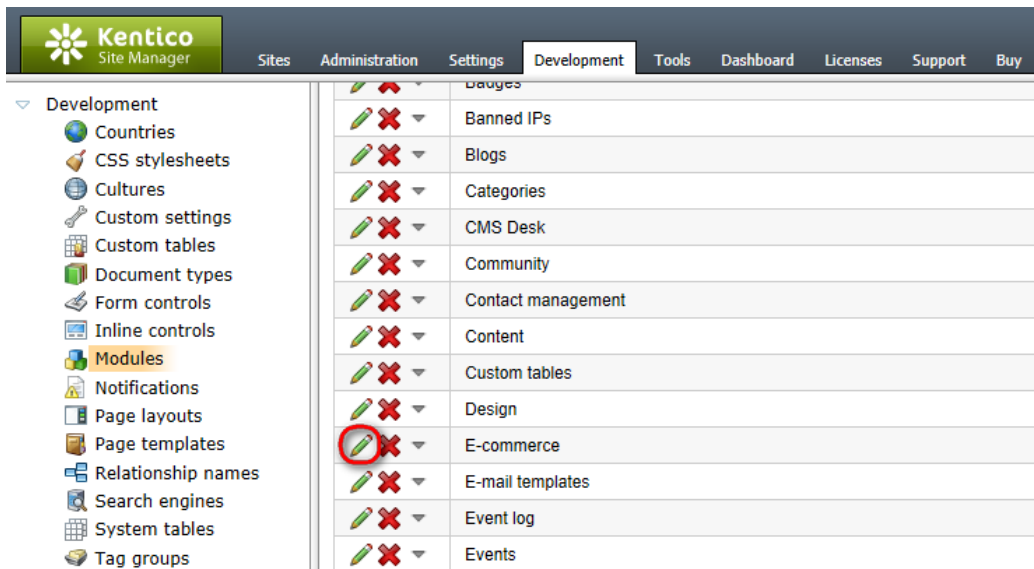

This permission also determines whether a given role is allowed to configure the properties of web parts through the On-site editing interface. |
| Edit ASCX code | Allows users to modify the ASCX code of page layouts and transformations. This permission does not affect the ability to edit the HTML versions of these objects. This should be considered a high-level permission, because it gives users the option to add and execute inline code. |
| Edit SQL code | Allows users to create or modify query objects and edit other fields containing SQL code, such as the WHERE condition properties of web parts. This should be considered a high-level permission, because it gives users the power to write and execute SQL queries against the website's database. |
| Destroy transformations | Allows users to delete the version history of transformation objects. |
| Destroy CSS stylesheets | Allows users to delete the version history of CSS stylesheet objects. |
| Destroy page layouts | Allows users to delete the version history of shared page layouts. |
| Destroy page templates | Allows users to delete the version history of page templates. |
| Destroy web part containers | Allows users to delete the version history of web part containers. |

| | |
|--------------------------|---|
| Destroy web part layouts | Allows users to delete the version history of web part layouts. |
|--------------------------|---|

For security reasons, the **Edit ASCX code** and **Edit SQL code** permissions may only be assigned by users designated as global administrators.

7.13.5.4 Module permissions management

Module permissions can be managed in the administration interface of each particular module. This is accessible after clicking the **Edit** (✎) icon next to the required module in **Site Manager -> Development -> Modules**.

In the module's administration UI, switch to the **Permission names** tab. Here, you can see a list of all permissions defined for the module. They are listed in the same order that will be used in the permission matrix (top-down order here equals to left-right order in the matrix). The **Move up** (↑) and **Move down** (↓) icons can be used to re-order permissions according to your needs.

Please note

New permissions can be created by clicking **New permission** above the list. However, each permission must be handled by the code of the module to actually take effect. Creating a permission in this UI on its own does not have any effects.

An example of handling permissions in custom module code can be found in the [Modules -> Developing custom modules](#) topic.

To adjust configuration of an existing permission, click the **Edit** (✎) icon next to it.

- Development
 - Countries
 - CSS stylesheets
 - Cultures
 - Custom settings
 - Custom tables
 - Device profiles
 - Document types
 - Form controls
 - Inline controls
 - Javascript files
 - Macro rules
 - Modules**
 - Notifications
 - Page layouts
 - Page templates
 - Relationship names
 - Search engines
 - System tables
 - Tag groups
 - Time zones
 - Translation services
 - UI cultures
 - Web part containers
 - Web parts
 - Web templates
 - Widgets
 - Workflows

Module properties

> Modules > E-commerce

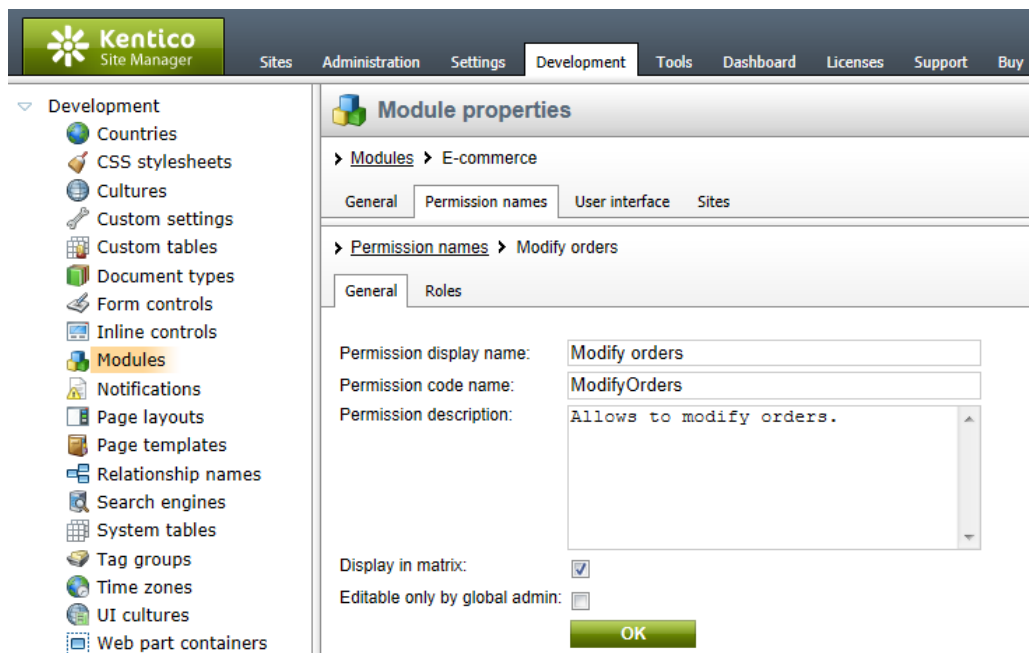

General | **Permission names** | User interface | Sites

New permission

| Actions | Display name | Code name |
|---------|-----------------------------|---------------------------|
| | Read data | EcommerceRead |
| | Modify data | EcommerceModify |
| | Modify global data | EcommerceGlobalModify |
| | Read configuration | ConfigurationRead |
| | Modify configuration | ConfigurationModify |
| | Modify global configuration | ConfigurationGlobalModify |
| | Read orders | ReadOrders |
| | Modify orders | ModifyOrders |
| | Read reports | ReadReports |
| | Read customers | ReadCustomers |
| | Modify customers | ModifyCustomers |
| | Access all departments | AccessAllDepartments |
| | Read products | ReadProducts |
| | Modify products | ModifyProducts |
| | Read discounts | ReadDiscounts |
| | Modify discounts | ModifyDiscounts |
| | Read manufacturers | ReadManufacturers |
| | Modify manufacturers | ModifyManufacturers |

The following properties of each permission can be configured on the **General** tab of its editing interface.

- **Permission display name** - name of the permission displayed in Kentico CMS UI.
- **Permission code name** - name of the permission used in website code.
- **Permission description** - text providing more details about the permission (typically where and when it is checked).
- **Display in matrix** - indicates if the permission should be displayed in the module's permissions matrix.
- **Editable only by global admin** - if enabled, the permission can only be granted to users or roles by the global administrator.

Direct assigning of permissions to roles

To assign the currently edited permission to particular roles conveniently without going to the **Administration -> Permissions** section, you can switch to the **Roles** tab of a permission's editing interface. Then select the site from the **Site** drop-down list and assign the permission to given roles using the check-boxes.

To check if the permission is granted to a user, you can select the user from the **Report for user** drop-down list. After doing so, a sum of all permissions granted to the user's roles is displayed in the first line, highlighted in green color. Roles where the selected user is a member will be highlighted in yellow color. If you enable the **Show only this user's roles** check-box, only the yellow roles will be displayed in the matrix.

The screenshot shows the Kentico Site Manager interface. The left sidebar contains a navigation menu with categories like 'Development', 'Modules', and 'Workflows'. The main content area is titled 'Module properties' and is currently displaying the 'Permission names' tab for the 'Modify orders' permission. The configuration shows the site set to 'Corporate site' and the report for user set to 'Andrew Jones (Andy)'. Below this, a table lists roles granted with the 'Modify orders' permission.

| Role | Modify orders |
|------------------------------|-------------------------------------|
| Andrew Jones (Andy) | <input type="checkbox"/> |
| Authenticated users | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> |
| CMS Community administrators | <input type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> |
| CMS Editors | <input type="checkbox"/> |
| CMS Readers | <input type="checkbox"/> |

7.13.6 UI personalization

7.13.6.1 Overview

UI personalization enables you to provide certain users of the website with **simplified user interface**. This is useful **typically for business users** who don't need to see all the **tabs, menu items, actions** and **parts of UI pages** which they don't use. Instead, they have the possibility to see only the things that they need for their job and are not overwhelmed by loads of other options.

Setting up personalized UI can significantly decrease the learning time for new end-users and makes the system generally easier to use and understand for them.

If you are new to UI personalization in Kentico CMS, we recommend you to take the following steps to fully understand it:

1. For UI personalization to be functional, you first need to enable it as described [here](#).
2. It is a good idea to start with the [Quick example](#) topic, where you can instantly see what UI personalization is good for.
3. With some basic information from the Quick example, you can get deeper knowledge of the terminology, concept and internals in the [How it works](#) chapter.
4. Finally, you can learn what parts of CMS Desk can be hidden in [Personalizable parts of CMS Desk](#).

With the knowledge gained in the chapters above, you can start making UI personalization settings for particular roles as described in the [UI profile configuration](#) topic. You can also modify or even create your custom UI elements as described in the [UI elements management](#) and the related [example](#) topics.

7.13.6.2 Quick example

To see UI personalization in practice, first enable UI personalization as described [here](#). Install one of the sample sites (e.g. Corporate Site) and try logging in to CMS Desk as the **Global Administrator** (login *administrator* with blank password). You will see the full-featured user interface as in the screenshot below.

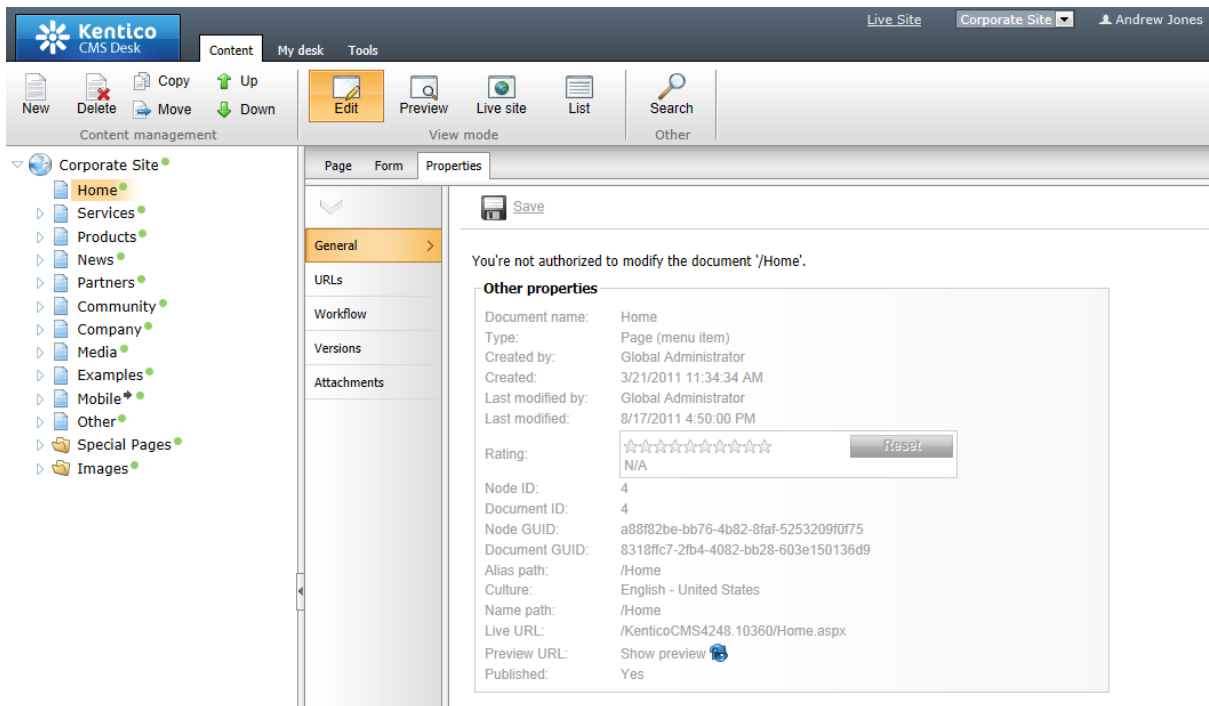

Now log out and try logging in as **Andrew Jones** (login *andy* with blank password). Andy is a member of the **CMS Basic users** role only. This is a role which was added to Kentico CMS to demonstrate the capabilities of UI personalization and its members see a simplified user interface.

As you can see in the screenshot below, the **Administration** tab in the top menu is not present. The **Design** tab in **Edit** mode is missing too. You can also notice the **WYSIWYG editor**, which offers only a limited number of actions.

If you switch to the **Properties** tab, you can notice the limited number of items in the left menu. Particular sections accessible via the menu also do not contain all the options available for administrators.

The **My desk** tab contains only three items.

There are no documents waiting for your approval.

The **Tools** tabs offers only the **Newsletters** module.

It is obvious that this UI is much easier to understand for an end user who only needs to send out newsletters and does not need to do anything else with the CMS.

To see a full overview of which parts of the UI can be hidden, please see [Personalizable parts of CMS Desk](#).

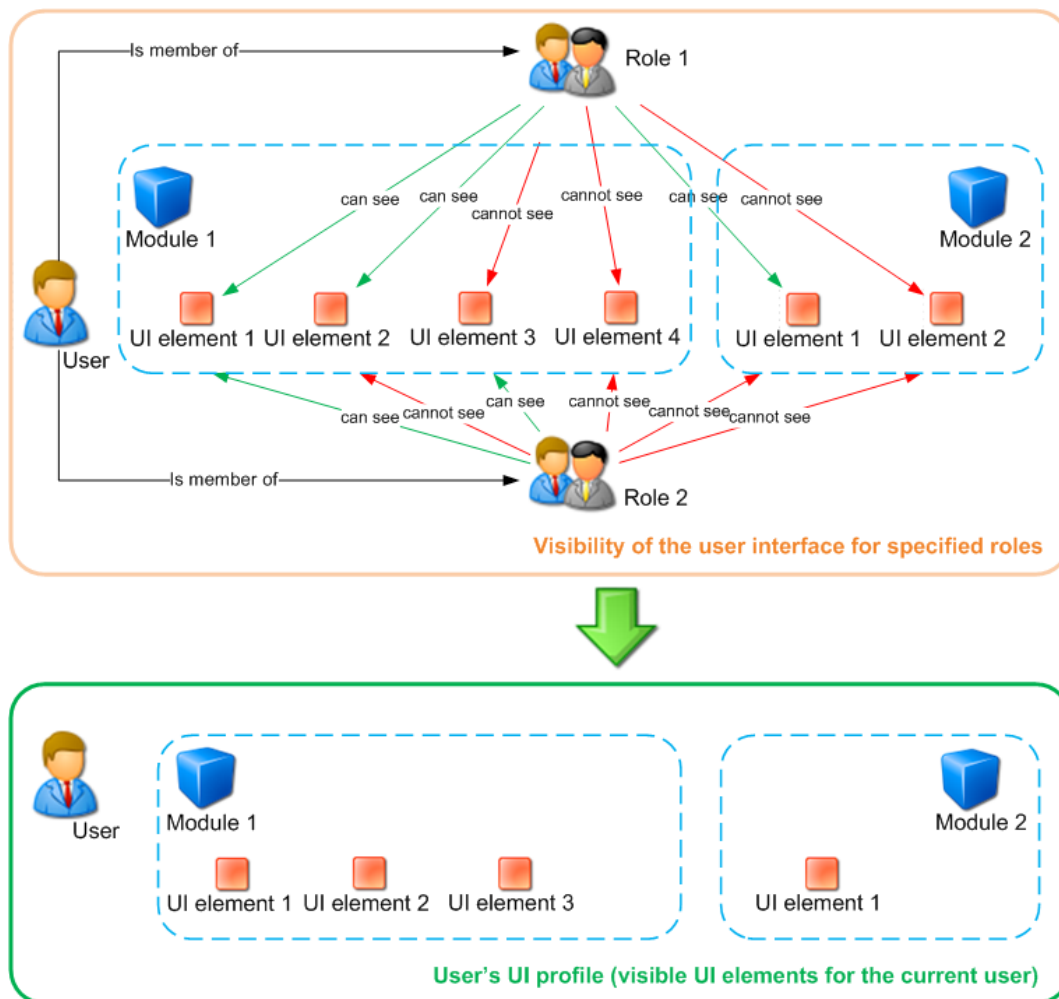

7.13.6.3 How it works

This chapter explains the principles behind Kentico CMS UI personalization. It is important to get familiar with the following two terms in order to fully understand the concept:

- **UI element** - page or part of a page in CMS Desk which can be hidden for users belonging to specified roles. It can be a *tab*, a *menu item* or a *group of controls*.
- **UI profile** - visibility settings of specified UI elements for a particular role. It is defined as a set of (role) x (UI element) relationships.

Each user's UI profile is defined by UI profiles of their roles. If a user wants to see a UI element, at least one role where the user is a member needs to have the UI element set as visible.

The following diagram illustrates how UI personalization settings from two roles are merged to create a user's UI profile.

Please note: The roles assigned to a user determine which UI profile will be displayed. A user who is assigned to site-specific roles will have a **site-related** UI profile. This means that a user can see a certain personalized UI when editing one site and a completely different UI when editing another site. On the other hand, if a user is a member of only global roles, the same UI profile will be displayed to them on all sites.

UI element display authorization

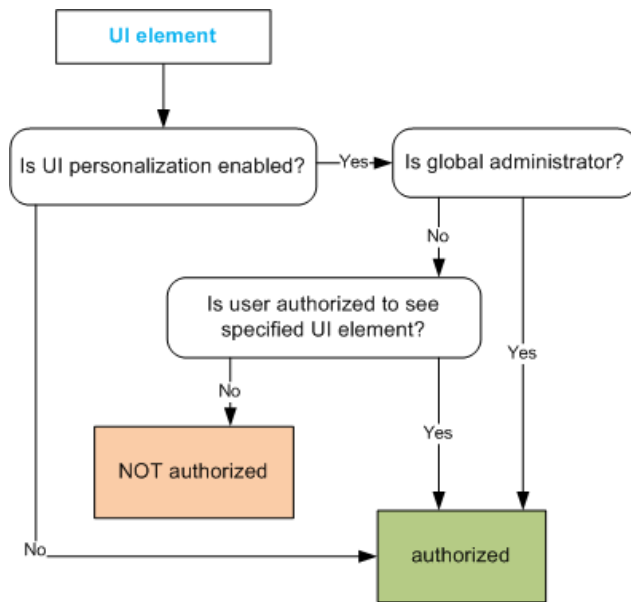

The diagram below shows the process of authorization when deciding if a single UI element should be

displayed to a user. This process is applied to UI elements in the following parts of the UI:

- main tabs in CMS Desk (Content, My Desk, Tools, Administration - only the tabs, not their content!)
- left menu in CMS Desk -> My Desk
- left menu in CMS Desk -> Tools
- left menu in CMS Desk -> Administration

This diagram shows the same authorization process in the remaining tabs and parts of pages:

UI element definitions vs. UI elements in the real user interface

The relation between the UI element definition in **Site Manager -> Modules -> edit (✎) a module -> User interface** and the UI elements in the real UI is different according to the type of UI element.

There are three basic types of UI elements: **tabs**, **menu items** and **groups of controls**.

Tabs in the following locations are **generated dynamically** from the defined UI elements, which means that when a new UI element is defined, the element gets instantly displayed in the UI:

- main tabs in CMS Desk (Content, My desk, ...)
- main tabs in Site Manager (Sites, Administration, Settings, ...)
- tabs in CMS Desk -> Edit (Page, Design, ...)
- vertical tabs in CMS Desk -> Edit -> Properties (General, Metadata, ...)
- tabs in CMS Desk -> My desk -> Account

Menu items in the following menus are also **generated dynamically**:

- CMS Desk -> My desk -> top menu
- CMS Desk -> Tools -> left menu
- CMS Desk -> Administration -> left menu

Groups of controls on particular UI pages (e.g. the Design, Other properties, Owner and Cache sections in CMS Desk -> Content -> Properties -> General) are **pre-defined** and their UI elements are bound to them. You cannot define a new group of controls on a page just by defining a new UI element.

More information related to this topic can be found in [Personalizable parts of CMS Desk](#).

7.13.6.4 Personalizable parts of CMS Desk

7.13.6.4.1 Overview

UI personalization can be applied to **CMS Desk only**. Site Manager cannot be personalized as it is typically used by administrators and developers who need the full UI rather than a simplified version.

As for CMS Desk, you can personalize the UI elements in the following parts of CMS Desk. Module names in parentheses show which module represents these parts of CMS Desk:

- [CMS Desk main tabs](#) (module CMS Desk)
- [CMS Desk -> Content tab](#) (module Content)
- [CMS Desk -> Content -> New](#) (Module New)
- [CMS Desk -> My desk tab](#) (module My desk)
- [CMS Desk -> Tools tab](#) (module Tools)
- [CMS Desk -> Administration tab](#) (module Administration)
- [WYSIWYG editor](#) (module WYSIWYG editor)
- [Media dialog](#) (module Media dialog)

Click particular sections to learn more.

7.13.6.4.2 CMS Desk main tabs

By default, CMS Desk has the following tabs: **Content**, **My desk**, **Tools**, **Administration**, **E-commerce** and **On-line marketing** - as highlighted in this screenshot:

To add a tab to CMS Desk:

1. Navigate to **Site Manager -> Development -> Modules**.
2. Edit (✎) the **CMS Desk** module and click the **User interface** tab.
3. Click **New element** and type a **Display name**, **Caption** and a **Target URL** that should be loaded when a user clicks the new tab.
4. Click **Save**.

When you open CMS Desk, you can see the new tab added at the end of the main menu. Click the tab to load the page that you defined in Target URL.

To show or hide a CMS Desk tab to or from a particular role:

1. Navigate to **Site Manager -> Development -> Modules**.
2. Edit (✎) the **CMS Desk** module and click the **User interface** tab.
3. In the UI element tree, click the tab that you want to hide and then click **Roles**.

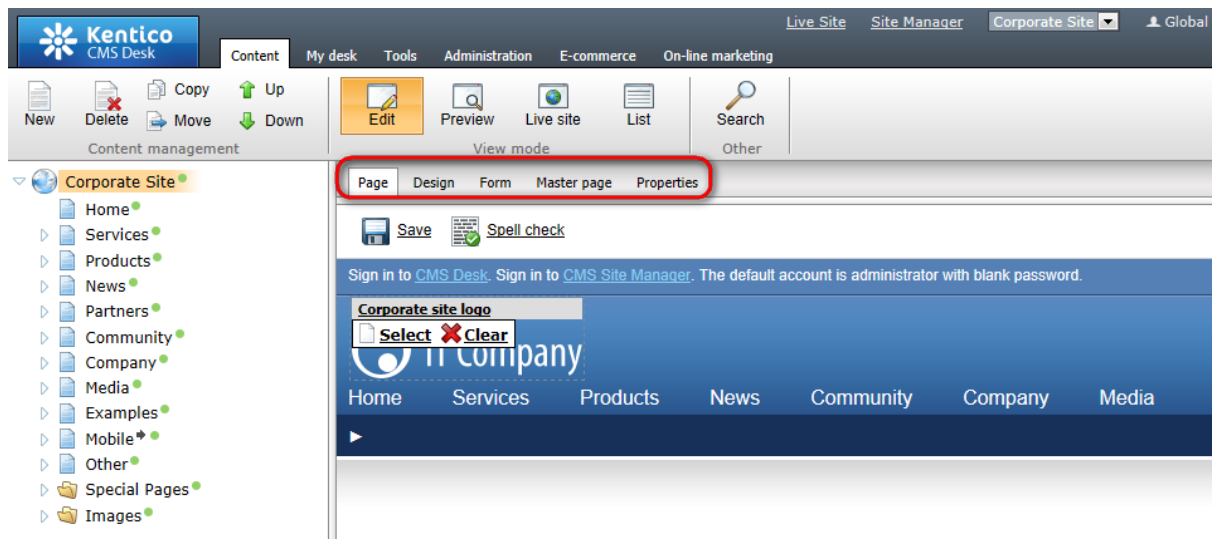

4. Select a site and check the boxes next to roles that you want to allow to see the tab, or uncheck the boxes next to roles that you want to hide the tab from.

7.13.6.4.3 CMS Desk -> Content tab

The **Content** tab provides vast possibilities of UI personalization. For easier explanation, we will divide them in **three groups**: **Edit mode** tabs, **Design** tab and **Properties** tab.

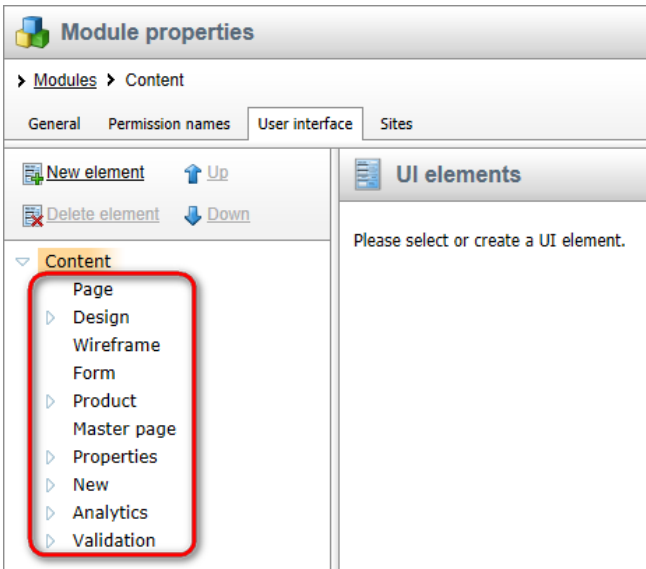

Edit mode tabs

You can hide any of the main tabs displayed in **Edit** mode as highlighted in the screenshot below.

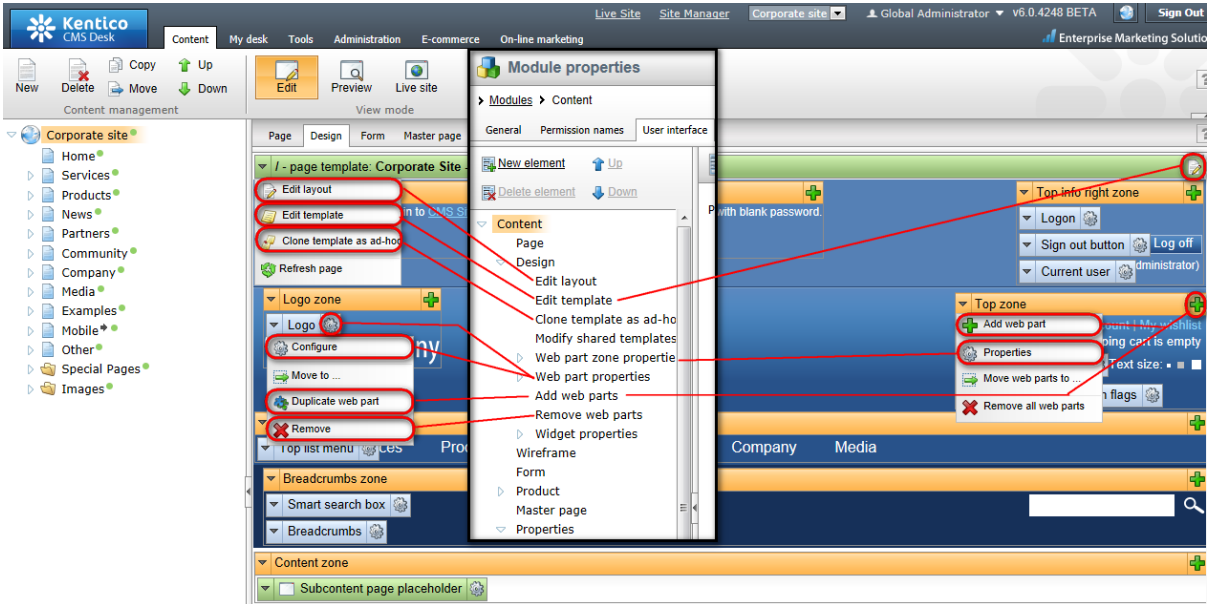

These main tabs are represented by the first-level UI elements of the **Content** module as highlighted below.

Please note that the **Product** tab is not displayed in the screenshot above as it is only displayed when a product type document is selected in the content tree. This is also the case of the **Master page** tab, which is displayed only when you are using Portal engine and the root of the content tree (the master page) is selected.

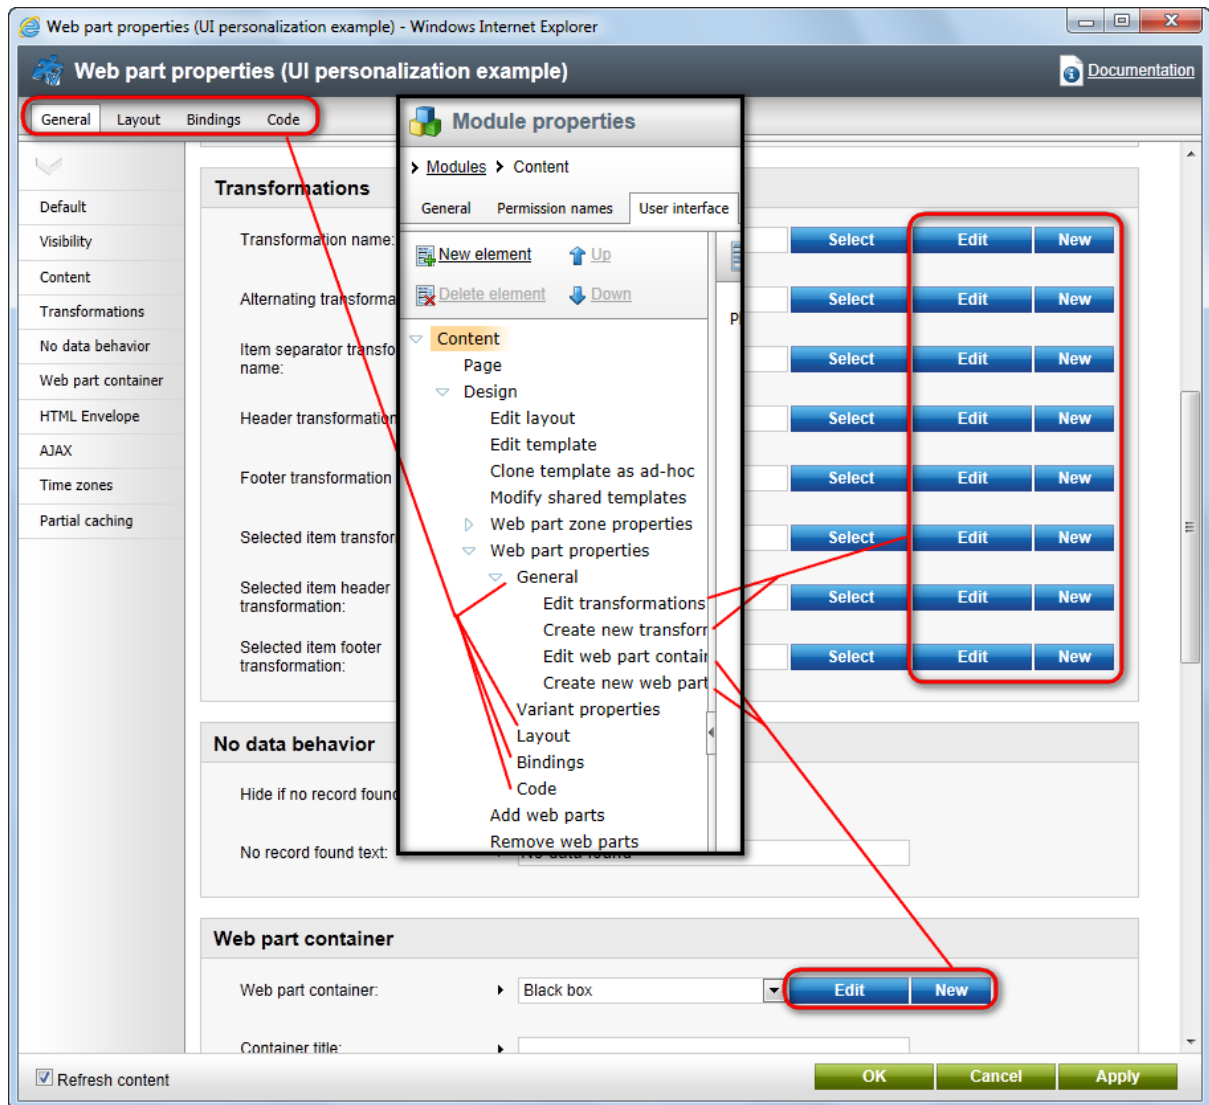

Design tab

On the **Design** tab, you customize all the essential editing actions highlighted in the screenshot below. The corresponding UI elements can be found under the **Design** node of the **Content** module's UI elements tree.

Web part properties dialog

You can hide the four main tabs - **General**, **Layout**, **Bindings** and **Code** - in the **Web part properties** dialog.

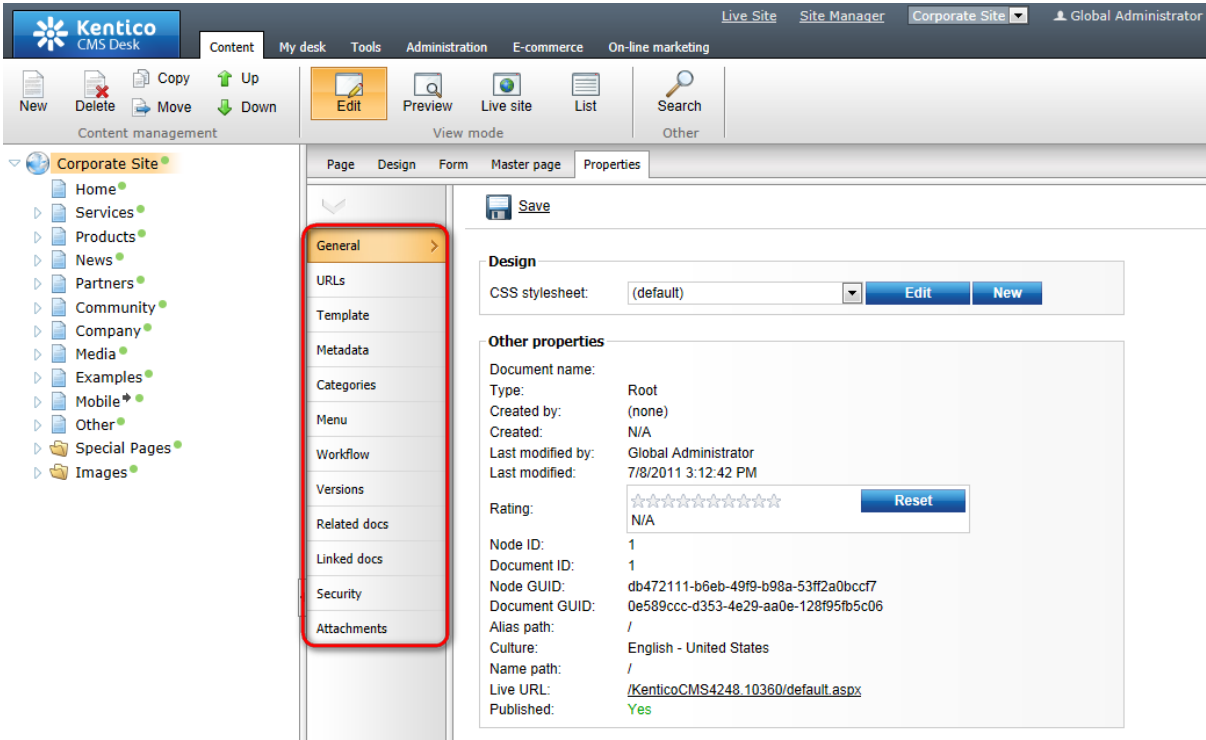

Properties tab

You can hide all items in the left menu on the **Properties** tab. You can also hide particular parts of the **General**, **URLs**, **Template**, **Metadata**, **Navigation** and **Security** pages. More information can be found on [this page](#).

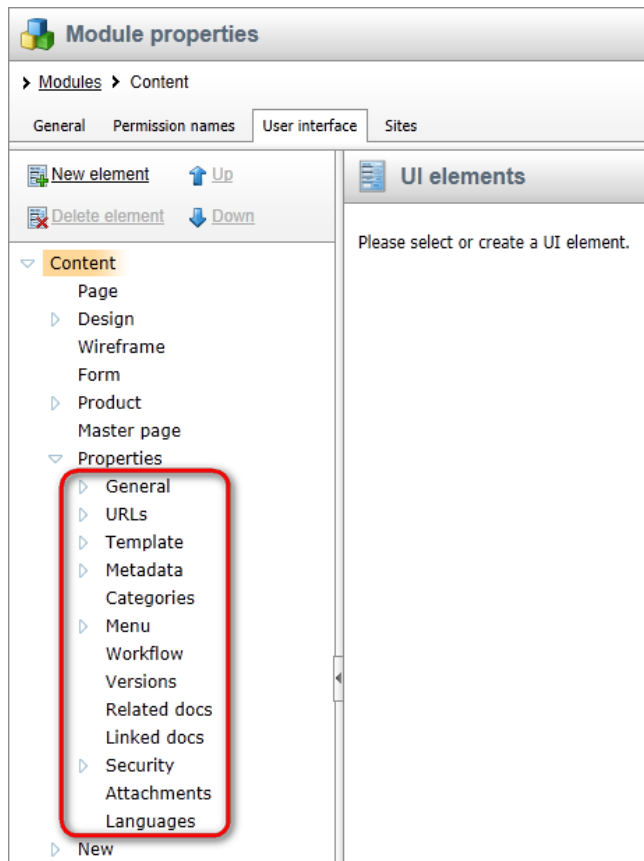

7.13.6.4.4 CMS Desk -> Content -> Edit -> Properties tab

This chapter describes UI personalization possibilities for the **Content -> Edit -> Properties** tab of a document.

First of all, you can hide all items in the left menu on the **Properties** tab as highlighted in the screenshot below.

In the **Content** module, you can find the relevant UI elements under the **Properties** node. These elements have the same names as the names of particular menu items.

You can also expand the **General**, **URLs**, **Template**, **Metadata**, **Navigation** and **Security** UI elements using the  icon in order to display their child UI elements. These child UI elements represent parts of the relevant pages as described in the text below:

General tab

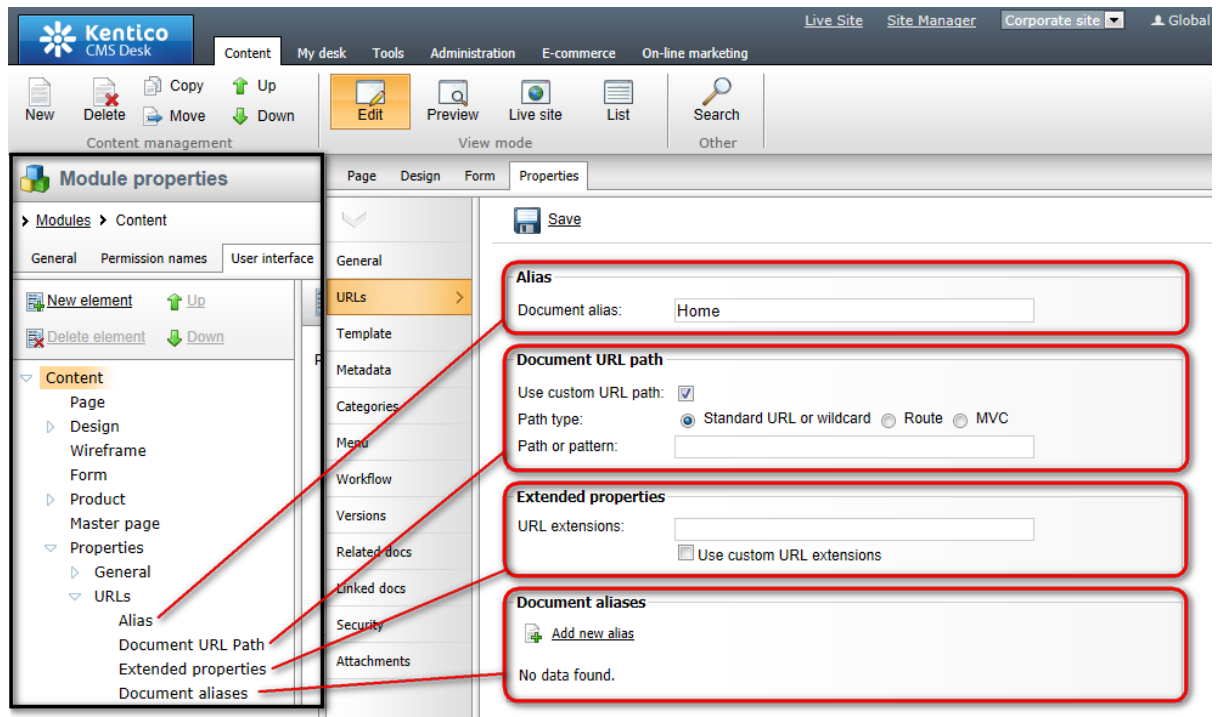

The **General** tab consists of the **Design**, **Other properties**, **Owner**, **Cache** and **Advanced** sections. The related UI elements have the same names as these sections, as you can see in the following screenshot:

The screenshot displays the Kentico CMS interface with the 'Module properties' dialog box open for a 'Content' module. The dialog is organized into several sections, each highlighted with a red box and connected to the 'Module properties' tree on the left by red arrows:

- Design:** Includes a 'CSS stylesheet' dropdown menu set to '(default)', with 'Edit' and 'New' buttons.
- Other properties:** Displays document metadata:
 - Document name: Root
 - Type: (none)
 - Created by: N/A
 - Created: N/A
 - Last modified by: Global Administrator
 - Last modified: 7/8/2011 3:12:42 PM
 - Rating: N/A (with a star rating bar and a 'Reset' button)
 - Node ID: 1
 - Document ID: 1
 - Node GUID: db472111-b6eb-49f9-b98a-53ff2a0bcc7
 - Document GUID: 0e589ccc-d353-4e29-aa0e-128f95fb5c06
 - Alias path: /
 - Culture: English - United States
 - Name path: /
 - Live URL: /KenticoCMS4248.10360/default.aspx
 - Published: Yes
- Owner:** Includes an 'Owner' text field with 'Select' and 'Clear' buttons, and an 'Owned by group' text field with a 'Change' button.
- Output cache:** Features radio buttons for 'Yes' and 'No' (selected), a 'Cache minutes' text field, and a 'Clear output cache' button.
- Search:** Contains a checkbox labeled 'Exclude this document from search'.
- On-line marketing:** Includes a checked checkbox for 'Log on-line marketing activity' and an 'Inherit' checkbox.
- Advanced:** Contains a link for 'Edit regions & web parts'.

URLs tab

The URLs tab consists of the **Path**, **Extended properties** and **Document aliases** sections. The related UI elements have the same names as these sections, as you can see in the following screenshot:

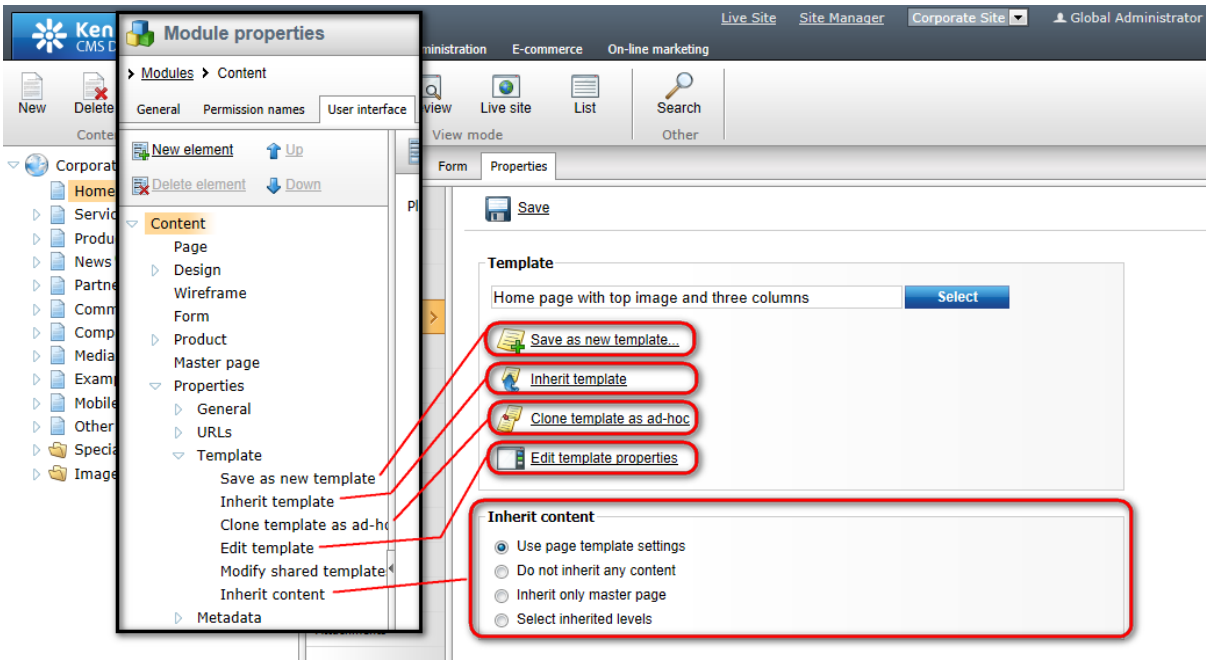

Template tab

On the **Template** tab, you can hide the **Save as new template**, **Clone template as ad-hoc** and **Edit template properties** actions. These actions are represented by the UI elements with the same names, as you can see in the screenshot below.

You can also hide the whole **Inherit content** section using the UI element with the same name.

The **Modify shared templates** UI element works as a permission: it determines if the users can modify shared page templates both from here and on the **Design** tab.

Metadata tab

The Metadata tab consists of two main sections. The **Page settings** section is represented by the **Page title, description, keywords** UI element. The **Tags** section is represented by the **Tags** UI element.

The screenshot displays the Kentico CMS 7.0 Developer's Guide interface. The top navigation bar includes 'Live Site', 'Site Manager', and 'Corporate Site'. The main toolbar contains icons for 'New', 'Delete', 'Copy', 'Move', 'Up', 'Down', 'Edit', 'Preview', 'Live site', 'List', and 'Search'. The 'Properties' tab is active, showing a 'Save' button and two sections: 'Page settings' and 'Tags'. The 'Page settings' section includes fields for 'Page title', 'Page description', and 'Page keywords', each with an 'Inherit' checkbox. The 'Tags' section includes a 'Page tag group' dropdown, an 'Inherit' checkbox, and a 'Page tags' field with a 'Select' button. A 'Module properties' dialog box is open on the left, showing a tree view of the site structure. Red boxes highlight the 'Page settings' and 'Tags' sections, and red arrows point from the 'Page title, description, tags' and 'Tags' items in the tree view to their respective sections in the 'Properties' tab.

Navigation tab

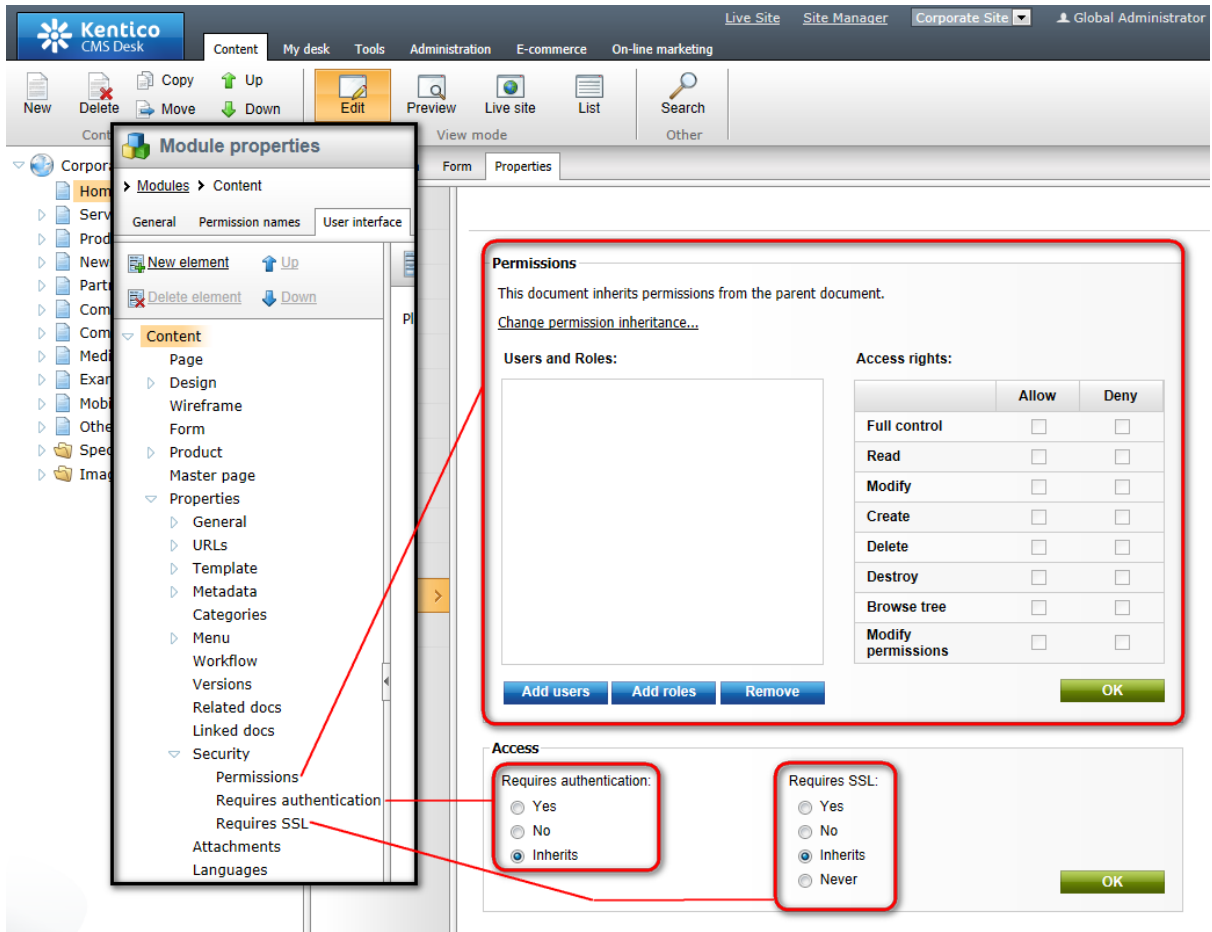

The **Navigation** tab consists of three sections - **Basic properties**, **Menu actions**, **Search**, **Menu design** - while these sections are represented by UI elements with the same names as shown in the following screenshot:

The screenshot displays the Kentico CMS Desk interface. The 'Module properties' dialog is open for a 'Content' module. The left-hand pane shows a tree view with the 'Menu' folder selected. The main area is divided into three sections, each highlighted with a red box:

- Basic properties:** Contains fields for 'Menu caption', 'Show in navigation' (checked), and 'Show in sitemap' (checked).
- Menu actions:** Contains radio buttons for 'Standard behavior' (selected), 'Inactive menu item', and 'Javascript command'. Below the 'Javascript command' is a text input field with an example: `alert('hello');return false;`. There is also a radio button for 'URL redirection' with an example: `http://www.mydomainxy.com or ~/products.aspx`.
- Menu design:** Contains a section for 'Menu item design' with input fields for 'Menu item style', 'Menu item CSS class', 'Menu item left image', 'Menu item image', and 'Menu item right image'.

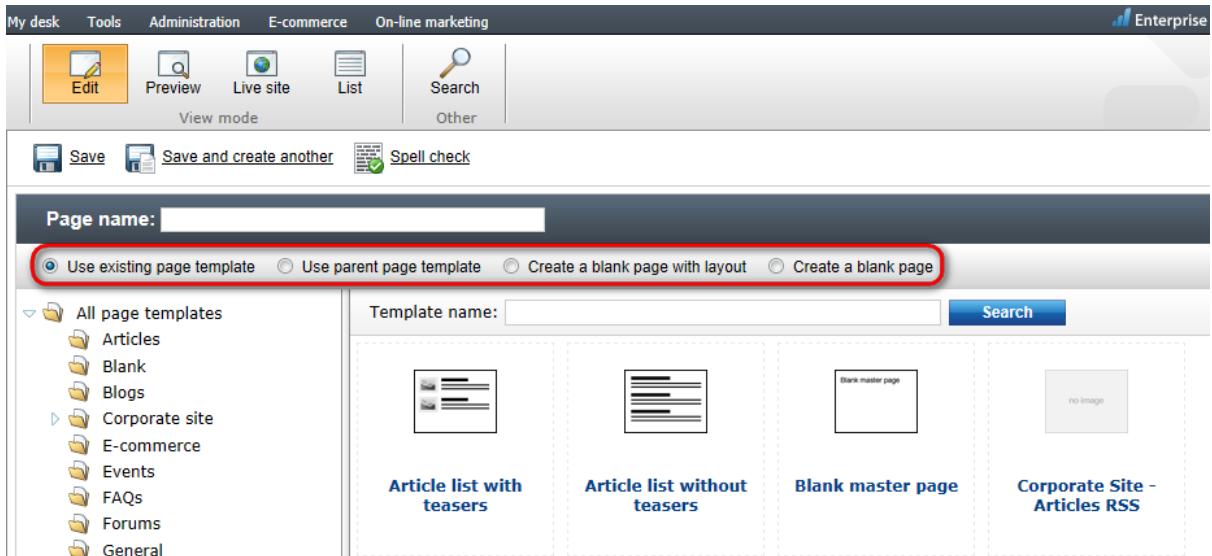

Security tab

The **Security** tab consists of the **Permissions** section, which is represented by the **Permissions** UI element, and the **Access** section, which is divided into two UI element - **Requires authentication** and **Requires SSL**:

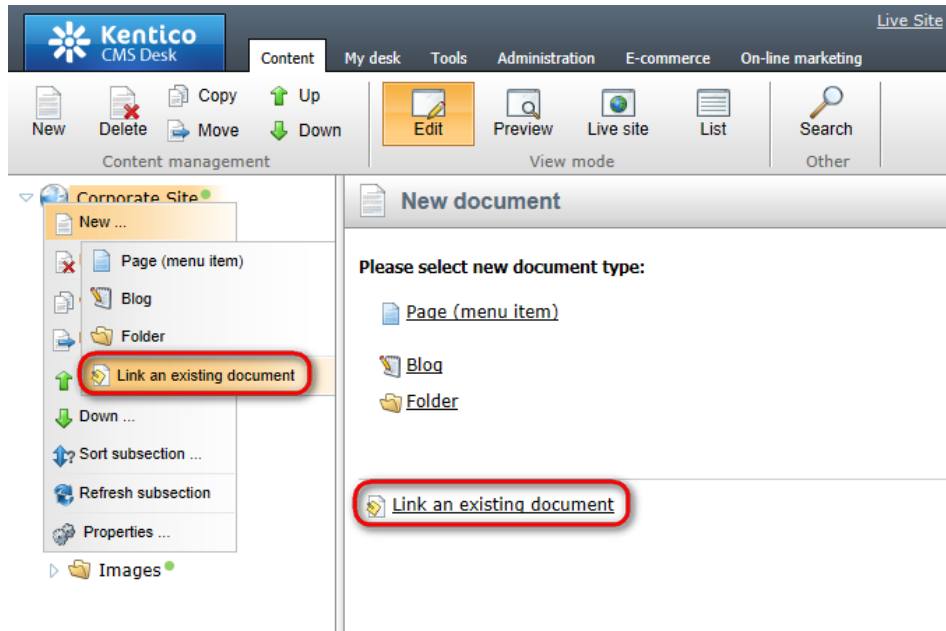

7.13.6.4.5 CMS Desk -> Content -> New

You can hide individual UI elements which are used when choosing a page template while creating a document.

You can also hide the **Link an existing document** link from:

- Context menu
- Document type selection page
- Drag & Drop operation

The list of these elements can be found on the **User interface** tab in **Site Manager -> Development -> Modules -> Edit () Content**.

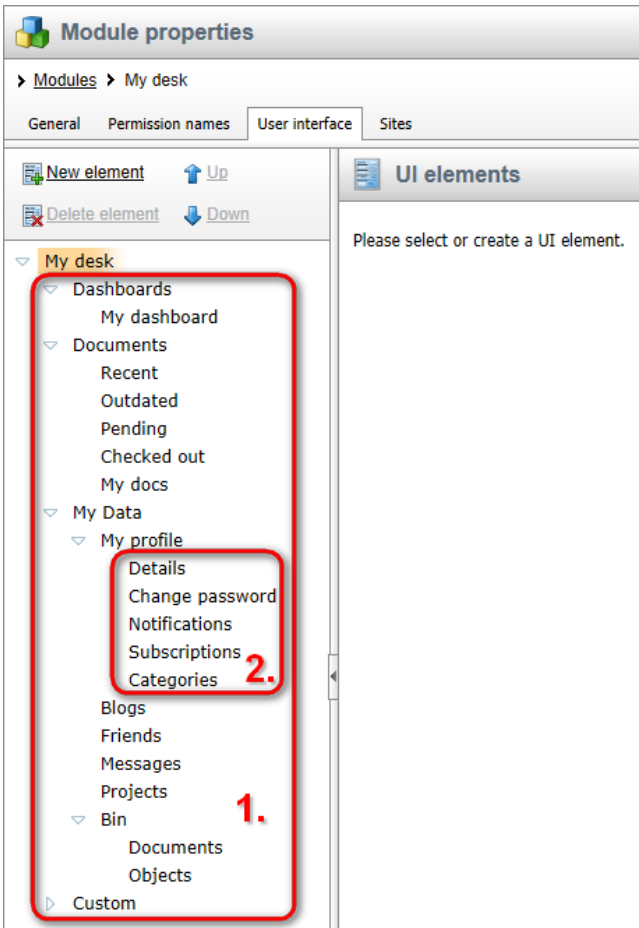

7.13.6.4.6 CMS Desk -> My desk tab

You can hide individual items or entire item groups in the top ribbon menu (1.) of My Desk. Additionally, you can also hide all five tabs of the **My profile** section (2.).

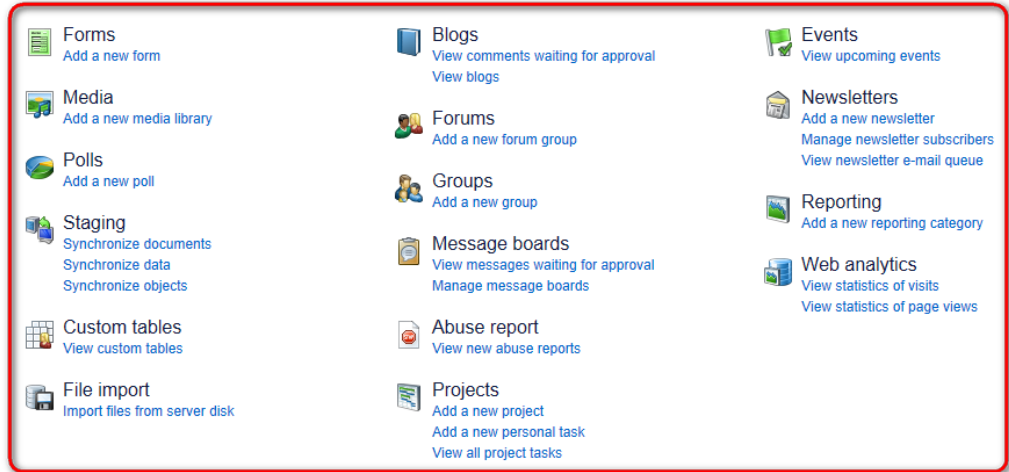

In the screenshot below, you can see the UI elements of the **My desk** module. Their names match the names of the menu items and tabs on the screenshot above.

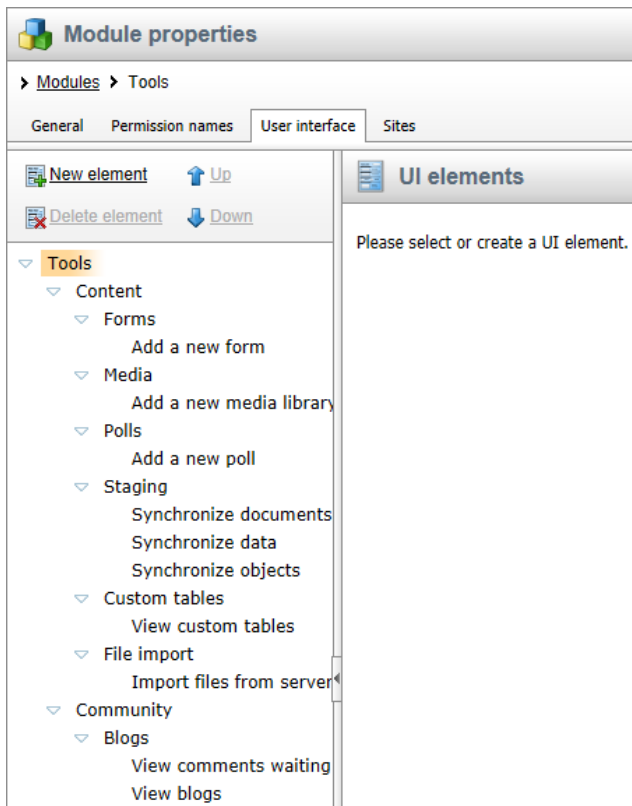

7.13.6.4.7 CMS Desk -> Tools tab

You can hide any item in the Tools ribbon and panel menu as highlighted in the following screenshot. Please note that the first-level UI elements, i.e. Content, Community etc., are not displayed in the panel menu:

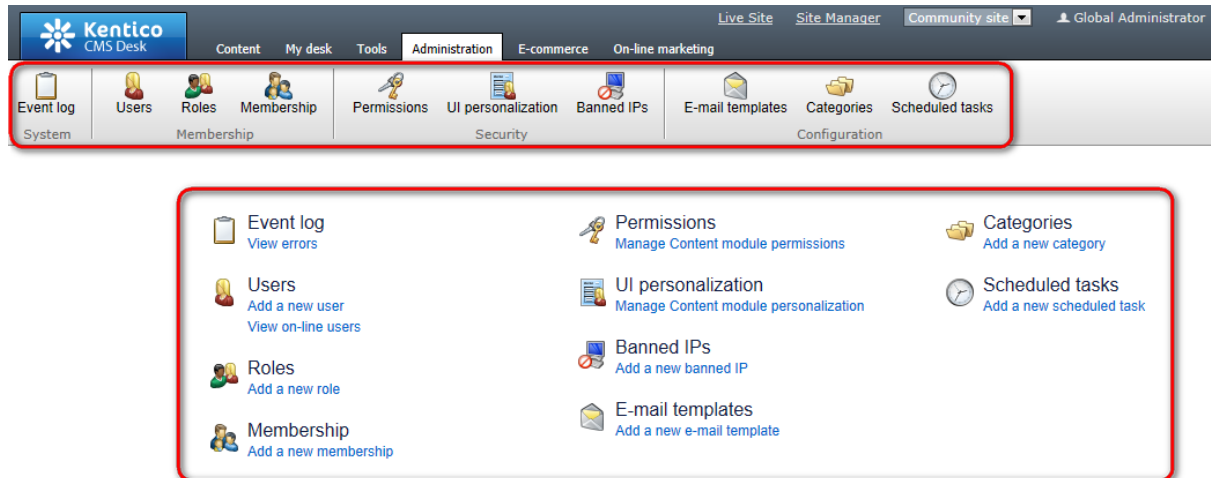

The Tools module has UI elements with the same names as the ribbon and panel menu items in the screenshot above.

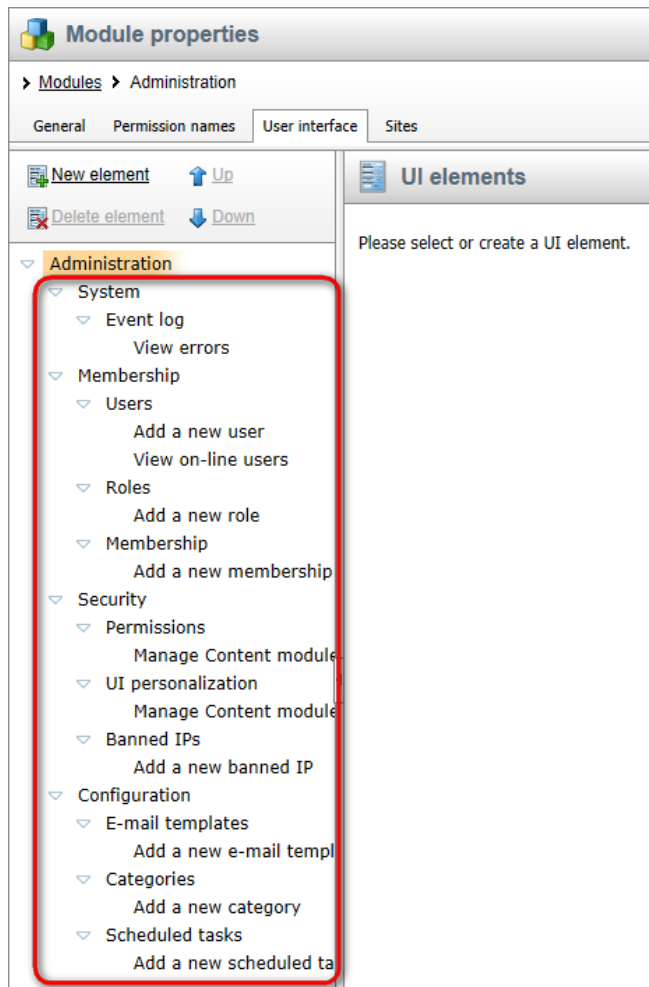

7.13.6.4.8 CMS Desk -> Administration tab

You can hide any item in the Administration ribbon and panel menu as highlighted in the following screenshot. Please note that the first-level UI elements, i.e. System, Membership etc., are not displayed in the panel menu:

The Administration module has UI elements with the same names as the ribbon and panel menu items in the screenshot above.

7.13.6.4.9 CMS Desk -> E-commerce tab

To learn how to customize your **CMS Desk -> E-commerce** tab, please refer to the [UI personalization](#) topic in the Security section of the E-commerce Guide.

7.13.6.4.10 WYSIWYG editor

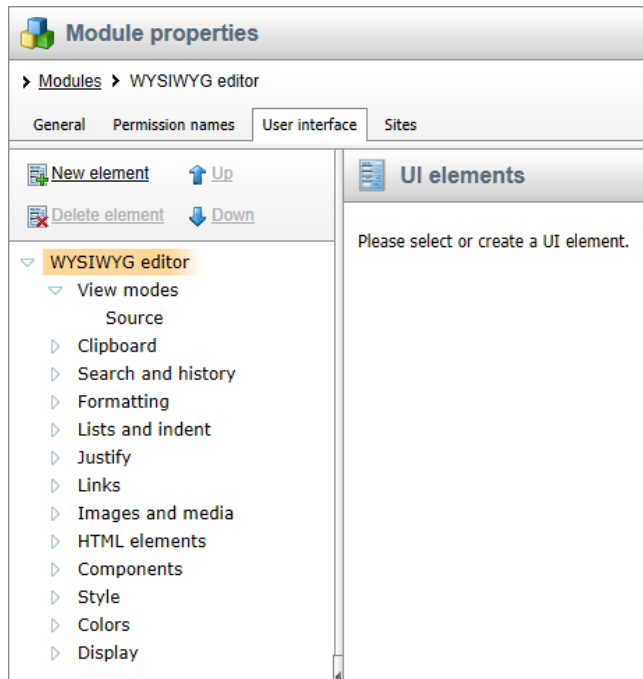

All action buttons on the [WYSIWYG editor](#) toolbar can be hidden. This can be particularly useful for content editors who do not need to use all these actions.

The **WYSIWYG editor** module has many UI elements grouped under several parent UI elements. The parent elements serve only for categorization purposes and do not represent any action buttons in the toolbar. You can display the sub-elements by clicking the  icon next to a particular UI element.

UI element names match tooltips displayed when you place your cursor over a particular

button in the WYSIWYG editor toolbar.

Custom toolbar actions

If you use your custom plug-in in the WYSIWYG editor and want its action button to be displayed or hidden based on UI profile settings, you need to create a new UI element in the WYSIWYG Editor module with the same code name as the code name of the plug-in.

How it works

1. Action buttons are loaded into the toolbar based on the [toolbar definition](#).
2. If UI personalization is enabled, action buttons get filtered according to the user's UI profile.

This means that only such UI elements are displayed in the toolbar that are available both in the user's UI profile and in the toolbar definition.

Toolbar personalization on the live site

Toolbar personalization on the live site is disabled by default. To change this, you need to enable it in your web.config file by adding the following key to the `/configuration/appSettings` section:

```
<add key="CKEditor:PersonalizeToolbarOnLiveSite" value="true" />
```

Once this is done, all UI personalization settings will be applied to the WYSIWYG editor on the live site.

More web.config settings can be found in [Appendix B - Web.config parameters -> WYSIWYG editor settings](#).

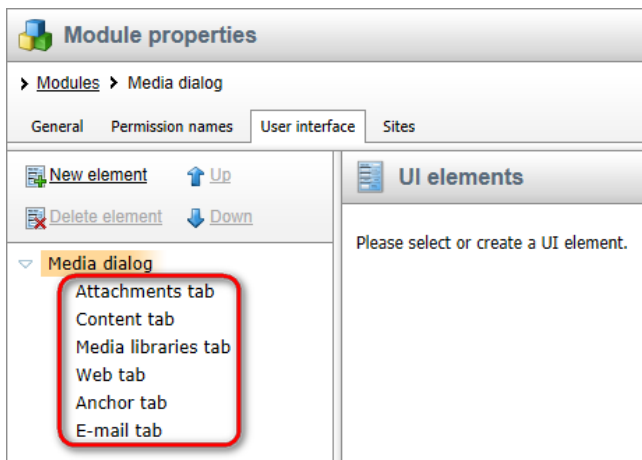

7.13.6.4.11 Media dialog

This dialog is displayed e.g. when using the [Insert image or media](#) or [Insert link](#) actions in the WYSIWYG editor or when selecting an image in the **Editable image** web part.

You can hide the dialog's tabs - **Attachments, Content, Media libraries, Web, Anchor** and **E-mail**.

UI elements are defined centrally in the **Media dialog** module. They are applied to all occurrences and versions of the dialog, even though some of these tabs are not displayed in all cases (e.g. the E-mail tab is not displayed in Insert image or media dialog).

7.13.6.5 Enabling UI personalization

For UI personalization to be functional, you need to go to **Site Manager -> Settings -> Security & Membership** and enable it using the **Enable UI personalization** check-box.

Using the **Site** drop-down, you can decide if you want to turn it on globally, or just for some particular sites in the system.

The screenshot shows the Kentico Site Manager Administration interface. The left sidebar contains a navigation tree with 'Security & Membership' selected. The main content area is divided into several sections:

- General Settings:** Deny login interval (10), Share user accounts on all sites (checked).
- Registrations:** Reserved user names (admin;root;administrator;sysadmin;sa), Registration requires e-mail confirmation (unchecked), Registration requires administrator's approval (unchecked), Delete non-activated user after (days) (5), Require unique user e-mails (checked).
- On-line users:** Monitor on-line users (unchecked), Store on-line users in database (unchecked), Update on-line users (minutes) (1).
- Content:** Check page permissions (Secured areas), Website logon page URL (~~/cmspages/logon.aspx), Access denied page URL.
- Administration:** Use SSL for administration interface (unchecked), **Enable UI personalization (checked)** (highlighted with a red circle).

7.13.6.6 UI profile configuration

In the following step-by-step example, you will learn how to define UI profile for a new role in **Site Manager** -> **Administration** -> **UI personalization**.

Let's presume that we want some users to be **Forum administrators** of our website. This means that they will not need to use the **Content** or **Administration** tabs at all, all they will be concerned about is the [Forums module](#) administration interface in the **Tools** menu and a few parts of the **My desk** section.

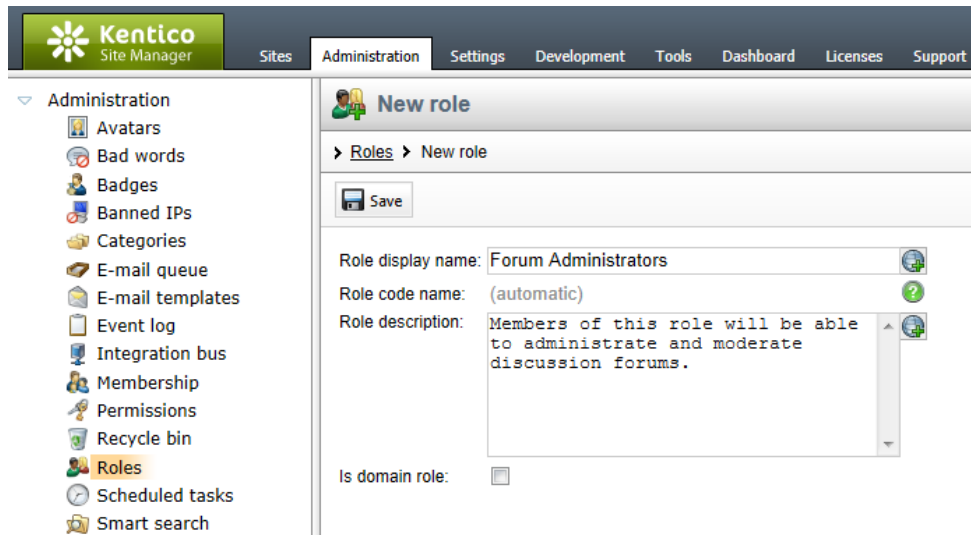

How to achieve it? We will create a new role and a new user who will be a member of this role only. Then we will define UI profile settings for this role and try logging in as the new user to see the simplified UI.

1. Install some of the sample sites or your own site and enable UI personalization for the site as described [here](#).

2. Go to **Site Manager** -> **Administration** -> **Roles**, choose your site in the **Site** drop-down and click on **New role** (👤). In the following dialog, enter these details:

- **Role display name:** Forum Administrators
- **Role description:** text describing the role
- **Is domain role:** leave the field unchecked

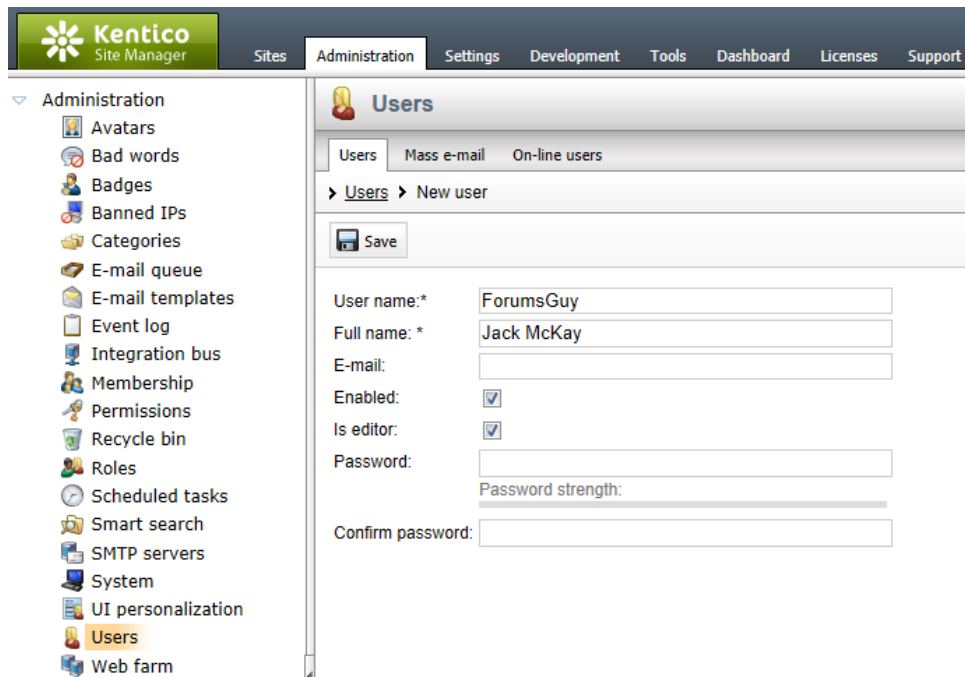

Click  **Save**.

3. Now let's create the user. Go to **Site Manager -> Administration -> Users** and click  **New user**. Enter the following details in the New user dialog:

- **User name:** ForumsGuy
- **Full name:** Jack McKay
- **Enabled:** enabled
- **Is editor:** enabled

Click  **Save**.

4. You will be redirected to the new user's editing interface. We first need to assign the user to our site.

Go to the **Sites** tab and add the site using the **Add sites** button.

The screenshot shows the Kentico Site Manager Administration interface. The left sidebar lists various administration tasks, with 'Users' highlighted. The main content area is titled 'Users' and shows the 'Users' tab selected. The breadcrumb path is 'Users > ForumsGuy'. Below this, the 'Sites' tab is active, showing a table of sites assigned to the user. The table has columns for 'Site name' and 'Add sites'. The 'Corporate Site' is listed with a checkbox and a blue 'Add sites' button. A message above the table states 'The changes were saved. The user is available for the following websites:'.

5. Now that the user belongs to our site, we can assign him to the **Forum Administrators** role, which also belongs to the site. Switch to the **Roles** tab, select your site from the **Site** drop-down list and use the **Add role** button to add the Forum Administrators role.

The screenshot shows the same Kentico Site Manager Administration interface, but now the 'Roles' tab is selected. The breadcrumb path is 'Users > ForumsGuy'. The 'Roles' tab is active, showing a dropdown menu for 'Site' set to 'Corporate Site'. Below this, a table lists roles assigned to the user. The table has columns for 'Action', 'Roles', and 'Valid to'. The 'Forum Administrators' role is listed with a checkbox and a blue 'Add roles' button. A message above the table states 'The user is member of the following roles:'.

6. Now that the user belongs to our role, we can set up UI personalization for the role. Go to **Site Manager -> Administration -> UI personalization** and choose:

- **Site:** your site
- **Role:** Forum Administrators

Please note: UI personalization settings are **site-related** unless they are defined for global roles. This means that members of one site-specific role can see a certain personalized UI when editing one site and a completely different UI when editing another site. More information on how UI personalization works can be found [here](#).

You can choose the module whose UI elements you want to set up using the **Module** drop-down. Full reference on the personalizable parts of CMS Desk and the appropriate modules can be found [here](#).

7. Let's start with the main tabs in CMS Desk, where we want only the **My desk** and **Tools** tabs visible. Choose **Module:** CMS Desk and make the following settings:

- **Content:** disabled
- **My desk:** enabled
- **Tools:** enabled
- **Administration:** disabled

The screenshot shows the Kentico CMS 7.0 Administration interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The left sidebar lists various administration modules, with 'UI personalization' highlighted. The main content area displays the 'UI personalization' settings for the 'Editor' dialog. The settings are as follows:

| Field | Value |
|---------|----------------------|
| Site: | Corporate Site |
| Role: | Forum Administrators |
| Module: | CMS Desk |

Below the settings, there are 'Expand all' and 'Collapse all' buttons. Under the 'CMS Desk (select all, unselect all)' section, the following modules are listed with their respective checkboxes:

- Content
- My desk
- Tools
- Administration
- E-commerce
- On-line marketing

8. On the My desk tab, we will need only the Account, Messages and Friends sections, all others are not needed for forum administrators. Choose **Module:** My Desk and enable only the UI elements listed below, do not enable the rest.

- **My data:** enabled
- **Account:** enabled
 - **Details:** enabled
 - **Change password:** enabled
 - **Notifications:** enabled
 - **Subscriptions:** enabled

- **Friends:** enabled
- **Messages:** enabled

The screenshot shows the Kentico Site Manager Administration interface. The left sidebar lists various administration options, with 'UI personalization' highlighted. The main content area displays the 'UI personalization' settings for the 'Corporate Site' site, under the 'Forum Administrators' role, for the 'My desk' module. The settings are organized into a tree view with expand/collapse options.

UI personalization

Dialogs: Editor

Site: Corporate Site

Role: Forum Administrators

Module: My desk

[Expand all](#) [Collapse all](#)

- My desk (select all, unselect all)
 - Dashboards (select all, unselect all)
 - My dashboard
 - Documents (select all, unselect all)
 - Recent
 - Outdated
 - Pending
 - Checked out
 - My docs
 - My Data (select all, unselect all)
 - My profile (select all, unselect all)
 - Details
 - Change password
 - Notifications
 - Subscriptions
 - Categories
 - Blogs
 - Friends
 - Messages
 - Projects
 - Bin (select all, unselect all)
 - Documents
 - Objects
 - Custom (select all, unselect all)

9. Finally, we need only the **Forums** option in the **Tools** menu. Choose **Module:** Tools and enable only the **Community** and **Tools** UI elements as you can see in the screenshot below. Leave all the remaining UI elements disabled.

The screenshot displays the Kentico Site Manager Administration interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The left sidebar lists various administration categories, with 'UI personalization' highlighted. The main content area is titled 'UI personalization' and shows configuration options for 'Dialogs' and 'Editor'. The 'Editor' tab is active, showing a 'Site' dropdown set to 'Corporate site', a 'Role' dropdown set to 'Forum Administrators', and a 'Module' dropdown set to 'Tools'. Below these options are 'Expand all' and 'Collapse all' buttons. The 'Tools' module is expanded, showing a tree view of sub-modules with checkboxes for selection. The 'Community' and 'Forums' sub-modules are checked.

- Administration
 - Avatars
 - Bad words
 - Badges
 - Banned IPs
 - Categories
 - E-mail queue
 - E-mail templates
 - Event log
 - Integration bus
 - Membership
 - Permissions
 - Recycle bin
 - Roles
 - Scheduled tasks
 - Smart search
 - SMTP servers
 - System
 - UI personalization**
 - Users
 - Web farm

UI personalization

Dialogs Editor

Site: Corporate site

Role: Forum Administrators

Module: Tools

[Expand all](#) [Collapse all](#)

- Tools (select all, unselect all)
 - Content (select all, unselect all)
 - Forms (select all, unselect all)
 - Media (select all, unselect all)
 - Polls (select all, unselect all)
 - Staging (select all, unselect all)
 - Custom tables (select all, unselect all)
 - File import (select all, unselect all)
 - Community (select all, unselect all)
 - Blogs (select all, unselect all)
 - Forums (select all, unselect all)
 - Groups (select all, unselect all)
 - Message boards (select all, unselect all)
 - Abuse report (select all, unselect all)
 - Collaboration (select all, unselect all)
 - Projects (select all, unselect all)
 - Events (select all, unselect all)
 - Marketing & Reports (select all, unselect all)
 - Newsletters (select all, unselect all)
 - Reporting (select all, unselect all)
 - Web analytics (select all, unselect all)

10. We can now verify what we have achieved. Log out of **Site Manager** and log back in to **CMS Desk** as the *ForumsGuy* user created in step 3. You will see the a simplified user interface as in the following screenshot.

If you switch to the **Tools** tab, there is only the **Forums** menu item present. It is evident that this UI is much easier to understand for a first-time end user.

7.13.6.7 UI element management

7.13.6.7.1 UI element management

The Kentico CMS user interface consists of modules. Modules contain particular UI elements. UI element is a page or part of a page in CMS Desk which can be hidden from a specified user. It can be:

- **tab**
- **menu item**
- **group of controls**

UI elements of a particular module can be edited or added in **Site Manager -> Development ->**

Modules. This is where you can see a list of all modules in the system. For information on which module represents which parts of the CMS, please refer to the [Personalizable parts of CMS Desk](#) chapter.

| Actions | Module name |
|---------|--------------------|
| | Abuse report |
| | Administration |
| | Bad words |
| | Badges |
| | Banned IPs |
| | Blogs |
| | Categories |
| | CMS Desk |
| | Community |
| | Contact management |
| | Content |
| | Custom tables |
| | Design |

If you want to manage UI elements of some module, click the **Edit** () icon next to the module and switch to the **User interface** tab. On the **User interface** tab, you can see all UI elements of the module in the tree on the left.

- You can re-order UI elements using the **Up** () and **Down** () buttons. This order will then be reflected in the real UI for tabs and menu items. Parts of pages (groups of controls) cannot be re-ordered this way.
- You can delete existing elements using the **Delete element** () button.
- New elements can be created using the **New element** () button (see the [example](#)), while the new element is always created under the currently selected node.

Settings for each UI element are divided into two tabs - **General** and **Roles**.

On the **General** tab, you can set the following properties of the UI element.

- **Display name** - the name of the element displayed in the administration interface (i.e. in the settings, not in the final UI). It can be entered either as plain text or as a localizable string in the `{mystringname$}` format.
- **Code name** - the name of the element used by developers in website code. It must be unique within a module.
- **Parent element** - using this drop-down list, you can change the hierarchical position of the element in the UI elements tree for this module. You can select either the name of the module (which places the element under the root) or one of the other UI elements (which places the element under the

selected element).

- **Element is custom** - if false, the element is a native part of Kentico CMS. Set this value to *TRUE* for your custom UI elements.

Menu item settings

- **Caption** - the caption of the UI element displayed in the final UI. It can be entered either as plain text or as a localizable string in the `{${mystringname$}}` format.
- **Target URL** - URL of the page which is the content of the UI element. You can enter both absolute (e.g. `http://www.google.com`) and relative (e.g. `~/CMSModules/Content/CMSDesk/Default.aspx`) URLs.
- **Icon path** - the icon displayed next to the UI element caption - applicable **only for menu items**. You can enter either a full relative path beginning with `~` (e.g. `~/App_Themes/Default/Images/CMSModules/list.png`) or a short path beginning under the *Images* folder of the current skin (e.g. `CMSModules/list.png`).
- **Description** - the description of the UI element.
- **Size** - the size of the UI element icon. Takes effect only for UI elements which are included in a ribbon-like toolbar.

Localization expressions, i.e. **Localize other languages** (🌐), **Remove localization** (✖) and **Localize** (🌐), are described in detail in the [Localization expressions](#) topic in the Development -> Multilingual and international support section.

On the **Roles** tab, you can directly configure which roles will be able to see the selected UI element. All roles belonging to the site selected in the **Site** drop-down list will be displayed in the matrix. The (*global*) option can be selected to configure global roles, i.e. those that are not limited to a single site.

UI personalization configuration is then performed the following way:

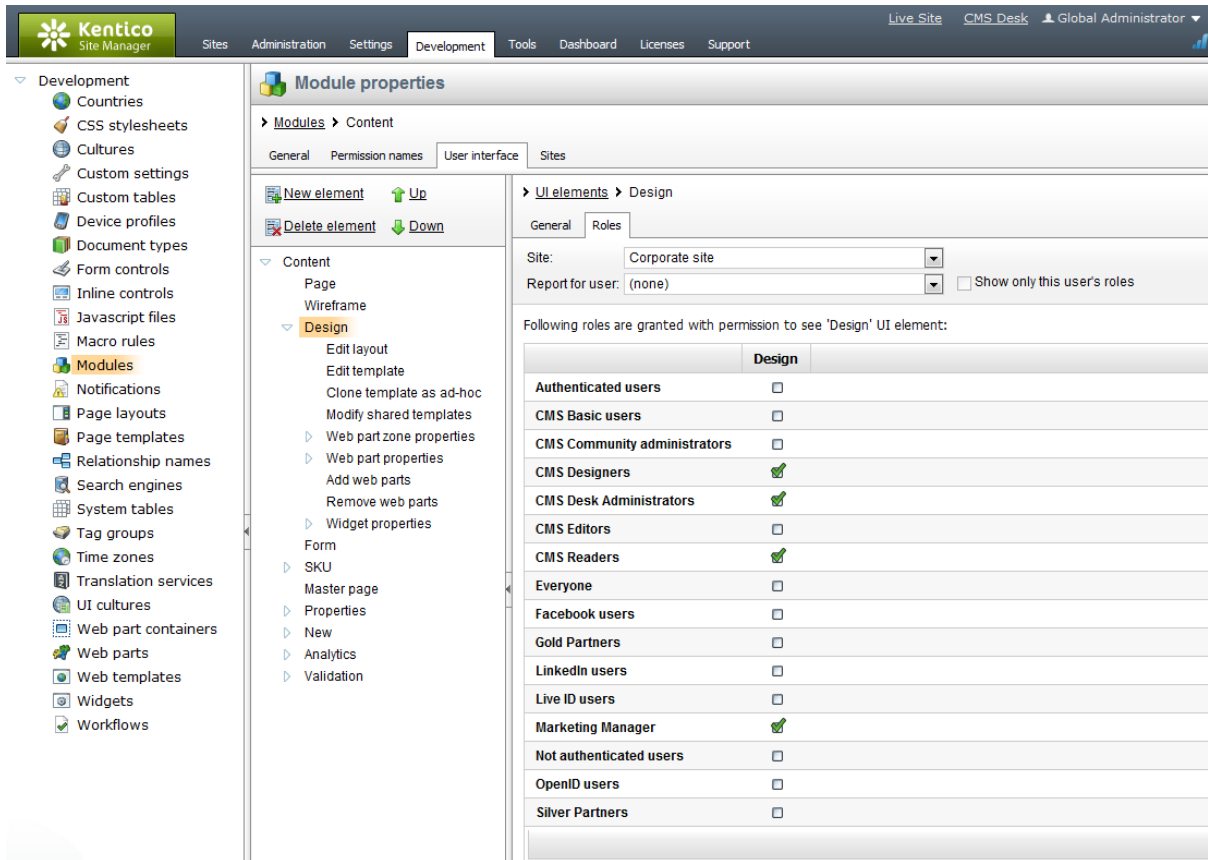

- If you enable (☑) a check-box, the UI element will be visible to members of the role.
- If you disable (☐) a check-box, members of the role will not see the UI element (unless they are

members of some other role which has it allowed).

To have the same UI access permissions like the parent assigned for the given UI element, click  **Copy permissions from parent**. All existing UI element permissions will be deleted and new ones based on the parent settings will be assigned.

Each user's UI profile is defined by UI personalization settings for their roles. If a user wants to see a UI element in the UI, at least one role where the user is member needs to have the UI element set as visible.

To check if a particular element is visible to a user, you can select the user from the **Report for user** drop-down list. After doing so, a sum of all permissions granted to the user's roles is displayed in the first line, highlighted in green color. Roles where the selected user is a member will be highlighted in pink color. If you enable the **Show only this user's roles** check-box, only the pink roles will be displayed in the matrix.

The screenshot shows the 'Module properties' dialog for the 'Design' UI element. The 'Roles' tab is selected, displaying a table of roles and their permissions for the 'Design' element. The 'Report for user' dropdown is set to '(none)'. The 'Show only this user's roles' checkbox is unchecked.

| Role | Design |
|------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> |
| CMS Community administrators | <input type="checkbox"/> |
| CMS Designers | <input checked="" type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> |
| CMS Editors | <input type="checkbox"/> |
| CMS Readers | <input checked="" type="checkbox"/> |
| Everyone | <input type="checkbox"/> |
| Facebook users | <input type="checkbox"/> |
| Gold Partners | <input type="checkbox"/> |
| LinkedIn users | <input type="checkbox"/> |
| Live ID users | <input type="checkbox"/> |
| Marketing Manager | <input checked="" type="checkbox"/> |
| Not authenticated users | <input type="checkbox"/> |
| OpenID users | <input type="checkbox"/> |
| Silver Partners | <input type="checkbox"/> |

Please note

Using  **Copy permissions from parent** affects all available sites, i.e. not only the currently selected one.

Because the root-level UI element cannot have any UI access permissions assigned, the button is disabled for all first-level UI elements.

> [UI elements](#) > Page template selection

General Roles

 Copy permissions from parent

Site: (global)

Report for user: (none) Show only this user's roles

Following roles are granted with permission to see 'Page template selection' UI element:

| | Page template selection |
|------------------------|--------------------------|
| Chat support engineers | <input type="checkbox"/> |

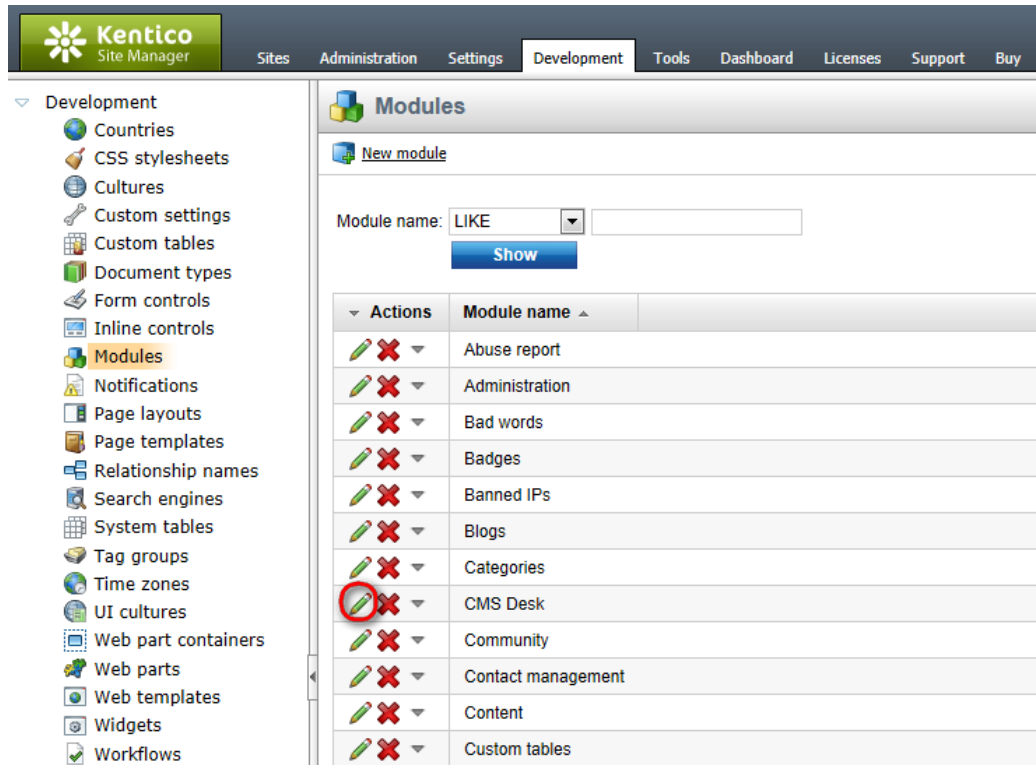

This is just another way to make the same configuration as described in the [UI profile configuration](#) topic, i.e. settings made here are reflected in **Site Manager -> Administration -> UI personalization** (see the screenshot below) and vice-versa.

The screenshot shows the Kentico Site Manager Administration interface. The 'Administration' menu is open, and 'UI personalization' is selected. The 'UI personalization' page has two tabs: 'Dialogs' and 'Editor'. The 'Editor' tab is active, showing configuration for 'E-commerce site', 'CMS Basic users', and 'CMS Desk'. Below the configuration fields are 'Expand all' and 'Collapse all' buttons. A list of modules is shown under 'CMS Desk (select all, unselect all)', with 'Content', 'My desk', and 'Tools' checked, and 'Administration', 'E-commerce', and 'On-line marketing' unchecked.

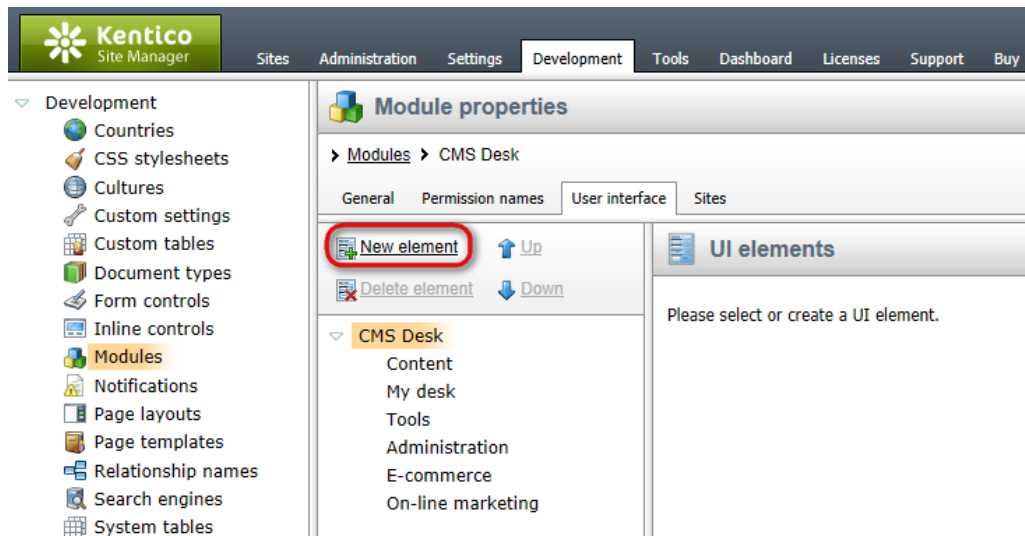

7.13.6.7.2 Example: Adding a new main tab to CMS Desk

In this example, you will learn how to add another tab next to the **Content**, **My desk**, **Tools**, **Administration**, **E-commerce** and **On-line marketing** tabs in **CMS Desk**. This procedure can be used to add your custom UI elements to any other [personalizable part](#) of the CMS. You can also integrate your custom modules into the UI this way, as described [here](#).

1. We know from [this chapter](#) that the main tabs belong to the **CMS Desk** module. Go to **Site Manager -> Development -> Modules** and **Edit** () the **CMS Desk** module.

2. In the module's administration interface, switch to the **User interface** tab. You can see the six UI elements representing the tabs in the tree on the left. Select the root of the tree and click the **New element** () button.

3. In the **New element** dialog, enter the following details:

- **Display name:** *Google*.
- **Code name:** *Google*.
- **Element is custom:** *TRUE*.

- **Caption:** *Go to Google.*
- **Target URL:** *http://www.google.com.*
- **Icon path** - please leave blank (icons can be used only for menu items, not for tabs).
- **Description** - you can leave blank.
- **Size** - either value (this property applies to the size of the UI element icon; takes effect only for UI elements which are included in a ribbon-like toolbar).

and click **OK**. The new UI element will be added to the tree as you can see in the screenshot below.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The 'Development' tab is active. On the left, a tree view shows the 'Development' folder expanded, with 'Modules' selected. The 'Google' element is highlighted under 'CMS Desk'. The main area displays the 'Module properties' dialog for the 'Google' element. The 'User interface' tab is selected, and the 'UI elements' section is expanded to show 'Google'. The 'General' sub-tab is active, showing the following settings:

- Display name: Google
- Code name: Google
- Parent element: CMS Desk
- Element is custom:
- Menu item settings:
 - Caption: Go to google
 - Target URL: http://www.google.com
 - Icon path: (empty)
 - Description: (empty)
- Size: Large Regular

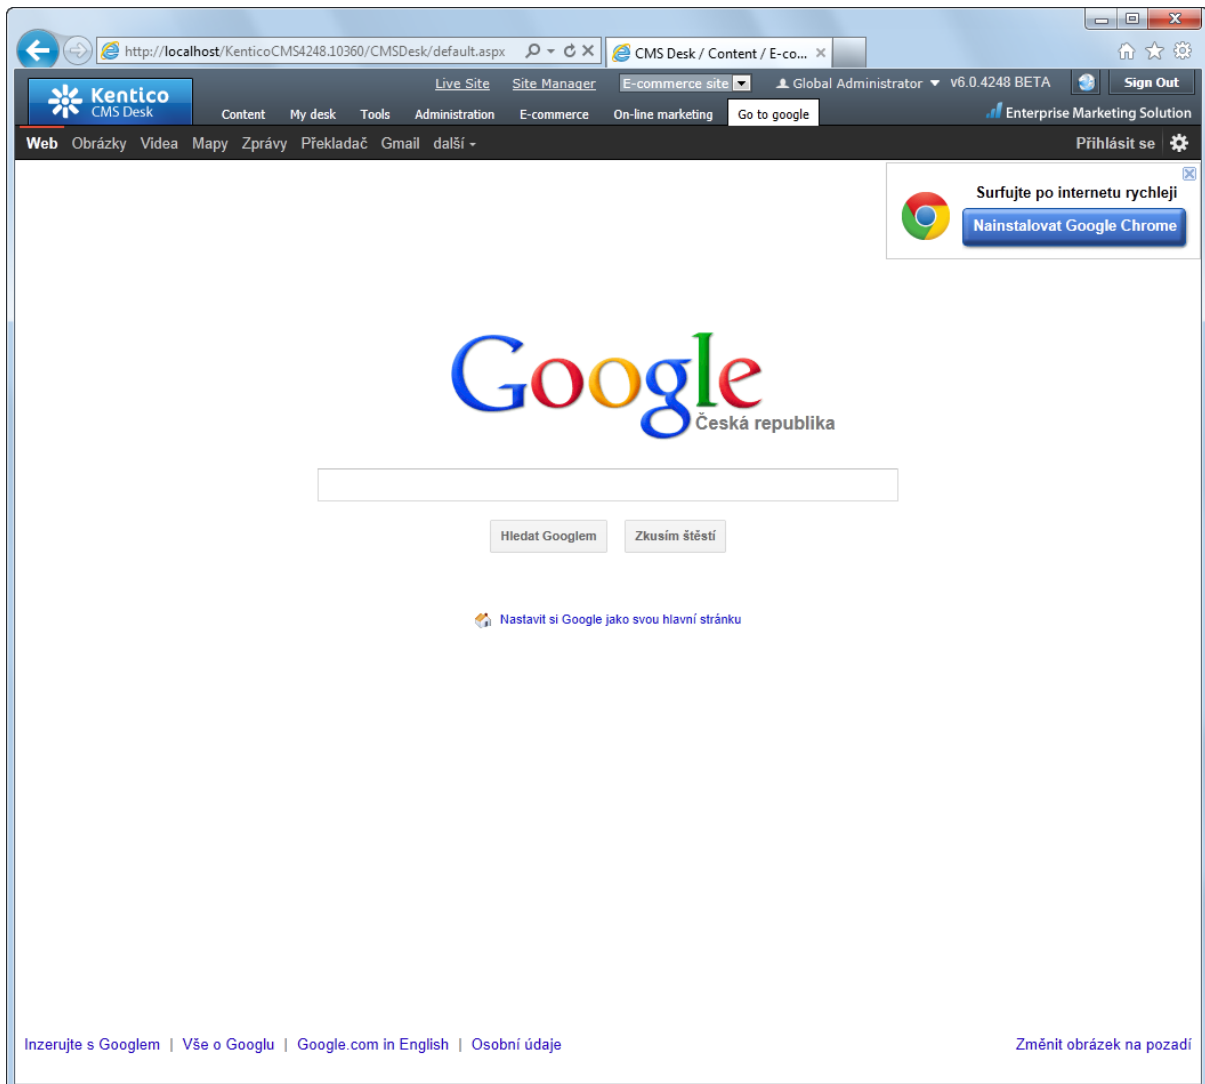

An 'OK' button is visible at the bottom of the dialog. A message at the top of the dialog states: 'The changes were saved.'

4. Switch to the **Roles** tab and enable the UI element for the desired roles.

The screenshot displays the Kentico CMS 7.0 Developer's Guide interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The 'Development' tab is active, and the 'User interface' sub-tab is selected. The main content area shows the 'Module properties' for the 'Google' UI element. The 'Roles' tab is active, showing a list of roles with checkboxes indicating their permissions for the 'Google' UI element. The roles listed are: Authenticated users, CMS Basic users, CMS Community administrators, CMS Designers, CMS Desk Administrators, CMS E-commerce Account Managers, CMS E-commerce Administrators, CMS E-commerce Editors, and CMS Editors. The 'Google' role is highlighted in the left sidebar.

| | Google |
|---------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> |
| CMS Community administrators | <input checked="" type="checkbox"/> |
| CMS Designers | <input checked="" type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> |
| CMS E-commerce Account Managers | <input checked="" type="checkbox"/> |
| CMS E-commerce Administrators | <input checked="" type="checkbox"/> |
| CMS E-commerce Editors | <input checked="" type="checkbox"/> |
| CMS Editors | <input checked="" type="checkbox"/> |

5. Now switch to **CMS Desk**, logged in as a member of one of the roles enabled in the previous step. You will see the new **Go to Google** tab next to the original six tabs as depicted below. If you click the tab, you will be able to view Google title page within your CMS UI.

Please note

If you try to add your own page that needs scrolling, the scrollbars will not be displayed automatically in the top level menu; i.e. under **CMS Desk header tabs**. This is because pages displayed under these tabs handle scrolling in a special way. To enable page scrolling here, it is recommended to create a new **.aspx page** containing a **frameset with just one scrolling-enabled frame** pointing to your page.

7.13.7 Memberships

7.13.7.1 Membership overview

This feature can be used to define special types of user membership for the website (or globally for all sites in the system).

Within the security model of Kentico CMS, membership objects perform a function similar to [roles](#). Users that belong to memberships are authorized to perform certain actions on the website, access secured content or similar. However, memberships do not directly allow individual permissions, but instead group together one or more existing roles. When a membership is assigned, it grants the given user the sum of all permissions defined for the contained roles. To learn how memberships can be created, configured and assigned to users in the administration interface, please proceed to the [Managing memberships](#) topic.

Typically, a membership will be associated with a certain product, which can then be purchased by users through the website's e-commerce features. This will allow them to gain access to restricted sections of the website or other types of premium content for a specified amount of time. For additional information about how you can offer various types of website membership as products, please see the [Product types -> Membership](#) topic in the E-commerce Guide.

Memberships versus roles

Memberships are mainly intended to be used in combination with e-commerce for live site users and customers, or for other specific purposes where an additional security layer that groups together multiple roles is useful.

If you need to define authorization options for different types of users, such as content editors or administrators for specific modules, it is recommended to do so directly using standard roles.

7.13.7.2 Managing memberships

The management interface for memberships can be found in the **Administration -> Membership** section, both in **CMS Desk** and **Site Manager**.

| Actions | Membership name |
|---------|-----------------|
| | Gold Partners |
| | Silver Partners |

Memberships can either be assigned to a specific site or defined as global objects that are available for all sites. In **CMS Desk**, only memberships that belong under the current site can be managed. When in **Site Manager**, you can select the site context using the **Site** drop-down list at the top of the page. To access the list of all global memberships in the system, choose the *(global)* option.

It is possible to edit (✎) or delete (✖) the memberships displayed in the list. New memberships can be created for the selected site (or globally) by clicking  **New membership**. You can specify the following properties when adding a new membership:

- **Membership name** - sets a name for the membership which is displayed in the administration interface.
- **Membership code name** - sets a name that serves as an identifier for the membership.
- **Membership description** - can be used to enter an optional text description for the membership.

There are four tabs available when editing (✎) a membership:

General

On this tab you can edit the same properties that were specified when the membership was created.

Roles

This tab is used to define which roles the membership should contain. When the membership is assigned to a user, it will grant all permissions allowed by the specified roles until it expires.

To add roles, click the **Add roles** button and check the boxes next to the appropriate roles in the displayed selection dialog. Only roles that belong under the same site as the membership can be chosen (global memberships may only contain global roles). Roles can be removed from the membership at any time using the checkboxes in the list together with the **Remove selected** button.

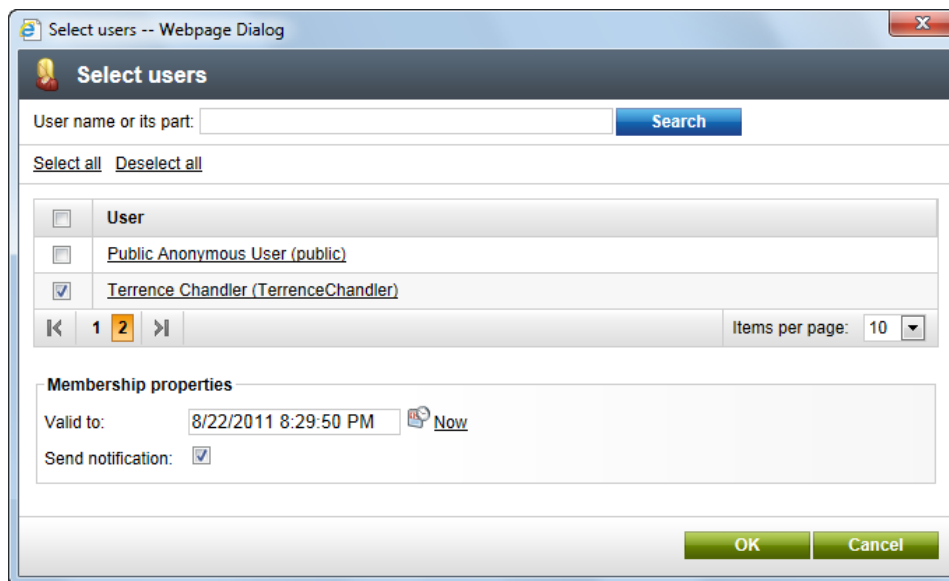

If you need to add a role under multiple memberships, you can save time by navigating to **Administration -> Roles** and editing (✎) the given role on its **Memberships** tab. Here you may easily assign it to any number of memberships using a single action.

Users

Here you can view which users are assigned to the currently edited membership. For as long as their membership is valid, the listed users will be authorized to perform any actions allowed for the roles that the membership contains, as defined on the **Roles** tab.

Typically users will be added automatically when they purchase the membership as a product, so it is not necessary to manually assign them one by one. The purpose of this tab is to allow administrators to monitor the membership and override its settings if necessary.

If you wish to add users, click the **Add users** button and check the boxes next to the appropriate users in the displayed selection dialog.

Only users who are assigned to the same site as the membership can be chosen (global memberships may be assigned to all users in the system). You can enter a name or its part into the textbox above the list and click **Search** to quickly find any user. The **Valid to** field can be used together with the  **Calendar** button to specify the exact date and time when the membership should expire for the given users. If this field is left empty, the users will be assigned to the membership for an unlimited time period. If you set an expiration date for the membership, you can also check the **Send notification** box to enable e-mail reminders that will be sent to the selected users before the membership becomes invalid.

Click **OK** to apply any changes.

The  **Change validity** action that is available for every listed user may be used to prolong or shorten the time interval for which the user should be assigned to the membership. This way you can set an expiration date or reactivate expired memberships for users.

Products

This tab displays a list of products with which the membership is associated, as well as additional

details. When purchased, these products assign the membership to the customer along with the authorization options that it provides. Membership as a type of product is described in the [Product types -> Membership](#) topic of the E-commerce Guide.

Setting memberships for users

It is also possible to directly manage the memberships of individual users via the administration interface in **CMS Desk / Site Manager -> Administration -> Users**. When editing a user, simply switch to the **Membership** tab where you can add or remove memberships to/from the user. Please note that global memberships can only be assigned by global administrators. Using the approach described above, you can set an expiration date for each of the memberships assigned to the user.

Displaying memberships on the live site

The [My account](#) web part from the **Membership -> Logon & Registration** category can be used to allow users to view a summary of their current memberships on the live site. If its **Other tabs -> Display my membership** property is enabled, the web part will display a list of all memberships assigned to the current user and their expiration dates.

The web part may also be configured using its **Memberships -> Memberships page URL** property to generate a link to a page where users can buy new memberships for the website or renew existing ones.

Membership expiration reminders

To help users keep track of their memberships and ensure that they know when it is necessary to renew a paid membership, the module includes an automatic notification feature.

There is a global [scheduled task](#) named **Membership reminder** that periodically checks memberships (once per day by default) and sends a notification e-mail to users whose membership will expire within the amount of days specified by the **Site Manager -> Settings -> Security & Membership -> Send Membership reminder (days)** field. You can configure this task and setting as needed.

The following memberships will expire soon:

- My paid membership, expires 8/17/2011 9:14:01 AM

To renew it, please follow these steps:

1. In My profile section on My memberships tab click the Buy membership button. You will be redirected to the Buy membership page.
2. Choose the required membership and add it to your shopping cart.
3. Finish your order.
4. Once the order is paid, your membership will be renewed.

This is an automatic reminder, please do not respond.
Thank you.

These reminders are only sent for memberships that were assigned with the **Send notification** flag enabled and for those that were purchased as a product with a limited duration. The content of the reminder e-mails is taken from the **Membership - Expiration notification** e-mail template, which can

be edited via the **Administration -> E-mail templates** interface.

When editing this e-mail template, you can use the `{% MembershipsTable %}` [context macro](#) to insert a list of all memberships that will soon expire for the given user. This list must be formatted via a **Text/XML** type [transformation](#), which you can specify through the `ApplyTransformation` method, for example:

```
{%MembershipsTable.ApplyTransformation  
("Ecommerce.Transformations.Order_MembershipsTable")%}
```

In addition to this special macro, you can also use all other standard macro expressions in the templates. See the [Development -> Macro expressions](#) chapter of this guide for more information about macro expressions in Kentico CMS.

7.13.8 Security

7.13.8.1 Secured website areas

Kentico CMS allows you to easily create secured website areas that are accessible only by authenticated users. When an non-authenticated (public) user comes to the secured section, they are redirected to the logon page specified for the site at **Site Manager -> Settings -> Security & Membership -> Website logon page URL**.

You can mark any section of the website as a secured site area by setting **Properties -> Security -> Requires authentication** to:

- **Yes** - page is secured, authentication is required to access it
- **No** - authentication is not required to access the page
- **Inherits** - value of the setting is required from the parent page

Configuration of a secured site area

This example explains how to secure the **Products** section of the sample Corporate Site.

1. Sign in as administrator to **CMS Desk**. Go to the **Content** section and click the **Products** document in the content tree.
2. Click **Properties -> Security**. Set the value of the **Requires authentication** attribute to **Yes** and click **OK**.
3. Go to **Site Manager -> Settings -> Security & Membership** and choose the *Corporate Site* site in the drop-down list. Make sure the **Website logon page URL** is set to *~/SpecialPages/Logon-page.aspx*. This is the URL of the site's logon page. You can either use the system logon page *~/cmspages/logon.aspx* or you can define your own as demonstrated on the sample Corporate Site.
4. Go to **CMS Desk -> Content**, click the *Logon Page* document under the *Special Pages* folder and select the **Design** tab. As you can see, the page is based on the *Corporate Site - Logon page* page template that contains the *Logon form web part* and the *Registration form web part*.

Checking access to page content

Page content is not secured by default, even if the current user is has the **Read** permission denied for the given page. You need to configure this either by setting **Check permissions** to true in the Editable region web part properties (local configuration) or globally by setting the value in **Site Manager -> Settings -> Security & Membership -> Check page permissions** to one of the following values:

- **All pages** - permissions will be checked for all documents on the website.
- **No page** - permissions will not be checked for any documents.
- **Secured areas** - permissions will be checked only for documents that are configured to require authentication.

If a user is not authorized to read a page, the *Access denied* page will be displayed to them. You can configure a custom access denied page by specifying its URL in the **Site Manager -> Settings -> Security & Membership -> Access denied page URL** field.

7.13.8.2 SSL (HTTPS) support

Kentico CMS allows you to specify which of the website's pages should only be accessible over the secured SSL protocol. When a user tries to open such a page with the standard HTTP protocol, they will automatically be redirected to the secured version of the same page (using the **https** URL scheme).

Please note: Kentico CMS does not configure your website for SSL/HTTPS. It may only be used to automatically redirect users to the appropriate URL. You need to perform the configuration itself manually using the standard IIS settings, as described in IIS documentation or in this article: [http://msdn.microsoft.com/cs-cz/magazine/cc301946\(en-us\).aspx](http://msdn.microsoft.com/cs-cz/magazine/cc301946(en-us).aspx)

In order to specify that a page should only be available through the SSL protocol, you need to go to **CMS Desk -> Content** and select the corresponding document in the content tree. Then you can choose one of the following options in **Properties -> Security -> Requires SSL**:

- **Yes** - users attempting to access the page will always be redirected to the HTTPS version of the page's URL.
- **No** - users will not be explicitly redirected to a secured URL when they access the page, but the protocol used in the current URL will remain unchanged (i.e. if a user navigates to the page from another page that is secured, this page will also use SSL).
- **Inherits** - the settings defined for the parent document will be used.
- **Never** - users trying to access the page through a secured URL will be explicitly redirected to the unsecured version of the page.

Securing the administration interface

You may also configure the same functionality for all pages that belong to the administration interface (**CMS Desk** and **Site Manager**). To do this, go to **Site Manager -> Settings -> Security & Membership** and check the **Use SSL for administration interface** field in the **Administration** category.

The screenshot shows the Kentico Site Manager Administration interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The 'Settings' page is displayed for the 'global' site. The left sidebar shows a tree view of settings categories: Content, URLs and SEO, Security & Membership (highlighted), System, On-line marketing, E-commerce, Community, Intranet & Collaboration, Versioning & Synchronization, Integration, and Cloud services. The main content area is divided into several sections: 'Registrations' (with settings for reserved user names, e-mail confirmation, administrator approval, non-activated user deletion, and unique e-mails), 'On-line users' (with settings for monitoring, database storage, and update frequency), 'Content' (with settings for page permissions, logon page URL, and access denied page URL), and 'Administration' (with settings for SSL, UI personalization, and automatic sign-in). The 'Use SSL for administration interface' checkbox in the Administration section is checked and highlighted with a red circle. At the bottom of the settings area, there is a link to 'Export these settings'.

Now all editors and administrators will be redirected to pages using the **https** URL scheme when they log in. Please note that this setting is applied to all sites in the system, so it is only available if you select the (*global*) option from the **Site** drop-down list.

Indirect SSL scenarios

In some cases, SSL decryption and encryption may not be performed directly by your application's server, but instead via a reverse proxy, such as an SSL offload device (for example an SSL accelerator in a load balanced web farm scenario). This means that requests are forwarded to the application internally using the standard HTTP protocol, even when the client accesses the page through HTTPS. If the settings described in the sections above are enabled for the website, it may result in a redirection loop.

You can solve this issue by adding custom code to the application's request handlers. It is necessary to appropriately set the **IsSSL** static property of the **CMS.GlobalHelper.URLHelper** class. If set to *true*, the system will treat all requests as secured, regardless of their URL format, and redirection to HTTPS page versions will not be performed by the application. Of course, it is necessary to correctly identify which requests originally used SSL, e.g. by checking the request headers.

Example

1. Open your web project, expand the **App_Code** folder (or **Old_App_Code** if you installed the project as a web application) and add a new class called **SSLRequestLoader.cs**.
2. Edit the class and add the following references:

[C#]

```
using CMS.SettingsProvider;  
using System.Collections.Specialized;  
using CMS.GlobalHelper;
```

3. Delete the default class declaration and its content. Instead extend the **CMSModuleLoader** partial class and define a new attribute for it as shown below:

[C#]

```
[SSLRequestLoader]  
public partial class CMSModuleLoader  
{  
    /// <summary>  
    /// Module registration  
    /// </summary>  
    private class SSLRequestLoaderAttribute : CMSLoaderAttribute  
    {  
        ...  
    }  
}
```

4. Enter the following code into the **SSLRequestLoaderAttribute** class:

[C#]

```
/// <summary>  
/// Called automatically when the application starts  
/// </summary>  
public override void Init()  
{  
    // Assigns a handler called before each request is processed  
    CMSRequestEvents.Begin.Before += HandleSSLRequests;  
}  
  
// Checks requests if they are forwarded as SSL  
private static void HandleSSLRequests(object sender, EventArgs e)  
{  
    if ((HttpContext.Current != null) && (HttpContext.Current.Request != null))  
    {  
        // Loads the request headers as a collection.  
        NameValueCollection headers = HttpContext.Current.Request.Headers;  
  
        // Gets the value from the X-Forwarded-Ssl header.  
        string forwardedSSL = headers.Get("X-Forwarded-Ssl");  
  
        URLHelper.IsSSL = false;  
    }  
}
```

```
// Checks if the original request used HTTPS.
if (forwardedSSL == "On")
{
    URLHelper.IsSSL = true;
}
}
```

The override of the **Init()** method (executed automatically when the application starts) is used to assign a handler that will be called before each request is processed.

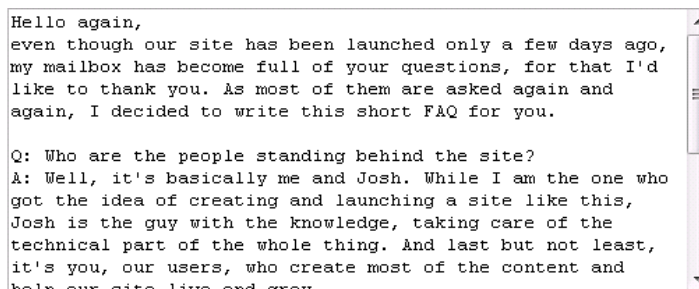

This example uses the **X-Forwarded-Ssl** header to check if the original request was submitted via HTTPS before it was forwarded to the application by the SSL offload device or load balancer. If this is the case, the **IsSSL** property is set to *true* and the system will process the request as if it used the HTTPS protocol.

The proxy device may use a different method to identify requests that were originally secured by SSL, so you will have to write a condition that fits your specific scenario (another typical approach is to check if the value of the **X-Forwarded-Proto** request header is *https*). You may also include additional custom code to fulfill any other security requirements, such as validation of the proxy's IP address.

7.13.8.3 Cross site scripting (XSS)

For your websites to be [Cross site scripting \(XSS\)](#) safe, the following rules need to be followed:

1. **Do not use the built-in WYSIWIG editor (HTML area (Formatted Text) form control)** to allow live site users to enter text (e.g. in user profiles, forums, etc.). Instead, use the **BBcode editor**.

```
Hello again,
even though our site has been launched only a few days ago,
my mailbox has become full of your questions, for that I'd
like to thank you. As most of them are asked again and
again, I decided to write this short FAQ for you.

Q: Who are the people standing behind the site?
A: Well, it's basically me and Josh. While I am the one who
got the idea of creating and launching a site like this,
Josh is the guy with the knowledge, taking care of the
technical part of the whole thing. And last but not least,
it's you, our users, who create most of the content and
help our site live and grow.
```

You can make users use the editor by selecting *BBcode editor* as the value of the **Form control** property when defining fields for document types (or other objects), as shown in the following image.

Document type properties

> Document types > Blog post

General Fields Form Transformations Queries Child types Sites E-commerce Alternative forms Search fields Documents Versions

Allow empty value:

Default value:

Translate field:

Display attribute in the editing form

Field appearance

Field caption:

Form control:

Field description:

Editing control settings

Columns:

Rows:

Size:

Advanced

2. When writing your transformations, use the following method to resolve text entered via the BBcode editor:

```
CMSHelper.CMSContext.ResolveDiscussionMacros(string inputText)
```

3. When writing your transformations, use the `Eval(string columnName, bool encode)` method with the second parameter enabled to display content of any field whose content was entered by the users, e.g.:

```
<%# Eval("PostSubject", true) %>
```

7.13.8.4 Clickjacking protection

Clickjacking is a type of attack where the attacker tricks a website user into clicking something different than what they see, thus performing an action that may for example reveal confidential data or have any other negative impact on the user. In a typical clickjacking scenario, the attacker places a transparent frame with a page, that contains a button or a link, over another element on a website. The underlying element can be an image or a video, which the user expects to play when they click it. Instead, they click the concealed link or button. This way the attacker can make the users perform unintended actions, usually on websites the users are authenticated on.

To prevent such attacks, Kentico CMS disallows embedding pages it renders into frames. It does that by including a special entry in the HTTP response headers:

```
X-frame-options: SAMEORIGIN
```

The header ensures that pages that are displayed in frames originate on the same server as the parent page. If they don't, browsers do not render them.

This feature is enabled by default for all websites and their pages, however, you can exclude paths where you don't want the header to be used. To do that, add the following key into the appSettings section of your web.config:

```
<add key="CMSXFrameOptionsExcluded" value="/Services" />
```

As a value, you can enter any alias path. All documents under this path will be excluded from the protection. Entering "/" turns off the protection altogether.

7.13.8.5 Configuration of allowed request parameters

In some cases, you may need to use super-secure configuration where any non-standard GET or POST parameter sent to your website results in an error. This allows you to avoid some of the possible vulnerabilities, including cross-site scripting and SQL injection.

This functionality is only used for the website, not for the administration interface.

How to configure the allowed parameters

First, you need to enable allowed parameter checking in the web.config file by setting the value CMSCheckParameters to true:

```
<add key="CMSCheckParameters" value="true" />
```

If you're not sure which parameters cause the problem, you can turn on reporting using the following web.config key:

```
<add key="CMSReportCheckParameters" value="true" />
```

All parameters are defined in the `~/parameters.config` file. The schema of the file is described in the file itself and it's rather simple. For every page or site section, you need to define a new `<location>` section with path specifying the page and allowed form (POST) and query (GET) parameters. The following example allows URL parameter `pagenumber` in the whole products section of the website:

```
<location path="/products/%">
  <queryparameters>
    <allow param="pagenumber" />
  </queryparameters>
</location>
```

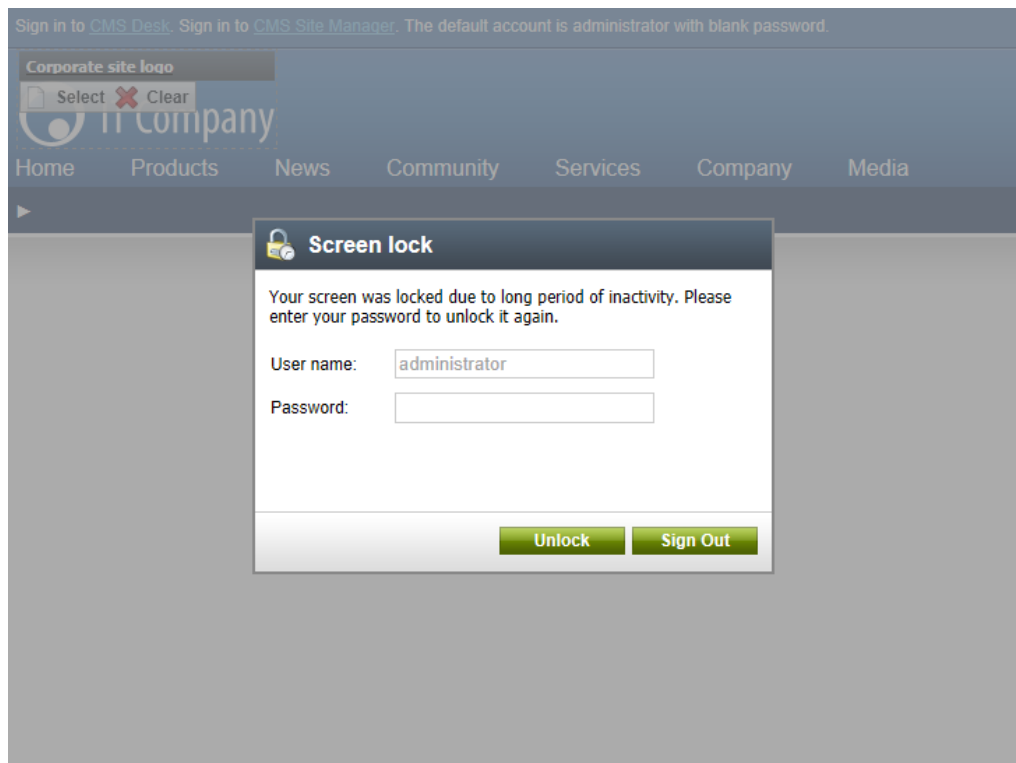

The **path** location specifies the path of the pages based on their alias path in Kentico CMS, while the **page** location is used for single pages that are not part of the Kentico CMS content (custom applications, etc.). The page location starts at the root of the web application and is used without slash (/) at the beginning.

Default allowed parameters

The common parameters of ASP.NET web forms and URL parameters **aliaspath** and **lang** are allowed by default.

7.13.8.6 Screen locking

To mitigate the risk of a security breach caused by a user, who is signed in to the administration interface and leaves their workstation unattended, Kentico CMS allows you to set up screen locking. This feature locks the working area of the browser with the administration interface after a specified time of inactivity, requiring to enter a password to unlock it.

To enable screen locking, open **Site Manager** and navigate to **Settings -> Security & Membership -> Protection -> Screen lock**, then turn on the **Enable screen lock** setting.

The **Screen lock** settings group offers the following additional settings:

- **Lock interval** - time of user inactivity in minutes until their screen is locked.
- **Warning interval** - time in seconds before the lock during which a warning with countdown to the lock will be displayed.

During the warning interval, users can click **Cancel** to start counting the lock interval again.

7.13.9 User registration

7.13.9.1 Available registration web parts

There are three different ways how you can let site visitors register on your site:

- Using the [Registration form](#) web part.
- Using the [Custom registration form](#) web part.
- Via [Third-party authentication](#).

7.13.9.2 Registration form web part

The **Registration form** web part is a ready-made web part that can be used right out of the box. You can just place it on any page of your website without setting any web part properties. However, if you want to modify the default behavior of the web part, you can set a number of properties. You can find a detailed description of these properties in the [Kentico CMS Web Parts](#) reference.

A screenshot of a registration form. It contains five input fields: "First name:" with the value "Andrew", "Last name:" with the value "Jones", "E-mail:" with the value "andy@localhost.com", "Password:" with a masked password of 12 dots and a "Password strength: Strong" indicator below it, and "Confirm password:" with a masked password of 12 dots. Below the fields is a "Register" button.

The password field in the form supports validation according to a password policy specified for the website and also calculates and displays the relative strength of the currently entered password. To learn more about how these security options can be configured, please see the [Password management - > Password strength policy](#) topic.

7.13.9.3 Creating a custom registration form

The **Custom registration form** web part can be used in situations when you want to use a different registration form than the default one provided by the **Registration form** web part. This is typically when you want users to provide different details or when you want to customize the form's layout.

In the following example, you will learn how to use a custom registration form on your site. You will create an **alternative form** and use it for registration via the **Custom registration form** web part. If you

are not familiar with the **Alternative forms** concept, please refer to the [Alternative forms](#) chapter first.

1. Go to **Site Manager -> Development -> System tables** and choose to **Edit** (✎) the **User** system table.

The screenshot shows the Kentico Site Manager interface. The left sidebar contains a navigation menu with 'System tables' selected. The main area displays a table of system tables. The 'User' table is highlighted, and its edit icon (a pencil) is circled in red.

| Actions | Class display name ^ | Class name | Table name |
|---------|--------------------------------|----------------------------|-----------------------|
| ✎ | Contact management - Account | OM.Account | OM_Account |
| ✎ | Contact management - Contact | OM.Contact | OM_Contact |
| ✎ | Ecommerce - Bundle | ecommerce.bundle | COM_Bundle |
| ✎ | Ecommerce - Customer | ecommerce.customer | COM_Customer |
| ✎ | Ecommerce - Order | ecommerce.order | COM_Order |
| ✎ | Ecommerce - Order item | ecommerce.orderitem | COM_Orderitem |
| ✎ | Ecommerce - Shopping cart | ecommerce.shoppingcart | COM_ShoppingCart |
| ✎ | Ecommerce - Shopping cart item | ecommerce.shoppingcartitem | COM_ShoppingCartSKU |
| ✎ | Ecommerce - SKU | ecommerce.sku | COM_SKU |
| ✎ | Group | Community.Group | Community_Group |
| ✎ | Media file | media.file | Media_File |
| ✎ | Newsletter - Subscriber | newsletter.subscriber | Newsletter_Subscriber |
| ✎ | User | cms.user | CMS_User |
| ✎ | User - Settings | cms.usersettings | CMS_UserSettings |

2. Switch to the **Alternative forms** tab and click the **Create new form** button above the list.

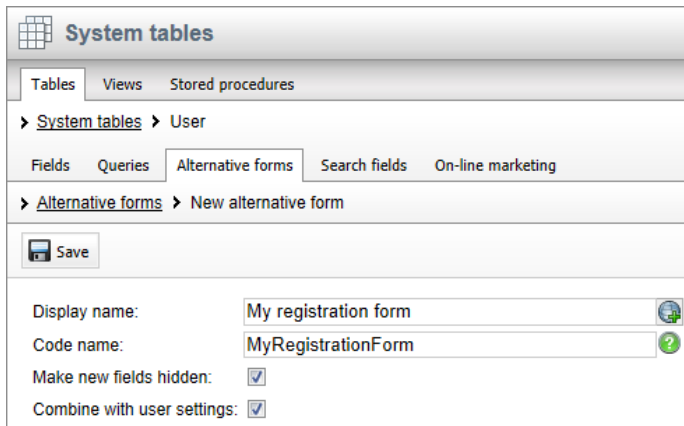

The screenshot shows the 'Alternative forms' tab for the 'User' system table. The 'Create new form' button is highlighted with a red box.

| Actions | Display name ^ | Code name | Hides new fields |
|---------|----------------------------------|-----------------------------|------------------|
| ✎ ✘ | Display profile | DisplayProfile | No |
| ✎ ✘ | Display profile (Corporate Site) | DisplayProfileCorporateSite | No |
| ✎ ✘ | Display profile (Intranet) | DisplayProfileIntranet | No |
| ✎ ✘ | Edit profile | EditProfile | No |
| ✎ ✘ | Edit profile (Community) | EditProfileCommunity | No |
| ✎ ✘ | Edit profile (Intranet) | EditProfileIntranet | No |
| ✎ ✘ | Edit profile (MyDesk) | EditProfileMyDesk | No |
| ✎ ✘ | Registration form | RegistrationForm | No |

3. Fill in the following details:

- **Display name:** My registration form
- **Code name:** MyRegistrationForm
- **Make new fields hidden:** checked; this ensures that new fields added to the system table are not displayed in the alternative form by default.
- **Combine with user settings:** checked; this ensures that all default user fields will be available.

Click  **Save**.

Display name: 

Code name: 

Make new fields hidden:

Combine with user settings:

4. Your new form is now created and you are redirected to the editing interface of it. Switch to the **Fields** tab.

On this tab, you can see the fields (columns) defined in the **User** system table. You can select a field from the list on the left. In the right part, you can modify its properties. We will want our registration form to contain the following fields:

- **UserName**
- **FirstName**
- **Email**
- **UserPassword**

Go through the attributes and check the **Display attribute in the editing form** check-box for those mentioned above, which will make them visible on our registration form. Click  **Save** to confirm the changes for every field. Uncheck the check-box for the remaining fields. For the **UserPassword** field, also choose the *Password with confirmation* option in the **Form control** drop-down.

The screenshot shows the 'System tables' configuration interface in Kentico CMS. The breadcrumb trail is: System tables > User > Alternative forms > My registration form. The 'Fields' tab is selected. A list of fields is shown on the left, with 'UserPassword*' selected. The right-hand panel shows the configuration for this field. The 'Database' section includes: Column name: UserPassword; Attribute type: Text; Attribute size: 100; Allow empty value: unchecked; Default value: empty; Translate field: unchecked. The 'Field appearance' section includes: Display attribute in the editing form: checked (highlighted with a red box); Default visibility: Display to all; Visibility control: Visibility (drop down list); Allow user to change field visibility: unchecked; Field caption: User password; Form control: Password with confirmation (highlighted with a red box); Field description: empty. A 'Save' button is located at the top left of the configuration panel. Below the field list, there are 'Quick links' for Database, Field appearance, Editing control settings, Validation, and CSS styles.

5. You can also switch to the **Layout** tab and define the registration form's layout using the built-in WYSIWYG editor.

To do it, check the **Use custom layout** check box and click the **Generate table layout** button. A default layout will appear in the editor. Try playing around a bit with the layout or just create something similar to what you see in the screenshot below. Click **Save** when you are finished.

The screenshot shows the 'System tables' interface in Kentico. The breadcrumb path is: System tables > User > Alternative forms > My registration form. The 'Layout' tab is selected. A 'Save' button is visible. A message states 'The changes were saved.' Below this, there is a checked checkbox for 'Use custom form layout' and a 'Generate table layout' button. The main area contains a rich text editor with the following text:

```

User name: $$input:UserName$$$validation:UserName$$
First name: $$input:FirstName$$$validation:FirstName$$
Last name: $$input:LastName$$$validation:LastName$$
Email: $$input:Email$$$validation:Email$$
User password: $$input:UserPassword$$$validation:UserPassword$$

```

On the right side, there is an 'Available fields' list with the following items:

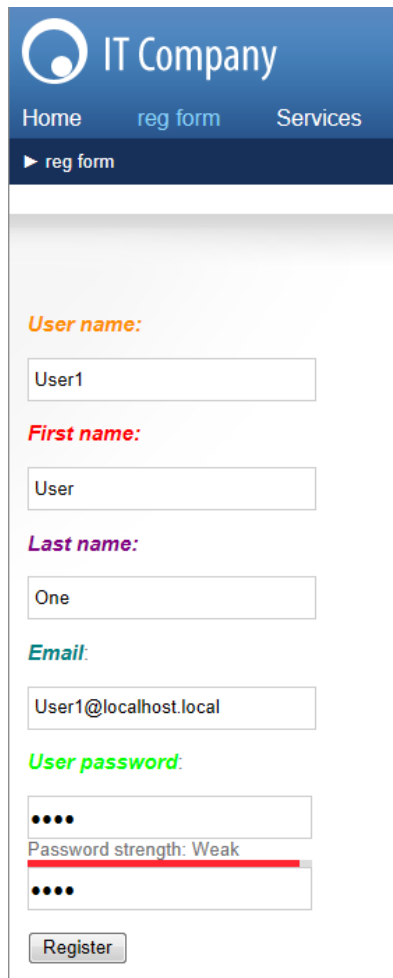

- UserPassword
- PreferredCultureCode
- PreferredUICultureCode
- UserEnabled
- UsersEditor
- UsersGlobalAdministrat
- UsersExternal
- UserPasswordFormat
- UserCreated
- LastLogon
- UserStartingAliasPath
- UserGUID
- UserLastModified
- UserLastLogonInfo

Below the list are five buttons: 'Insert label', 'Insert input', 'Insert validation label', 'Insert submit button', and 'Insert visibility control'.

6. Now switch to **CMS Desk**. Choose or create a page where you want to add the registration form and select it in the content tree. Switch to the **Design** tab and add (+) the **Membership -> Custom registration form** web part to the page. Set the following property of the web part:

- **Alternative form** - cms.user.MyRegistrationForm

7. If you switch to the live site now and go to your page with the Custom registration form web part, you should see the custom registration form that you created. You can now try to register to your website using the form and verify that the user has been created in **Site Manager -> Administration -> Users**.

The screenshot shows a registration form for 'IT Company'. The form is titled 'reg form' and is located under the 'reg form' menu item. The form fields are as follows:

- User name:** Input field containing 'User1'.
- First name:** Input field containing 'User'.
- Last name:** Input field containing 'One'.
- Email:** Input field containing 'User1@localhost.local'.
- User password:** Two input fields for password, both containing four dots. Below the first field is a password strength indicator showing 'Password strength: Weak' with a red progress bar.
- Register:** A button to submit the form.

7.13.9.4 Registration approval and double opt-in

By default, users can sign-in to the site immediately after successful registration. However, the two options highlighted in the following screenshot can be enabled in **Site Manager -> Settings -> Membership & Security**. By enabling these options, you can include additional steps in the registration procedure.

The screenshot shows the Kentico Site Manager interface. The left sidebar contains a navigation menu with 'Security & Membership' selected. The main content area is titled 'Security & Membership' and includes a 'Save' button and a 'Reset these settings to default' link. Below this, there is a note: 'These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.' The settings are organized into sections: 'General', 'Registrations', and 'On-line users'. In the 'Registrations' section, the 'Registration requires e-mail confirmation' checkbox is checked and highlighted with a red box. Other settings include 'Administrator's e-mail' (admin@localhost.local), 'Send membership reminder (days)' (10), 'Deny login interval' (10), 'Share user accounts on all sites' (checked), 'Use site prefix for user names' (unchecked), 'Reserved user names' (admin,root,administrator,sysadmin,sa), 'Delete non-activated user after (days)' (5), and 'Require unique user e-mails' (checked). The 'On-line users' section has 'Monitor on-line users' and 'Store on-line users in database' both unchecked.

Registration requires e-mail confirmation

If checked, newly registered users will receive a confirmation e-mail to the e-mail address specified during registration. This e-mail contains a confirmation link that has to be clicked in order to activate the account. The e-mail is based on the **Membership - Registration confirmation** e-mail template.

Thank you for registering at our site. Please click the link below to complete your registration:

http://localhost/KenticoCMS_7.0.4562/CMSPages/Dialogs/UserRegistration.aspx?userid=80cd1b3a-615d-4308-9f2b-fa186ed9f637

You can find your credentials below:

Username: j.smith@localhost.local

Password: 123456

After clicking the link, the user will be redirected to the page specified in the **E-mail confirmation page** property of the web part used for registration. This page must contain the [Registration e-mail confirmation](#) web part to work correctly.

By default, the `~/CMSPages/Dialogs/UserRegistration.aspx` page is used, which displays the following message:

Your user account is now active. You can sign in using your user name and password. [Click here to continue.](#)

The link at the end of the message will redirect the user to the title page of the website. The user can

then log in using the registration details received in the e-mail.

Registration requires administrator's approval

If this option is enabled, users will not be able to sign-in immediately after registration. Their registration will have to be approved by the site administrator. At this point, users will receive an e-mail based on the **Membership - Registration waiting for approval** e-mail template. You can see the default version of the e-mail in the screenshot below.

Thank you for registering at our site CorporateSite. Your registration must be approved by administrator.

Registration details:

Username: j.smith@localhost.local
Password: 123456

If the option is enabled, the **Waiting for approval** tab will be displayed in **Site Manager -> Administration -> Users**. On this tab, site administrators can **Approve** (✓) or **Reject** (✗) a user's registration.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The left sidebar lists various administration options, with 'Users' selected. The main content area is titled 'Users' and has tabs for 'Users', 'Waiting for approval', 'Mass e-mail', and 'On-line users'. The 'Waiting for approval' tab is active, showing a table of users. The table has columns for 'Actions', 'User name', 'Full name', 'E-mail', 'Nickname', 'Created', and 'Enabled'. A single user is listed: 'j.smith@localhost.local' with full name 'John Smith' and email 'j.smith@localhost.local', created on '7/10/2012 8:37:18 AM'. The 'Enabled' column shows 'No'. There are 'Approve all selected users' and 'Reject all selected users' buttons above the table. A search bar and 'Search' button are also visible.

| Actions | User name ^ | Full name | E-mail | Nickname | Created | Enabled |
|---------|-------------------------|------------|-------------------------|----------|----------------------|---------|
| ✓ ✗ | j.smith@localhost.local | John Smith | j.smith@localhost.local | | 7/10/2012 8:37:18 AM | No |

After the administrator's approval, users receive another e-mail, confirming that their account has been approved and can be used. The e-mail is based on the **Membership - Registration approved** e-mail template. You can see the default appearance of the e-mail in the screenshot below.

Your registration has been approved by administrator. Now you can sign in using your username and password.

[Click here to navigate to the web site](#)

Enabling both options

When both of the options mentioned above are enabled, the e-mail with the confirmation link is sent first. After the user's confirmation, registration will have to be approved by the administrator.

Default redirection

If you have one or both of the options enabled, it is important to properly set the **Redirect to URL** property of the web part used for registration. This means that users should not be redirected to any page displaying information about their user account (like the **Members -> Profile** page on the sample Community Starter site), because the account will not be active yet (it is waiting for e-mail activation or approval). Such a page would display an error message, which might be misleading for the users.

E-mail notification addresses

In case you wish to use notification e-mails to inform administrators about new user registrations that require approval, the target address cannot be specified via the registration web part itself if e-mail confirmation is also enabled.

Instead, it must be entered into the properties under the **E-mail settings** category of the [Registration e-mail confirmation](#) web part placed on the used confirmation page.

Third party authentication issues

Using double opt-in or registration approval in combination with [Third-party authentication services](#) may cause certain problems for first-time users. In these cases, new users are by default created without an e-mail address when they log in for the first time. This means that they cannot activate their account via e-mail confirmation or receive notifications informing that their account must be approved by an administrator.

These issues can be avoided by creating a **Required user data page** where users must enter an e-mail address for their account, as described in the chapter linked above.

7.13.9.5 User registration e-mails

In **Site manager -> Administration -> E-mail templates**, you can find the [E-mail templates](#) used for the automatic e-mail notifications related to user registration. Messages based on the following templates are sent to users when they register, depending on the site configuration (please see [Registration approval and double opt-in](#) for more information):

- **Membership - Registration** - sent to new users as a welcome e-mail after they successfully register (if the used registration web part is configured to do so).
- **Membership - Registration confirmation** - sent to users after registration if e-mail confirmation (double opt-in) is required.
- **Membership - Registration waiting for approval** - sent to users after registration if an administrator's approval is needed to activate the account.
- **Membership - Registration approved** - informs users that their account has been approved by an administrator.

The templates below are used for notifications sent to administrators:

- **Membership - Notification - New registration** - notifies administrators when a new user registers on the site.
- **Membership - Notification - Waiting for approval** - lets administrators know that a new user is waiting for their approval.

Any of these templates can be edited as needed, so you may fully customize the content of the e-mails. You can use the following [context macros](#) to include dynamic values in their text. Please note that some of the macros are only available in specific templates.

- **{% FirstName %}** - the first name of the new user.
- **{% LastName %}** - the last name of the new user.
- **{% Email %}** - the e-mail address entered during registration by the user.
- **{% UserName %}** - the user name of the new account. If you are using site prefixes for user names, all occurrences of this macro in e-mail templates should have the prefix trimmed out through the following method: `{%TrimSitePrefix(UserName)%}`
- **{% Password %}** - the password specified for the new account.
- **{% ConfirmAddress %}** - returns the URL of the page where the user can confirm their registration (intended for sites where double opt-in is enabled).
- **{% HomePageURL %}** - resolves into the URL of the site's home page. This is only available in the *Registration approved* template.

In addition to the special ones listed above, you can also use all other standard macro expressions in the templates. See the [Development -> Macro expressions](#) chapter of this guide for more information about macro expressions in Kentico CMS.

7.13.9.6 Shared user accounts

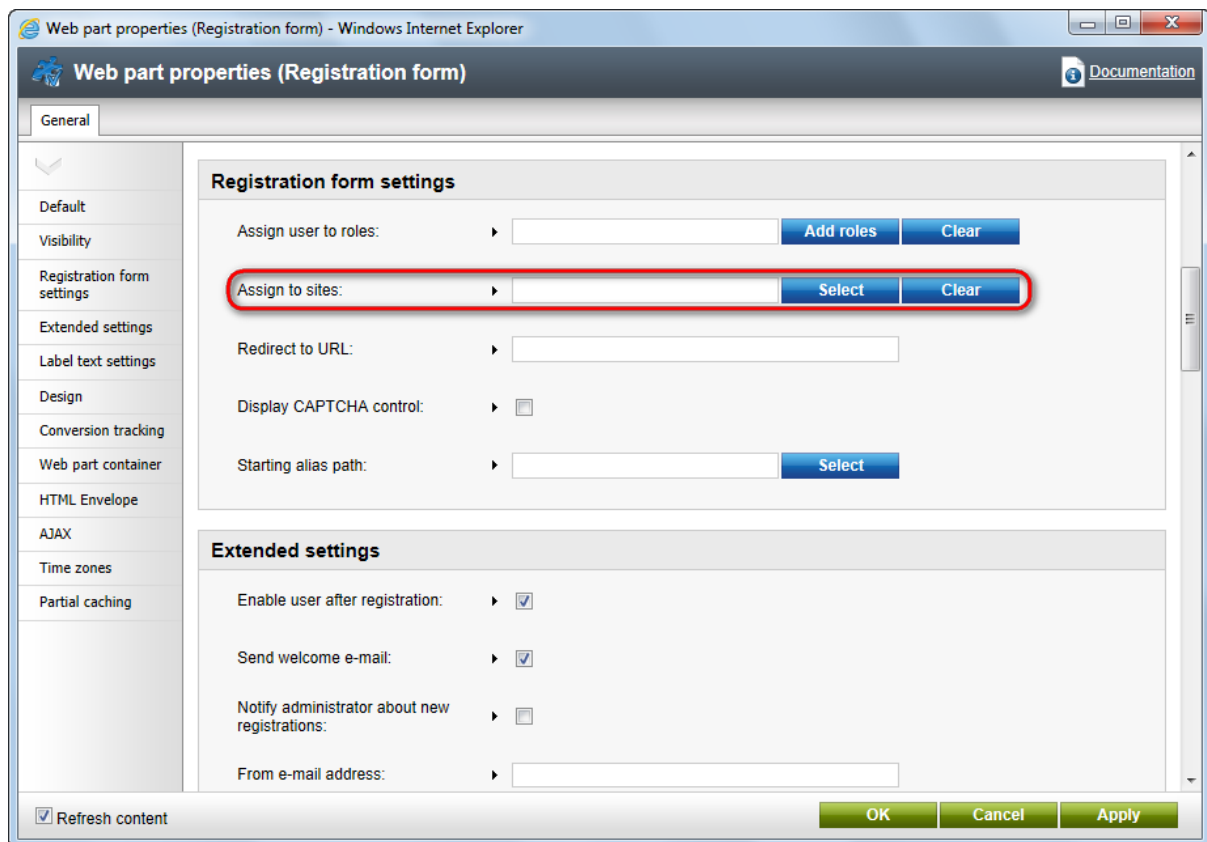

User accounts can be shared among all sites running on one Kentico CMS installation. This means that if a user creates an account on one site, they can automatically log-on to the other sites running on the same installation using the same credentials.

This behavior can be switched on or off in **Site Manager -> Settings -> Membership & Security**, using the **Share user accounts on all sites** check-box.

- If the check-box is enabled, user accounts created on one site will be shared among all the sites running on the installation.
- If the check-box is disabled, new accounts will be assigned only to the current site and not the others.

The screenshot shows the Kentico CMS Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The 'Settings' tab is active, and the 'Security & Membership' section is selected in the left sidebar. The main content area displays the 'Security & Membership' settings for the 'global' site. The 'General' section contains several settings, with 'Share user accounts on all sites' checked and highlighted by a red box. Other settings include 'Administrator's e-mail' (admin@localhost.local), 'Send membership reminder (days)' (10), and 'Deny login interval' (10). The 'Registrations' section includes 'Reserved user names' (admin,root;administrator.sysadmin,sa), 'Registration requires e-mail confirmation' (unchecked), 'Registration requires administrator's approval' (unchecked), 'Delete non-activated user after (days)' (5), and 'Require unique user e-mails' (checked).

However, registration web parts have the **Assign to sites** property. Using this property, you may determine which sites the user accounts created via the web part will be assigned to.

The screenshot shows the 'Web part properties (Registration form)' dialog box. The 'General' tab is selected. The 'Registration form settings' section contains several properties: 'Assign user to roles' with 'Add roles' and 'Clear' buttons; 'Assign to sites' with 'Select' and 'Clear' buttons (highlighted with a red circle); 'Redirect to URL'; 'Display CAPTCHA control' with a checkbox; and 'Starting alias path' with a 'Select' button. The 'Extended settings' section includes 'Enable user after registration' (checked), 'Send welcome e-mail' (checked), 'Notify administrator about new registrations' (unchecked), and 'From e-mail address'. At the bottom, there is a 'Refresh content' checkbox and 'OK', 'Cancel', and 'Apply' buttons.

User name prefixes and shared accounts

It is recommended to avoid using shared accounts together with the **Use site prefixes for user names** option that can also be enabled in **Site Manager -> Settings -> Security & Membership**.

Prefixes allow the creation of users with names that are not globally unique. If the **Share user accounts on all sites** setting is enabled, this may lead to problems with multiple identical user names on a single site.

7.13.10 Badges

7.13.10.1 Badges

Users may be labeled with badges. These are images with a short title, expressing a user's activity level, importance or role in the context of the website. They can be displayed in forum posts, on user public profiles or in your own custom controls.

There are two types of badges:

- **Automatic badges** - these are assigned to users based on their number of [activity points](#). Every time a user gains activity points, for example by posting on the website's forums, the system automatically checks whether the level required for a new badge has been reached and updates it if this is the case.
- **Non-automatic badges** - assigned to users by site administrators. These are permanent unless manually changed, regardless of the number of activity points acquired by the given user.

In the screenshot below, you can see one of the pre-defined badges in a forum post.

7.13.10.2 Defining badges

Badges can be defined in **Site Manager -> Administration -> Badges**. On this page, you can see a list of currently defined badges. You can **Edit** (✎) or **Delete** (✖) badges in the list or define a new badge by clicking the **New badge** button at the top part of the page.

| Actions | Name | Top limit | Is automatic | Image preview |
|---------|-----------------|-----------|--------------|---------------|
| ✎ ✖ | Advanced member | 100000 | Yes | |
| ✎ ✖ | Valued member | 30 | Yes | |
| ✎ ✖ | Member | 10 | Yes | |
| ✎ ✖ | Site admin | 0 | No | |

When creating a new badge, the following properties can be specified:

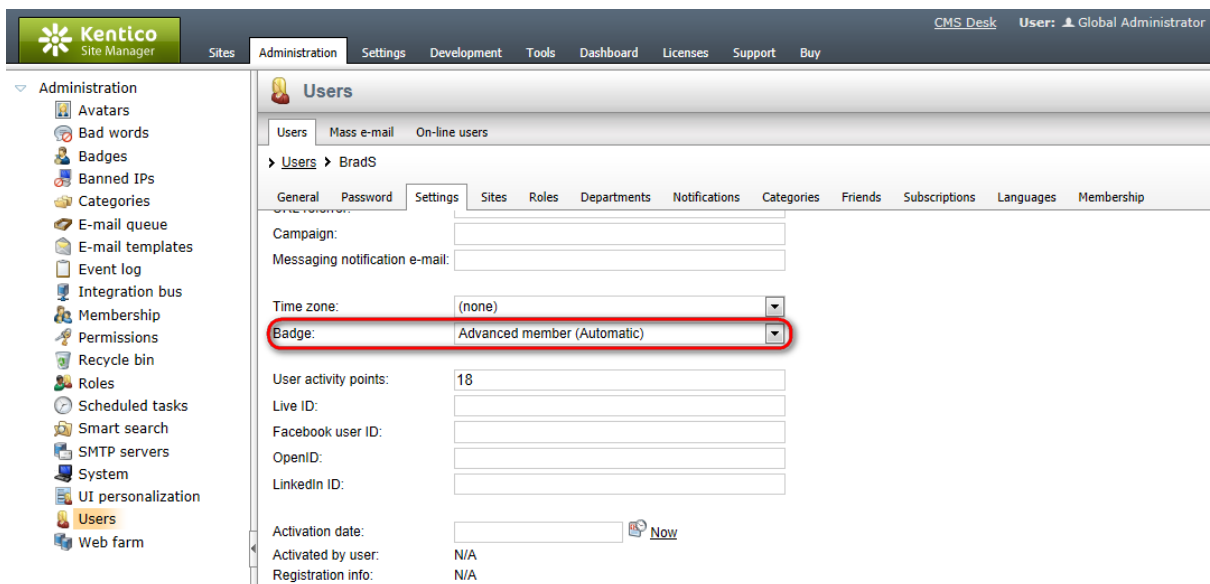

- **Display name** - name of the badge displayed on the website and in the administration interface.
- **Code name** - a unique name that serves as an identifier for the badge, for example in the API. You can leave the default (*automatic*) option to have the system generate an appropriate code name based on the display name.
- **Image URL** - sets the path of the image that will be displayed as a representation of the badge. This can be a URL, a relative path from the root of the web project (starting with "~/") or a path under the default theme folder (~/*App_Themes/Default/Images/*), e.g. */Objects/CMS_Badge/Default/advancedmember.gif*.

- **Is automatic** - if checked, the badge will be assigned to users automatically based on the number of gained activity points. Otherwise the badge will need to be assigned manually by site administrator and will remain assigned permanently, regardless of the number of activity points.
- **Top limit** - this property only affects automatic badges. The system assigns the badge to users who have less activity points than the limit. If a user fulfills this condition for multiple badges, the system always assigns the one with the lowest *Top limit* value.

7.13.10.3 Assigning badges to users

Site administrators can assign badges to users in **Site Manager / CMS Desk -> Administration -> Users -> Edit (✎) user -> Settings**. It can be done via the **Badge** drop-down list.

This approach is typically used to assign non-automatic badges to users. However, automatic badges can also be assigned in this way.

The screenshot shows the Kentico Site Manager Administration interface. The left sidebar contains a navigation menu with categories like Administration, Bad words, Badges, Banned IPs, Categories, E-mail queue, E-mail templates, Event log, Integration bus, Membership, Permissions, Recycle bin, Roles, Scheduled tasks, Smart search, SMTP servers, System, UI personalization, Users, and Web farm. The main content area is titled 'Users' and shows the configuration for user 'BradS'. The 'Settings' tab is selected, and the 'Badge' dropdown menu is highlighted with a red circle, showing 'Advanced member (Automatic)' selected. Other fields include Campaign, Messaging notification e-mail, Time zone (none), User activity points (18), Live ID, Facebook user ID, OpenID, LinkedIn ID, Activation date (with a 'Now' button), Activated by user (N/A), and Registration info (N/A).

7.13.10.4 Activity points

Users can gain activity points for their activity on the site. Based on the number of gained activity points, automatic badges can be assigned to users. For this feature to be functional, you have to configure the following settings in **Site Manager -> Settings -> Community**:

- **Enable user activity points** - enables the logging of activity points for users.
- **Activity points for blog posts** - number of activity points that users receive for adding a blog post.
- **Activity points for blog comment post** - number of activity points that users receive for adding a blog post comment.
- **Activity points for forum post** - number of activity points that users receive for adding a forum post.
- **Activity points for message board post** - number of activity points that users receive for adding a message board post.

The screenshot shows the Kentico CMS 7.0 Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The user is logged in as 'Global Administrator'. The left sidebar shows a tree view of settings categories, with 'Community' selected. The main content area is divided into several sections:

- Group settings:** Includes fields for 'Group template path', 'Groups security access denied path', 'Group management path', and 'Group profile path', each with a 'Select' button.
- Group invitation:** Includes 'Invitation acceptance path' (with 'Select' button) and 'Group invitation expires after (days)' (set to 0).
- Members:** Includes 'Member management path' (with 'Select' button), 'Member profile path' (with 'Select' button), 'Enable friends' (checked), and 'Friend management path' (with 'Select' button).
- Activity points (highlighted in red):** Includes 'Enable user activity points' (checked), and four numeric input fields for activity points: 'Activity points for blog post' (3), 'Activity points for blog comment post' (1), 'Activity points for forum post' (1), and 'Activity points for message board post' (1).

7.13.10.5 Available form controls

The following form controls can be used in your custom fields to display the badges of users:

- **Viewer - Badge image (ViewBadgeImage)** - used for displaying the image of a badge.
- **Viewer - Badge text (ViewBadgeText)** - used for displaying the *Display name* of a badge.

7.13.10.6 Badges internals and API

7.13.10.6.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used by Badges. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module's classes, please refer to [Kentico CMS API Reference](#).

7.13.10.6.2 Database tables

The following database table is used to store information about badges:

- **CMS_Badge** - contains records representing badges.

| CMS_Badge | | | |
|---|-------------------|------------------|-------------------------------------|
| | Column Name | Data Type | Allow Nulls |
|  | BadgeID | int | <input type="checkbox"/> |
| | BadgeName | nvarchar(100) | <input type="checkbox"/> |
| | BadgeDisplayName | nvarchar(200) | <input type="checkbox"/> |
| | BadgeImageUrl | nvarchar(200) | <input checked="" type="checkbox"/> |
| | BadgeIsAutomatic | bit | <input type="checkbox"/> |
| | BadgeTopLimit | int | <input checked="" type="checkbox"/> |
| | BadgeGUID | uniqueidentifier | <input type="checkbox"/> |
| | BadgeLastModified | datetime | <input type="checkbox"/> |
| | | | <input type="checkbox"/> |

7.13.10.6.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes for managing badges can be found in the **CMS.SiteProvider** namespace.

CMS_Badge table API:

- **BadgeInfo** - represents one badge object.
- **BadgeInfoProvider** - provides management functionality for badges.

7.13.10.6.4 API examples

7.13.10.6.4.1 Overview

These topics show examples of how the API of badges can be used:

- [Managing badges](#)
- [Managing user badges](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Administration\Badges\Default.aspx.cs**.

The badge API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.SiteProvider;
```

7.13.10.6.4.2 Managing badges

The following example creates a badge.

```
private void CreateBadge()
{
    // Create new badge object
    BadgeInfo newBadge = new BadgeInfo();

    // Set the properties
    newBadge.BadgeDisplayName = "My new badge";
    newBadge.BadgeName = "MyNewBadge";
    newBadge.BadgeTopLimit = 50;
    newBadge.BadgeImageUrl = "~/App_Themes/Default/Images/Objects/CMS_Badge/
Default/siteadmin.gif";
    newBadge.BadgeIsAutomatic = true;

    // Save the badge
    BadgeInfoProvider.SetBadgeInfo(newBadge);
}
```

The following example gets and updates a badge.

```
private bool GetAndUpdateBadge()
{
    // Get the badge
    BadgeInfo updateBadge = BadgeInfoProvider.GetBadgeInfo("MyNewBadge");
    if (updateBadge != null)
    {
        // Update the properties
        updateBadge.BadgeDisplayName = updateBadge.BadgeDisplayName.ToLower();

        // Save the changes
        BadgeInfoProvider.SetBadgeInfo(updateBadge);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates badges.

```
private bool GetAndBulkUpdateBadges()
{
    // Prepare the parameters
    string where = "BadgeName LIKE N'MyNewBadge%'";

    // Get the data
    DataSet badges = BadgeInfoProvider.GetBadges(where, null);
    if (!DataHelper.DataSourceIsEmpty(badges))
    {
        // Loop through the individual items
        foreach (DataRow badgeDr in badges.Tables[0].Rows)
        {
            // Create object from DataRow
            BadgeInfo modifyBadge = new BadgeInfo(badgeDr);

            // Update the properties
            modifyBadge.BadgeDisplayName = modifyBadge.BadgeDisplayName.ToUpper();

            // Save the changes
            BadgeInfoProvider.SetBadgeInfo(modifyBadge);
        }

        return true;
    }

    return false;
}
```

The following example deletes a badge.

```
private bool DeleteBadge()
{
    // Get the badge
    BadgeInfo deleteBadge = BadgeInfoProvider.GetBadgeInfo("MyNewBadge");

    // Delete the badge
    BadgeInfoProvider.DeleteBadgeInfo(deleteBadge);

    return (deleteBadge != null);
}
```

7.13.10.6.4.3 Managing user badges

The following example assigns a badge to a specific user.

```
private bool AddBadgeToUser()
{
    // Get user object
    UserInfo user = UserInfoProvider.GetUserInfo(CMSContext.CurrentUser.UserName);
```

```
// Get badge object
BadgeInfo myBadge = BadgeInfoProvider.GetBadgeInfo("MyNewBadge");

if ((user != null) && (myBadge != null))
{
    // Add badge to user settings
    user.UserSettings.UserBadgeID = myBadge.BadgeID;

    // Update user object in database
    UserInfoProvider.SetUserInfo(user);

    return true;
}

return false;
}
```

The following example updates the activity points of a specific user.

```
private bool UpdateActivityPoints()
{
    // Get user
    UserInfo user = UserInfoProvider.GetUserInfo(CMSContext.CurrentUser.UserName);

    // If user exists
    if (user != null)
    {
        // Update activity points of the user
        BadgeInfoProvider.UpdateActivityPointsToUser
(ActivityPointsEnum.BlogCommentPost, user.UserID, CMSContext.CurrentSiteName,
true);

        return true;
    }

    return false;
}
```

The following example removes a user's badge.

```
private bool RemoveBadgeFromUser()
{
    // Get user
    UserInfo user = UserInfoProvider.GetUserInfo(CMSContext.CurrentUser.UserName);

    // If user exists
    if (user != null)
    {
        user.UserSettings.UserBadgeID = 0;

        // Save updates
    }
}
```

```
        UserInfoProvider.SetUserInfo(user);  
        return true;  
    }  
  
    return false;  
}
```

7.13.11 Custom field visibility

7.13.11.1 How it works

The visibility control functionality is designed to enable registered users to decide which fields of their public profile will be visible to other users. You can find an example of how this works on the sample **Community site**.

1. Run the **Community site** and sign out of the administration interface. Log on to the site using the **Sign in** form on the right. Enter *David* with a blank password and click **Log on**.
2. Once logged in, the **Shortcuts** menu is displayed instead of the Sign in form. Click the **Edit my profile** link to open the user's profile editing page.
3. There is a set of radio buttons under the **E-mail** field. This control allows users to configure the visibility of their e-mail address in the profile. The following four options are available:
 - **Nobody** - the field cannot be seen by anyone (only by the profile's owner).
 - **All** - the field is visible for all visitors.
 - **Site members** - the field is only displayed to authenticated users.
 - **Friends** - the field is only displayed to the user's [friends](#).

Choose **Site members** and click **OK**.

Personal settings | Change password | Notifications

Username: David

Full name: David Silver

Email: david.silver@localhost.local

Display my e-mail to: Nobody All Site members Friends

Nickname: David

Signature: * * D-a-v-i-d * *

Messaging notification e-mail:

Time zone: (none)

Avatar:

Upload: Browse...

Select pre-defined avatar

Gender: Male Female

Date of birth: 5/6/1987

4. You have just configured the user's profile so that only authenticated users can see the e-mail address. Let's verify that it really works. Sign out and visit David's profile as an unauthenticated site visitor. From the site's main menu, select **Members** and click David's icon in the list below. You should see his profile, but the e-mail address is not present.

Member profile

David

7.13.11.2 Enabling visibility controls

The visibility selection drop-down list can be added to any field of the user's profile, not just the e-mail field shown in the example in the [How it works](#) topic. This can be changed in **Site Manager -> Development -> System tables**. Choose to **Edit** () the **User (CMS_User)** system table and switch to the **Alternative forms** tab.

If you are not familiar with the **Alternative forms** concept, please read the [Module Alternative forms](#) chapter first.

The **User** system table represents the database table that stores information about registered users. Each of the four alternative forms that you see in the list is used in a specific situation when the system accesses the table:

- **Registration form** - when registering a new user using the **Custom registration form** web part.
- **Display profile** - when displaying a user's public profile using the **User public profile** web part.
- **Edit profile** - when editing a user's profile using the **My account** web part.
- **Edit profile (MyDesk)** - when editing the user profile in **CMS Desk -> My Desk -> Account -> Details**.

The visibility field can be set in each of these forms.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The left sidebar lists various development tools, with 'System tables' highlighted. The main content area shows the 'System tables' configuration page, which includes tabs for 'Tables', 'Views', and 'Stored procedures'. The 'System tables' tab is active, and the 'User' table is selected. The 'Fields' tab is active, and the 'Alternative forms' sub-tab is selected. A table of system tables is displayed with the following columns: Actions, Display name, Code name, and Hides new fields. The table contains the following rows:

| Actions | Display name | Code name | Hides new fields |
|---------|----------------------------------|-----------------------------|------------------|
| | Display profile | DisplayProfile | No |
| | Display profile (Corporate Site) | DisplayProfileCorporateSite | No |
| | Display profile (Intranet) | DisplayProfileIntranet | No |
| | Edit profile | EditProfile | No |
| | Edit profile (Community) | EditProfileCommunity | No |
| | Edit profile (Intranet) | EditProfileIntranet | No |
| | Edit profile (MyDesk) | EditProfileMyDesk | No |
| | Registration form | RegistrationForm | No |

Let's assume that we want the **Full name** field to be optionally hidden in the public profiles of users, based on the configuration made in the profile editing section of each specific user.

1. **Edit** () the **Edit profile (Community)** alternative form, which is the form that is used by the **My profile** web part on the Community site. Switch to the **Fields** tab and select **FullName** from the list on the left. Select **Visibility (radio buttons - horizontal)** from the **Visibility control** drop-down. Check the **Allow user to change field visibility** checkbox and finally click **Save**.

The screenshot shows the Kentico Site Manager interface. The left sidebar contains a navigation menu with categories like 'Development', 'Custom settings', 'Form controls', etc. The main area is titled 'System tables' and shows the configuration for the 'User' table. The 'Alternative forms' tab is active, and the 'Fields' sub-tab is selected. The 'Full Name' field is highlighted in the 'Available fields' list. The 'Field appearance' section is expanded, showing the 'Visibility control' dropdown set to 'Visibility (radio buttons - horizontal)'. A red box highlights the 'Visibility control' and 'Allow user to change field visibility' options.

2. Switch to the **Layout** tab. We will need to create another line in the table and add the visibility control into it.

Place the cursor into the FullName line (where the `$$label:FullName$$` value is). Right click and choose **Row -> Insert Row After** from the context menu. Into the first column of the new row, enter: *Display my full name to:*

Now we will add the visibility control itself. Place the cursor into the second column, select **FullName** from the **Available fields** list and click the **Insert visibility control** button. The result should look as in the screenshot below.

When you are finished, click **Save**.

7.13.11.3 Use in custom form layouts

If you want to define a custom form layout and use the visibility drop-down list for some field, you have to do the following two things:

- the **Allow user to change visibility** check-box must be enabled for each field that you want to use the drop-down list for. If it is not enabled, the drop-down list will not be functional.
- add the drop-down list manually to the form, using the **Insert visibility control** button:
 1. Go to **Site Manager -> Development -> System tables**. Choose to **Edit**  the **User** system table and switch to the **Alternative forms** tab. Choose to **Edit**  the **Edit profile** alternative form and switch to the **Layout** tab. Check the **Use custom form layout** check-box.
 2. Click the **Generate form layout** button. A default form layout will be generated and you can make modifications to it.
 3. Enter the visibility controls by placing the cursor to the desired location, selecting the appropriate field and clicking the **Insert visibility control** button. Click **Save** when you are finished.

7.13.11.4 Configuring the web parts

If you want to enable visibility controls in these web parts, you have to add the controls to the appropriate alternative forms and set the following properties of the web parts:

User public profile

- **Form name** - specifies the full name of the desired alternative form (*cms.user.DisplayProfile* by default).
- **Apply visibility settings** - check this to enable the visibility controls.
- **Use visibility settings from form** - can be used to select from which form visibility settings should be loaded if the Apply visibility settings property is enabled. If empty, the form specified in the Form name property will be used.

Custom registration form

- **Alternative form** - specify the full name of the desired alternative form (*cms.user.RegistrationForm* by default).

My account

- **Form name** - specify the full name of the desired alternative form (*cms.user.EditProfile* by default).
- **Allow user to edit field visibility** - check to enable the visibility controls.

7.13.12 Authentication

7.13.12.1 Authentication overview

The system supports both forms and Windows authentication. The **forms authentication** stores user names and passwords in the database and requires users to log on. The **Windows authentication** gets user identity from the network credentials and automatically creates a corresponding user in the database, including the user's roles (if they exist in the CMS database).

Accessing current user data in code

When the user is authenticated, a `CMS.CMSHelper.CurrentUserInfo` object representing the current user is stored in the session variable **CMSCurrentUser** and is accessible through the **CMSHelper.CMSContext.CurrentUser** property. All operations after authentication then use the user profile and user roles assigned to this object.

[C#]

```
// gets the user name of the current user
string userName = CMS.CMSHelper.CMSContext.CurrentUser.UserName;
```

Configuring forms authentication

Forms authentication is configured as the default option. It uses standard ASP.NET forms authentication and its settings, which you can find in your application's **web.config** file:

```
<system.web>

...

<authentication mode="Forms">
  <forms loginUrl="CMSPages/logon.aspx" defaultUrl="Default.aspx"
name=".ASPXFORMSAUTH" timeout="60000" slidingExpiration="true" />
</authentication>

...

</system.web>
```

If you're running multiple web projects in virtual directories, and the projects have the same machine key defined, users logging in to one of the websites will be automatically logged in to sites running on other projects. To prevent that, add the **path** parameter to the above code in each project, as in the following example:

```
<authentication mode="Forms">
  <forms loginUrl="CMSPages/logon.aspx" defaultUrl="Default.aspx"
name=".ASPXFORMSAUTH" timeout="60000" slidingExpiration="true" path="KenticoCMS" /
>
```

```
</authentication>
```

Additional configuration options related to user passwords may also be defined in the system, as described in the [Password management](#) chapter.

Membership provider and ASP.NET 2.0 Membership support

Kentico CMS contains an ASP.NET 2.0 Membership provider for its user database. This means you can use ASP.NET 2.0 Membership API and controls, such as Login control. However, Kentico CMS uses its own user information database instead of the ASP.NET 2.0 Membership tables. Please see [Membership internals and API -> Database tables](#) for detailed information about the membership database structure.

Configuring Windows authentication

Please see the [Windows authentication \(Active Directory\)](#) sub-chapter to learn more.

Configuring custom authentication

If you want to retrieve user and role information from an external source (such as a custom database), you need to configure the system as described in the [Integrating authentication with external systems](#) topic.

7.13.12.2 Session management

This topic provides a brief overview of how Kentico CMS handles sessions and provides advice on how to mitigate session-based security threats.

When a public user requests a page for the first time, the system creates a session for her. The session stores information about the user, such as the current culture, or the contents of the user's shopping cart.

When the user logs in to the system, the system maintains her session so that the user can keep her session data. However, this can pose a threat, since an attacker could create a session and then trick a user into using the session. The user will then share the same session with the attacker. This way the attacker can acquire sensitive information from the session.

To prevent session based attacks, you can insert the following settings key into the **appSettings** section of your **web.config** file:

```
<add key="CMSRenewSessionAuthChange" value="true" />
```

The key will cause the system to renew the session (abandon the old one and create a new one) every time a user logs in or out.

Important!

If you enable this setting, users will not be able to preserve their session data after logging in or out.

7.13.12.3 Automatic user name completion

Most web browsers support storing user names that you use to access secured areas of websites. This feature, called **Autocomplete**, allows you to conveniently log into frequently used services without the need to type your user name every single time. However, Autocomplete can pose a security threat when used, e.g., on a public computer.

Kentico CMS allows you to set whether you want browsers to offer this feature to users logging in to your website. By default, it is turned on. You can change this in **Settings -> Security & Membership -> Protection -> Enable Autocomplete**. This setting influences the following log-on dialogs:

- Logon page to CMS Desk and Site manager
- Logon web parts
- Shopping cart web part

7.13.12.4 Windows authentication (Active Directory)

7.13.12.4.1 Configuring Windows authentication (Active Directory)

Kentico CMS supports Windows integrated authentication. It means that when a user signs in to a Windows domain, Kentico CMS automatically recognizes their identity without requiring a user name and password.

Moreover, Kentico CMS is able to automatically import the authenticated users from domain (Active Directory) into the user database, including their roles.

Configuration

1. Before you configure your project for *Windows authentication*, you need to create a user account that will be the same as your current domain name and assign this user account with administrator permissions. This will allow you to access all features as an administrator once you sign in using *Windows authentication*.

2. Sign in as an administrator to **Site Manager** and go to **Administration -> Users**. Create a new user with the following values:

- **User name:** your domain user name in format *domain-username*, example: *office-johns*
- **Full name:** your full name

Click **OK**.

3. On the **General** tab, set the following values:

- **Is global administrator:** yes
- **Is external user:** yes
- **Is domain user:** yes

Click **OK**.

4. Now you can switch the application to the *Windows authentication* mode. Edit the *web.config* file of the web project and change the following line:

```
<authentication mode="Forms" >
```

to:

```
<authentication mode="Windows" >
```

5. (Optional) When using *Windows authentication*, you may also want to have the following settings in your *web.config* file so that the windows authentication is required for access to the live site. By default, this code is already present in a commented block in your *web.config*, so you can just uncomment it to achieve the result.

```
<location path="" >
  <system.web>
    <authorization>
      <deny users="?" />
    </authorization>
  </system.web>
</location>
```

6. Save the modified *web.config* file. Close all browsers with Kentico CMS and open the website in a new browser. Try to go to **<web project>\cmssitemanager** to make sure you are recognized as a global administrator.

With this configuration, when an authenticated user comes to the site, their user account is created in Kentico CMS database automatically and their domain groups are imported as roles into Kentico CMS database. It means that the users and roles are not imported on a regular basis, but they are imported when the user comes to Kentico CMS website.

If you are experiencing the 401 error on Windows 7 or Windows Server 2008, learn the solution to the problem [here](#).

Sign out button missing with Windows authentication

When Windows authentication is enabled, the **Sign out** button in the top right corner of **CMS Desk** or **Site Manager** is not displayed. The same applies to the live site, where the sign out link is not displayed in all web parts that can be used to sign out.

Forbidden characters replacement on Active Directory import

When importing users and roles, forbidden characters in their names are replaced by the character defined in **Site Manager** -> **Settings** -> **URLs and SEO** -> **Forbidden characters replacement**.

Dash "-" is the default value and therefore it is used in this example (*domain-username* instead of *domain\username*). If you are using a different character, please change the entered user name accordingly.

You can override this setting by using the following keys in the *AppSettings* section of your *web.config* file. In both cases, the value must be exactly one character which will be used as the replacement character:

- `<add key="CMSForbiddenUserNameCharactersReplacement" value="-" />`
- `<add key="CMSForbiddenRoleNameCharactersReplacement" value="-" />`

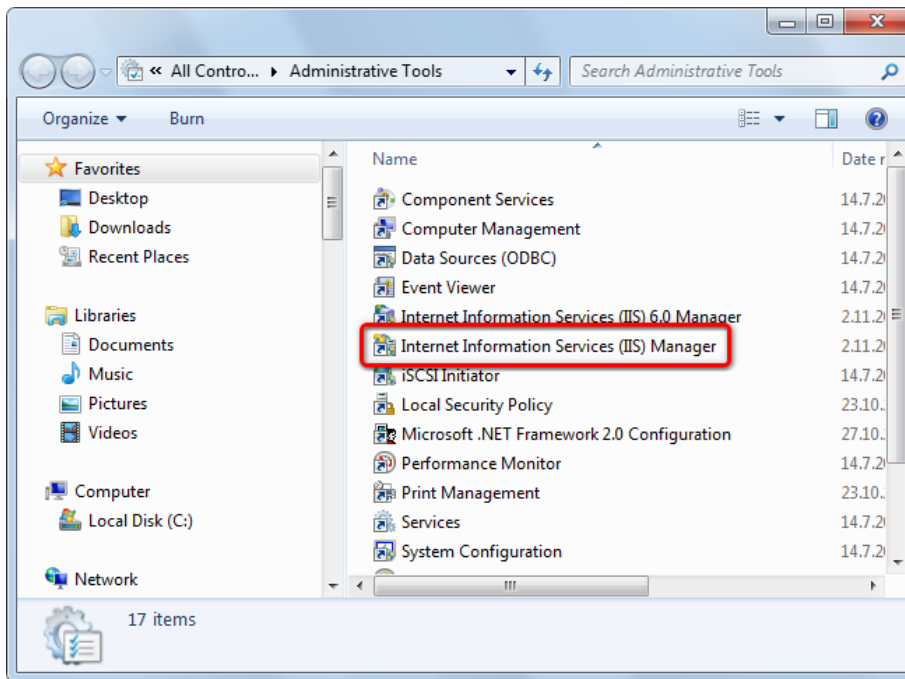

If you want to achieve the same functionality as in **older versions** of Kentico CMS (**office\username**), forbidden characters replacement can be turned off completely using the following two keys. This may cause problems when using wildcard URLs with user names in the wildcard part and is therefore not recommended.

- `<add key="CMSEnsureSafeUserNames" value="false" />`
- `<add key="CMSEnsureSafeRoleNames" value="false" />`

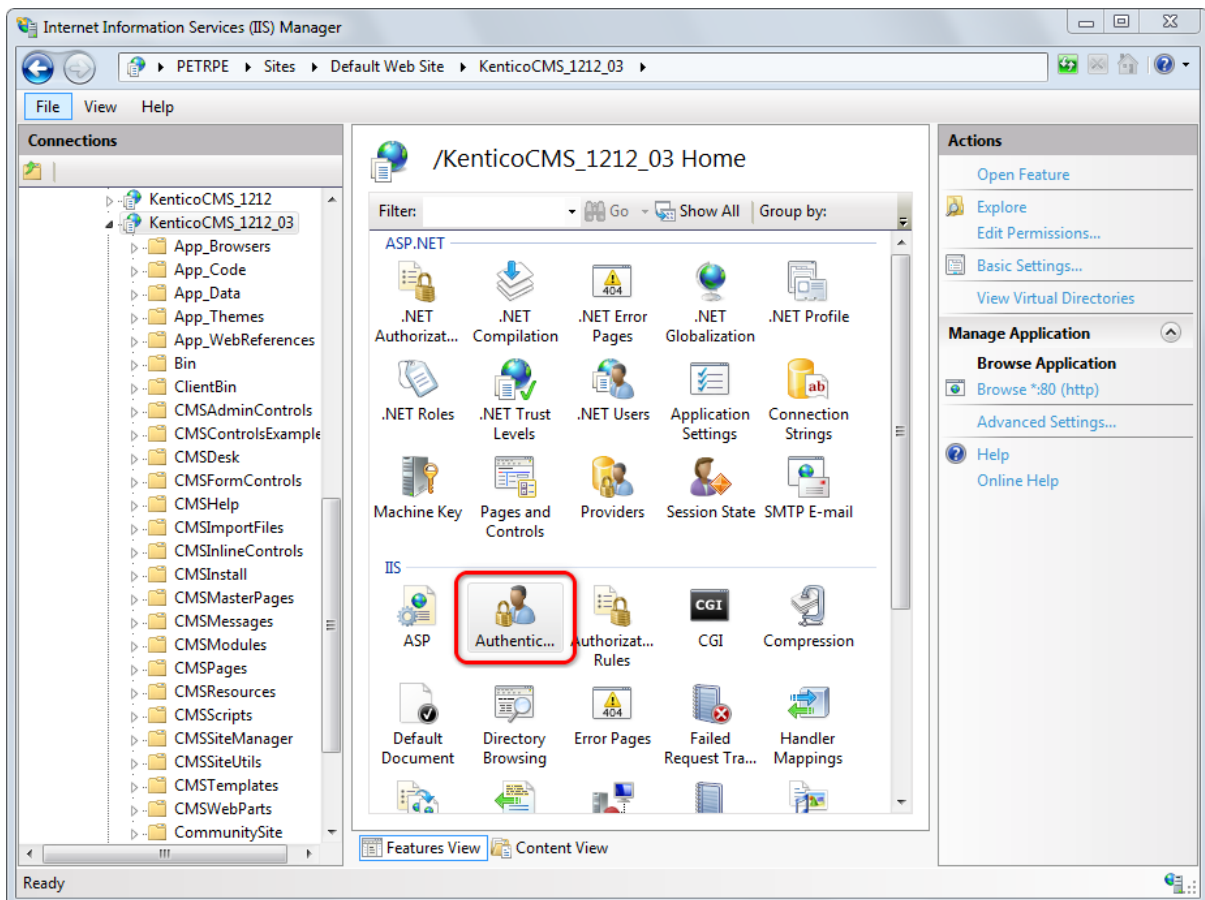

7.13.12.4.2 Windows authentication on Windows 7/2008 R2/Vista (IIS7 or higher)

If you are experiencing the **401 error** with Windows authentication on **Windows 7, Windows Server 2008 R2** or **Windows Vista**, you have to **set up your IIS** the following way:

1. Go to **Start** -> **Control Panel** -> **Administrative Tools** and start the **Internet Information Services (IIS) Manager**.

2. Locate and select your site in IIS tree and click on the **Authentication** icon.

3. Enable **Windows Authentication** by clicking on the **Enable** link in the **Actions** menu.

Windows Authentication missing in the list

The default installation of Windows 7, Windows 2008 R8 and Windows Vista does not contain Windows Authentication by default. If it is missing in the list in step 3 above, you need to install it.

To do it, go to **Control Panel -> Programs and Features -> Turn windows features on or off**. Scroll down to *IIS*, expand all of the nodes to find the *Security* node and under it, check the Windows Authentication check-box. Click **OK** to save the settings.

7.13.12.4.3 Securing a web site section using Windows authentication

It is also possible to secure only a certain section of your website using Windows authentication. In the following example, you will learn how to set the **Products** section of the sample **Corporate site** to be secured by the Windows authentication:

1. Locate your web project on the disk (typically *c:\inetpub\wwwroot\<web project>*). Create a new directory in your web project's folder and give it the same name as the filename in the document's URL.

In this case, the filename is *Products.aspx*, so we will create a folder named **Products**.

2. Open the IIS and locate the folder in the tree. Select it and open the **Authentication** configuration on the right.

3. Right-click **Anonymous Authentication** and choose to **Disable** it.

4. Open the web.config file of your web project and change value of the **mode** attribute of the

authentication tag to **Windows**. Also find the section marked with **Windows authentication BEGIN** and change the path parameter of the location tag to the name of the created directory, which will be **Products** in our case:

```
...
<authentication mode="Windows">
...

<!-- Windows authentication BEGIN -->
<location path="Products">
  <system.web>
    <authorization>
      <deny users="?" />
      <allow users="*" />
    </authorization>
  </system.web>
</location>
<!-- Windows authentication END -->
```

5. The authentication is now configured. If you try to access any of the menu items placed under the **Products** section, **Windows authentication** will be required. However, if you also want the authentication to be required for the **Products** main page (which is obviously not located under itself, hence requires no authentication now), you will have to use the following workaround.

Create a new page under the **Products** section, give it the same content as the main page has got and redirect the **Products** link in the menu to this new page. Because the new page is located under the **Products** section, windows authentication will be required for it.

The screenshot shows the Kentico CMS Desk interface. The left sidebar displays a tree view of the site structure, with the 'Products' folder selected. The main content area shows the 'Menu' properties for a selected item. The 'Menu actions' section is expanded, and the 'URL redirection' option is selected and highlighted with a red circle. The 'URL redirection' field contains the value '~ /Products/Main.aspx'. Below this field, there is an example: 'Example: http://www.mydomainxy.com or ~/products.aspx'.

7.13.12.5 Configuring mixed mode authentication

Mixed mode authentication enables users to sign in to your website using both Windows authentication and standard forms authentication.

**Important!**

During a sign-in, if an already existing forms user has the same user name as a domain user you want to sign in with, the system signs in the forms user. As a result, an account cannot be created for the domain user. You can avoid this behavior by renaming the existing forms user.

To enable mixed authentication mode:

1. Edit your application's *web.config* file.
2. Add the LDAP connection string of your Active Directory service into the **configuration/connectionStrings** section:

```
<connectionStrings>
...
<add name="CMSADConnectionString" connectionString="<LDAP connection string>" />
</connectionStrings>
```

Replace the **<LDAP connection string>** text in the code above with the actual connection string. Enter it in according to the following format:

```
LDAP://mydomain.example.com/DC=mydomain,DC=example,DC=com
```

The first part is the full domain. In the second part, the same domain is divided into DC (domain component) units.

3. Modify the **membership** and **roleManager** elements under the **configuration/system.web** section according to the following:

```
<membership defaultProvider="CMSProvider" userIsOnlineTimeWindow="30">
  <providers>
    <clear/>
    <add name="CMSProvider" type="CMS.MembershipProvider.CMSMembershipProvider"
connectionStringName="CMSConnectionString" enablePasswordRetrieval="false"
enablePasswordReset="true" requiresQuestionAndAnswer="false"
requiresUniqueEmail="true" passwordFormat="Hashed" />
    <add name="CMSADProvider"
type="CMS.MembershipProvider.CMSADMembershipProvider"
connectionStringName="CMSADConnectionString" connectionUsername="username"
connectionPassword="password" />
  </providers>
</membership>
```

```
<roleManager defaultProvider="CMSRoleProvider" enabled="true"
cacheRolesInCookie="true" cookieName=".ASPROLES" cookieTimeout="30" cookiePath="/"
cookieRequireSSL="false" cookieSlidingExpiration="true" cookieProtection="All">
  <providers>
    <clear/>
    <add name="CMSRoleProvider" type="CMS.MembershipProvider.CMSRoleProvider"
connectionStringName="CMSConnectionString" applicationName="SampleApplication"
writeExceptionsToEventLog="false" />
    <add name="CMSADRoleProvider" type="CMS.MembershipProvider.CMSADRoleProvider"
connectionStringName="CMSADConnectionString" connectionUsername="username"
connectionPassword="password" />
  </providers>
</roleManager>
```

Replace the following values:

- **username** - your own active directory user name, including the fully qualified domain name. For example, office.example.com\johns
- **password** - your active directory password

When you have entered this code into your *web.config*, users can log in using their Active Directory user name (without the domain) and password, or using their standard Kentico CMS user name and password.

Mixed authentication on Windows XP

When running the application on Windows XP, users need to enter AD usernames including the domain name: *<domain name>user*

You can also allow users to sign in using their full Active Directory user name (e.g. *MyName@office.example.com*). For this to work, you have to add the following key to the *AppSettings* section of your *web.config* file:

```
<add key="CMSADDefaultMapUserName" value="userPrincipalName" />
```

7.13.12.6 Integrating authentication with external systems

Kentico CMS allows you to write a custom authentication provider. In this way, the provided user name and password are checked against an external user profile source/authentication source and if the user is successfully authenticated, the user account is automatically created/updated in the Kentico CMS database, without copying the user password.

You can integrate your custom authentication provider with Kentico CMS using the [Global events and their handling](#) approach.

7.13.12.7 Single sign-on

Single sign-on is a feature which enables users to authenticate just once and then access multiple websites without the need to enter logon credentials again for each site. There are two ways how you can achieve this:

- [Single sign-on on the same main domain](#) - this approach lets you configure single sign-on for multiple sites running on the same main domain (e.g. `site1.example.com`, `site2.example.com`, etc.) in the IIS. The sites need not be using Kentico CMS.
- [Single sign-on across different domains](#) - this approach requires all websites to be running in a single instance of Kentico CMS, while they can use completely different domains.

The sections below describe necessary configuration for each approach.

Single sign-on on the same main domain

Single sign-on on the same main domain is supported in the following scenarios:

Forms Authentication

If you are using Forms authentication and you need to share user identity across applications that run on the same main domain while all of them use standard ASP.NET 2.0 Forms authentication, you need to ensure that:

1. All applications use the same user database or at least the same user names. You may need to integrate the authentication using a [custom security handler](#).
2. The `web.config` file of all applications uses the same authentication cookie name and the path is set to `/`:

```
<authentication mode="Forms">
  <forms name=".ASPXFORMSAUTH" path="/" ...="" />
</authentication>
```

3. The `web.config` file of all applications uses the same [machine key](#). The machine key is not present in the `web.config` by default. You can generate it using various machine key generators that can be found on the Internet. Once you have a key generated, you can add it to the `<system.web>` section the following way:

```
<system.web>
  ...
  <machineKey validationKey="ABCD0708...." decryptionKey="DDFF8943...."
validation="SHA1" />
  ...
</system.web>
```

4. If your applications run on different sub-domains, such as `www.example.com` and `forums.example.com`, you need to set the domain attribute of the authentication cookie to the main domain so that it's shared across domains:

```
<forms name=".ASPXFORMSAUTH" path="/" domain=".mywebsite.com" ...="" />
```

Windows Authentication

If you are using Windows authentication, the user identity is shared within the Windows domain. No additional configuration is required.

Single sign-on across different domains

Single sign-on across completely different domains in the same instance of Kentico CMS can be enabled by checking the **Automatically sign-in user when site changes** check-box in **Site Manager -> Settings -> Security & Membership**.

With this option enabled, no further configuration is necessary - users only need to enter their logon credentials once. After that, they can switch between different sites running in the CMS using the **Site** drop-down list in CMS Desk, without the need to enter their logon credentials for each domain.

The single sign-on functionality is also achievable on your custom pages using Kentico CMS API. The following code example shows how you can authenticate a user with a particular username in your code:

[C#]

```
string userName = "testuser";  
// Authenticates user with specified user name  
CMSContext.AuthenticateUser(userName, false);
```

The second code example shows how you can generate a URL with a user authentication token. When a user accesses this URL, they are automatically authenticated.

[C#]

```
string userName = "testuser";  
// Get user with specified user name  
UserInfo userInfo = UserInfoProvider.GetUserInfo(userName);  
// Get authentication URL for specified user and target URL  
string url = AuthenticationHelper.GetUserAuthenticationUrl(userInfo, "/  
default.aspx");  
// Redirect user to target URL and authenticate him  
URLHelper.Redirect(url);
```

7.13.12.8 Displaying personalized content

Kentico CMS allows you to personalize the displayed content based on the current user.

Personalization in short

1. If you want to customize content displayed to the users, you need to grant or deny the READ permission to these users and turn on the **Check permissions** attribute of the appropriate web parts.
2. When the user is not authenticated, the system uses a special user **Public anonymous User (public)**.

Checking the permissions of the current user allows basic personalization, but the [Content personalization](#) module may be used to achieve much more advanced personalization scenarios according to completely custom conditions.

Example: Personalizing the Products menu

In this example, you will learn how to display the **Products** section only to members of the **Customers** and **Partners** roles and how to display the **Smartphones** category only to the members of the **Partners** role.

1. Sign in to **CMS Desk** as administrator.
2. Go to **Administration -> Roles**, select the *Corporate Site* from the **Sites** drop-down list and create new roles **Customers** and **Partners**.
3. Go to **Administration -> Users** and create a new user **Customer1** with the following values:
 - **User name:** Customer1
 - **Full name:** Testing Customer
 - **Enabled:** true
 - **Is editor:** no

Click **OK**. Go to the **Sites** tab and assign the user to the *Corporate Site*. Go to the **Roles** tab and add the user to the **Customers** role.

4. Create another user **Partner1** with the following values:
 - **User name:** Partner1
 - **Full name:** Testing Partner
 - **Enabled:** true
 - **Is editor:** no

Click **OK**. Go to the **Sites** tab and assign the user to the *Corporate Site*. Go to the **Roles** tab and add the user to the **Partners** role.

5. Navigate to **Site Manager -> Settings -> Security & Membership** and set **Check page permissions** to *All pages*. This ensures that the security settings assigned in the following steps will be checked for all documents (pages) on the website.

6. Switch to **CMS Desk -> Content** and click the root of the content tree. Switch to **Properties -> Security**.

First, we need to grant the **Read** permission for the whole website to the **Public anonymous user (public)**, **Customers** and **Partners** roles.

Click **Add users**, select these three users and click **OK**. When the users are added, grant the **Read** permissions to them using the check-box () , as you can see in the screenshot below. You need to click **OK** in order to save the settings.

The screenshot shows the Kentico CMS Desk interface. The left sidebar displays the content tree with 'Corporate Site' expanded. The main area shows the 'Properties' tab for a document, with the 'Security' sub-tab selected. The 'Permissions' section indicates that the document does not inherit permissions from its parent. Below this, there are two columns: 'Users and Roles' and 'Access rights'. The 'Users and Roles' list includes 'Testing Customer (Customer1)', 'Testing Partner (Partner1)', and 'Public Anonymous User (public)'. The 'Access rights' table has columns for 'Allow' and 'Deny'. The 'Read' row has a checked checkbox in the 'Allow' column, which is circled in red. At the bottom, there are buttons for 'Add users', 'Add roles', 'Remove', and 'OK'. The 'Add users' button is also circled in red.

| | Allow | Deny |
|--------------------|-------------------------------------|--------------------------|
| Full control | <input type="checkbox"/> | <input type="checkbox"/> |
| Read | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Modify | <input type="checkbox"/> | <input type="checkbox"/> |
| Create | <input type="checkbox"/> | <input type="checkbox"/> |
| Delete | <input type="checkbox"/> | <input type="checkbox"/> |
| Destroy | <input type="checkbox"/> | <input type="checkbox"/> |
| Browse tree | <input type="checkbox"/> | <input type="checkbox"/> |
| Modify permissions | <input type="checkbox"/> | <input type="checkbox"/> |

7. Now we will hide the product categories from public users. In the content tree, click **/Products/ Smartphones** and switch to the **Properties -> Security** tab. The permissions that you configured for the root of the content tree are inherited by this document. We need to break the inheritance. Click the **Change permission inheritance** link.

Permissions

This document inherits permissions from the parent document.

[Change permission inheritance...](#)

Users and Roles:

- Testing Customer (Customer1)
- Testing Partner (Partner1)
- Public Anonymous User (public)

Access rights:

| | Allow | Deny |
|--------------------|-------------------------------------|--------------------------|
| Full control | <input type="checkbox"/> | <input type="checkbox"/> |
| Read | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Modify | <input type="checkbox"/> | <input type="checkbox"/> |
| Create | <input type="checkbox"/> | <input type="checkbox"/> |
| Delete | <input type="checkbox"/> | <input type="checkbox"/> |
| Destroy | <input type="checkbox"/> | <input type="checkbox"/> |
| Browse tree | <input type="checkbox"/> | <input type="checkbox"/> |
| Modify permissions | <input type="checkbox"/> | <input type="checkbox"/> |

In the following dialog, choose **Break inheritance and copy parent permissions**.

8. Now select the **Public Anonymous User (public)** and deny the **Read** permission.

9. Repeat the last two steps for the **Laptops and Tablets** page. Also deny the **Smartphones** category for the **Customers** role.

10. The permissions are not checked by web parts by default, so we need to configure the web parts so that they check the **Read** permission of the current user.

Choose the root in the content tree and click the **Design** tab. Configure (⚙️) the **Top list menu** (CSS list menu) web part and set its **Check permissions** property in the **System settings** category to true () . Click **OK**. Repeat the same for the **CSS list menu** and **Featured products** web parts on the **/Products** page.

11. Sign out. If you mouse-over the **Products** menu item as a public user, you will see that the sub-categories representing the restricted sections are no longer displayed.

12. Sign in as user **Customer1** (use the logon mini-form at the top right of the page) and navigate to **Products** via the main menu. You will see a page like the one below. As you can see, the **Smartphones** section and **Smartphone** products are not displayed to this user.

Sign in to [CMS Desk](#). Sign in to [CMS Site Manager](#). The default account is administrator with blank password. Testing Customer (Customer1) [Log off](#)

You have learned how to personalize the content displayed to users based on their permissions.

7.13.13 Password management

7.13.13.1 Overview

Passwords are a critical part of any authentication process. Kentico CMS provides various password-related features that you can leverage to achieve the level of security required by your website. These settings can be found in **Site Manager -> Settings -> Security & Membership -> Passwords**.

The features include:

- A set of [password encryption format](#) options.
- Ability to reset and [recover user passwords](#).
- Ability to [specify password strength](#) and policy to enforce the specified strength.
- Ability to set time after which [passwords expire](#) and users are required to change them.
- [Locking a user's account](#) when they enter an incorrect password too many times.

7.13.13.2 Password format

There are multiple different formats that can be used to store passwords in the database. They may be saved either in plain text or as the result of a security hash function. You can choose which option should be used via the **Password format** setting.

By default, passwords are stored using the *SHA2* hash format with the additional application of a *salt*. A salt is a string that is appended to passwords before they are encrypted, which helps protect against dictionary or other types of brute force attacks. It also ensures that every user has a different password hash, even if multiple users have the same password. The GUID of each user is assigned as the salt for the password. If you wish to further increase the length of the salt, you can add the following key to the /

configuration/appSettings section of your web.config file:

```
<add key="CMSPasswordSalt" value="SaltText" />
```

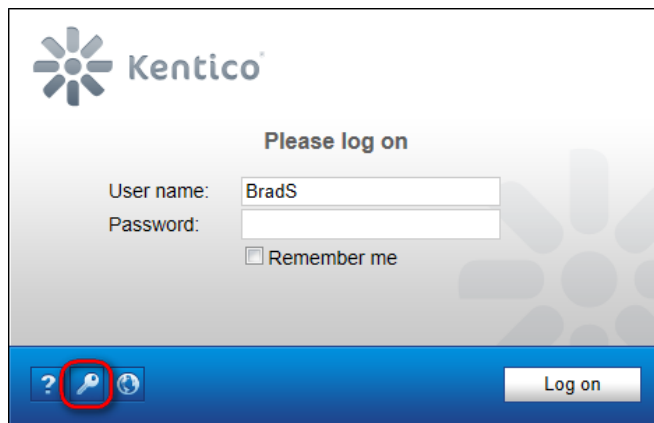

The value of this key will be added to the salt after the user GUID.

If you change the password format, please keep in mind that this only affects how future passwords will be stored. Existing passwords will remain unchanged. You will need to reset all passwords, so that they are stored in the new format. For this reason, it is recommended to set the appropriate format directly after installation, before you create user accounts or allow users to start registering.

7.13.13.3 Password recovery

If a user forgets their password, they may retrieve or reset it, provided they have access to the e-mail address specified for their account. A password may be recovered by submitting a request through one of the website's logon forms.

By default, a forgotten password button is included on the logon page of the CMS Desk and Site Manager administration interface.

You can hide the button by adding the following key to the **/configuration/appSettings** section of your web.config file:

```
<add key="CMSShowForgottenPassLink" value="false" />
```

On the live site, users can recover their password through [Logon form](#) web parts that have their **Allow forgotten password retrieval** property enabled.

The screenshot shows a web form for user authentication and password recovery. It contains the following elements:

- A text input field labeled "User name:" with the value "Andy".
- A text input field labeled "Password:" which is currently empty.
- A checkbox labeled "Remember me" which is unchecked.
- A button labeled "Log on".
- A link labeled "Forgotten password".
- A text input field labeled "Your user name or e-mail:" with the value "Andy".
- A button labeled "Send password".

When submitting the request, users can either type in their user name or e-mail address. If a user name is entered, the recovery e-mail will be sent to the given account's address. In cases where an address is used, the request will affect the password of the user account with the corresponding address. Password recovery e-mails are sent from the address specified in the **Send password e-mails from** setting.

Depending on the value of the **Reset password requires e-mail approval** setting, one of two possible password recovery modes will be used.

Password reset without e-mail approval

If the **Reset password requires e-mail approval** setting is *disabled*, then users who request their password will receive an e-mail containing the password directly. If the current [password format](#) is plain text, the existing password will be sent to the user. If an encrypted password format is used, the system will generate a new password for the user.

Password reset with e-mail approval

If the **Reset password requires e-mail approval** setting is *enabled*, several steps will be added to the process. Users who submit a password recovery request through a logon form will first receive an e-mail containing a link to a page where they can manually set a new password. This option is more secure, because the password cannot be read from the e-mail by potential attackers. Also, the reset link is only valid temporarily. The time period during which the link is valid can be specified in hours by the **Reset password interval** setting.

When a user clicks the link in the e-mail, they will be redirected to the default **~/CMSModules/Membership/CMSPages/ResetPassword.aspx** system page, where they will be able to enter a new password. The URL of the link contains a token in its query string that automatically identifies the user whose password should be changed. After someone visits the link, it becomes invalid and cannot be accessed again.

If you wish to use a custom page for this purpose, simply create a new page on the website according to your specific requirements and place the [Reset password](#) web part on it. This web part displays a form with the same functionality as described above for the **ResetPassword.aspx** system page. After you create the page, enter its URL into the **Reset password page URL** website setting, or into the same property of individual **Logon form** web parts.

If the **Send e-mail with reset password** setting is enabled, users will receive another e-mail containing their new password once they successfully reset it.

Global administrator password

If you happen to lose the password for your administrator account and cannot access the management interface, you can use one of the following techniques to recover:

- **Reset password via web.config key** - insert the following key to the **appSettings** section of your web.config:

```
<add key="CMSAdminEmergencyReset" value="<your username>;<your new password>;[true/false]" />
```

The first and second parameter specify your user name and your new password, delimited by a semicolon. The third parameter is optional and indicates whether you want to create a new user with global administrator rights.

The key will be automatically deleted after you gain access to the user interface.

- **Clear password in database** - find your user record in the **CMS_User** table and clear the contents of the **UserPassword** column. Then sign in to the administration interface with a blank password and set a new password.

Password recovery e-mail templates

The e-mails sent to users during the password retrieval process are based on [E-mail templates](#), which can be found in **Site manager -> Administration -> E-mail templates**. The following password-related templates are available:

- **Membership - Forgotten password** - sent to users when they use the password recovery feature and the *Reset password requires e-mail approval* setting is disabled.
- **Membership - Change password request** - sent as a reply to password recovery requests if *Reset password requires e-mail approval* is enabled.
- **Membership - Changed password** - sent to users if their password is changed by an administrator, either manually or by generating a new one.
- **Membership - Resend password** - used if the current password information is sent to a user from the administration interface (this can only be done if passwords are stored in plain text format).

These templates can be edited as needed, so you may fully customize the content of the e-mails. You can enter the following [context macros](#) to include dynamic values in their text:

- **{% UserName %}** - the name of the user's account. If you are using site prefixes for user names, all occurrences of this macro in e-mail templates can have the prefix trimmed out with the following method: `{% TrimSitePrefix(UserName)%}`
- **{% Password %}** - the current (new) password of the given user.
- **{% LogonURL %}** - returns the URL of the page where the retrieval password request was submitted. Only available in the *Forgotten password* template.

The two macros below are available specifically in the **Change password request** template:

- **{% ResetPasswordURL %}** - resolves into the URL of the page where the user can change their password.
- **{% CancelURL %}** - returns the URL of a page that will cancel the request when opened. This can be used to create links that users can click in situations where someone else requested a new password for their user account (either intentionally or accidentally).

In addition to the special ones listed above, you can also use all other standard macro expressions in the templates. See the [Development -> Macro expressions](#) chapter of this guide for more information about macro expressions in Kentico CMS.

7.13.13.4 Password strength policy

The system can be configured to use a password policy, which means that new passwords entered by users will be validated according to a certain set of requirements. Passwords that do not meet the specified conditions will be rejected.

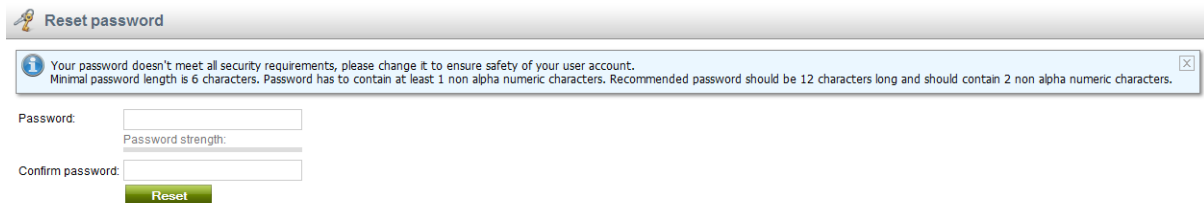

To enforce a password policy on your website, enable the **Use password policy** setting. The specific rules of the policy can be configured through the remaining settings in the category:

- **Minimal length** - sets the minimum number of total characters required for user passwords.
- **Number of non alphanumeric characters** - sets the minimum number of non alphanumeric characters (i.e. any character except for numbers and letters) that must be present in a password in order for it to be accepted.
- **Regular expression** - can be used to enter a regular expression that will be used to validate user passwords. For example: `^(?=.*[a-z])(?=.*[A-Z]).*$`
This sample expression would require passwords to contain at least one lower case letter, upper case letter and number. The minimum amount of characters would be determined by the other policy settings.

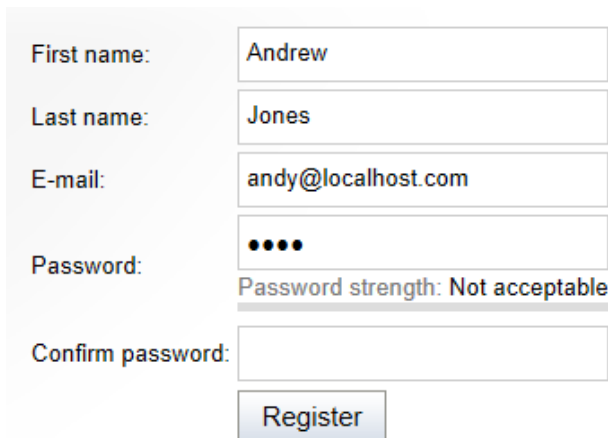

The requirements defined by all three settings are combined together to form the final password policy.

The policy is applied in all sections of the website where a new password can be entered. This includes various types of web parts that display forms on the live site, such as [My account](#) or the [Registration form](#), and the administration interface (**Administration -> Users**). The requirements of the policy, except for the regular expression, are additionally observed when the system automatically generates new passwords. This is also the case if the **Use password policy** setting is disabled, so you can affect how passwords should be generated even if you do not wish to set a policy for your website's users.

When you introduce a password strength policy, existing users are by default allowed to keep their passwords unchanged. To force existing users to observe the policy, enable the **Force password policy on logon** setting. With this setting enabled, the system will check whether a user's password meets the policy requirements every time a user logs in. When the password doesn't meet the requirements, the user is presented with a form that allows to change the password.

When a user types in a password, it is validated in real time and its status is reflected by an indicator below the field. If a policy is set, passwords that do not fulfill the requirements will be rejected with the *Not acceptable* status.

Valid passwords will have a different status displayed according to their relative strength, which is calculated based on the recommended values for the total password length (12 by default) and number of non alphanumeric characters (2 by default). If a password policy is not enabled for the website, the current strength status of passwords will still be shown, but only as a recommendation and all passwords will be accepted.

To help users come up with an appropriate password, you can use the **Policy violation message** setting to specify a text message that will be displayed to users who attempt to enter a password that does not fulfill the requirements of the password policy. If left empty, a default message will be shown, informing about the minimum password length and number of non alphanumeric characters. If you wish to use a regular expression, it is recommended to describe its requirements in a custom message. If your site has multiple cultures (languages) assigned to it, you can enter a different message for each language via the **Localize** (🌐) action available next to the setting's field.

Customizing the password strength indicator

You can change the recommended values that are used to calculate the password strength by editing the code of the appropriate controls:

To set different values globally for the entire application, edit the code behind of the `~/CMSModules/Membership/FormControls/Passwords/PasswordStrength.ascx` control and enter different numbers into the `mPreferredLength` and `mPreferredNonAlphaNumChars` variables.

You can also override the values for specific instances where this control is used through its **PreferredLength** and **PreferredNonAlphaNumChars** properties (e.g. in the code of the *Registration form* web part).

The appearance of individual password strength status labels may be customized through CSS styles. Each one has a different class assigned, e.g. *PasswordStrengthNotAcceptable*

Password policy and strength in custom forms

When creating custom forms, you can easily add password fields that validate according to the specified policy and display password strength.

To do this, specify either the **Password strength** or **Password with confirmation form control** for the given field, which will automatically ensure the functionality described above.

7.13.13.5 Password expiration

With the available password settings, you can set the passwords to expire after a specified amount of time.

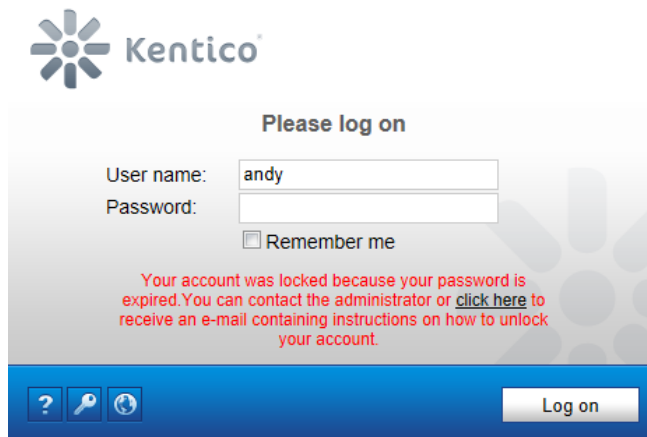

You can turn on password expiration with the **Enable password expiration** setting. When a user logs in to the system, the password expiration period (specified in days by the **Password expiration period** setting) is added to the time when the user last modified their password, and then compared with the current time. If the resulting time is earlier than the current time, the particular user's password has expired.

The expiration leads to one of the two following scenarios, which can be set by the **Password expiration behavior** setting.

- **Show warning** - displays a warning text. The user can click the **Change the password now** link to open a dialog that will allow them to conveniently change their password.

- **Lock account** - locks the user's account, requiring the user to unlock their account and change their password.

The system can warn the users that their password is about to expire. You can adjust the period during which users will be displayed with the warning via the **Password expiration warning period** setting.

Notifying live site users

By default, notifications related to password expiration are displayed only in the administration interface. To notify also live site users, place the **Password expiration** web part on a page.

Resetting a password

Users can change their expired password on a special page. You can either use the default page (`~/CMSModules/Membership/CMSPages/ResetPassword.aspx`), or specify a custom page in the **Reset password page URL** setting.

A custom password reset page should contain one of the following components:

- **Reset password web part** - a web part you can use in the Portal engine development model.
- **ResetPassword control** - an alternative to the Reset password web part, which can be placed on an ASPX page. The control is located in `~/CMSModules/Membership/Controls/ResetPassword.ascx`.

Notifying users by e-mail

By turning the **Send password expiration e-mail setting** on or off, you can specify whether you want to notify users about the expiration of their password via e-mail.

The **Site Manager -> Administration -> E-mail templates** section contains a predefined template (**Membership - Password expiration**) that is sent to users when their password expires. The template contains the `{% ResetPasswordUrl %}` macro, which is resolved to a link that points to the URL of the page that allows to change the user's password.

Extending password validity

To extend the validity of any user's password, edit the user in **CMS Desk or Site Manager -> Administration -> Users** and on the **General** tab, click **Extend validity**. The password's validity will be reset to the **Password expiration period** setting's value and the user enabled in case their account has been locked due to expired password.

| | |
|-------------------------|---------------------------------------|
| Created: | 10/21/2008 4:37:52 PM |
| Last logon: | N/A |
| Last logon information: | |
| Invalid logon attempts: | 0 attempt(s) Reset |
| Password expires in: | 4 day(s) Extend validity |
| Starting alias path: | <input type="text"/> |

7.13.13.6 Invalid logon attempts

One of the most common threats to website security is stealing user accounts. To compromise an account, attackers use a simple method, which tries to guess the password for that account, either by combining different characters, or by selecting passwords from a dictionary. This threat can be easily eliminated by introducing a limit of invalid logon attempts, which means users will have their account locked after entering an incorrect password for the specified number of times. Users cannot log in to a locked account.

You can set up limiting the number of allowed invalid logon attempts in **Settings -> Security & Membership -> Protection** in the **Invalid logon attempts** group, which contains the following settings:

- **Maximum invalid logon attempts** - specifies the number of attempts to log in that the user can try before the system locks their account and denies access. If set to zero, account locking will be disabled.
- **Send unlock account e-mail** - indicates whether an e-mail should be sent to the user if their account gets locked.
- **Unlock user account path** - allows selecting the path (or typing in the URL) of a custom page, on which the user can unlock their account.

Resetting the number of invalid logon attempts

When you edit a user in **Site Manager -> Administration -> Users**, you can view the number of invalid logon attempts the user made in the **Invalid logon attempts** field. To reset the number back to zero and unlock (enable) the user's account in case the user has reached the limit, click the **Reset** button.

| | |
|-------------------------|---------------------------------------|
| Created: | 10/21/2008 4:37:52 PM |
| Last logon: | N/A |
| Last logon information: | |
| Invalid logon attempts: | 2 attempt(s) Reset |
| Password expires in: | 4 day(s) Extend validity |
| Starting alias path: | <input type="text"/> |

7.13.13.7 Unlocking an account

A user account can be locked for one of the following reasons:

- The user's [password expires](#).

- The user reaches the limit of [invalid logon attempts](#).

The following text describes how you can provide users with means to unlock their accounts.

Password expired

When an account is locked due to password expiration, the particular user will be required to change their password in order to unlock their account. To learn how to facilitate that, refer to the [Password expiration](#) topic.

Alternatively, you can extend the password's validity, as described in the [Password expiration](#) topic.

Invalid logon attempts exceeded

When an account is locked due to exceeding the number of invalid logon attempts, the particular user will have to manually unlock their account. You can enable them to do that by directing them to the `~/CMSModules/Membership/CMSPages/UnlockUserAccount.aspx` page.

Alternatively, you can create a custom page for unlocking accounts, on which you can place one of the following components:

- **Unlock user account web part** - a web part you can use in the Portal engine development model.
- **UnlockUserAccount control** - an alternative to the Unlock user account web part, which can be placed on an ASPX page. The control is located in `~/CMSModules/Membership/Controls/UnlockUserAccount.ascx`.

Notifications

You can then specify whether you want users to receive an e-mail notifying them that their account has been locked in the **Send unlock account e-mail** setting. The notification e-mail uses the **Membership - User account locked** template. You can inset a link to the account unlock page with the `{% UnlockAccountUrl %}` macro.

Users can also be notified directly when logging in. To enable this option, set the **Display account lock information message** setting to true. However, enabling this feature is not recommended, since it can reveal to a potential attacker the fact, that they've managed to lock a user's account.

7.13.14 Third-party authentication services

7.13.14.1 Overview

Third-party authentication services provide an alternative way how users can log in and register to your site. This way, they do not need to go through the registration process and create a new username and password for your site. Instead, they can use the same username and password that they already use on some popular site (like Windows Live, Facebook, LinkedIn, Google, Yahoo!, etc.). Even new users can log on to your site like this, in which case a new user account is created.

Kentico CMS supports the following authentication providers:

- [Windows Live ID](#)
- [OpenID](#)

- [Facebook Connect](#)
- [LinkedIn](#)

Click the links above to learn more about how to set up authentication using the particular provider.

7.13.14.2 Windows Live ID

7.13.14.2.1 Overview

Windows Live ID is a single sign-on service provided and maintained by Microsoft. By integrating Live ID into your website, you can allow site visitors to log in to your website using their Live ID login and password.

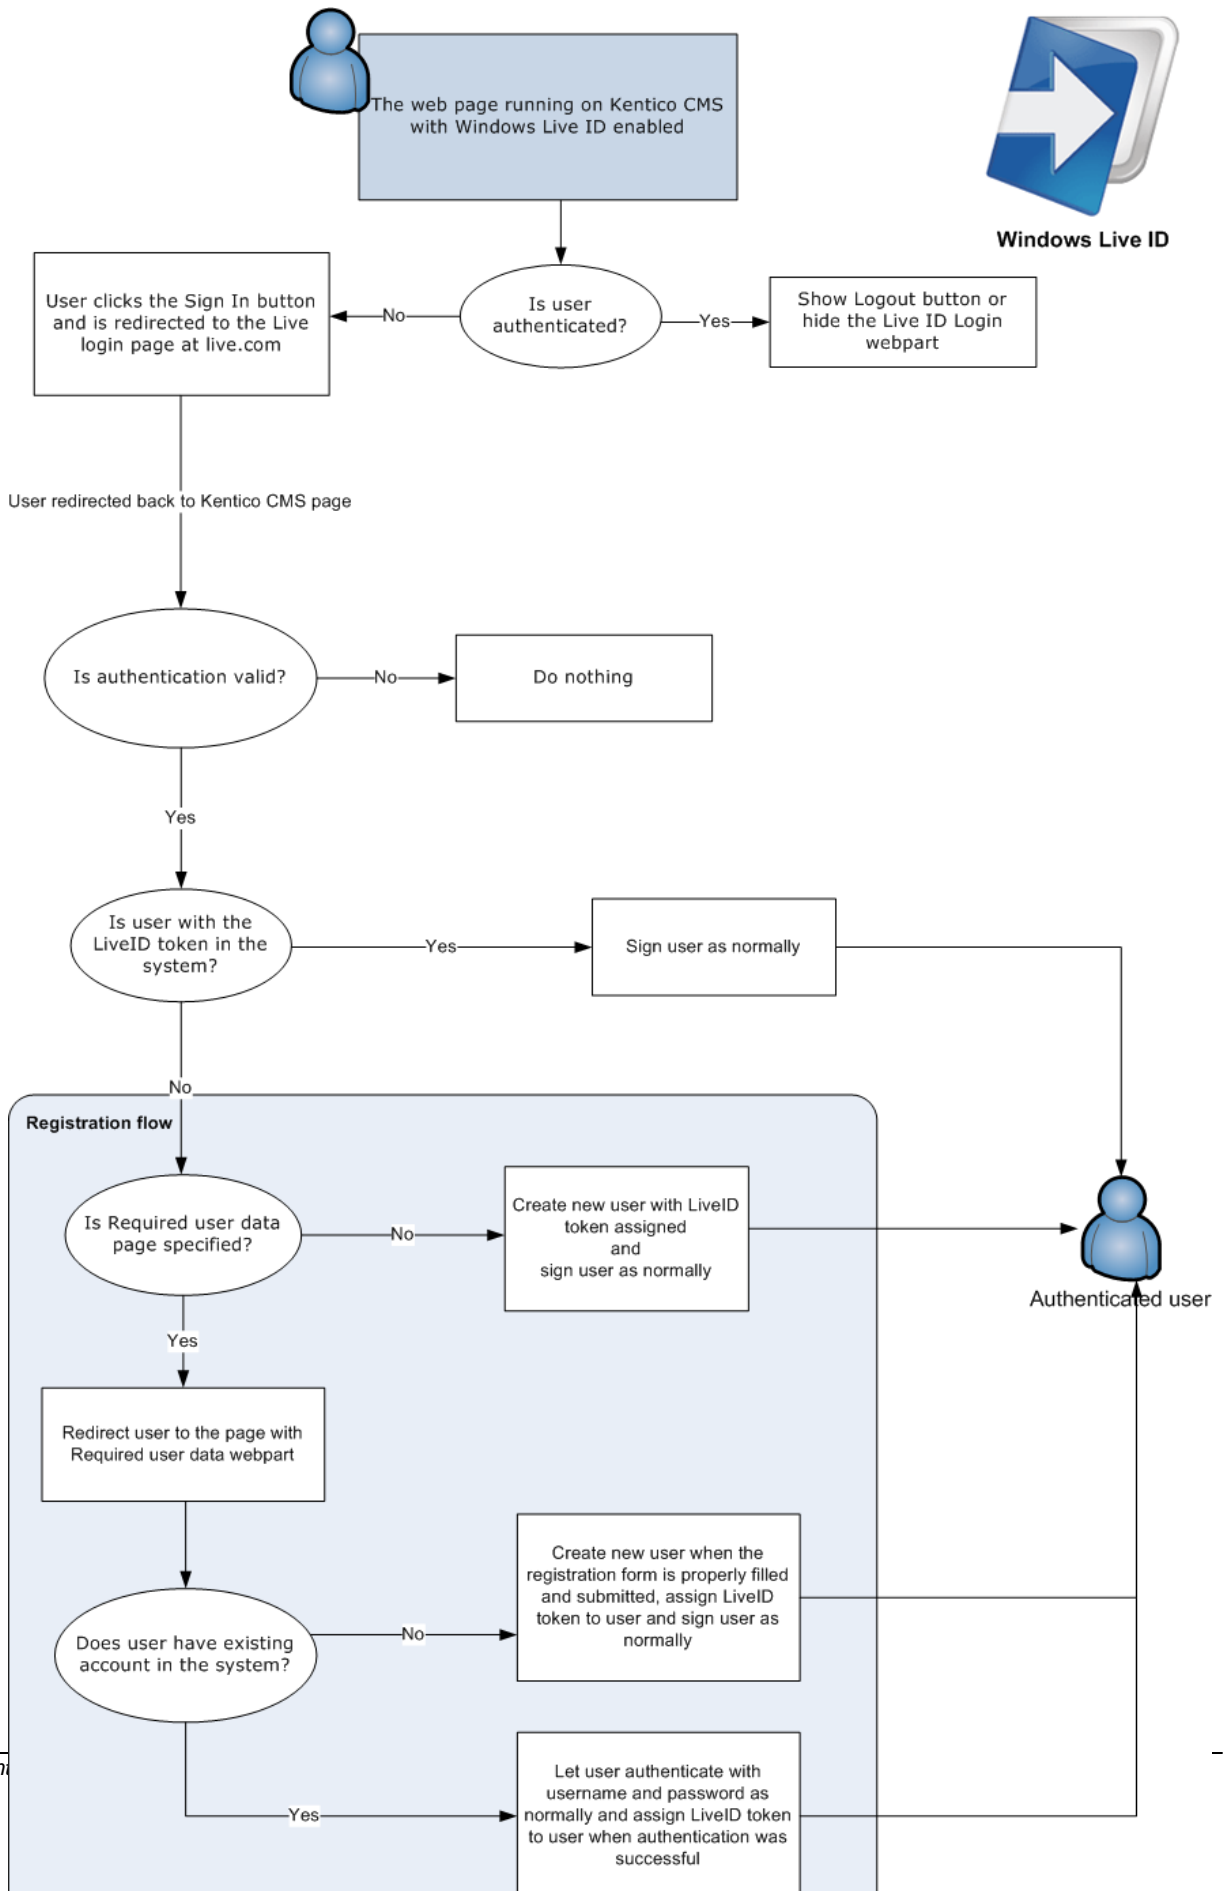

How to start using Windows Live ID

For this to work on your site, you have to do the following:

1. Register your website at <https://manage.dev.live.com/> - to learn how this can be done, please refer to [Registering your application](#).
2. Set up Kentico CMS for Live ID authentication - for more details, please see the [Settings](#) topic.
3. Use one of the Live ID web parts on the appropriate page on your site - more information in the [Available web parts](#) topic.

How it works

The following diagram shows how the process of Live ID login works.

Windows Live ID

Registration approval and double opt-in

If your site is configured to require [registration approval or double opt-in](#), first-time users who attempt to log in with their Live ID will be redirected to the standard logon page without any further information, which may lead to confusion.

This issue can be avoided by creating a **Required user data page** (described later in this chapter) where users must enter an e-mail address for their account. When this is done, users will receive a notification e-mail about the status of their account.

7.13.14.2.2 Registering your application

To enable Live ID logon for your website, you must register it on the Windows Live application management site at the following address: <https://manage.dev.live.com/>.

1. Once on the page, sign in with your Windows Live ID (you may need to create an account if you don't already have one) and you will be redirected to the application registration page.
2. Here, enter an appropriate **Application name** that will be used to identify your website in the Windows Live user interface (click **Create application** if you already have an application registered and wish to add another one):

Windows Live

Home My Apps Learn Interactive SDK Documentation Downloads Forums Showcase

Connect your application to Windows Live

My applications

Provide the name of your application that users will see in Windows Live.

Application name*

Language*

Use only letters, digits, and underscores. 129-character limit.

Select your application's primary language.

Clicking **I accept** means that you agree to the Windows Live [Terms of Use](#). Read the [privacy statement](#).

Read the terms of use and the privacy statement, then click the **I accept** button to register the application.

3. On the next screen, click on the **Application Settings Page** link and switch to the **API Settings** tab. Type the fully qualified domain name of your website into the **Redirect domain** field and select the appropriate **Mobile client app** option.

My Web Application

My applications ► My Web Application ► API Settings

Settings

Basic Information

API Settings

Localization

Client ID: [Redacted]

Client secret: [Create a new client secret](#)

Redirect domain:

Mobile client app: Yes No

[Save](#) [Cancel](#)

This is a unique identifier for your application. For security purposes, don't share your client secret with anyone.

Windows Live enforces this domain in your OAuth 2.0 redirect URI that exchanges tokens, data, and messages with your application. You only need to enter the domain, for example <http://www.contoso.com>.

Mobile client applications use a different OAuth 2.0 authentication flow. Only select "Yes" if your app is a mobile app. [Learn More](#)

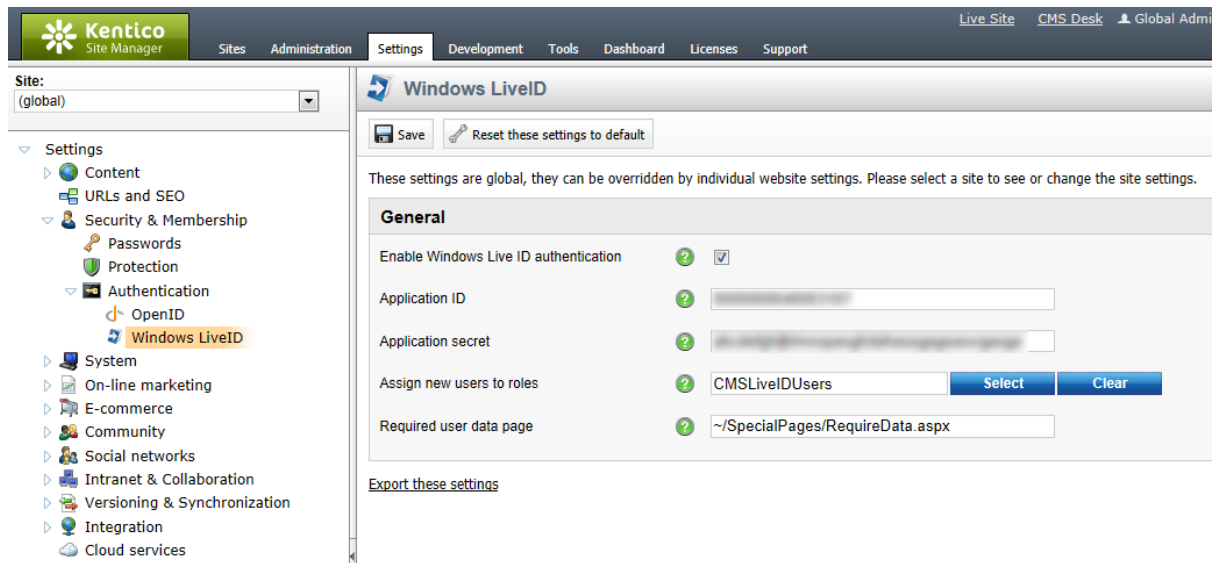

Click **Save** when you are done. Note the **Client ID** and **Client secret** values, since they will be required later when filling in the Live ID authentication [settings](#) in Kentico CMS.

4. You can also specify additional details for your application on the **Basic Information** tab, such as a logo or links to the terms of service and privacy policy of your website. The **Localization** tab may be used to set a different application name for individual languages. These options affect the logon page to which users will be redirected when they try to authenticate on your website using Live ID.

7.13.14.2.3 Settings

Live ID authentication settings are located in **Site Manager -> Settings -> Security & Membership -> Authentication -> Windows LiveID**. Before you start entering values, make sure you have the right site selected using the **Site** drop-down list in the top left part of the page.

- **Enable Windows Live ID authentication** - indicates if Windows Live ID authentication should be enabled.
- **Application ID** - identifier of your website. Enter the *Client ID* that you received when registering your website.
- **Application secret** - secret code that will be used to encrypt messages transferred between your website and the Live ID server. Enter the *Client secret* that you received when registering your website.
- **Assign new users to roles** - new users registered via Live ID authentication will be assigned to the roles specified here.
- **Required user data page** - URL of a page containing the *Required LiveID user data* web part. If entered, new Live ID users who log into the site will not have their user account created immediately, but will first be redirected to the specified page where they will be required to enter some additional data (or merge with an existing account) using the web part.

Compatibility with Live ID users created in older versions

Due to changes in the Windows Live ID service, Kentico CMS currently uses a different authentication mode (by default) than versions prior to 6.0, i.e. 5.5 R2 or older. Each mode generates a different authentication token for the same Live ID. As a result, users created under the original mode cannot be recognized or authenticated by the new one.

If your system contains Live ID users from an older version (e.g. after performing an upgrade procedure or as a result of a user import), you may wish to switch back to the original authentication mode in order to preserve the functionality of these user accounts. To do this, add the **CMSUseServerSideLiveIDAuthentication** key into the **/configuration/appSettings** section of your *web.config* file, as shown below:

```
<add key="CMSUseServerSideLiveIDAuthentication" value="false" />
```

Setting its value to *false* will ensure that backward compatibility is kept. Please note that new users registered via Live ID authentication while this key is false will only work with the original mode (additionally, Live ID users created under the new mode will no longer be recognized). Working with both authentication modes at the same time is currently not possible.

7.13.14.2.4 Available web parts

After you register your site at <https://manage.dev.live.com/> and enter the necessary settings, you can use the following two web parts on your website to allow authentication via Windows Live ID. The web parts are located under the **Membership -> LiveID** category in the web part catalog.

Windows LiveID

This web part can be used to let site visitors sign in to your website using their Live ID. It can be placed on any page of your website. The web part is hidden to authenticated users and will be displayed only to unauthenticated public site visitors. With default settings, the web part appears as in the following screenshot.

Although the web part works fine with default settings, it has the following properties to fine-tune its behavior:

- **Sign in text** - if entered, a link with the entered text will be used instead of the default sign in image.
- **Sign out text** - if entered, a link with the entered text will be used instead of the default sign out image.
- **Show sign out** - if enabled, the web part will display a sign out link to authenticated users.
- **Show as button** - if enabled, buttons will be used instead of standard text links.
- **Sign in image** - specifies the URL of an image that will be used for the sign in button if the *Sign in text* property is empty.
- **Sign out image** - specifies the URL of an image that will be used for the sign out button if the *Sign out text* property is empty.

- **Notify administrator about new registrations** - if enabled, a notification e-mail will be sent to the website administrator when a new registration is performed via the web part.

LiveID required data

In some cases, you may want new users to provide some extra details before their account is created. For example, if your site is configured to require [registration approval or double opt-in](#), all users need a valid e-mail address to help activate their account.

This can be achieved using the *Live ID required data* web part. The web part must be placed on the page specified by the **Required user data page** in **Site Manager -> Settings -> Security & Membership -> Authentication -> Windows LiveID**.

The following properties of the web part are the most important:

- **Allow forms authentication** - if checked, new users will be able to enter a password for their new account so that they can log in the usual way as well as via LiveID.
- **Allow existing user** - if enabled, users are allowed to join their existing account with their Live ID.
- **Default target URL** - if no return URL is passed, users will be redirected to the URL entered here after merging or creating their account.
- **Hide for no LiveID** - if checked, the web part will be hidden if the page with it is displayed without being a Live ID logon request (e.g. when accessed by entering its URL into the browser).

Other specific web part properties are explained in [Kentico CMS Web Parts](#) reference or after clicking the help link (?) link in the top right corner of the web part properties window.

| Existing user | New user |
|------------------------------------|---|
| User name: <input type="text"/> | User name: <input type="text" value="Petr_Penicka"/> |
| Password: <input type="password"/> | E-mail: <input type="text" value="petr.penicka@kentico.coi"/> |
| <input type="button" value="OK"/> | Password: <input type="password" value="....."/> |
| | Password strength: Average |
| | Confirm password: <input type="password" value="....."/> |
| | <input type="button" value="OK"/> |

The screenshot above shows how the web part looks with both the **Allow forms authentication** and **Allow existing user** options enabled. In the left part, existing site users can merge their current user account with the Live ID just by entering their user name and password. In this case, the Live ID Token will be added to the LiveID field of the existing user account. New users can enter the required details in the right part of the web part.

7.13.14.3 OpenID

7.13.14.3.1 Overview

[OpenID](#) is an open, decentralized standard for authenticating users. It is currently being used by popular websites like [Google](#), [Yahoo!](#), [MySpace](#), [Flickr](#) and many more. Logon credentials used on all of these sites can be used to log on to your Kentico CMS site.

How to start using OpenID

OpenID is easier to use than the rest of the supported third-party authentication services. For it to work on your site, you don't need to register your site, all you need to do is take the following steps:

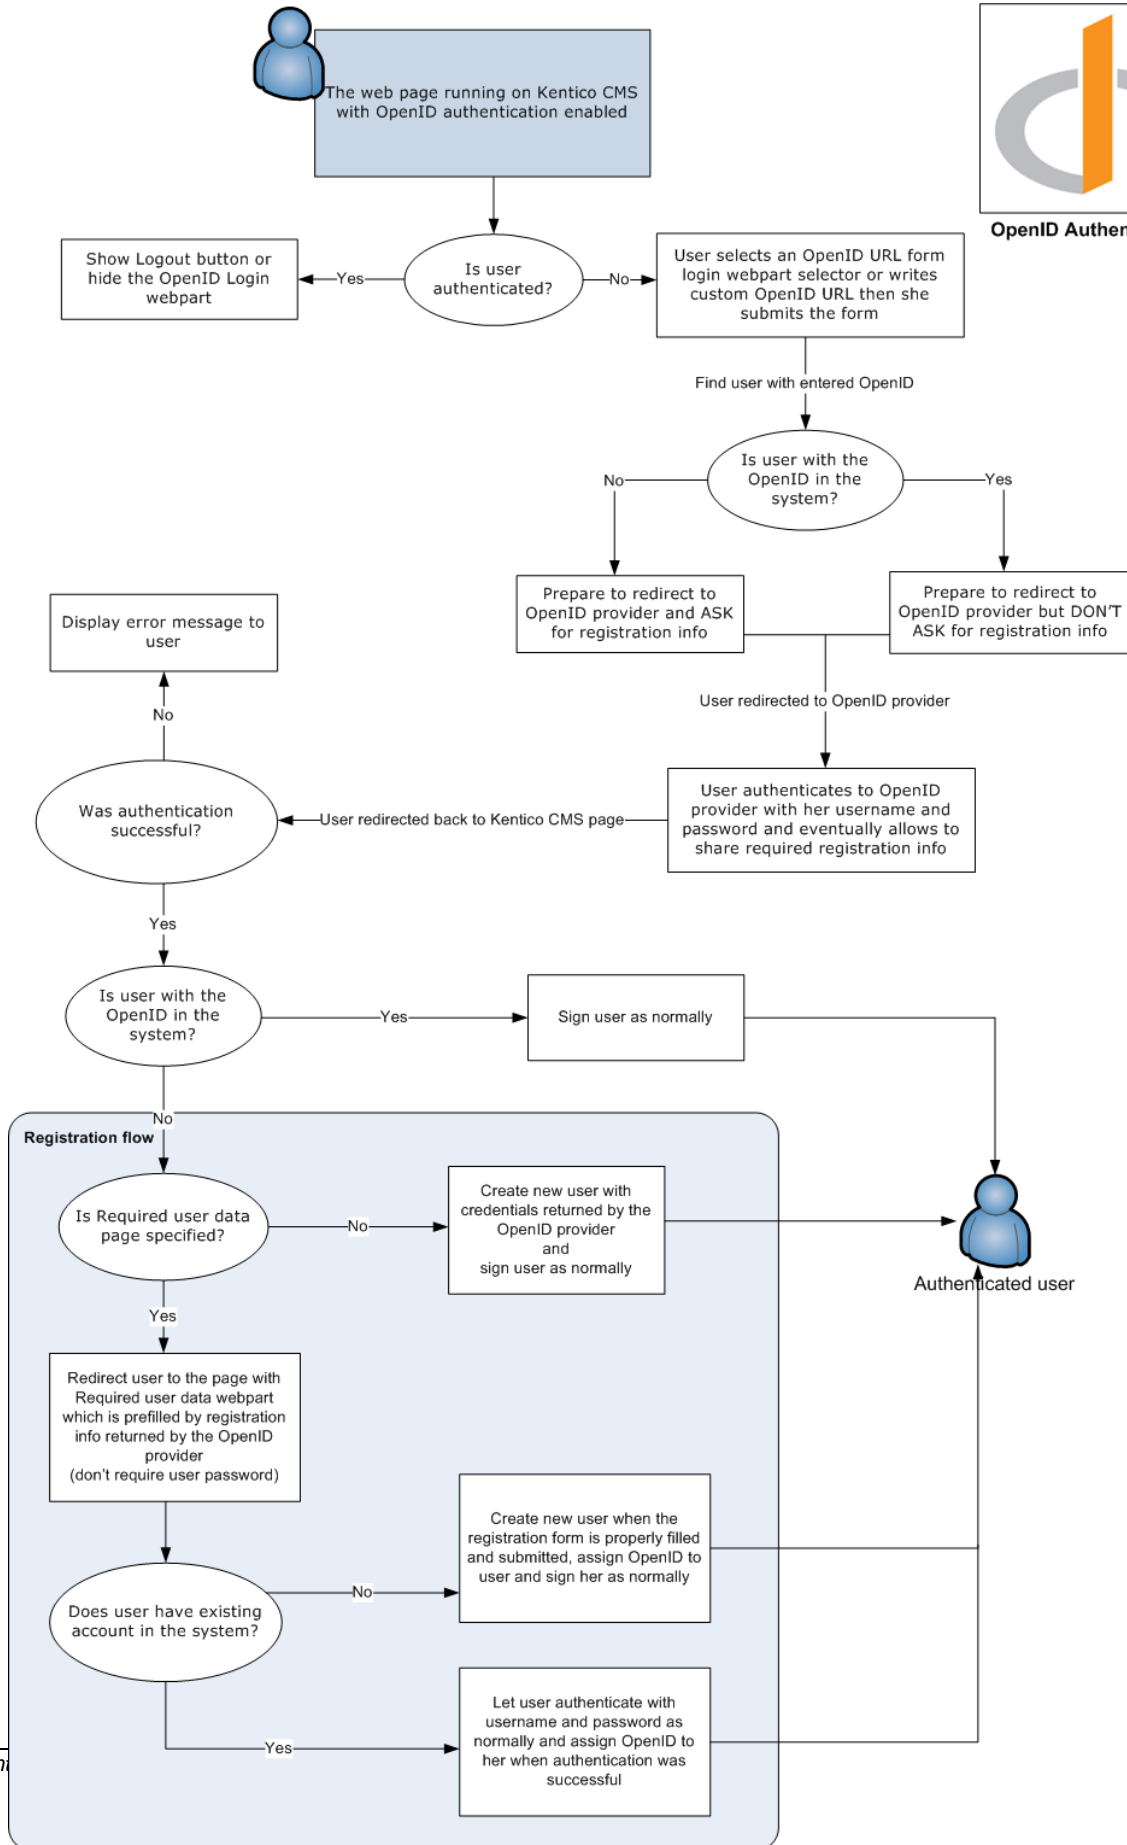

1. Set up Kentico CMS for OpenID authentication - see the [Settings](#) topic.
2. Use one of the OpenID web parts on any page of your site - see the [Available web parts](#) topic.

How it works

The following diagram shows how the process of OpenID login works:

OpenID Authentication

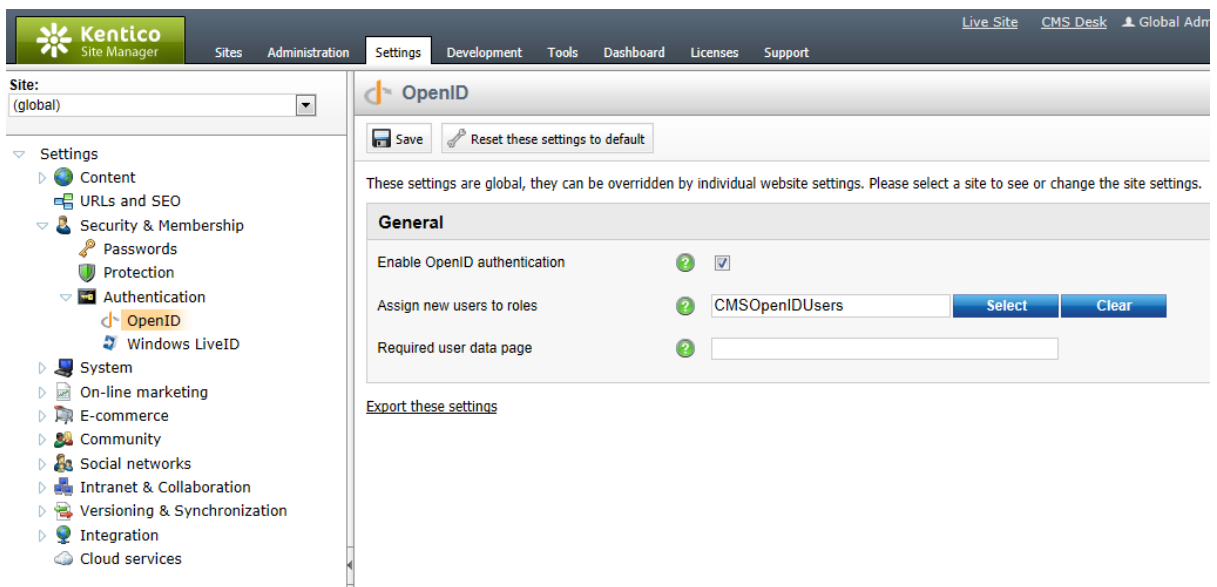

7.13.14.3.2 Settings

First of all, you need to browse to the `~/Bin/DotNetOpenAuth.dll.rename` file and rename it to `DotNetOpenAuth.dll`. The library is renamed in the default installation because it doesn't support [medium-trust environment](#). Then you need to configure OpenID settings in the administration interface of the CMS.

OpenID authentication settings are located in **Site Manager -> Settings -> Security & Membership -> Authentication -> OpenID**. Before you start making the settings, make sure you have the right site selected using the **Site** drop-down list at the top left part of the page.

- **Enable OpenID** - indicates if OpenID authentication is enabled.
- **Assign new users to roles** - new users registered via OpenID will be assigned to these roles.
- **Required user data page** - URL of the page where the *OpenID required data* web part resides; if entered and a new OpenID user logs in to the site for the first time, their user account is not created automatically, but they are redirected to this page and required to enter some additional data (or merge with an existing account) using the web part.

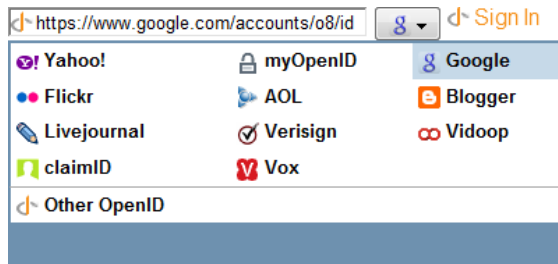

7.13.14.3.3 Available web parts

After configuring the [settings](#), you can use the following two web parts on your website to allow OpenID authentication. The web parts are located under the **Membership** category in the web part catalog.

OpenID logon

This web part can be used to let site visitors sign in to your website using their OpenID. It can be placed on any page of your website. With default settings, the web part appears as in the screenshot below.

It lets you choose from a number of websites which support OpenID and where you might already have an account. If you choose one and click Sign In, you will be redirected to the logon page on that site. After successful logon, you will be redirected back to the Kentico CMS site where you came from, but you will be authenticated and a new account will be created in case this is your first logon.

Even though the web part works fine with default settings, it has the following specific properties to fine-tune its behavior:

- **Providers** - Providers used for OpenID login. Each provider must be specified on a single line. Total number of 3 parameters should be included for each provider:

- 1 - provider display name
- 2 - provider login URL
- 3 - provider icon name placed in `~/CMSWebParts/Membership/OpenID/OpenID_files/`.

Each parameter must be separated by '|'. The third parameter is optional and if not supplied then the default OpenID icon will be displayed. Provided URL must be the login URL of the OpenID provider. If the username (or blog name, user id, etc.) is part of the URL, then use the `##username##` macro to replace the username part of the URL.

Example: `myOpenID|http://##username##.myopenid.com/|myopenid.ico`

- **Display textbox** - indicates if the OpenID provider textbox should be visible; if disabled then only the sign in button will be visible
- **Sign in text** - if entered, a link with the entered text will be used instead of the default sign in image
- **Sign out text** - if entered, a link with the entered text will be used instead of the default sign out image
- **Show sign out** - if checked, the sign out link will be displayed after the user logs in
- **Show as button** - if checked, buttons will be used instead of links
- **Sign in image** - if set, the image will be used as the sign in link
- **Sign out image** - if set, the image will be used as the sign out link
- **Required data for new users** - using these settings, you can request additional data from the OpenID provider, which will be added to the newly created user account. In case that you are using the *OpenID required data* web part, the requested data will be pre-filled in the web part.

OpenID required data

In some cases, you may want new users to provide some extra details before their account is created. For example, if your site is configured to require [registration approval or double opt-in](#), all users need a valid e-mail address to help activate their account.

This can be achieved using the *Open ID required data* web part. The web part must be placed on the page specified by the **Required user data page** value in **Site Manager -> Settings -> Security & Membership -> Authentication -> OpenID**.

The following properties of the web part are the most important:

- **Allow forms authentication** - if checked, new users will be able to enter a password for their new account so that they can log in the usual way as well as via OpenID
- **Allow existing user** - if enabled, users are allowed to join their existing account with OpenID
- **Default target URL** - if no return URL is passed, users will be redirected to the URL entered here after merging or creating the account
- **Hide for no OpenID** - if checked, the web part will be hidden if the page with it is displayed without OpenID logon (e.g. when accessed by entering its URL into the browser)

Other specific web part properties are explained in [Kentico CMS Web Parts Reference](#) or after clicking the help link (?) link in the top right corner of the web part properties window.

The screenshot displays two side-by-side registration forms. The 'Existing user' form on the left has fields for 'User name:' and 'Password:', followed by an 'OK' button. The 'New user' form on the right has fields for 'User name:' (containing 'Petr_Penicka'), 'E-mail:' (containing 'petr.penicka@kentico.coi'), 'Password:' (with a strength indicator showing 'Average'), and 'Confirm password:', followed by an 'OK' button.

The screenshot above shows how the web part looks with both the **Allow forms authentication** and **Allow existing user** options enabled. In the left part, an existing site users can merge their current user account with the OpenID by just entering their user name and password. In this case, the OpenID will be added to the OpenID field of the existing user account. New users can enter the required details in the right part of the web part.

7.13.14.4 Facebook Connect

7.13.14.4.1 Overview

Facebook is one of the most popular social networking sites in the world. With its continuously growing number of registered users, it is likely that visitors who come to your site will already have a Facebook account. In this case, it could be convenient for them to use their Facebook logon details than to go through another registration on your site. That's why you should consider using Facebook Connect authentication.

How to start using Facebook Connect

For Facebook Connect to work on your site, you need to register the site. Follow these steps:

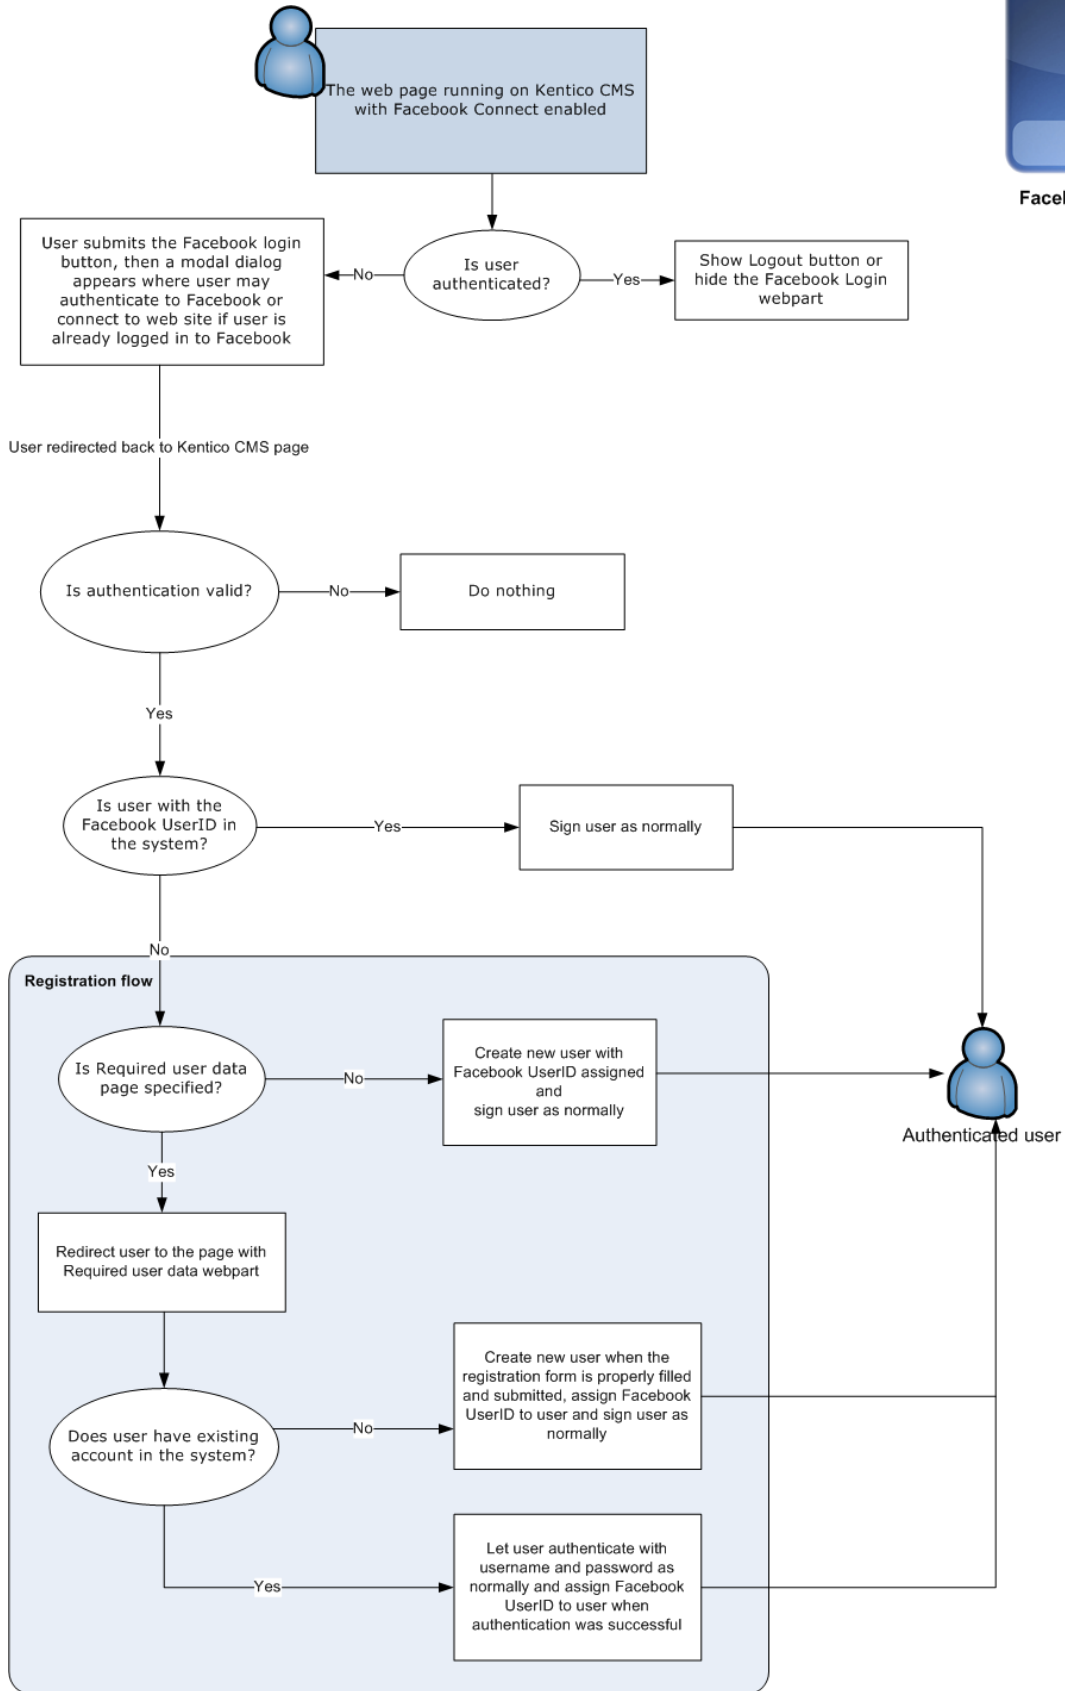

1. Register your website at <http://www.facebook.com/developers/createapp.php> - for more information, see the [Registering your application](#) topic.
2. Set up Kentico CMS for Facebook Connect authentication - see the [Settings](#) topic.
3. Use one of the Facebook Connect web parts on any page of your site - see the [Available web parts](#) topic.

How it works

The following diagram shows how the process of Facebook Connect login works:

Facebook Connect

7.13.14.4.2 Registering your application

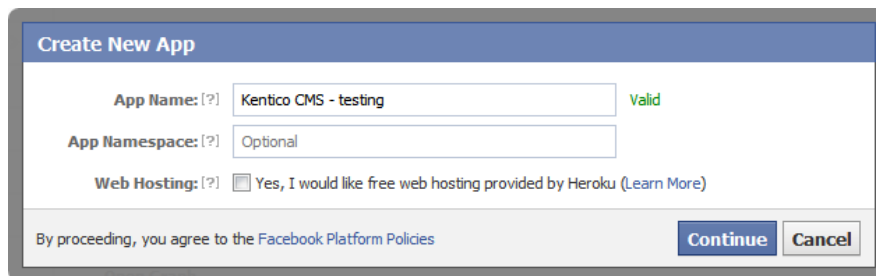

To use Facebook Connect authentication on your website, you need to register the site at <http://www.facebook.com/developers/createapp.php>. You need to have a Facebook account to get to the page (you can create it here <http://www.facebook.com/>).

The following text describes the registration procedure and points out important information that you obtain during it. Please note that the design of the screenshots below may not be identical as Facebook changes its design quite often.

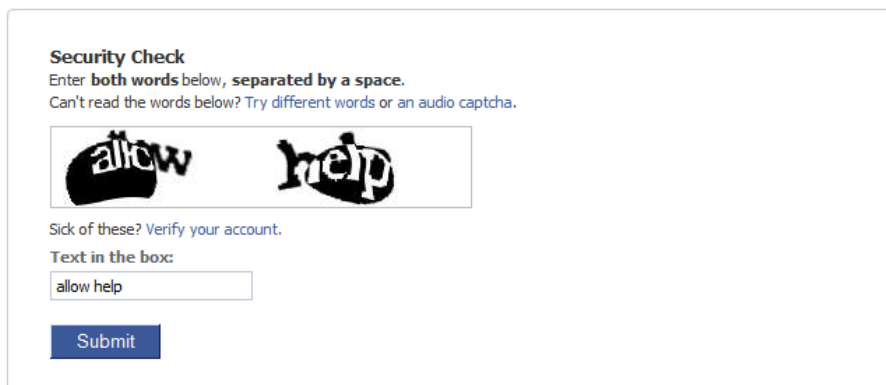

1. With a facebook account created and logged in, visit <http://www.facebook.com/developers/createapp.php>. Enter the following details into the form:

- **App Name:** enter the name of your website, e.g. Kentico CMS - testing

Read and **Agree** to the *Facebook Platform Policies* and click **Continue**.

2. Retype the CAPTCHA on and click **Submit**.

3. Your application will be registered and you will see the **Basic** tab of its editing interface. Here, you should focus on the two keys highlighted in the screenshot below, as you will need to enter them in **Site Manager -> Settings -> Social networks -> Facebook**:

- **App ID** - this is what you will enter into the **API Key** field
- **App secret** - this is what you will enter into the **Application secret** field

Copy them accordingly into your Kentico CMS instance as described in the [Settings](#) chapter.

4. Check **Website with Facebook login** option. Here, you need to enter the URL of your website into

the **Site URL** field. Click **Save Changes**.

The screenshot displays the Facebook Developers console for the 'Kentico CMS - testing' app. The interface includes a navigation menu on the left with sections for Settings (Basic, Permissions, Payments, Advanced), App Details, Localize, Open Graph, Roles, and Insights. The main content area is titled 'Apps > Kentico CMS - testing > Basic'. At the top, the 'App ID' and 'App Secret' fields are highlighted with a red box. Below this, the 'Basic Info' section contains several input fields: 'Display Name' (Kentico CMS - testing), 'Namespace', 'Contact Email' (user@mysite.com), 'App Domains', 'Category' (Other), 'Hosting URL', and 'Sandbox Mode' (Disabled). The 'Select how your app integrates with Facebook' section is also highlighted with a red box, showing a list of integration options. The 'Website with Facebook Login' option is selected, and its 'Site URL' field is filled with 'http://www.mysite.com'. A 'Save Changes' button is located at the bottom of the configuration area.

Authentication on localhost

Using Facebook Connect authentication on **localhost** may result in incorrect behavior of the authentication. This behavior is by design of the Facebook Connect API. To achieve the required functionality, a standard domain name must be used and the domain name entered in this step must match the domain where your web application is actually running.

Your web application is now registered at Facebook. With proper [settings](#) and [web parts](#), users will be able to authenticate to your site using their Facebook logon details. You can also set up [Autoposting](#) of content to Facebook directly from CMS Desk.

7.13.14.4.3 Settings

Facebook Connect authentication settings are located in **Site Manager -> Settings -> Social networks -> Facebook**. Before you start adjusting the settings, make sure you have the right site selected using the **Site** drop-down list at the top left part of the page.

General

- **API key** - key obtained during registration of your application on Facebook (as described in [Registering your application](#) topic).
- **Application secret** - key obtained during registration of your application on Facebook.

The two following settings are not required for Facebook Connect authentication. They are used only for the purposes of auto-posting on a website's Facebook page.

- **Facebook Page ID** - Specifies the Page ID (approximately 15 digits) obtained from the URL of the Facebook page associated with the website.
- **Access token** - Click the **Get** button to retrieve a token from Facebook after confirming permissions for the application. The API key, Application secret and Facebook Page ID fields must be filled in. When the token is retrieved, you can see its expiration date. After it expires or when auto-posting is no longer functional, click the **Get** button again to renew the token.

Authentication

- **Enable Facebook Connect** - indicates if Facebook Connect authentication is enabled.
- **Assign new users to roles** - new users registered via Facebook Connect will be assigned to these roles.
- **Required user data page** - URL of the page where the *Facebook Connect required data* web part resides. If entered and a new Facebook Connect user logs in to the site, their user account is not created automatically, but they are redirected to this page and required to enter some additional data (or merge with an existing account) using the web part.

URL shortening

- **URL shortener** - May be used to select a URL shortening service that will be used for all links in Facebook posts.

The screenshot shows the Kentico CMS 7.0 Settings interface. The top navigation bar includes 'Live Site', 'CMS Desk', and 'Global Admin'. The main navigation menu has 'Settings' selected. The left sidebar shows a tree view of settings categories, with 'Social networks' expanded to show 'Facebook' selected. The main content area is titled 'Facebook' and contains the following sections:

- General:** Fields for API key, Application secret, Facebook Page ID, and Access token. A 'Get' button is next to the Access token field.
- Authentication:**
 - 'Enable Facebook Connect authentication' is checked.
 - 'Assign new users to roles' is set to 'CMSFacebookUsers' with 'Select' and 'Clear' buttons.
 - 'Required user data page' is set to '~/SpecialPages/RequiredData.aspx'.
- URL shortening:** 'URL shortener' is set to '(none)'.

Buttons for 'Save' and 'Reset these settings to default' are at the top. A note states: 'These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.' An 'Export these settings' link is at the bottom.

7.13.14.4.4 Available web parts

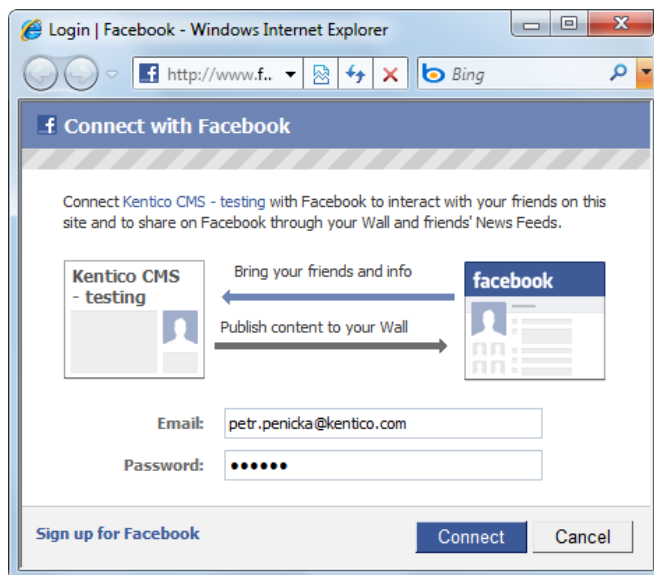

After configuring the [settings](#), you can use the following two web parts on your website to allow Facebook Connect authentication. The web parts are located under the **Membership** category in the web part catalog.

Facebook Connect login

This web part can be used to let site visitors sign in to your website using their Facebook username and password. It can be placed on any page of your website. The web part is hidden to authorized users and will be displayed only to unauthorized public site visitors. With default settings, the web part appears as in the screenshot below.

If you click the button, a new pop-up window opens, letting you log on using your Facebook username and password.

After successful logon, you will be redirected back to the Kentico CMS site where you came from, but you will be authenticated and a new account will be created in case that this is your first logon.

Even though the web part works fine with default settings, it has the following specific properties to fine-tune its behavior:

- **Sign in text** - if entered, link with the entered text will be used instead of the default sign in image
- **Size** - you can choose from 5 pre-defined sizes of the button
- **Length** - specifies which text label to use on a button with size specified as *small*, *medium*, *large*, or *xlarge*; specify short for the text label *Connect* only or long for the text label *Connect with Facebook*
- **Use latest version** - check this box if you want to use the latest Facebook Connect login buttons; don't check this box if you need to use the original Facebook Connect login buttons
- **Show sign out** - if checked, sign out link will be displayed after the user logs in
- **Sign out text** - if entered, link with the entered text will be used instead of the default sign out image
- **Show as button** - if checked, buttons will be used instead of links
- **Sign out image** - if set, the image will be used as sign out link

Facebook Connect required data

In some cases, you may want new users to provide some extra details before their account is created. For example, if your site is configured to require [registration approval or double opt-in](#), all users need a valid e-mail address to help activate their account.

This can be achieved using the *Facebook Connect required data* web part. The web part must be placed on the page specified by the **Required user data page** value in **Site Manager -> Settings -> Social networks -> Facebook**.

The following properties of the web part are the most important:

- **Allow forms authentication** - if checked, new users will be able to enter a password for their new account so that they can log in the usual way as well as via Facebook Connect

- **Allow existing user** - if enabled, users are allowed to join their existing account with their Facebook user ID
- **Default target URL** - if no return URL is passed, users will be redirected to the URL entered here after merging or creating the account
- **Hide for no Facebook user ID** - if checked, the web part will be hidden if the page with it is displayed without Facebook Connect logon (e.g. when accessed by entering its URL into the browser)

Other specific web part properties are explained in [Kentico CMS Web Parts Reference](#) or after clicking the help link (?) link in the top right corner of the web part properties window.

The screenshot displays two side-by-side form sections. The left section, titled 'Existing user', contains fields for 'User name:' and 'Password:', followed by an 'OK' button. The right section, titled 'New user', contains fields for 'User name:' (filled with 'Petr_Penicka'), 'E-mail:' (filled with 'petr.penicka@kentico.coi'), 'Password:' (masked with dots), and 'Confirm password:' (masked with dots). Below the password field is a 'Password strength: Average' indicator with a blue progress bar. An 'OK' button is located at the bottom of the 'New user' section.

The screenshot above shows how the web part looks with both the **Allow forms authentication** and **Allow existing user** options enabled. In the left part, an existing site user can merge their current user account with the Facebook user ID by just entering their user name and password used on your site. In this case, the Facebook user ID will be added to the **Facebook user ID** field of the existing user account. New users can enter the required details in the right part of the web part.

7.13.14.5 LinkedIn

7.13.14.5.1 Overview

[LinkedIn](#) is a business-related social networking website. By integrating LinkedIn authentication into your website, you can let users log on to your website using their LinkedIn user name and password.

How to start using LinkedIn authentication

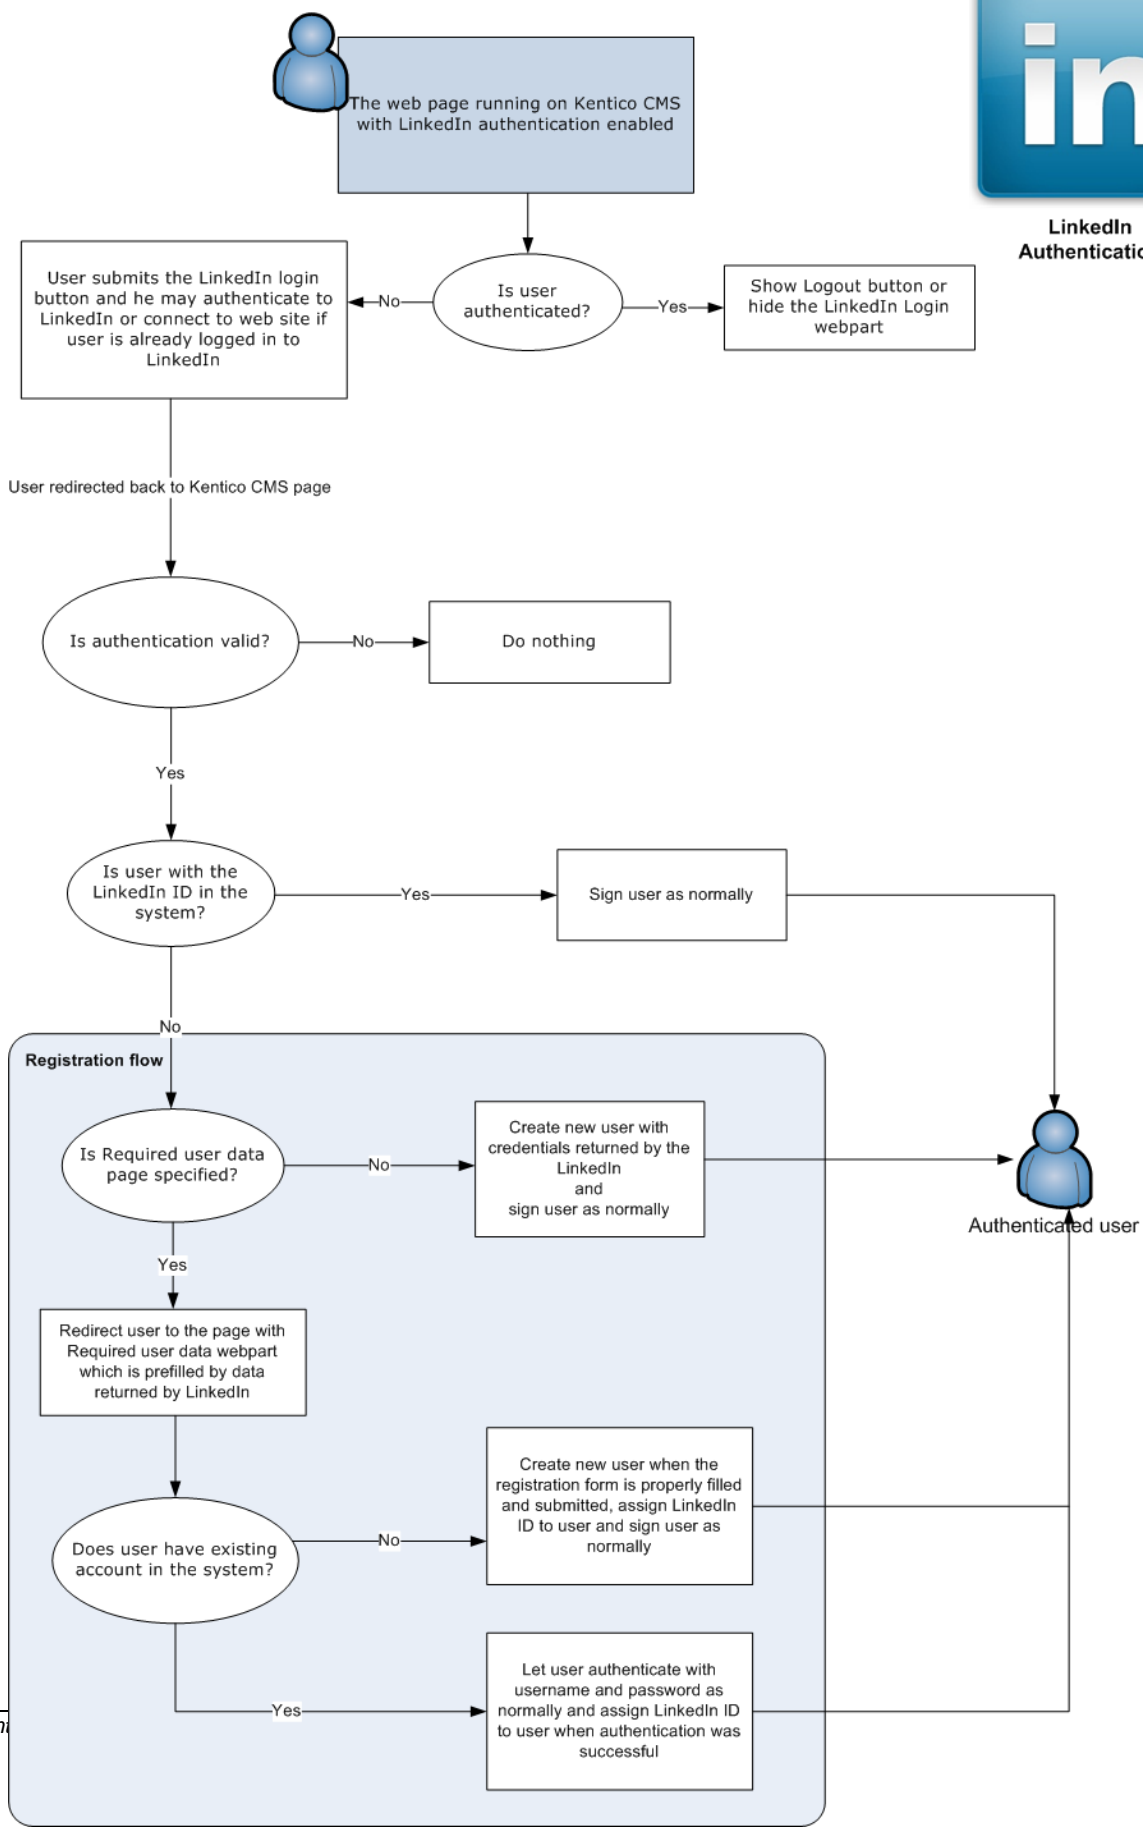

1. Register your application at <https://www.linkedin.com/secure/developer> - see the [Register your application](#) topic.
2. Set up Kentico CMS for LinkedIn authentication - see the [Settings](#) topic.
3. Use one of the LinkedIn web parts on any page of your site - see the [Available web parts](#) topic.

How it works

The following diagram shows how the process of LinkedIn authentication works:

LinkedIn Authentication

7.13.14.5.2 Registering your application

To use LinkedIn authentication on your website, you first need to register your application at LinkedIn and generate an API key for it. To do that, go through the following steps:

1. Go to <https://www.linkedin.com/secure/developer> and log on using your LinkedIn logon credentials. You need to have a LinkedIn account in order to do this, so if you do not have one, please create it first by clicking the **Join LinkedIn** link in the logon form.
2. Once logged in, you will be redirected to the list of your registered applications. Click the **Add New Application** link.

LinkedIn DeveloperNetwork

List of Applications

You have not added any applications yet.

[+ Add New Application](#)

[« Back to LinkedIn Developer Network](#)

[LinkedIn.com Home](#) | [About](#) | [Blog](#) | [Careers](#) | [Advertising](#) | [Recruiting Solutions](#) | [Tools](#) | [Developers](#) | [Upgrade Your Account](#)
Copyright © 2011 LinkedIn Corporation. All rights reserved. | [User Agreement](#) | [Privacy Policy](#) | [Copyright Policy](#)

3. The **Add New Application** dialog will be displayed. Fill in at least the required fields (marked with red asterisks), agree to the terms of use and finally click the **Add Application** button.

LinkedIn DeveloperNetwork

Add New Application

Fill out the form to register a new application:

Company Info

* **Company Name:**

Account Administrators: You will be assigned as an account administrator.

Additional Administrators:

Administrators appearing here will be account administrators for all applications from this company. Administrators can edit application details and add/remove other administrators and developers.

Application Info

* **Application Name:**

* **Description:**

Integration URL:

Example URL where the integration will go live.

App Logo Secure URL:

URL of an 80x80 logo for your app. SSL is required now.

JavaScript API Domain:

Fully-qualified domain name of all pages that will call the JavaScript API with this key (required if using JS API).

* **Application Type:**

If your application qualifies as more than one type, create a new application for each one.

* **Application Use:**

What best describes your application?

* **Live Status:**

While in development, your network updates will only go to the developers you choose. When live, they will go to your connections.

Application Developers:

Network updates you send will appear only for developers you list.

Include yourself as a developer for this application

Interface Language:

- English
- French
- German
- Italian
- Portuguese

Enter all the languages for your application interface. LinkedIn uses this information to better provide you support.

Programming Tools:

- PHP
- C++
- C#
- Java
- ColdFusion

Enter all the development languages and tools you use. LinkedIn uses this information to provide you better support.

Contact Info

* **Developer Contact Email:**

* **Phone:**

Support Contact Email:

Phone:

Business Contact Email:

Phone:

OAuth User Agreement

OAuth Redirect URL:

URL to return users to your app after they grant access. Only used if you do not pass in a redirect URL when you send the user to grant access.

* **Agreement Language:**

Select the display language of the user agreement screen. Browser Locale Setting is recommended.

Term of Service

* **Agree:** I agree and accept the LinkedIn API Terms of Use

4. If you specified all required details correctly, you will be redirected to a confirmation page. On this page, you can find the **API Key** and **Secret Key** values. These values need to be entered in setting of Kentico CMS in order for the LinkedIn authentication to be functional. See the [Settings](#) topic for more details.

LinkedIn® DeveloperNetwork

7.13.14.5.3 Settings

First of all, you need to navigate to the `~/Bin/DotNetOpenAuth.dll.rename` file and rename it to **DotNetOpenAuth.dll**. The library is renamed in the default installation because it doesn't support [medium-trust environment](#). Then you need to configure LinkedIn settings in the administration interface of the CMS.

LinkedIn authentication settings are located in **Site Manager -> Settings -> Social networks -> LinkedIn**. Before you start configuring the settings, make sure you have the right site selected using the **Site** drop-down list at the top left part of the page.

General

- **API key** - key obtained during [registration of your application](#) at LinkedIn.
- **Application secret** - key obtained during registration of your application at LinkedIn.

The following setting is not required for LinkedIn authentication. It is used mainly for certain LinkedIn web parts.

- **Access token** - Sets the site-wide access token required to execute LinkedIn API calls that require authorization.

Authentication

- **Enable LinkedIn authentication** - indicates if LinkedIn authentication is enabled.
- **Assign new users to roles** - new users registered via LinkedIn authentication will be assigned to these roles.
- **Required user data page** - URL of the page where the *LinkedIn required data* web part resides. If entered and a new LinkedIn user logs in to the site for the first time, their user account is not created automatically, but they are redirected to this page and required to enter some additional data (or merge with an existing account) using the web part.

URL shortening

- **URL shortener** - May be used to select a URL shortening service that will be used for all links in LinkedIn posts.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The 'Settings' page is for the 'LinkedIn' web part. The left sidebar shows a tree view of settings categories, with 'Social networks' expanded to show 'LinkedIn' selected. The main content area is titled 'LinkedIn' and contains the following settings:

- General**
 - API key: [text input]
 - Application secret: [text input]
 - Access token: [text input] [Get]
- Authentication**
 - Enable LinkedIn authentication:
 - Assign new users to roles: [CMSLinkedInUsers] [Select] [Clear]
 - Required user data page: [~/SpecialPages/RequiredData.aspx]
- URL shortening**
 - URL shortener: [(none)]

Buttons for 'Save' and 'Reset these settings to default' are at the top. A note states: 'These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.' An 'Export these settings' link is at the bottom.

7.13.14.5.4 Available web parts

When you have registered your application as described in the [Registering your application](#) topic and after configuration of all required [Settings](#), you may add the following web parts to pages of your website in order to enable users authenticate using their LinkedIn logon credentials.

LinkedIn logon

This web part can be used to let site visitors sign in to your website using their LinkedIn logon credentials. It can be placed on any page of your website. The web part is hidden to authenticated users and will be displayed only to unauthenticated public site visitors. With default settings, the web part appears as in the following screenshot.

Although the web part works fine with default settings, it has the following properties to fine-tune its behavior:

- **Sign in text** - if entered, a link with the entered text will be used instead of the default sign in image.
- **Sign out text** - if entered, a link with the entered text will be used instead of the default sign out image.
- **Show sign out** - if enabled, the web part will display a sign out link to authenticated users.
- **Show as button** - if enabled, buttons will be used instead of standard text links.
- **Sign in image** - specifies the URL of an image that will be used for the sign in button if the *Sign in text* property is empty.
- **Sign out image** - specifies the URL of an image that will be used for the sign out button if the *Sign*

out text property is empty.

- **Required data for new users** - using these settings, you can request additional data from the LinkedIn user account, which will be added to the newly created user account. In case that you are using the *LinkedIn required data* web part, the requested data will be pre-filled in the web part.
- **Notify administrator about new registrations** - if enabled, a notification e-mail will be sent to the website administrator when a new registration is performed via the web part.

LinkedIn required data

In some cases, you may want new users to provide some extra details before their account is created. For example, if your site is configured to require [registration approval or double opt-in](#), all users need a valid e-mail address to help activate their account.

This can be achieved using the *LinkedIn required data* web part. The web part must be placed on the page specified by the **Required user data page** value in **Site Manager -> Settings -> Social networks -> LinkedIn**.

The following properties of the web part are the most important:

- **Allow forms authentication** - if checked, new users will be able to enter a password for their new account so that they can log in the usual way as well as via their LinkedIn logon credentials.
- **Allow existing user** - if enabled, users are allowed to join their existing accounts with the LinkedIn accounts.
- **Default target URL** - if no return URL is passed, users will be redirected to the URL entered here after merging or creating the account.
- **Hide for no LinkedIn** - if checked, the web part will be hidden if the page with it is displayed without LinkedIn logon (e.g. when accessed by entering its URL into the browser).

Other specific web part properties are explained in [Kentico CMS Web Parts Reference](#) or after clicking the help link (??) link in the top right corner of the web part properties window.

The screenshot displays two side-by-side form sections. The left section, titled 'Existing user', contains two text input fields: 'User name:' and 'Password:'. Below these fields is a blue 'OK' button. The right section, titled 'New user', contains four text input fields: 'User name:' (pre-filled with 'Petr_Penicka'), 'E-mail:' (pre-filled with 'petr.penicka@kentico.coi'), 'Password:' (masked with dots), and 'Confirm password:' (masked with dots). Below the password fields is a 'Password strength: Average' indicator with a blue progress bar. A blue 'OK' button is located at the bottom of the right section.

The screenshot above shows how the web part looks with both the **Allow forms authentication** and **Allow existing user** options enabled. In the left part, an existing site users can merge their current user account with the LinkedIn account by just entering their user name and password. In this case, their LinkedIn ID will be added to the LinkedIn ID field of the existing user account. New users can enter the required details in the right part of the web part.

7.13.14.6 Managing imported users

When a user signs in through a third-party authentication service for the first time, Kentico CMS automatically creates a new user account for them. If you edit such an account in **Site Manager -> Administration -> Users**, you can see that it has the following specific settings:

General tab

On the General tab, you can notice that the **User name** and **Full name** fields have been automatically filled with a string in the following format:

User name

- **Live ID:** *liveid_<liveidtoken>*
- **OpenID:** *openid_<openid>*
- **Facebook Connect:** *facebookid_<facebookuserid>*

Full name

- **Live ID:** *LiveID - <liveidtoken>*
- **OpenID:** *OpenID - <openid>*
- **Facebook Connect:** *Facebook ID - <facebookuserid>*

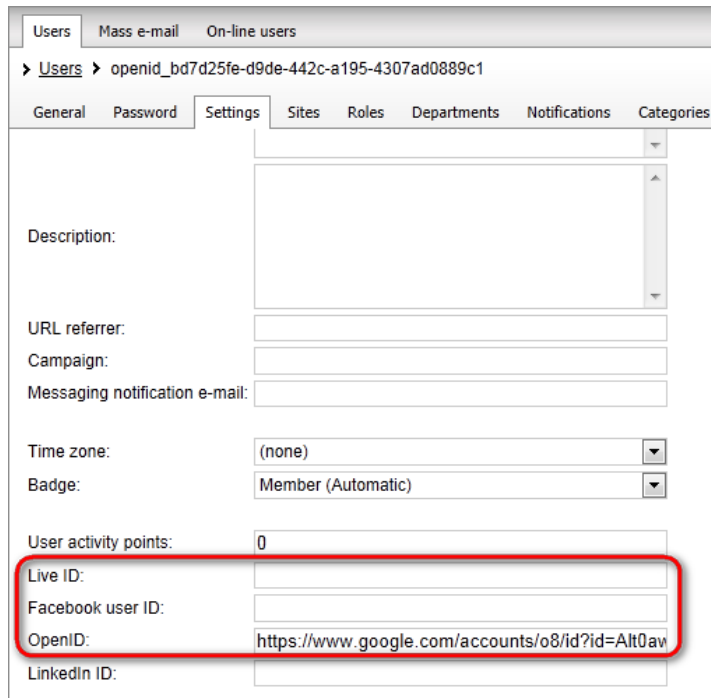

These values can be changed manually without any effects on the functionality.

You can also notice that the **Is external user** check-box is enabled. It indicates that the user account is imported from some external user database and disables forms authentication for the user, i.e. the user can only log in using the third-party authentication service. When merging an existing account with third-party authentication using one of the **<provider> required user data** web parts, the existing account that you want to merge must not have this option enabled (because forms authentication using the web part would not work).

The screenshot shows the 'Users' management interface in Kentico CMS. The 'General' tab is selected for a user account. The 'User name' and 'Full name' fields are populated with the OpenID string 'openid_bd7d25fe-d9de-442c-a195-4307ad0889c1'. The 'Is external user' checkbox is checked, indicating that the user is imported from an external database. Other fields like 'First name', 'Middle name', 'Last name', and 'E-mail' are empty. The 'Enabled' checkbox is also checked, while 'Is editor', 'Is global administrator', 'Is domain user', and 'Is hidden' are unchecked.

If you switch to the **Settings** tab, you can notice the **Live ID**, **Facebook user ID** and **OpenID** fields. This is where the user's ID from the particular provider is stored.

You can change the values manually if you need to. You just need to make sure that the entered ID is valid. In such a case, the newly entered ID will be used when the user logs in. You can also delete the value, in which case no ID will be assigned to the user. In this case, please remember to disable the **Is external user** option on the **General** tab so that the user can log in using forms authentication.

The screenshot shows the 'Users' management interface in Kentico CMS. The 'Settings' tab is selected for a user with ID 'openid_bd7d25fe-d9de-442c-a195-4307ad0889c1'. The 'Settings' tab contains several fields: 'Description' (text area), 'URL referrer' (text), 'Campaign' (text), 'Messaging notification e-mail' (text), 'Time zone' (dropdown menu set to '(none)'), 'Badge' (dropdown menu set to 'Member (Automatic)'), 'User activity points' (text input set to '0'), 'Live ID' (text input), 'Facebook user ID' (text input), 'OpenID' (text input with the value 'https://www.google.com/accounts/o8/id?id=Alt0av'), and 'LinkedIn ID' (text input). A red rectangular box highlights the 'Live ID', 'Facebook user ID', and 'OpenID' fields.

7.13.15 Membership internals and API

7.13.15.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used for the management of website membership (users and roles). You will also see the most common [API examples](#).

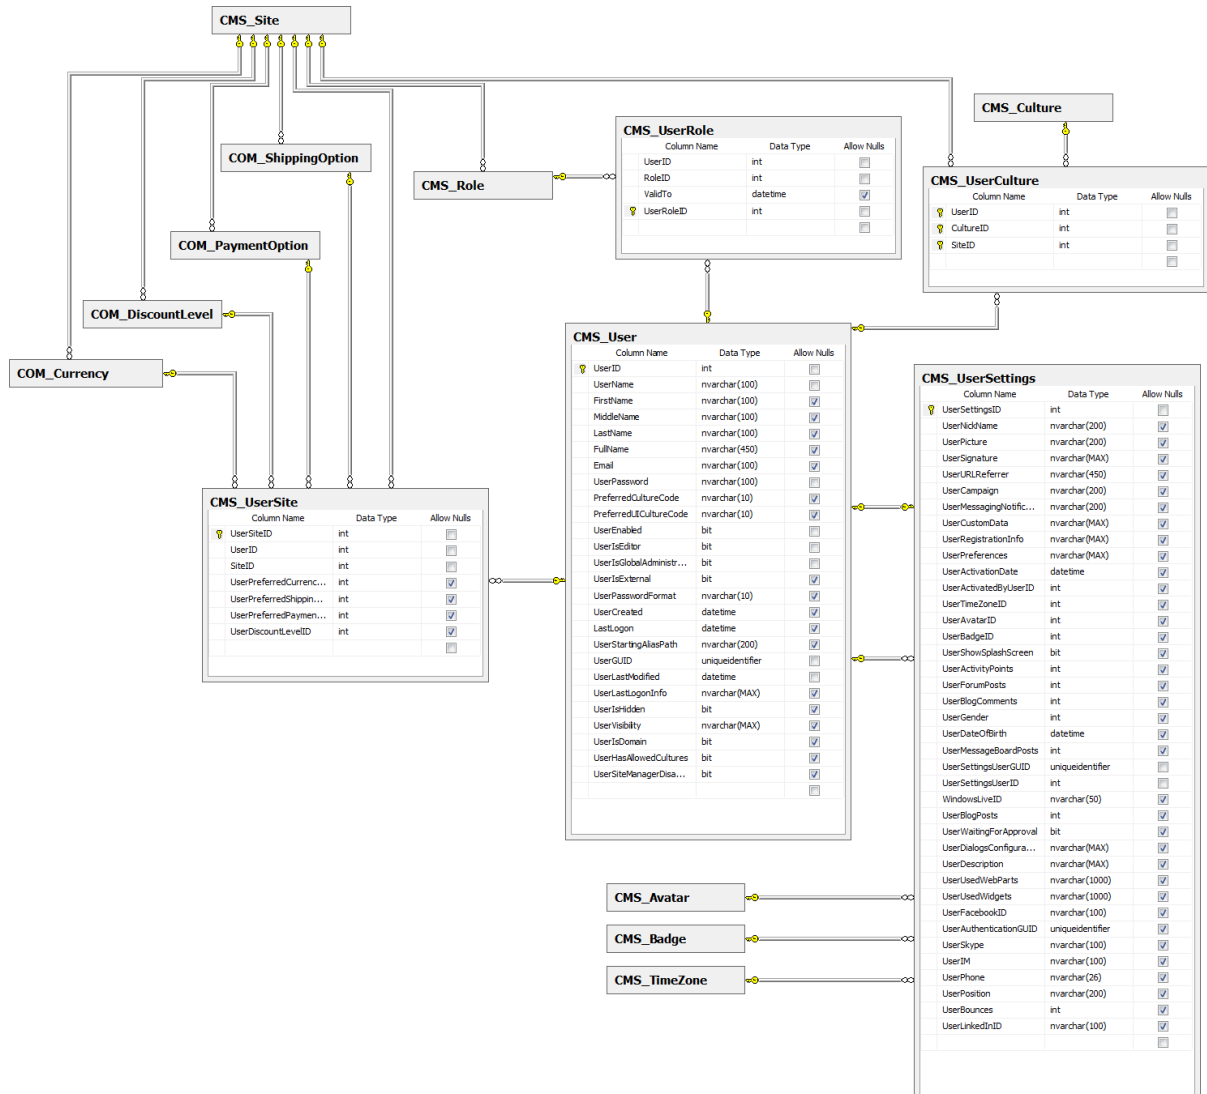

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module's classes, please refer to [Kentico CMS API Reference](#).

7.13.15.2 Database tables

The following database tables are used to store information about users:

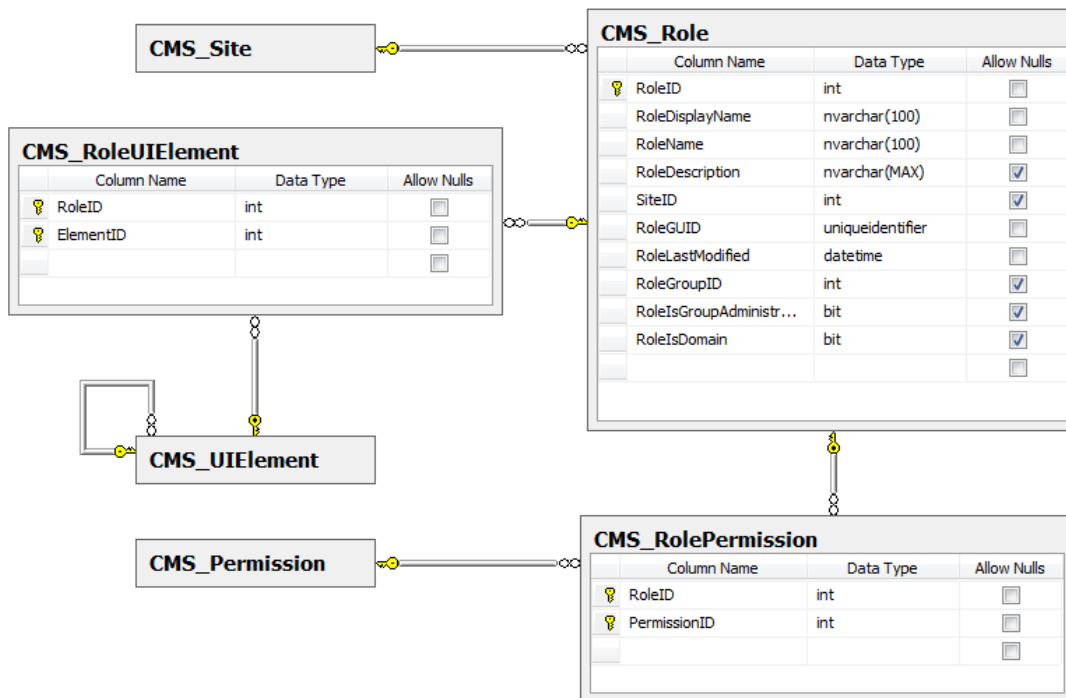

- **CMS_User** - contains records representing users.
- **CMS_UserSite** - stores relationships between users and sites. Each entry indicates that a specific user account is available on a given site.
- **CMS_UserRole** - stores relationships between users and roles. Each entry indicates that a specific role is assigned to a given user. This table is also used to store the expiration date for roles that are assigned for a limited time period.

- **CMS_UserCulture** - stores relationships between users and content cultures. Each entry indicates that a user may edit the content of documents belonging to a specified culture/language (if the given user is an editor).
- **CMS_UserSettings** - stores the advanced settings of users.

The following tables store information about roles and permissions:

- **CMS_Role** - contains records representing roles.
- **CMS_Permission** - stores permissions.
- **CMS_RolePermission** - stores relationships between roles and permissions. Each entry indicates that a permission is granted to a given role.
- **CMS_RoleUIElement** - stores relationships between roles and UI elements. Each entry indicates that a specified UI element will be displayed to members of a given role.

7.13.15.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes used for membership management can be found in the **CMS.SiteProvider** namespace.

CMS_User table API:

- **UserInfo** - represents one user object.
- **UserInfoProvider** - provides management functionality for users.

CMS_UserSite table API:

- **UserSiteInfo** - represents a relationship between a user and a site.
- **UserSiteInfoProvider** - provides management functionality for user-site relationships.

CMS_UserRole table API:

- **UserRoleInfo** - represents a relationship between a user and a role.
- **UserRoleInfoProvider** - provides management functionality for user-role relationships.

CMS_UserCulture table API:

- **UserCultureInfo** - represents a relationship between a user and a culture.
- **UserCultureInfoProvider** - provides management functionality for user-culture relationships.

CMS_UserSettings table API:

- **UserSettingsInfo** - represents the advanced settings of a user.
- **UserSettingsInfoProvider** - provides management functionality for user settings.

CMS_Role table API:

- **RoleInfo** - represents one role object.
- **RoleInfoProvider** - provides management functionality for roles.

CMS_Permission table API:

- **PermissionNameInfo** - represents one permission object.
- **PermissionNameInfoProvider** - provides management functionality for permissions.

CMS_RolePermission table API:

- **RolePermissionInfo** - represents a relationship between a role and a permission.
- **RolePermissionInfoProvider** - provides management functionality for role-permission relationships.

CMS_RoleUIElement table API:

- **RoleUIElementInfo** - represents a relationship between a role and a UI element.
- **RoleUIElementInfoProvider** - provides management functionality for relationships between roles and UI elements.

7.13.15.4 API examples

7.13.15.4.1 Overview

These topics show examples of how the API of for membership management can be used:

- [Managing users](#)
- [Users and sites](#)
- [Managing roles](#)
- [Roles and user](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Administration\Membership\Default.aspx.cs**.

The membership API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.SiteProvider;
```

7.13.15.4.2 Managing users

The following example creates a user.

```
private void CreateUser()
{
    // Create new user object
    UserInfo newUser = new UserInfo();

    // Set the properties
    newUser.FullName = "My new user";
    newUser.UserName = "MyNewUser";

    // Save the user
    UserInfoProvider.SetUserInfo(newUser);
}
```

The following example gets and updates a user.

```
private bool GetAndUpdateUser()
{
    // Get the user
    UserInfo updateUser = UserInfoProvider.GetUserInfo("MyNewUser");
    if (updateUser != null)
    {
        // Update the properties
        updateUser.FullName = updateUser.FullName.ToLower();

        // Save the changes
        UserInfoProvider.SetUserInfo(updateUser);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates users.

```
private bool GetAndBulkUpdateUsers()
{
    // Prepare the parameters
    string where = "UserName LIKE N'MyNewUser%'";

    // Get the data
    DataSet users = UserInfoProvider.GetUsers(where, null);
    if (!DataHelper.DataSourceIsEmpty(users))
    {
        // Loop through the individual items
        foreach (DataRow userDr in users.Tables[0].Rows)
        {
            // Create object from DataRow
            UserInfo modifyUser = new UserInfo(userDr);

            // Update the properties
            modifyUser.FullName = modifyUser.FullName.ToUpper();

            // Save the changes
            UserInfoProvider.SetUserInfo(modifyUser);
        }

        return true;
    }

    return false;
}
```

The following example deletes a user.

```
private bool DeleteUser()
{
    // Get the user
    UserInfo deleteUser = UserInfoProvider.GetUserInfo("MyNewUser");

    // Delete the user
    UserInfoProvider.DeleteUser(deleteUser);

    return (deleteUser != null);
}
```

The following example checks if the credentials of a user are valid for a specified site using forms authentication.

```
private bool AuthenticateUser()
{
    // Get the user
    UserInfo user = UserInfoProvider.GetUserInfo("MyNewUser");
    if (user != null)
    {
        if (AuthenticationHelper.AuthenticateUser("MyNewUser", "",
```

```
CMSContext.CurrentSiteName) != null)
    {
        return true;
    }
}

return false;
}
```

7.13.15.4.3 Users and sites

The following example assigns a user to a site.

```
private bool AddUserToSite()
{
    // Get the user
    UserInfo user = UserInfoProvider.GetUserInfo("MyNewUser");
    if (user != null)
    {
        int userId = user.UserID;
        int siteId = CMSContext.CurrentSiteID;

        // Save the binding
        UserSiteInfoProvider.AddUserToSite(userId, siteId);

        return true;
    }

    return false;
}
```

The following example removes a user from a site.

```
private bool RemoveUserFromSite()
{
    // Get the user
    UserInfo removeUser = UserInfoProvider.GetUserInfo("MyNewUser");
    if (removeUser != null)
    {
        int siteId = CMSContext.CurrentSiteID;

        // Get the binding
        UserSiteInfo userSite = UserSiteInfoProvider.GetUserSiteInfo(
removeUser.UserID, siteId);

        // Delete the binding
        UserSiteInfoProvider.DeleteUserSiteInfo(userSite);

        return true;
    }
}
```

```
    return false;
}
```

7.13.15.4.4 Managing roles

The following example creates a role.

```
private void CreateRole()
{
    // Create new role object
    RoleInfo newRole = new RoleInfo();

    // Set the properties
    newRole.DisplayName = "My new role";
    newRole.RoleName = "MyNewRole";
    newRole.SiteID = CMSContext.CurrentSiteID;

    // Save the role
    RoleInfoProvider.SetRoleInfo(newRole);
}
```

The following example gets and updates a role.

```
private bool GetAndUpdateRole()
{
    // Get the role
    RoleInfo updateRole = RoleInfoProvider.GetRoleInfo("MyNewRole",
    CMSContext.CurrentSiteID);
    if (updateRole != null)
    {
        // Update the properties
        updateRole.DisplayName = updateRole.DisplayName.ToLower();

        // Save the changes
        RoleInfoProvider.SetRoleInfo(updateRole);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates roles.

```
private bool GetAndBulkUpdateRoles()
{
    // Prepare the parameters
```

```
string where = "RoleName LIKE N'MyNewRole%'";

// Get the data
DataSet roles = RoleInfoProvider.GetRoles(where, null);
if (!DataHelper.DataSourceIsEmpty(roles))
{
    // Loop through the individual items
    foreach (DataRow roleDr in roles.Tables[0].Rows)
    {
        // Create object from DataRow
        RoleInfo modifyRole = new RoleInfo(roleDr);

        // Update the properties
        modifyRole.DisplayName = modifyRole.DisplayName.ToUpper();

        // Save the changes
        RoleInfoProvider.SetRoleInfo(modifyRole);
    }

    return true;
}

return false;
}
```

The following example deletes a role.

```
private bool DeleteRole()
{
    // Get the role
    RoleInfo deleteRole = RoleInfoProvider.GetRoleInfo("MyNewRole",
CMSContext.CurrentSiteID);

    // Delete the role
    RoleInfoProvider.DeleteRoleInfo(deleteRole);

    return (deleteRole != null);
}
```

7.13.15.4.5 Roles and users

The following example assigns a role to a user.

```
private bool CreateUserRole()
{
    // Get role and user objects
    RoleInfo role = RoleInfoProvider.GetRoleInfo("MyNewRole",
CMSContext.CurrentSiteID);
    UserInfo user = UserInfoProvider.GetUserInfo("MyNewUser");
}
```

```
if ((role != null) && (user != null))
{
    // Create new user role object
    UserRoleInfo userRole = new UserRoleInfo();

    // Set the properties
    userRole.UserID = user.UserID;
    userRole.RoleID = role.RoleID;

    // Save the user role
    UserRoleInfoProvider.SetUserRoleInfo(userRole);

    return true;
}

return false;
}
```

The following example removes a role from a user.

```
private bool DeleteUserRole()
{
    // Get role and user objects
    RoleInfo role = RoleInfoProvider.GetRoleInfo("MyNewRole",
    CMSContext.CurrentSiteID);
    UserInfo user = UserInfoProvider.GetUserInfo("MyNewUser");

    if ((role != null) && (user != null))
    {
        // Get the user role
        UserRoleInfo deleteRole = UserRoleInfoProvider.GetUserRoleInfo
        (user.UserID, role.RoleID);

        // Delete the user role
        UserRoleInfoProvider.DeleteUserRoleInfo(deleteRole);

        return true;
    }

    return false;
}
```

7.14 Mobile development

The mobile development features available in Kentico CMS allow you to craft the design and contents of pages to be easily viewable on various types of mobile devices. By grouping devices with similar properties into device profiles and creating page layouts specifically designed for the device profiles, you can provide visitors with websites that bring an optimal browsing experience and require a minimum amount of scrolling and zooming.

Topics:

- [Enabling mobile development features](#)
- [Creating device profiles](#)
- [Resizing images for devices](#)
- [Creating page layouts for devices](#)
- [Mapping shared layouts](#)
- [Creating mobile pages](#)
 - [Allowing visitors to override the device detection](#)
 - [Adjusting web part properties for specific device profiles](#)
 - [Using device-specific transformations](#)
- [Creating a separate mobile section](#)
- [Device macro reference](#)

7.14.1 Enabling mobile development features

Enabling device profiles

Device profiles in Kentico CMS allow you to customize the layout and content of pages according to the specific devices that visitors use to view the pages. To start using device profiles, enable them in the settings first.

1. Open **Site Manager** and navigate to **Settings -> Content -> Content management**.
2. (Optional) Select a site where you want to enable device profiles.
3. In the **Mobile development** section, check the **Enable device profiles** setting.
4. Click  **Save**.

With device profiles enabled, the system evaluates whether the device that is requesting a page belongs to one of the device profiles defined in **Site Manager -> Development -> Device profiles**. See [Creating device profiles](#) for details.

Setting up device detection

By default, Kentico CMS only detects a limited set of mobile devices. The basic detection uses XML data stored in the `~/App_Data/CMSModules/DeviceProfile/devices.xml` file, which contains information about specific devices.

Each device has a set of properties describing its capabilities and a list of user agents used for identification. For example:

```
<Device name="Nokia_710" displayname="Nokia - 710" width="480" height="800"
mobile="true">
  <UserAgent>
    Mozilla/5.0 (compatible; MSIE 9.0; Windows Phone OS 7.5; Trident/5.0;
    IEMobile/9.0; NOKIA; Lumia 710)
  </UserAgent>
  <UserAgent>
```

```
    Mozilla/5.0 (compatible; MSIE 9.0; Windows Phone OS 7.5; Trident/5.0;
    IEMobile/9.0; NOKIA; 710)
    </UserAgent>
</Device>
```

You can manually expand the data by adding devices and their user agents. The system reloads the data every time the application starts, so you need to restart the application for changes to take effect.

When [creating device profiles](#), you can assign the devices from the XML file using the device selector.

Using 51degrees.mobi device data

The 51degrees.mobi mobile device detection software integrated into Kentico CMS allows you to extend the detection data to include all devices that are available on the market. The data also provides access to all device properties (listed in the [device macro reference](#)).

To use this data, you need to obtain a license from 51degrees.mobi and register it within Kentico CMS.

1. Buy a license for Premium Data at [51degrees.mobi](#). You will receive either a license key that enables you to download device data automatically, or a data file that you need to manually upload into the system.
2. Go to **Site Manager -> Settings -> Integration -> 51degrees.mobi**.
3. Enter your 51degrees.mobi license key into the text box and click **Activate**, or select a data file from your disk and click **Upload**.
4. Click  **Save**.

The system now has access to the 51degrees.mobi mobile device data set. You can select devices directly from the device selector when [creating device profiles](#) and you can access additional device properties within the [CurrentDevice object](#).

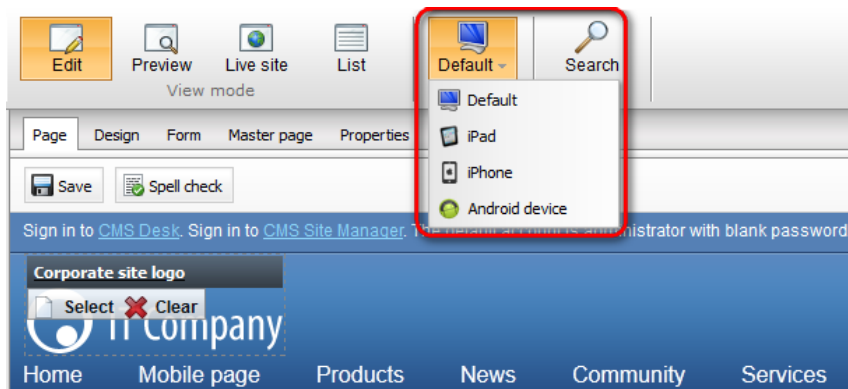

7.14.2 Creating device profiles

Device profiles in Kentico CMS allow you to customize the layout and content of pages according to the parameters of the devices that visitors use to view the pages. Before you start using device profiles, [enable them](#) in the settings first.

1. Open **Site Manager** and navigate to **Development -> Device profiles**.
2. Click  **New profile**.
3. Type the **Display name** of the device profile.
4. Fill in the parameters that define which devices belong to the profile. You can combine these parameters as needed.
 - **Devices** - select devices directly from a list.
 - **User agents** - allows you to identify devices based on [user agents](#). The profile includes devices that contain the entered text in their user agent string. You can add multiple entries, each on a new line.

- **Macro** - use the [macro rule designer](#) to specify the condition that devices must meet to fit the device profile, or type in any macro condition. You can use the *CurrentDevice* object to retrieve data of the current device. See [Device macro reference](#) and [Macro expressions documentation](#) for more details.
5. (Optional) Set the **Preview width** and **Preview height**. The preview dimensions of the device profile determine the following:
- The maximum size of images if [automatic image resizing for devices](#) is enabled.
 - The size of the displaying area when [previewing](#) pages in CMS Desk.
6. Click  **Save**.

Once you create a device profile, it appears in the device selector in CMS Desk.

You can then select a device profile using the selector and start [Creating page layouts for devices](#), which will be used on individual pages instead of the default layouts if the current device fits the profile. Or you can [Map layouts](#) that will replace shared layouts when the current device fits the profile.

7.14.3 Resizing images for devices

You can configure the system to automatically resize images to match the dimensions of [device profiles](#):

1. Go to **Site Manager -> Settings -> Content -> Content management**.
2. Enable the **Resize images according to device profile** setting.
3. Click  **Save**.

When a user views the website on a device that matches a certain profile, images automatically reduce their maximum side size to the larger of the dimensions set for the given profile.

To change the dimensions of device profiles:

1. Go to **Site Manager -> Development -> Device profiles**.
2. Edit () a profile.
3. Set the **Preview width** and **Preview height** properties (the values are in pixels).
4. Click  **Save**.

Note

The resizing only works for images loaded through one of the Kentico CMS system pages (getattachment, getmetafile, getmedia, etc.). Device profile resizing does not work for images that use web links or direct paths in their source.

See also:

- [Linking pages and files](#)
- [GetFile.aspx parameters](#)

Disabling the resizing for individual images

If you wish to disable device profile resizing for an image, add the **resizemode=1** query string parameter to the image source URL.

For example:

```

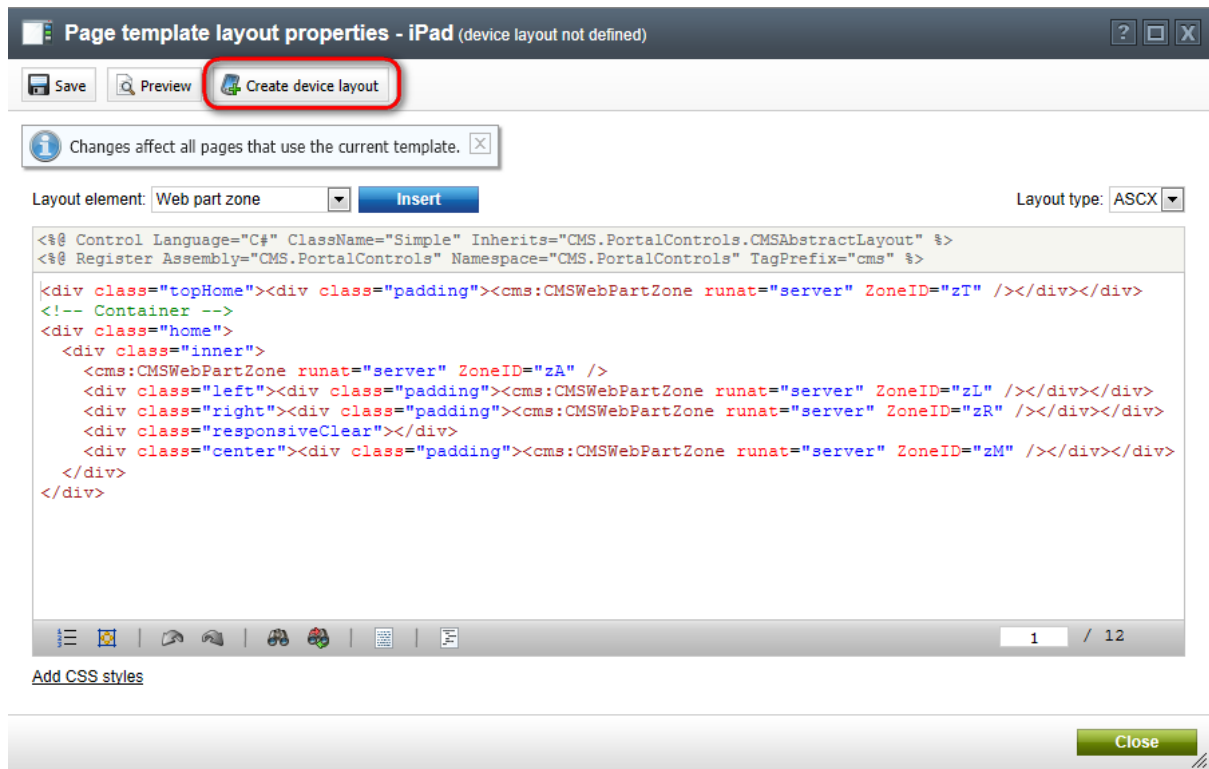

```

7.14.4 Creating page layouts for devices

Various devices have different capabilities and screen resolutions, which makes it difficult to build a single [page layout](#) suitable for all devices. Individual [page templates](#) allow you to define alternative page layouts for specific device profiles. Pages based on these templates automatically use the appropriate layout according to the device profile detected for each visitor.

To create a dedicated device layout for a page:

1. Open **CMS Desk** and select the document representing the page in the content tree.
2. Select the **Design** tab.
3. Switch to the device profile for which you intend to create the layout using the selector on the main CMS Desk toolbar.
4. Click **Edit layout** () on the header of the page's template area. The template's page layout editing dialog opens.
5. Click  **Create device layout**.

The **New device layout** dialog opens.

6. Select the source for the new device layout's initial content:

- **Copy from device profile** - copies the layout code from the template's default page layout or from one of its other device profile layouts.
- **Use existing layout** - allows you to select an existing shared page layout.
 - If you leave the **Copy as custom** box checked, the system creates the device layout as a separate copy of the selected layout. Otherwise the page template directly uses the shared layout for the device profile (changes made to the layout code affect all pages based on the same shared layout).
- **Use empty layout** - creates a new custom layout for the device profile with a single web part zone and no other formatting.

Click **OK**.

7. Define the code of the page layout for the given device profile.

Adding web part zones

The page template allows you to share web part content between the default page layout and device layouts. To implement this scenario, use identical ID values (**ZoneID** attributes) for the web part zones in the code of the template's various page layouts.

If you add web part zones with unique zone IDs, the zones will only be available in the specific device layout. When the system renders the page, it only displays the content

of zones that exist in the currently active page layout.

8. (Optional) Click [Add CSS styles](#) below the layout's code. The **CSS styles** editor appears, where you can define any device-specific CSS classes used within the layout code. The page loads these styles when a visitor views it on a device that matches the given profile. See also: [CSS for page components](#)

9. Click  **Save** and **Close** the dialog.

The page now automatically adjusts its layout based on the device profile detected for individual visitors.

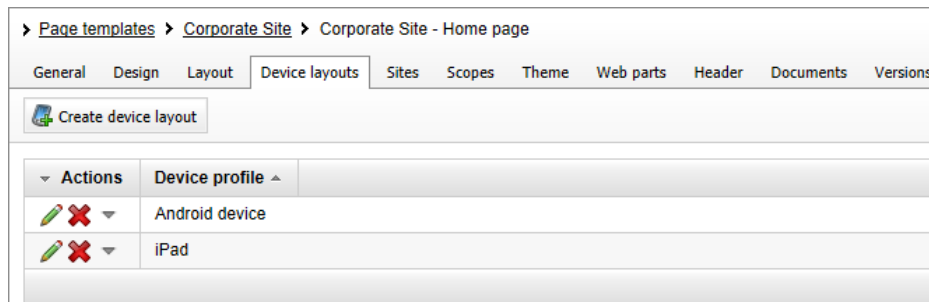

You can modify the web part content of the page for different device profiles by using the **Design** tab of CMS Desk in combination with the device selector. See [Creating mobile pages](#) for details.

Managing device layouts

You can also manage device layouts through the page template editing interface.

1. Go to **Site Manager -> Development -> Page templates** and select a page template.
2. Open the **Device layouts** tab.

This tab displays a list of the template's page layouts designed for specific device profiles. You can  **Create device layouts** and edit () or delete () existing ones.

3. Create or edit a device layout. The following sub-tabs become available:

- **Layout** - allows you to modify the device layout's code.
- **Design** - displays the current page template in Design mode (using the given device layout).
- **Versions** - allows you to view the device layout's [version history](#).

Any changes made on these tabs have the same effect as when editing page layouts directly in CMS Desk.

7.14.5 Mapping shared layouts

Device profiles allow you to replace shared [page layouts](#) with other layouts that are customized for displaying on the particular device. For example, if a page uses a three-column layout, it won't fit on a mobile phone's display. Using layout mappings, you can replace the columns with rows and thus reorganize the content of the page to be readable on the particular device.

Preparing shared layouts for mapping

You can only create mappings for layouts that are **convertible**.

1. Go to **Site Manager -> Development -> Page layouts** and edit the layout for which you want to have alternatives for different devices.
2. Check the **Is convertible** box.
3. Enter the **Number of zones** that the layout contains. The system automatically counts the number of web part zones in the layout code, but you can manually override the value (for example in the case of [conditional layouts](#) or layouts that load web part zones dynamically).
4. Save the layout.

The layout appears in the list of layouts on the Layout mapping tab in the device profile editing interface, where you can map it to a layout that will replace it when the particular device requests a page that uses the layout.

Mapping shared layouts

Prerequisite: Enable the **Enable layout mapping** setting for the website in **Site Manager -> Settings -> Content -> Content management**.

1. Go to **Site Manager -> Development -> Device profiles** and edit the device profile for which you want to map layouts.
2. Switch to the **Layout mapping tab**.

Device profiles

> Profiles > Android device

General Theme **Layout mapping**

For each device profile and layout (source layout) you can customize which layout (target layout) you can customize which layout (target layout) you can customize which layout (target layout). The arrow indicates the direction of layout mapping. You can choose a target layout by clicking on the right side of the grid.

Source layout name: LIKE

Full page → Rows

Grid 2x2 cells → Rows

Grid 3x2 cells → Rows

3. Find the layout that you want to create a mapping for on the left side of the grid.
4. Click the question mark on the right side to create a new mapping, or click a mapped layout on the right side to change the mapping. The **Select a target layout** dialog opens.
5. If you want to select a layout that has a different number of web part zones than the original, uncheck **Show only layouts with a matching number of zones**.
6. Click a layout to select it and click **OK** to confirm the selection.

The mapping is complete. If a device requests a page that uses the layout on the left and the device fits the device profile, the page will use the mapped layout instead.

You can now start designing pages for different device profiles using the Design mode in CMS Desk in combination with the device selector. See [Creating mobile pages](#) for details.

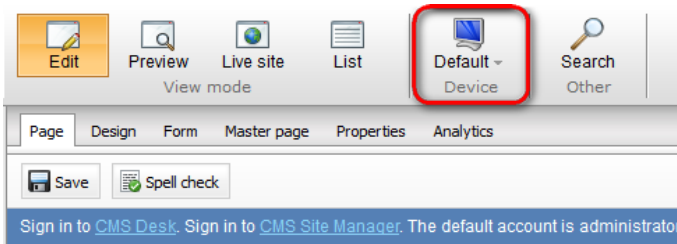

7.14.6 Creating mobile pages

This topic describes tasks that are common when developing mobile pages using Kentico CMS.

Switching device views

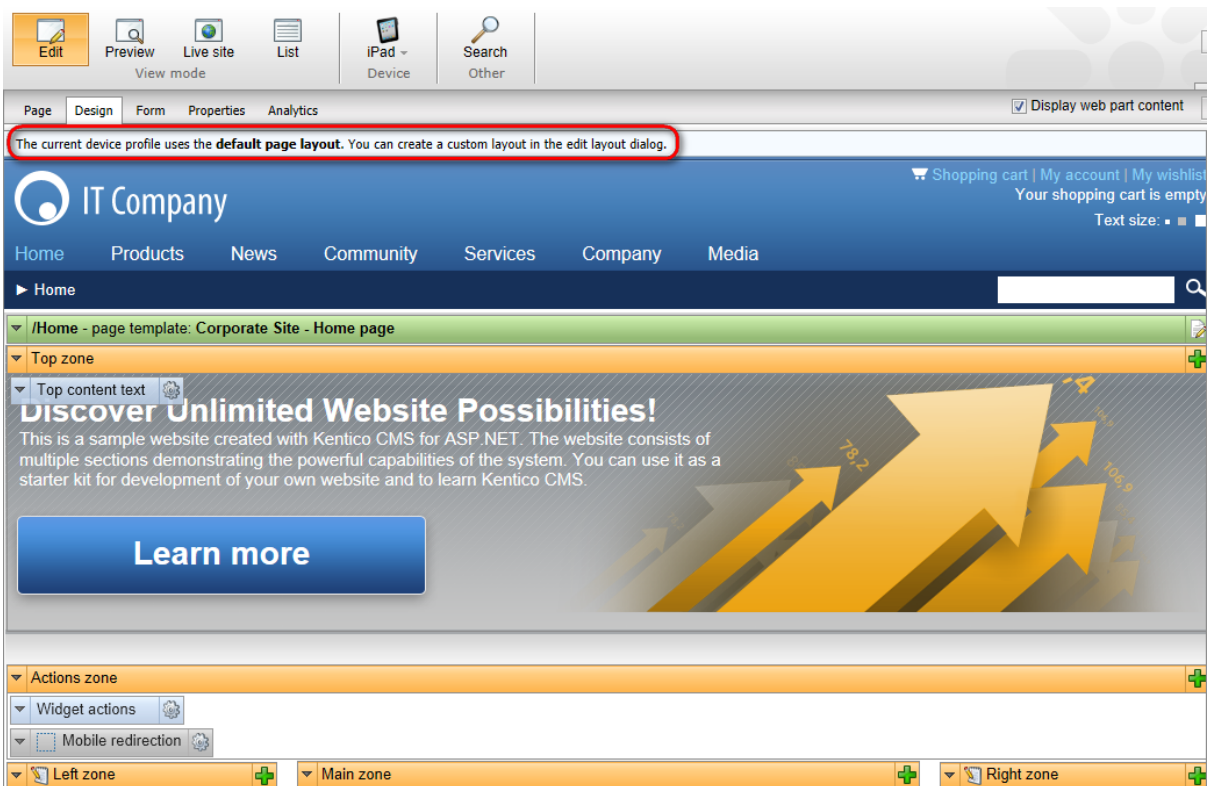

Kentico CMS allows you to develop pages and page templates for a particular device. Once you [enable](#) and [create](#) device profiles, the device selector appears in CMS Desk and you can switch the context of the Edit mode to a different device.

1. Click the Device selector. A list of enabled device profiles appears.

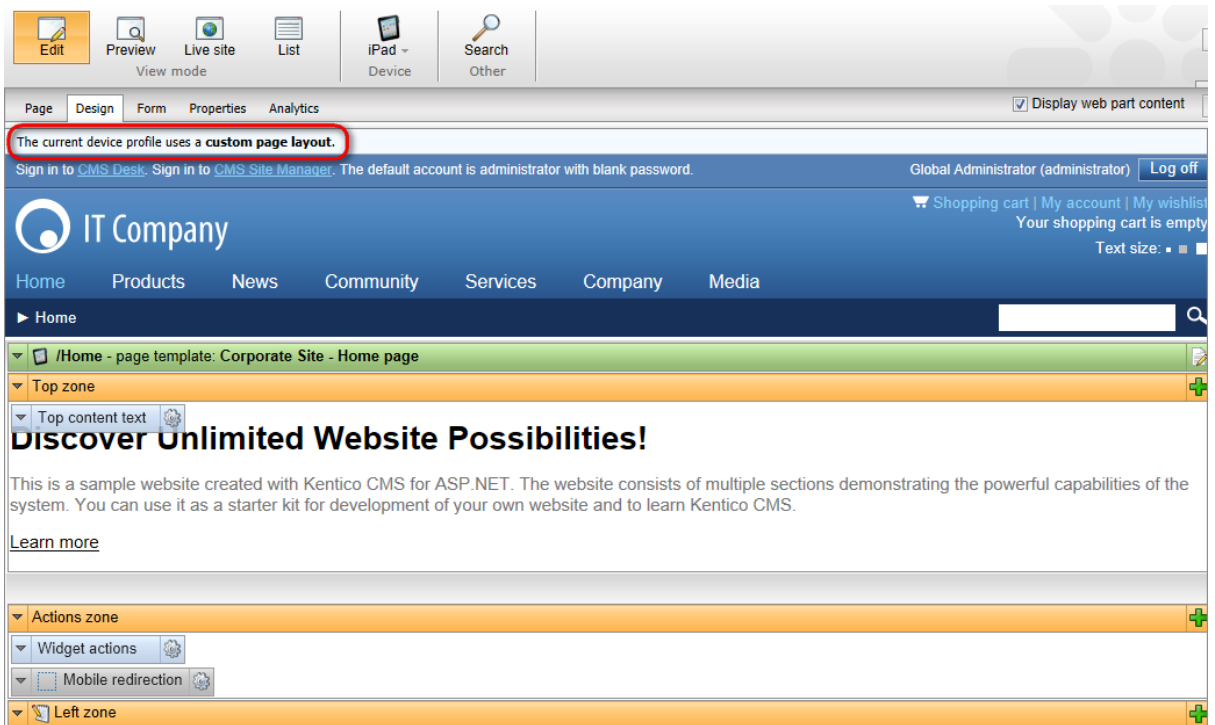

2. Click a device profile.

By default, when you switch to the **Design** tab, you can see and modify the contents of the default page layout for the current page, as in the following image:

If you created a device-specific page layout for the current page template, or if the page uses a shared layout that has a layout mapping defined for the current device profile, you can see the structure of the given device-specific layout.

The screenshot displays the Kentico CMS interface. At the top, there are icons for Edit, Preview, Live site, List, iPad Device, and Search. Below these are tabs for Page, Design, Form, Properties, and Analytics. A red box highlights the message: "The current device profile uses a custom page layout." Below this, there are links for "Sign in to CMS Desk" and "Sign in to CMS Site Manager". The user is logged in as "Global Administrator (administrator)". The main content area shows the "IT Company" logo and navigation menu. The page layout is expanded to show the "Top zone" containing a "Top content text" widget with the heading "Discover Unlimited Website Possibilities!". Below this are "Actions zone" with "Widget actions" and "Mobile redirection" widgets, and a "Left zone".

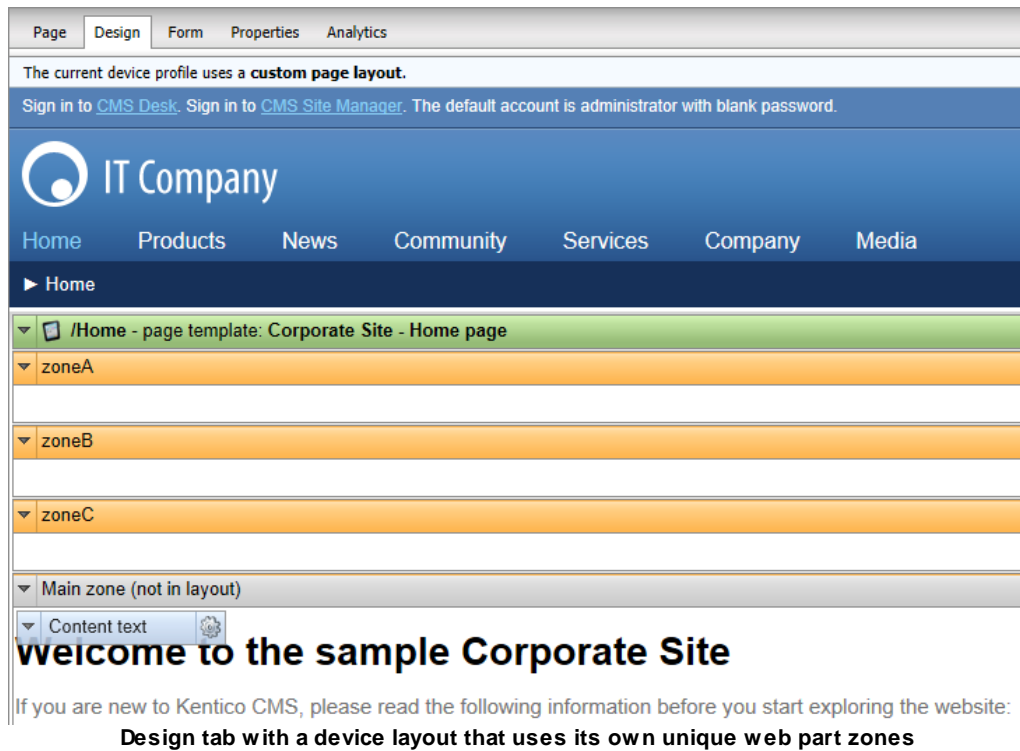

Device layout priority

[Custom device layouts](#) always take priority over [shared layout mappings](#). If you defined a custom device layout for a page's template, the page always uses the custom layout even if the template originally uses a shared layout with a mapping for the current device.

Page templates share web part zones between their default page layout and all device layouts. If you modify the content or configuration of a web part zone, the changes also affect the output of the template's other page layouts that contain a zone with the same ID.

You can find all web part zones that do not exist in the current page layout at the bottom of the page with a gray header and the *(not in layout)* suffix.

When the system renders the page on the live site, it only displays the content of zones that exist in the currently active page layout.

Previewing pages on different devices

The Preview and Live site modes in CMS Desk allow you to view pages as they would appear on different devices. Before you can use this, you must [enable](#) and [create](#) device profiles.

Note

The Preview and Live site mode only imitate the size and appearance of the device. The pages are still rendered with your browser engine.

1. Switch to the device profile that you want to preview.
2. Click Preview or Live site.

The page is shown in a frame that imitates a tablet device. To rotate the device 90 degrees, click **Rotate device preview**.

Customizing the preview frame

Kentico CMS allows you to customize the dimensions and looks of the Preview and Live site modes when using the modes with a device profile selected. This way you can make it look like you were

looking at the actual device with the content displayed on its screen.

The preview consists of nine pieces, eight forming the frame and one center piece, which contains the content of the page.

1. Edit the device profile for which you want to design your custom preview frame.
2. On the general tab, enter the **Preview width** and **Preview height**.
3. Switch to the **Theme** tab and upload files that will represent pieces of the frame. Upload the following pieces and their alternatives for the rotated version of the preview frame:
 - top left, top center and top right piece
 - center left and center right piece
 - bottom left, bottom center and bottom right piece

It is recommended to upload the files into a separate folder.

4. On the Theme tab, click **New file** to create a new stylesheet. Name it *DeviceProfile*.
5. In the stylesheet, specify which image corresponds to which part of the preview frame. Each part of the frame has a CSS class. Use the following pattern to construct a CSS selector that identifies a particular class:

```
.DeviceFrame.<device profile name>[.Rotated] .<vertical direction> .<horizontal direction>
```

- Add the `.Rotated` suffix to identify pieces of the device when it is rotated.
- Replace `<vertical direction>` with one of the following: *TopLine*, *CenterLine*, *BottomLine*
- Replace `<horizontal direction>` with one of the following: *LeftPiece*, *CenterPiece*, *RightPiece*

The following is an example definition of a preview frame piece.

```
.DeviceFrame.iPad.Rotated .TopLine .LeftPiece
{
  background-image: url('../Images/top_left_rotated.png');
  width: 126px;
  height: 114px;
}
```

Allowing visitors to override the device detection

Some visitors may prefer to view the standard version of the website (i.e. the content of the *Default* device profile) even when using a device that fits into a different device profile. Kentico CMS provides a component that allows users to switch between the content created for the detected device profile and the default version of the website.

1. Select a page in CMS Desk and view it on the **Design** tab. For best results, use a page that visitors can access anywhere on the site, such as the master page.

2. [Add](#) the [Switch mobile device detection](#) web part onto the page.
3. Click the **Configure** (⚙️) action of the web part and type in values for the following properties:
 - **Mobile link content** - sets the text of the link that the web part displays on the device-specific version of the site. This link allows users to switch to the default version of the website.
 - **Desktop link content** - sets the text of the link that returns visitors to the device-specific version of the site.
4. (Optional) Define the *SwitchDeviceDetection* CSS class in the website's stylesheet or directly in the web part's CSS styles. The web part applies this class to the generated links. See also: [CSS stylesheets and design](#)

The web part appears only for visitors whose device matches a non-default device profile. If a visitor switches to the default (desktop) content, the web part displays a link that re-enables device detection for the given visitor and returns them to the device-specific version of the site.

Adjusting web part properties for specific device profiles

If you need to change the behavior of web parts according to the current device profile, insert the appropriate [macro expressions](#) into the web part properties. This allows you to dynamically adjust pages that use the same content for their default page layout and device layouts.

See also: [Device macro reference](#)

Example

The following steps show how to make a web part visible only for the *Android device* profile.

1. Open CMS Desk and select the page containing the web part.
2. Switch to the **Design** tab and click the **Configure** (⚙️) action of the web part. The **Web part properties** dialog opens.
3. Click the **Visibility** section of the web part properties to expand it.
4. Click **Edit value** (▸) next to the checkbox of the **Visible** property. The **Edit value** dialog opens.
5. Enter the following macro expression:

[K#]

```
{% CurrentDeviceProfileName == "Android_device" %}
```

6. Click **Save** to insert the macro value into the property.
7. Click **OK** to save the configuration of the web part.

The system evaluates the macro expression when rendering the page. If the name of the current device profile matches the text (*Android_device*), the macro returns a true value, which dynamically enables the web part's **Visible** property.

Using device-specific transformations

The [transformations](#) that you use to display data have a significant effect on the design of pages. If you need to assign different transformations for specific devices or device profiles, add [macro expressions](#) into the transformation properties of the appropriate web parts.

See also: [Device macro reference](#)

Example

This example demonstrates how to create and assign a dedicated transformation for displaying news documents on mobile devices.

1. Open the sample Corporate Site in CMS Desk.
2. Select the **News** document and switch to the **Design** tab.
3. Click the **Configure** (⚙️) action of the *News repeater* web part. The **Web part properties** dialog opens.
4. Scroll down to the **Transformation** property and click **New** next to the textbox. The **New transformation** dialog opens.
5. Type *NewsList_mobile* as the **Transformation name** and enter the following code:

```
<div class="description" style="width:500px;">
  <a class="header bold" href="<%# GetDocumentUrl() %>"><%# Eval("NewsTitle",
true) %></a>
  <p>
    <%# Eval("NewsSummary") %><br /><br />
    <span class="black bold"><%# GetUserFullName(Eval<int>("NodeOwner")) %> | </
span>
    <span class="gray"><%# Eval("NewsReleaseDate") %></span>
  </p>
</div>
```

This is a simplified version of the default *corporatesite.transformations.NewsList* transformation, without teaser images and with a limited text width.

6. Click  **Save** and **Close** the dialog.
7. Click **Edit value** (▾) next to the **Transformation** property. The **Edit value** dialog opens.
8. Enter the following macro expression:

[K#]

```
{%}
```

```
if (CurrentDevice.IsMobile AND
    GlobalObjects.DocumentTypes["CorporateSite.Transformations"]
    .Children.Transformations.Exists(CodeName == "NewsList_mobile"))
    {"corporatesite.transformations.NewsList_mobile"}
else
    {"corporatesite.transformations.NewsList"}

%}
```

This macro evaluates a condition and returns the transformation name according to the result.

- The *CurrentDevice.IsMobile* part of the condition checks whether the page is being viewed by a mobile device. This directly searches the data available for the current device (the device profile of the current visitor does not affect the result).
- The second condition checks if the *corporatesite.transformations.NewsList_mobile* transformation actually exists in the system. While not necessary in this example, similar conditions allow you to load transformations designed for specific devices. In these cases, you can use a dynamic parameter in the transformation name, such as the exact device name (*CurrentDevice.DeviceName*).

9. Click **Save** to insert the macro value into the property and then **OK** to save the configuration of the web part.

When a visitor views the News page on a mobile device, it automatically displays the simplified list of news items according to the new transformation (*corporatesite.transformations.NewsList_mobile*).

News List

News title:

Community Website Section

As a result of our continuous effort to improve our services, we have recently introduced the **Community** section of our website. It is a place where you can both receive interesting information about the company from various communication channels and express your opinions and thoughts yourselves.

Global Administrator | 6/28/2011 1:00:00 AM

Company Growth Exceeds Expectations

Our company growth has reached astonishing 256% in the last financial year. It is not only thanks to the excellent and devoted work of our employees, but mainly thanks to you, our faithful customers. Therefore, we would like to thank you for your loyalty and state a promise that we will keep to the high standard of products and services we currently provide.

Luke Hillman | 6/17/2011 12:00:00 AM

Users with non-mobile devices can still see the original full-sized transformation (*corporatesite.transformations.NewsList*).

7.14.7 Creating a separate mobile section

Kentico CMS allows you to create a dedicated sub-section of the website for visitors with mobile devices.

You can redirect users to the mobile section by placing the [Mobile device redirection](#) web part placed onto the website's main landing page. This web part redirects mobile users to one of two URLs

according to the user agent of the detected device.

Device detection

The **Mobile device redirection** web part uses its own device detection logic that is *not* related to the [device data](#) or [device profiles](#).

You can configure the behavior of the web part through its properties:

| | |
|------------------------------|---|
| Small device redirection URL | URL to which the web part redirects mobile devices recognized as small. The properties below determine which devices are considered large or small. |
| Large device redirection URL | URL to which the web part redirects mobile devices recognized as large. The properties below determine which devices are considered large or small. |
| Redirect Android | Determines if Android mobile devices are considered as small or large devices.

If you set the value to <i>Automatic</i> , Android devices are recognized as small. Choose <i>Never</i> to disable redirection for Android devices. |
| Redirect BlackBerry | Determines if BlackBerry mobile devices are considered as small or large devices.

If you set the value to <i>Automatic</i> , BlackBerry devices are recognized as small. Choose <i>Never</i> to disable redirection for BlackBerry devices. |
| Redirect iPad | Determines if iPad devices are considered as small or large devices.

If you set the value to <i>Automatic</i> , iPad devices are recognized as large. Choose <i>Never</i> to disable redirection for iPad devices. |
| Redirect iPhone | Determines if iPhone devices are considered as small or large devices.

If you set the value to <i>Automatic</i> , iPhone devices are recognized as small. Choose <i>Never</i> to disable redirection for iPhone devices. |
| Redirect Nokia | Determines if Nokia mobile devices are considered as small or large devices.

If you set the value to <i>Automatic</i> , Nokia devices are recognized as small. Choose <i>Never</i> to disable redirection for Nokia devices. |
| Always redirect | When the website is accessed from a mobile device, the system stores a redirection cookie in the device's browser.

If you disable this property, the web part does not redirect devices if the cookie is already present in the browser, i.e. redirection is only done for the first visit. If enabled, the web part redirects mobile devices on every |

| | |
|----------------------------------|---|
| | visit. |
| Other small devices (User agent) | Specifies a list of additional user agents that the web part recognizes as small mobile devices.

Enter each user agent on a separate line. |
| Other large devices (User agent) | Specifies a list of additional user agents that the web part recognizes as large mobile devices.

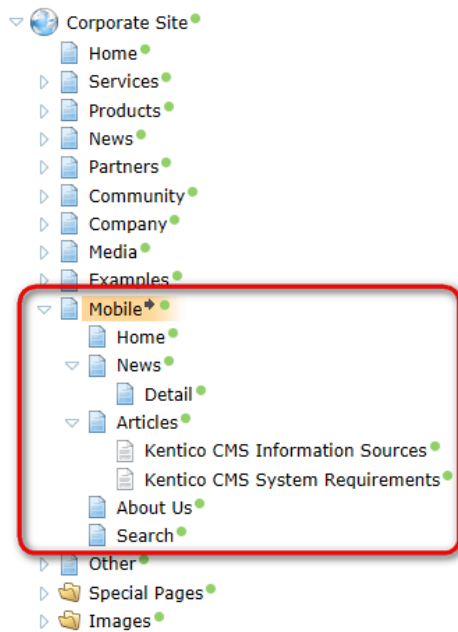

Enter each user agent on a separate line. |

Example

The sample **Corporate Site** contains an example of a mobile website section. The main **Home** page uses a *Mobile device redirection* web part to send mobile visitors to a dedicated website section.

The **Mobile** page serves as the master page of the mobile section. This page does not use [template inheritance](#), so it doesn't display content from the site's main master page. Under it, you can find the following pages:

- **Home** - mobile users get redirected to this page from the site's main *Home* page. The page uses a [Repeater](#) web part to dynamically load content from the [Editable text](#) region on the website's main *Home* page.
- **News** - uses a [Repeater](#) web part to display the *News* documents stored under the website's main /*News* section. The news item titles link to the */Mobile/News/Detail* page, which uses a [wildcard URL](#) (*/Mobile/News/{id}*) containing the *ID* of the exact news item.
- **Articles** - the [Repeater](#) web part on this page displays the articles stored under it. The content is stored directly in the mobile section. It is not shared with the rest of the site.
- **About us** - contains only two [Editable text](#) web parts. Its content is separate and used only in the mobile section.
- **Search** - this page is not accessible through navigation. The [Smart search box](#) on the *Mobile* master page redirects users here if they perform a search within the mobile section. The page displays search results using the [Smart search results](#) web part.

The figure below shows what the mobile section looks like when viewed on various mobile devices:

CSS stylesheet for the mobile section

The pages of the mobile section use a different CSS stylesheet than the rest of the website — **Corporate Site – Mobile**. The mobile section's master page has the stylesheet assigned in **Properties -> General -> CSS stylesheet**. All pages in the mobile section inherit this configuration and use the

same stylesheet.

7.14.8 Device macro reference

CurrentDevice

The *CurrentDevice* object holds information about the device detected for the current visitor. The system identifies devices based on their user agent and retrieves the data about the capabilities of devices from the integrated 3rd party component [51degrees.mobi](#) or the `~\App_Data\CMSModules\DeviceProfile\devices.xml` file.

You can take advantage of the *CurrentDevice* object when defining conditions for [device profiles](#) and in general [macro expressions](#).

The following list presents the properties of the **CurrentDevice** object. Most of the properties are only available in the [51degrees.mobi Premium data](#):

- BitsPerPixel - color depth that the device's display supports.
- BrowserName
- BrowserVendor
- BrowserVersion
- CcppAccept - list of MIME types that the device supports.
- CookieCapable - indicates if the device can accept cookies.
- DeviceName
- HardwareModel
- HardwareName
- HardwareVendor
- HasCamera
- HasKeypad
- HasQwertyPad
- HasTouchscreen
- HasTrackpad
- HasVirtualQwerty
- HtmlVersion
- IsCrawler
- IsMobile
- IsTablet
- JavaScript - indicates if the device supports JavaScript.
- LayoutEngine - name of the rendering engine that the device uses.
- MaxScreenSize - size of the longer side of the device's screen.
- PlatformName
- PlatformVendor
- PlatformVersion
- ScreenPixelsHeight
- ScreenPixelsWidth
- StreamingAccept
- SupportedBearers
- UserAgent

CurrentDeviceProfile

To get information about the [device profile](#) assigned to the current visitor, use the *CurrentDeviceProfile* object in macros:

- You can access the device profile's system data through its properties, for example: `{% CurrentDeviceProfile.ProfilePreviewWidth %}`
- To directly get the device profile's name, use the following expression: `{% CurrentDeviceProfileName %}`

7.15 Microsoft Silverlight integration

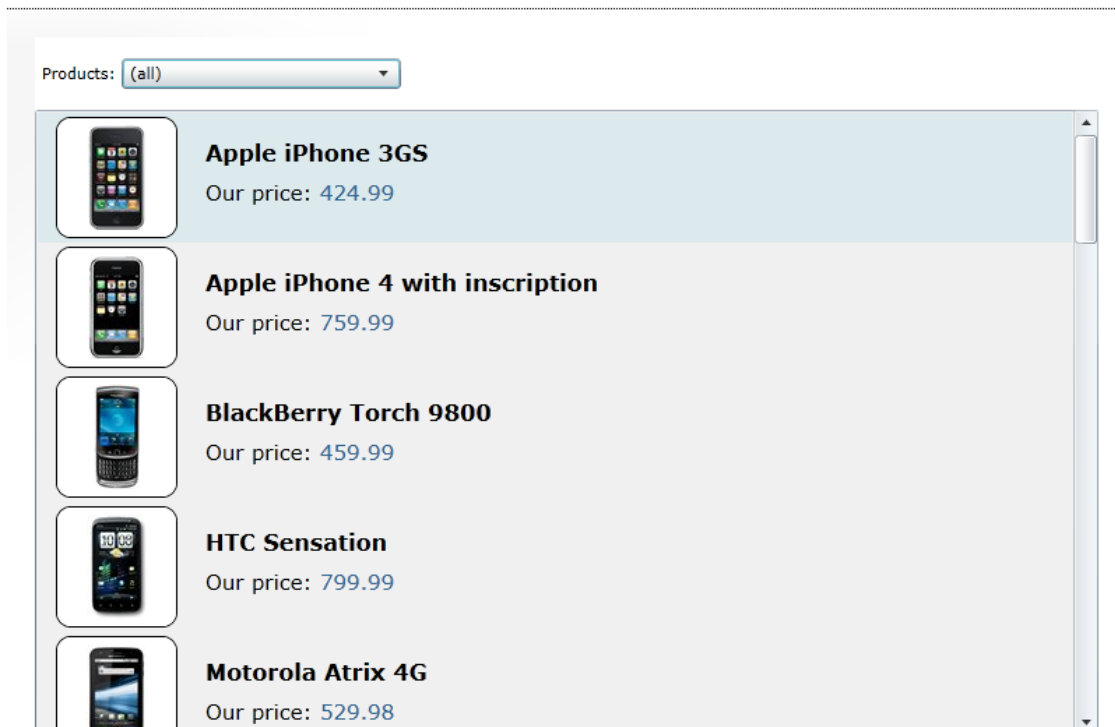

7.15.1 Overview

Kentico CMS comes with native support of **Microsoft Silverlight**. Microsoft Silverlight is a cross-browser, cross-platform technology for building and delivering the media experiences and Rich Interactive Applications (RIA) for the Web.

Silverlight applications run in the internet browser. All you need is a small plug-in installed in your browser. The plug-in is free and in case that users access a site containing a Silverlight application without this plug-in installed, they will be able to install Silverlight using an install banner leading to the download link.

You can find a live example of use of the Silverlight application web part on the **Corporate Site** sample website, on a page under **Corporate site -> Examples -> Web parts -> Silverlight -> Silverlight application**.

Example of the web part:

How it works in general

1. The developer creates a website with a built-in Silverlight application.
2. The site visitor navigates to that site using an internet browser.
3. If the user does not already have the required plug-in installed in the browser, they are automatically prompted to install it.
4. The Silverlight application is executed.

Creating Silverlight applications

Silverlight is a **.NET Framework** based technology, so if you are familiar with development using **Visual Studio** and one of the **.NET Framework languages** like **C#**, it will be much easier for you to learn Silverlight.

For developing Silverlight applications, you will need at least **Microsoft Visual Studio** with **Silverlight Tools**. There is one more powerful tool for designers - **Expression Blend**, which enables you to create application design in a really comfortable way. We also strongly recommend installing the **Silverlight Toolkit**, which brings many new controls that can be used in your Silverlight applications.

Visit the [Silverlight community](#) site where you can download all the required components. What is more, you can find valuable tutorials there, which can help you get started in the development of Silverlight applications.

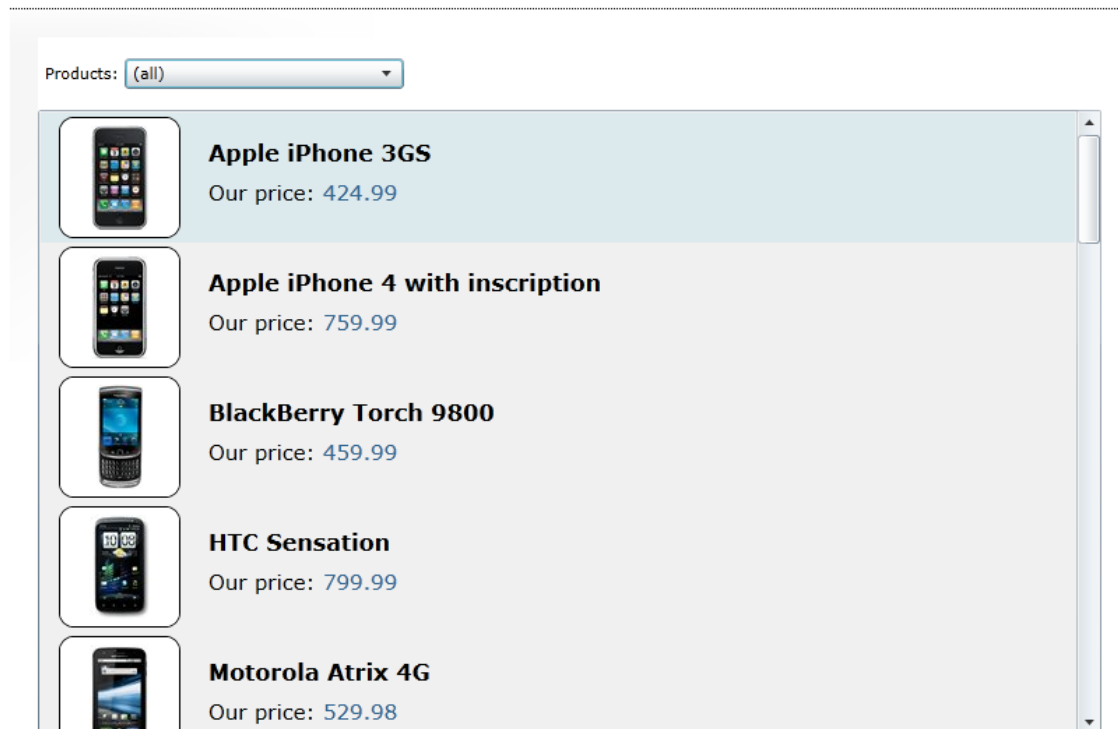

We also recommend reading the official [Microsoft Silverlight documentation](#).

- To learn how to add a Silverlight application to your site, please refer to the [Adding a Silverlight application to your site](#) topic.
- If you would like to learn how to configure Internet Information Services (IIS) to enable Silverlight applications on your site, please refer to the [IIS configuration](#) topic.

7.15.2 Adding a Silverlight application to your site

To add a Silverlight application to your site, you will need to use the **Silverlight application** web part, which is a container for Silverlight applications.

You can find a live example of use of this web part on the **Corporate Site** sample website, on a page under **Corporate site -> Examples -> Web parts -> Silverlight -> Silverlight application**.

Example of the web part:**Adding a Silverlight application web part to a website**

1. Go to **CMS Desk** and from the content tree, choose the page where you would like to add your Silverlight application.
2. Switch to the **Design** tab.
3. Click the **Add web part** (+) icon at the top right-hand corner of the web part zone where you want to place the application.
4. Choose the **Silverlight -> Silverlight application** web part.
5. Click **OK**.
6. Configure the web part properties:
 - **Application path** - path to your Silverlight application; e.g. *~/ClientBin/MyApplication.xap*.
 - **Minimum version** - minimum version of Silverlight required by the silverlight application to run by this web part.
 - **Container width** - width of the application container; can be entered either as an integer value (e.g. 315) or as a percentage value (e.g. 59%).
 - **Container height** - height of the application container; can be entered either as an integer value (e.g. 315) or as a percentage value (e.g. 59%).
 - **Container background** - background of the application container; can be entered in hexadecimal (e.g. #323232) format or selected from a Color picker, which is displayed after clicking the Select button; if no value is entered, white color is used.
 - **Endpoint address** - web service endpoint address the client application can connect to; if specified,

its value is added as parameter with 'endpoint' key to the application parameters collection; you need to handle this parameter in your Silverlight application for it to take effect.

- **Parameters** - Silverlight application parameters in the following format: `<key1>=<value1>`, `<key2>=<value2>`,...
- **Alternate content** - custom HTML content which is displayed to users when Silverlight plug-in is not installed; leave blank if you want the default alternate content to be displayed.

7. Click **OK**.

Now you can switch to the **Live site** and enjoy your Silverlight application running on your Kentico CMS website.

7.15.3 IIS configuration

Silverlight introduces three new file extensions (MIME types):

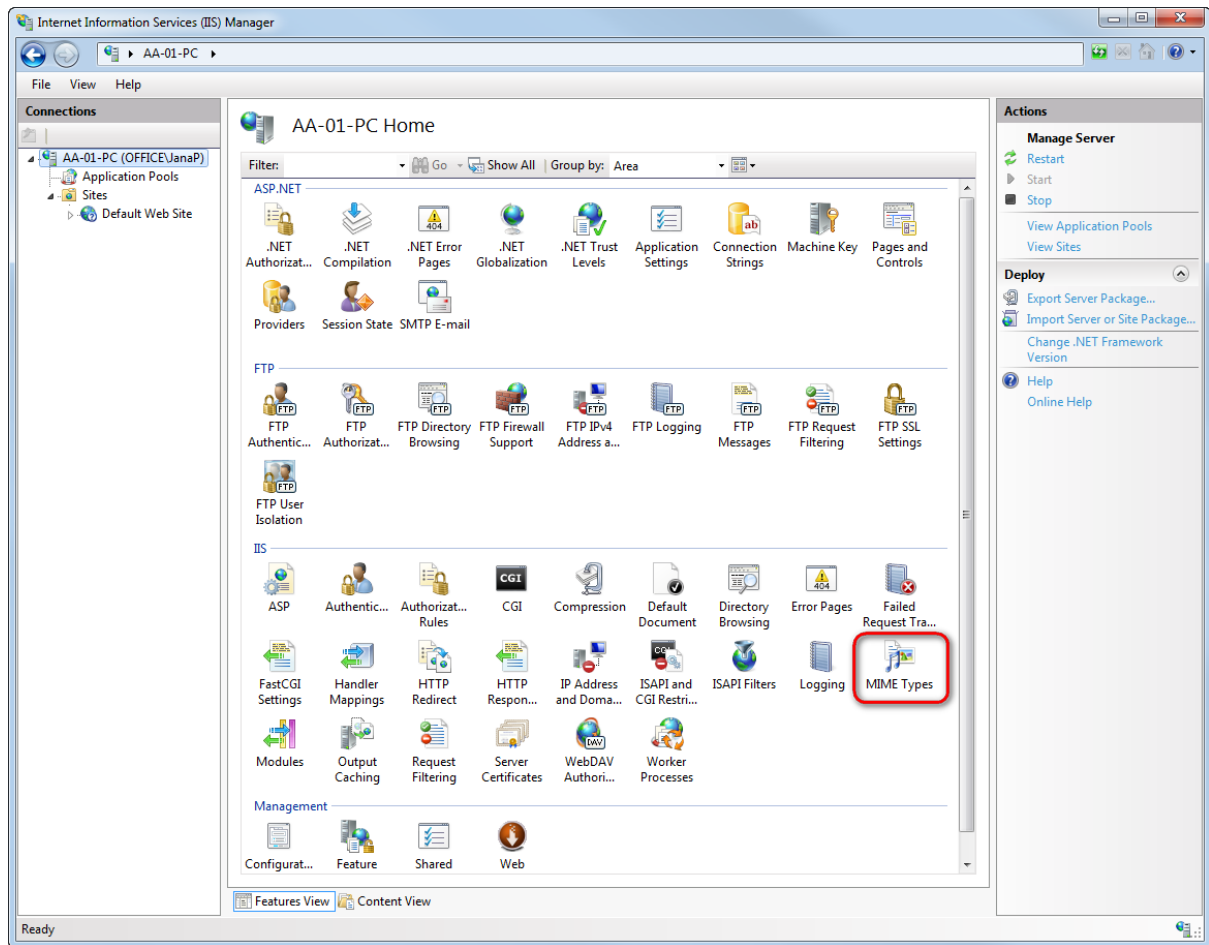

- **.xaml**
- **.xap**
- **.xbap**

All these MIME types need to be configured in your IIS. By default, they are already implemented in IIS 7 (and above) in Windows Server 2008 and Windows Vista SP1.

If you run Windows Vista without SP1, you will have to add these extensions into your IIS.

Adding Silverlight MIME types into IIS on Windows Vista

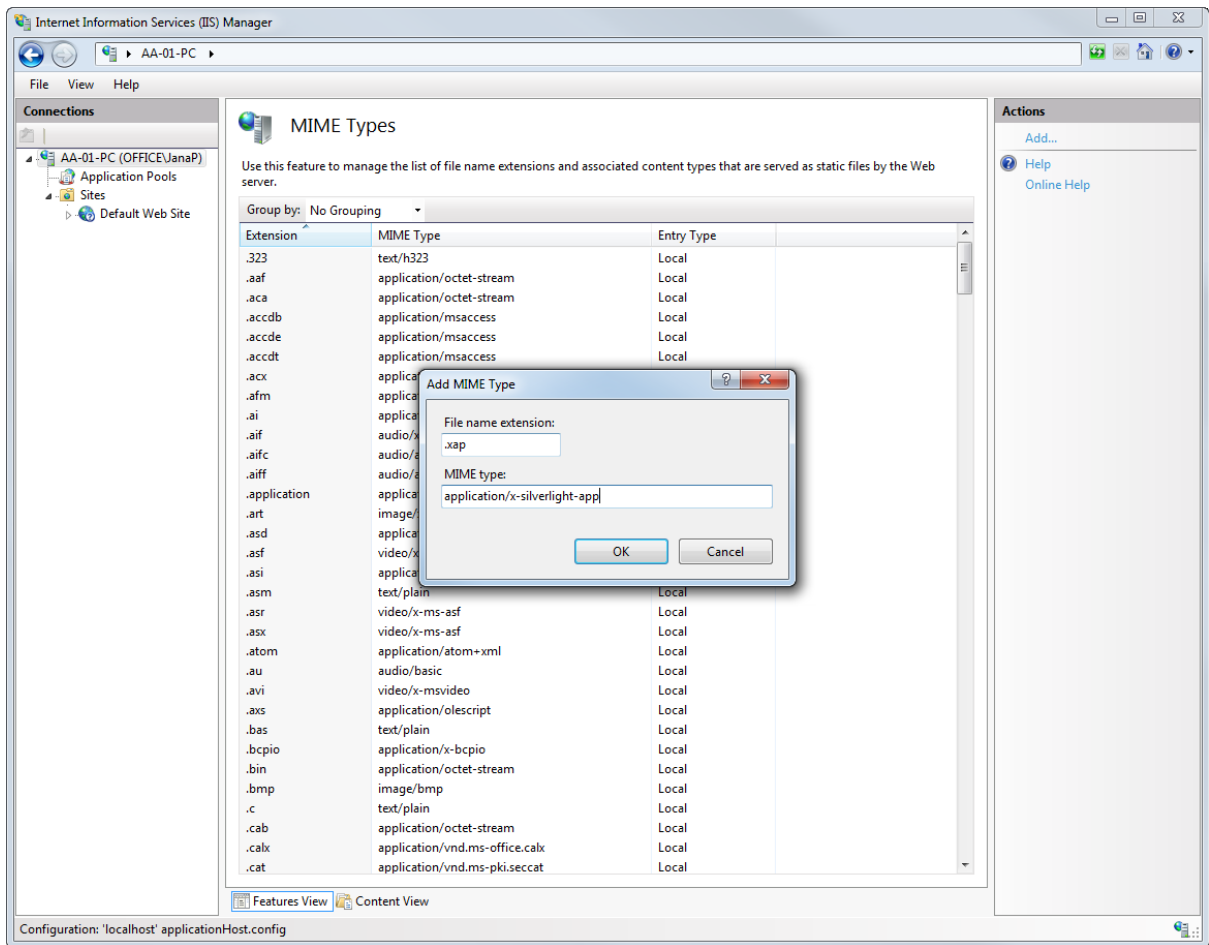

1. Open **IIS Manager**.
2. Double-click **MIME types** in the IIS section.

3. Click **Add...**

4. Type the following information:

- **File name extension:** .xap
- **MIME type:** application/x-silverlight-app

5. Click **OK**.

6. Repeat for the other two types:

- **File name extension:** .xaml
- **MIME type:** application/xaml+xml
- **File name extension:** .xbap
- **MIME type:** application/x-ms-xbap

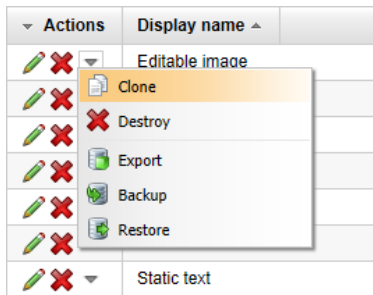

You have now configured your IIS to support Silverlight applications.

7.16 Object cloning

7.16.1 Overview

Cloning provides an easy way to create an exact copy of an object. It is supported for all objects throughout the system, from the most basic records to complex data structures such as document types or user accounts. If you wish to reuse any part of an existing item or create a modified version of it, cloning is much more efficient than adding a new object of the given type and manually carrying over the values and various configuration options from the original.

To clone an object, find it on the listing page in the appropriate section of the administration interface, click the **Other actions** button next to it and select the **Clone** option in the drop-down menu.

Objects that are displayed in a tree menu instead of a standard list may be cloned via a button available in the panel above the tree.

Using the clone action opens a dialog where you can specify exactly how the cloned object should be created. In most cases, you will be asked to enter a *display name* and *code name* for the new object. Further settings can be accessed by clicking **Show advanced settings**, which offers the following options:

- **Delete clone on failure** - if enabled, the new object will be removed if an error occurs during any part of the cloning process.
- **Keep fields localized** - if checked, the cloned object will transfer all localization macros (i.e. resource strings) placed inside its fields. Otherwise they will be replaced by the values entered for the default culture. This does not affect the *Display name* field, which is filled in manually using the *New object display name* field.

Additional settings depend on the type of the cloned object. They typically allow you to choose what types of associated data should be cloned along with the given object, such as for example child objects, attachments, bindings to other objects etc.

Clone Web part

You are about to clone Web part 'Editable image'.

General

New object display name:

New object code name:

[Hide advanced settings](#)

Delete clone on failure:

Keep fields localized:

Clone object attachments:

Web part specific options

Clone web part to category:

Clone web part files:

Cloned web part file name:

Copy folder within App_Themes:

Clone web part layouts:

Many objects also offer even more configuration options in the **specific options** section. These must be specified so that the system can correctly create the clone (particularly in the case of complex objects). Information about individual settings can be found in the tooltip displayed when hovering over the names of fields.

7.16.2 Cloning objects through the API

If necessary, objects may also be cloned by calling the appropriate API in your custom code (for example in [global event handlers](#) or in the logic of user controls and [web parts](#)).

The following sample code demonstrates how this can be done. The **CloneCountry** method in the example creates a clone of the USA country object, including all child states. It also manually sets the country code values of the new object.

[C#]

```
using CMS.SiteProvider;
using CMS.SettingsProvider;

...

public void CloneCountry()
{
    // Gets the country to be cloned.
    CountryInfo country = CountryInfoProvider.GetCountryInfo("USA");
    if (country != null)
    {
        // Prepares the settings used for the cloning process.
        CloneSettings settings = new CloneSettings()
        {
            // Sets the clone names.
            CodeName = "MyClonedCountry",
            DisplayName = "My Cloned Country",

            // Ensures that the state objects under the country are also cloned.
            IncludeChildren = true,

            // Registers a callback method that performs additional actions before
            the clone is added.
            BeforeCloneInsertCallback = ChangeCountryCodes
        };

        // Clones the country according to the defined settings.
        country.Generalized.InsertAsClone(settings);
    }
}

private void ChangeCountryCodes(CloneSettings settings, BaseInfo
cloneToBeInserted)
{
    // Changes the values of additional fields before the clone is inserted to the
    DB.
```

```
CountryInfo country = cloneToBeInserted as CountryInfo;
if (country != null)
{
    country.CountryThreeLetterCode = "MCC";
    country.CountryTwoLetterCode = "MC";
}
}
```

Before an object can be cloned, it is necessary to prepare an instance of the **CloneSettings** class (from the **CMS.SettingsProvider** namespace). By assigning values to the properties of this object, you can configure how the cloning process will be performed. In addition to the code name and display name, the available properties correspond with the advanced cloning settings. In the example, the **IncludeChildren** flag is set to true, so all state objects under the given country will also be cloned and assigned to the new country.

The **BeforeCloneInsertCallback** property is used to register a custom handler method that will be executed just before the clone is inserted into the database. Such methods allow you to implement any functionality required to correctly clone the object. The object that is being cloned and the corresponding *CloneSettings* object are passed as parameters, so you can dynamically set the values based on the currently assigned clone settings.

Other possible callback options are:

- **AfterCloneInsertCallback** - executed after the cloned object itself is created and inserted, but before the system starts cloning any associated child objects or bindings.
- **AfterCloneStructureInsertCallback** - called once all objects included in the cloning process are created.

Finally, the clone action itself is performed by calling the **InsertAsClone** method for the original country object (converted to a generalized object type), with the prepared *CloneSettings* specified through the parameter.

7.17 Object versioning

7.17.1 Overview

Similarly as [versioning of documents](#), object versioning allows creation of versions when an object in Kentico CMS is edited and saved. This is convenient in case that you want to compare particular versions or roll back to one of the previous ones. This may potentially save lots of repeated work when some unwanted modifications are made to an object and you want to get the object to the original state.

Versioning is only possible for certain object types. In the [Supported object types](#) topic, you can find their list, together with exact locations of the administration interface sections where these objects can be edited and where their versions can be viewed and managed.

Even though object versioning is enabled and functional by default, it is recommended to configure settings related to it in **Site Manager -> Settings -> Versioning & synchronization -> Object versioning**. To learn more about all settings that can be adjusted there, please refer to the [Configuring object versioning](#) topic.

Once object versioning is enabled and configured, new versions are created when objects are modified

under certain circumstances. In the [Using object versioning](#) topic, you can find exact information about when versions are created and how they can be viewed, compared and managed.

Another feature related to object versioning is the [Objects recycle bin](#). This feature allows certain objects to be deleted to the recycle bin instead of being deleted permanently. Objects deleted to the recycle bin can be restored, so you may avoid unwanted deletion of an object and the subsequent need to create it again.

In the [Object versioning internals and API](#) sub-chapter, you can find information about database tables and classes that are used by object versioning, as well as several examples of how object versions can be managed using Kentico CMS API.

7.17.2 Supported object types

In the following table, you can find all object types that support versioning. In the **Editing interface** column, you can find the exact location within Kentico CMS administration interface where objects of the particular type can be edited. If versioning is enabled for a particular object type, the **Versions** tab where particular versions of the edited object can be viewed and managed is available directly in the respective editing interface.

| Object type | Editing interface |
|---------------------------|---|
| Alternative forms | <ul style="list-style-type: none"> • CMS Desk -> Tools -> Forms -> edit (✎) -> Alternative forms -> edit (✎) • Site Manager -> Development -> Document types -> edit (✎) -> Alternative forms -> edit (✎) • Site Manager -> Development -> Custom tables -> edit (✎) -> Alternative forms -> edit (✎) |
| CSS stylesheets | <ul style="list-style-type: none"> • CMS Desk -> Content -> Edit -> Properties -> General -> click Edit • Site Manager -> Development -> CSS stylesheets -> edit (✎) • other interfaces containing the stylesheet selector (e.g. when editing a site, department, etc.) |
| Custom table definitions | <ul style="list-style-type: none"> • Site Manager -> Development -> Custom tables -> edit (✎) |
| Document type definitions | <ul style="list-style-type: none"> • Site Manager -> Development -> Document types -> edit (✎) |

| <p>* Only shared page layouts are versioned — custom layouts are versioned as part of the data of the parent page template.</p> <p>** Only custom queries and web part layouts are versioned — system queries and default web part layouts are not versioned.</p> | |

7.17.3 Configuring object versioning

Object versioning settings can be adjusted in **Site Manager -> Settings -> Versioning & synchronization -> Object versioning**. The following settings are available:

| General | |
|-------------------------------|---|
| Enable object versioning | Globally enables or disables object versioning. This option is enabled by default. If disabled, no versions are created when objects are modified. |
| Delete objects to recycle bin | <p>Determines which objects should be moved to recycle bin when deleted:</p> <ul style="list-style-type: none"> • No - no objects are moved to recycle bin when deleted, i.e. they are deleted permanently. • Versioned objects only - only objects that support versioning and |

| | |
|--|---|
| | <p>whose versioning is enabled by the settings below are moved to recycle bin when deleted.</p> <ul style="list-style-type: none"> • All objects - all objects that support staging synchronization are moved to recycle bin when deleted. |
| Team development | |
| Use check-in/check-out for objects | Indicates if object locking (check-in/check-out) should be used for virtual objects. |
| Keep new objects checked out | Indicates if new objects are automatically checked out upon creation. |
| Version history | |
| Version history length (major versions) | Indicates how many major versions of a single object will be stored in its version history. If the number of major versions exceeds this value, the oldest versions are deleted. If set to 0, major versions history length is not limited. |
| Version history length (minor versions) | Indicates how many minor versions of a single object will be stored in its version history. If the number of versions exceeds this value, the oldest version is deleted. If set to 0, minor versions history length is not limited. |
| Save to last version if younger than (minutes) | If an object is edited and saved within this number of minutes since it was last saved, changes made to it are saved to the last version. If it is saved after more minutes since it was last saved, a new version is created. If set to 0, a new version is created whenever you save an edited object. |
| Promote to major version if older than (hours) | If an object is edited and saved after this number of hours since it was last saved, a new major version is created. If it is saved earlier, a new minor version is created or the changes are saved to the latest version (depending on the setting above). If set to 0, major versions are never created automatically. |
| Use object versioning for | |
| Alternative forms | Indicates if versioning of document type, on-line forms and custom table alternative forms is allowed. |
| CSS stylesheets | Indicates if versioning of CSS stylesheets is allowed. |
| Custom table definitions | Indicates if versioning of custom table definitions is allowed. |
| Document type definitions | Indicates if versioning of document type definitions is allowed. |
| E-mail templates | Indicates if versioning of e-mail templates is allowed. |
| Form definitions | Indicates if versioning of on-line form definitions (the Forms module) is allowed. |
| Media files | Indicates if versioning of media files (the Media module) is allowed. This options is disabled by default because versioning of large media files may consume an extensive amount of database space. |
| Media files versioned extensions | Extensions of versioned media files. Only media files with extensions enumerated here will be versioned. |

| | |
|----------------------|--|
| Newsletter issues | Indicates if versioning of newsletter issues is allowed. |
| Newsletter templates | Indicates if versioning of newsletter templates is allowed. |
| Page layouts | Indicates if versioning of page layouts is allowed. |
| Page templates | Indicates if versioning of page templates is allowed. |
| Queries | Indicates if versioning of document type and custom table queries is allowed. Only custom queries are versioned — system queries are not versioned because they are re-generated by the system automatically when their parent object is modified. |
| Report graphs | Indicates if versioning of report graphs is allowed. |
| Report tables | Indicates if versioning of report tables is allowed. |
| Report values | Indicates if versioning of report values is allowed. |
| Report definitions | Indicates if versioning of report definitions is allowed. |
| Transformations | Indicates if versioning of document type and custom table transformations is allowed. |
| Web part containers | Indicates if versioning of web part containers is allowed. |
| Web part layouts | Indicates if versioning of web part layouts is allowed. |
| Workflows | Indicates if versioning of workflow objects is allowed. |

7.17.4 Using object versioning

If object versioning is enabled as described in the [Configuring object versioning](#) topic, the **Versions** tab is displayed in [editing interfaces](#) of objects whose versioning is allowed. On this tab, particular versions of the currently edited object are created when objects are edited under certain circumstances described in the following paragraph.

How versions are created and numbered

The following points summarize when new versions are created and what numbering is used for them:

- The current version is always the one in the top line of the grid. If object versioning is disabled additionally when there are already some versions, the top version needn't contain current object data if the object was edited after object versioning had been disabled.
- If you create a new object, the initial 0.1 version is created on the tab automatically.
- If you edit an existing object that had been created before object versioning was enabled, there are no versions on the tab initially. When you edit it and save the modifications, two versions are created: 1.0 with the original data and 1.1 with the currently saved data.
- Every other edit and save creates a new minor version (the version number is incremented by 0.1) if you save after the number of minutes configured in the **Save to last version if younger than (minutes)** setting since last save. If you save within the number of minutes, object data is saved to the last version.

- If you edit and save after the number of hours configured in the **Promote to major version if older than (hours)** setting, the latest version is promoted to a major version and the new version follows the new major numbering (i.e. latest 2.3 is promoted to 3.0 and the new one is numbered 3.1).
- The current version can also be promoted to a major version manually by clicking the **Make current version major** button above the **Object history** listing.

Management of versions on the Versions tab

You can perform a number of actions with versions listed on the **Versions** tab. Above the grid, you can find the following two buttons:

- **Make current version major** - promotes the current object version to a new major version (e.g. if the latest version is 2.3, it is promoted to 3.0).
- **Destroy history** - deletes all listed versions of the object.

In each object's row, you can find the following actions in the **Actions** column:

-  **View version** - opens a new window where field data of the version can be inspected and compared side-by-side with data of another version. See the [Version data view and comparison](#) section below for more details.
-  **Rollback version** - performs rollback of the object to the particular version. If the object has some child objects (e.g. alternative forms, transformations, queries, ...), they are not included in the rollback.
-  **Delete** - deletes the version so that it is no longer available in the version history.

The following action is available in the object menu accessible by clicking the ▾ button in an object's line:

-  **Rollback with children** - if the object has some child objects (e.g. alternative forms, transformations, queries, ...), it performs rollback of the object to the particular version, while child object data are rolled back as well. If it does not have any child objects, only the object itself is rolled back.

General Versions

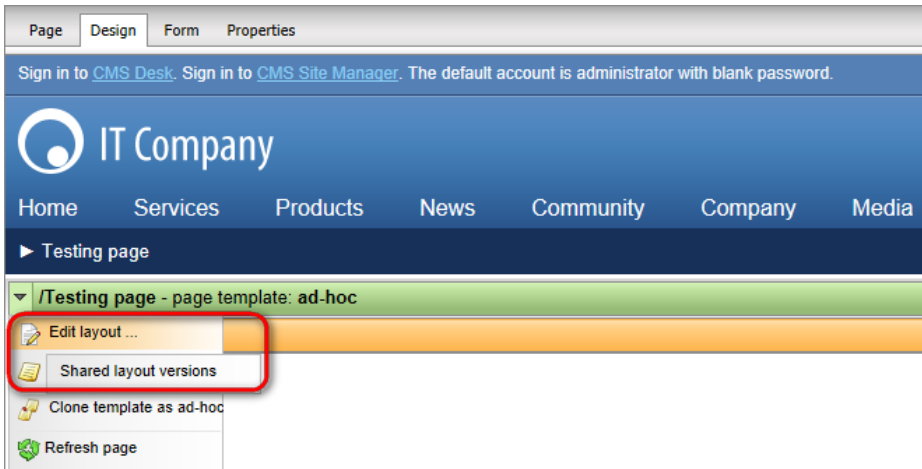

Object history: Make current version major Destroy history

| Actions | Modified by | Modified | Version number |
|---|--------------------------------------|----------------------|----------------|
|    ▾ | Global Administrator (administrator) | 8/28/2011 4:00:01 PM | 1.1 |
|    ▾ | Global Administrator (administrator) | 8/28/2011 3:58:36 PM | 1.0 |

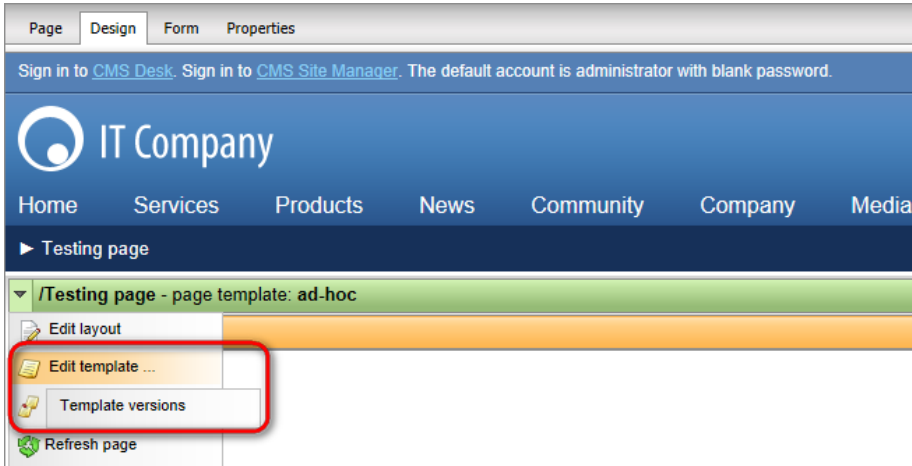

Items per page: 10 ▾

Management of versions in CMS Desk -> Content -> Edit -> Design

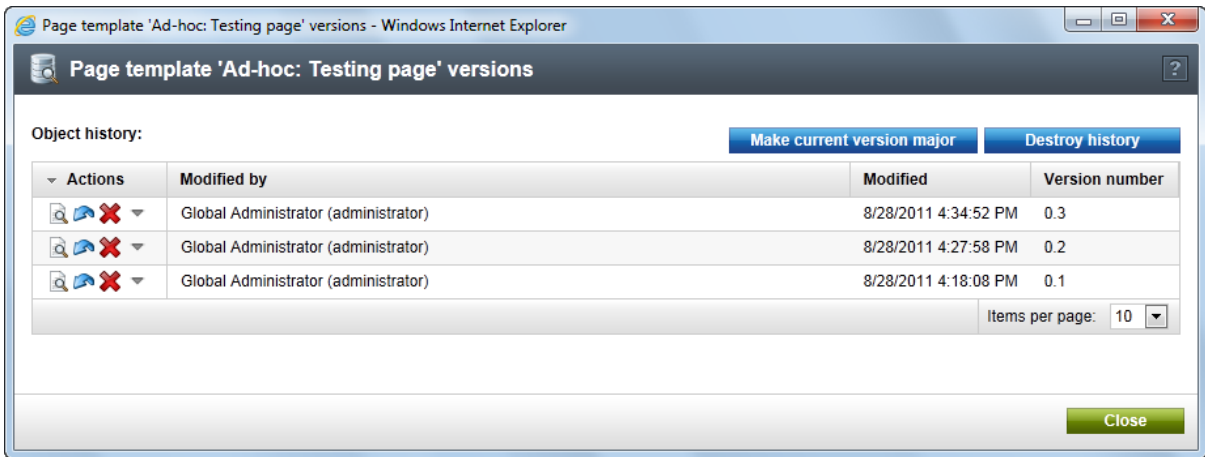

If you expand a page template's drop-down menu and hold your mouse pointer over the  **Edit layout** menu item, an additional menu item **Shared version layouts** appears.

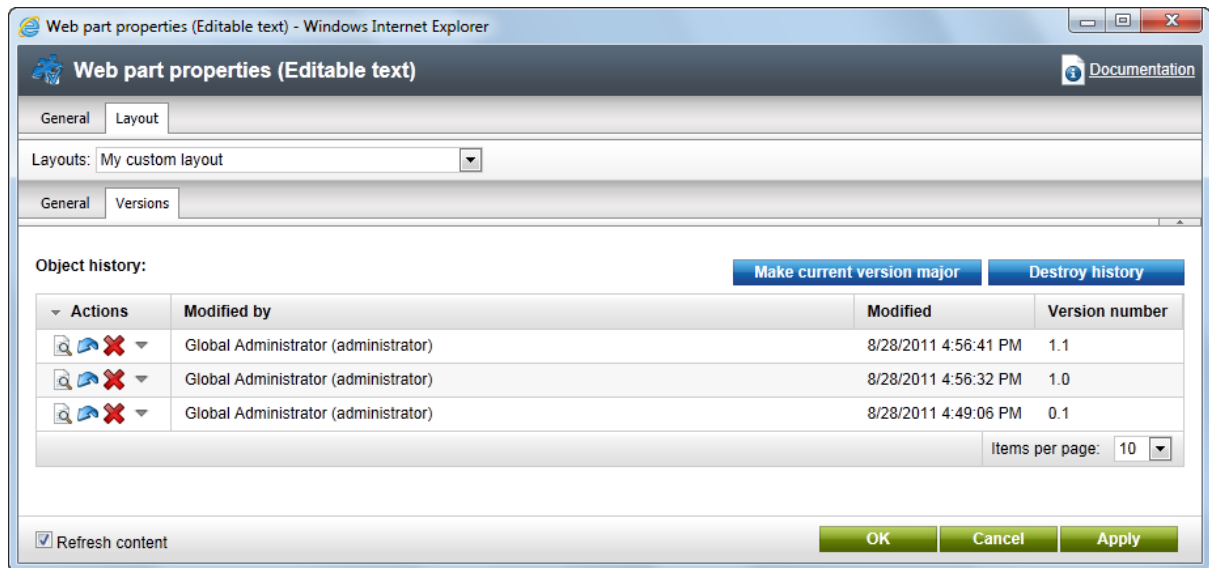

Similarly, if you hold the mouse pointer over the  **Edit template** menu item, an additional menu item **Template versions** appears.

After clicking both of the menu items mentioned above, a dialog box appears, letting you view and manage versions of the page layout or template. The same actions as on the **Versions** tab described [above](#) can be performed here.

The **Versions** tab is also available in the **Web part properties** dialog if you choose a custom layout on the **Layout** tab. Again, the same options as described [above](#) can be performed here.

Version data view and comparison

If you click the **View version** icon in a version's row in the listing, a pop-up window is displayed. In this pop-up window, you can view data stored in fields of an object version and compare it to another version. If there is more than version of the object, the following options are available:

- **Compare to** - by selecting a version in this drop-down list, field data of the selected version get compared side-by-side with field data of the originally viewed version in the table below. Differences between the two versions are highlighted in **red font**.
- **Display all data** - by enabling this option, all data related to the object and all its child objects will be displayed in the table below.

In the top right corner of a version's column in the table, you can find the following action icons:

- **Roll back to this version** - this icon is displayed when the **Display all data** option is disabled. Clicking the icon performs rollback of the object to the respective version. If the object has some child objects (e.g. alternative forms, transformations, queries, ...), they are not included in the rollback.
- **Roll back with children to this version** - this icon is displayed instead of the one above when the **Display all data** option is enabled. If the object has some child objects (e.g. alternative forms, transformations, queries, ...), it performs rollback of the object to the particular version, while child object data are rolled back as well. If it does not have any child objects, only the object itself is rolled back.

7.17.5 Objects recycle bin

It is possible to configure that deleted objects are removed to recycle bin instead of being deleted permanently. This is possible by enabling the **Delete objects to recycle bin** option in **Site Manager -> Settings -> Versioning & synchronization -> Object versioning**. See the [Configuring object versioning](#) topic for more details on how it can be configured. Once the option mentioned above is enabled, deleted objects (only those that match the configuration) are moved to the recycle bin.

Global administrators can view objects removed by all user in **Site Manager -> Administration -> Recycle bin -> Objects**. Using the **Select site** drop-down list, you can select a site for that the deleted objects will be displayed. You can also choose (**global objects**) to display only objects that are not site-related, or (**all sites or global**) to display all objects in the recycle bin. Using the filter above the grid, you can define specific criteria and click **Show** to display only objects that match the criteria.

The following actions are available for each of the listed objects:

-  **View** - opens a new window where detailed view of data stored in fields of the objects is displayed.
-  **Restore** - restores the object, i.e. moves it from the recycle bin back to the respective part of the administration interface.
-  **Delete** - removes the object from the recycle bin so that it is removed permanently and can't be restored.

The following actions are available in the menu accessible by clicking the ▾ button. Their functionality depends on the type of object:

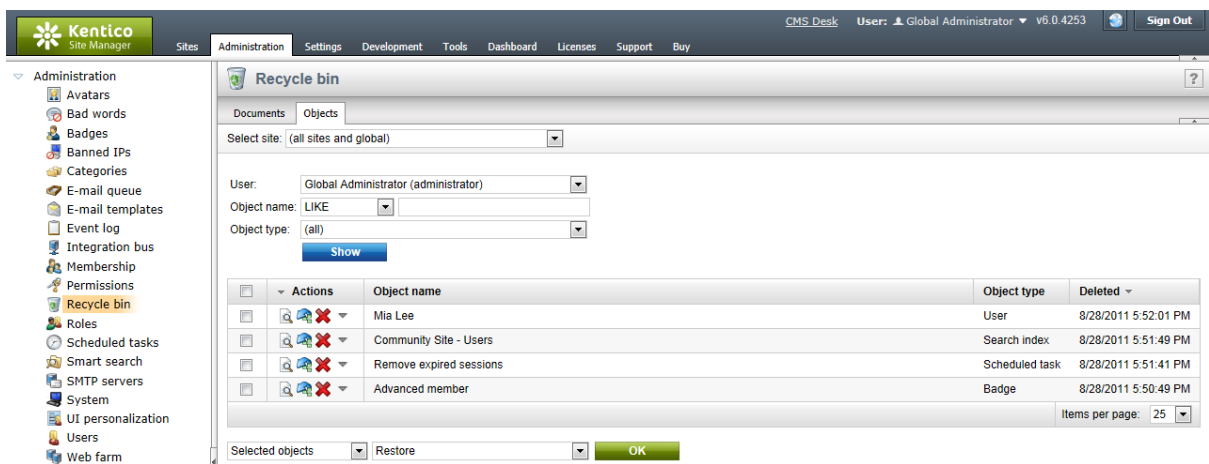

- Global objects without site bindings:
 -  **Restore without site bindings** - performs the standard restore action.
 -  **Restore to current site** - performs the standard restore action.
- Global objects with site bindings:
 -  **Restore without site bindings** - restores the object, but does not assign it to any website.
 -  **Restore to current site** - restores the object and assigns it to the current website (the one that is using the domain in the current URL).

- Site objects (objects whose definition contains the *SiteID* column):
 -  **Restore without site bindings** - performs the standard restore action.
 -  **Restore to current site** - restores the object and assigns it to the current website (the one that is using the domain in the current URL).

Using the two drop-down lists below the grid, you can perform the **Restore**, **Delete**, **Restore without site bindings** and **Restore to current site** actions to more objects in a single click. Using the first drop-down list, you can choose:

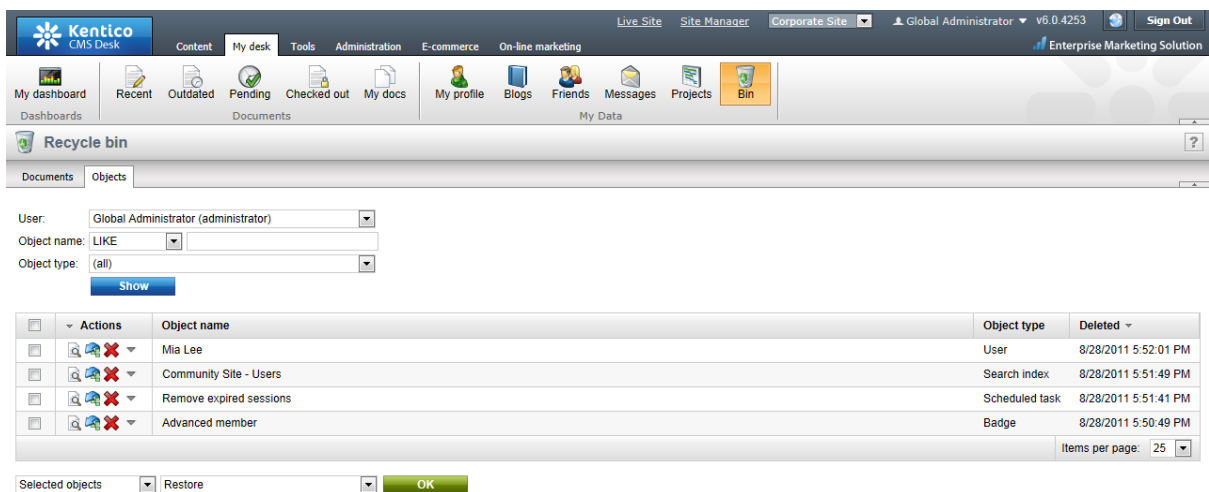

- **All objects** - the bulk action will be performed to all objects in the recycle bin.
- **Selected objects** - the bulk action will be performed to objects selected using the check-boxes ()

Using the second drop-down list, choose the required action and click **OK** to perform it.

| Actions | Object name | Object type | Deleted |
|---|-------------------------|----------------|----------------------|
|   | Mia Lee | User | 8/28/2011 5:52:01 PM |
|   | Community Site - Users | Search index | 8/28/2011 5:51:49 PM |
|   | Remove expired sessions | Scheduled task | 8/28/2011 5:51:41 PM |
|   | Advanced member | Badge | 8/28/2011 5:50:49 PM |

Objects that were deleted by the current user can be viewed in **CMS Desk -> My desk -> Recycle bin -> Objects**. Here, only global objects and objects related to the current site are displayed. Therefore, the **Select site** drop-down list is not available here and the **User** drop-down list in the filter is available only to global administrators. Otherwise, the same actions as described above can be performed.

| Actions | Object name | Object type | Deleted |
|---|-------------------------|----------------|----------------------|
|   | Mia Lee | User | 8/28/2011 5:52:01 PM |
|   | Community Site - Users | Search index | 8/28/2011 5:51:49 PM |
|   | Remove expired sessions | Scheduled task | 8/28/2011 5:51:41 PM |
|   | Advanced member | Badge | 8/28/2011 5:50:49 PM |

7.17.6 Object versioning internals and API

7.17.6.1 Overview

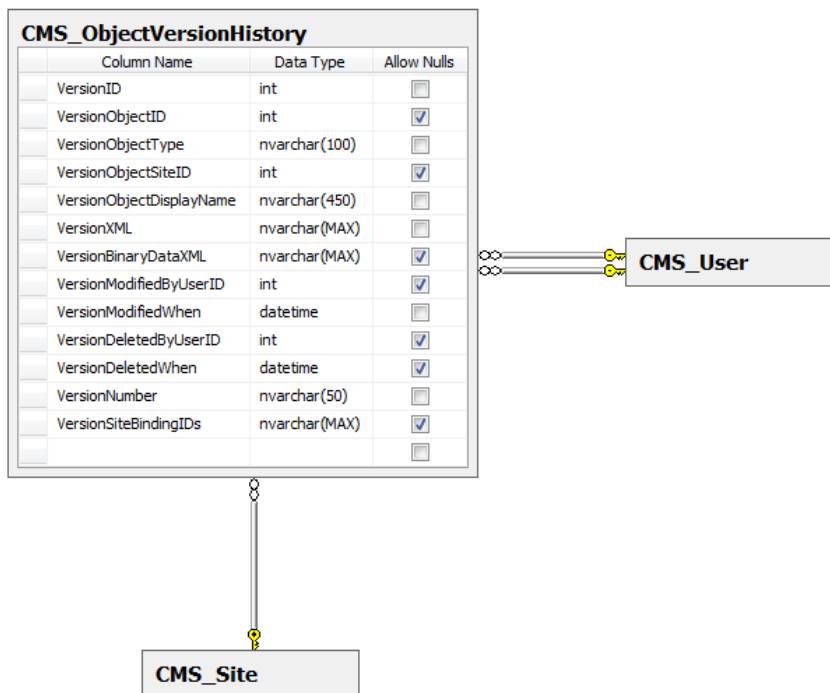

In this chapter, you will learn which [database tables](#) and [API classes](#) are used to provide the object versioning functionality. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the related classes, please refer to [Kentico CMS API Reference](#).

7.17.6.2 Database tables

The following database tables are used by object versioning:

- **CMS_ObjectVersionHistory** - contains records representing particular versions of versioned objects.

7.17.6.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes for object versioning can be found in the **CMS.Synchronization** namespace.

CMS_ObjectVersionHistory table API:

- **ObjectVersionManager** - provides functionality for management of object versions.
- **ObjectVersionHistoryInfo** - represents one object version.

7.17.6.4 API examples

7.17.6.4.1 Overview

These topics show examples of how the object versioning API examples can be used:

- [Object versioning](#)
- [Object recycle bin](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Development\ObjectVersioning\Default.aspx.cs**.

The object versioning API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.Synchronization;
using CMS.SettingsProvider;
```

7.17.6.4.2 Object versioning

The following example creates a versioned CSS stylesheet.

```
private bool CreateVersionedObject()
{
    // Create new css stylesheet object
    CssStylesheetInfo newStylesheet = new CssStylesheetInfo();

    // Check if object versioning of stylesheet objects is allowed on current site
    if (ObjectVersionManager.AllowObjectVersioning(newStylesheet))
    {
        // Set the properties
        newStylesheet.StylesheetDisplayName = "My new versioned stylesheet";
    }
}
```

```
newStylesheet.StylesheetName = "MyNewVersionedStylesheet";
newStylesheet.StylesheetText = "Some versioned CSS code";

// Save the css stylesheet
CssStylesheetInfoProvider.SetCssStylesheetInfo(newStylesheet);

// Add css stylesheet to site
int stylesheetId = newStylesheet.StylesheetID;
int siteId = CMSContext.CurrentSiteID;

CssStylesheetSiteInfoProvider.AddCssStylesheetToSite(stylesheetId,
siteId);

    return true;
}

return false;
}
```

The following example creates a new version of the CSS stylesheet created by the example above.

```
private bool CreateVersion()
{
    // Get the css stylesheet
    CssStylesheetInfo newStylesheetVersion =
    CssStylesheetInfoProvider.GetCssStylesheetInfo("MyNewVersionedStylesheet");
    if (newStylesheetVersion != null)
    {
        // Check if object versioning of stylesheet objects is allowed on current
        site
        if (ObjectVersionManager.AllowObjectVersioning(newStylesheetVersion))
        {
            // Update the properties
            newStylesheetVersion.StylesheetDisplayName =
            newStylesheetVersion.StylesheetDisplayName.ToLower();

            // Create new version
            ObjectVersionManager.CreateVersion(newStylesheetVersion, true);

            return true;
        }
    }

    return false;
}
```

The following example performs rollback of the CSS stylesheet to the original version.

```
private bool RollbackVersion()
{
    // Get the css stylesheet
```

```
CssStyleSheetInfo stylesheet = CssStyleSheetInfoProvider.GetCssStyleSheetInfo
("MyNewVersionedStyleSheet");
if (stylesheet != null)
{
    // Prepare query parameters
    string where = "VersionObjectID =" + stylesheet.StyleSheetID + " AND
VersionObjectType = '" + stylesheet.ObjectType + "'";
    string orderBy = "VersionModifiedWhen ASC";
    int topN = 1;

    // Get dataset with versions according to the parameters
    DataSet versionDS = ObjectVersionHistoryInfoProvider.GetVersionHistories
(where, orderBy, topN, null);

    if (!DataHelper.DataSourceIsEmpty(versionDS))
    {
        // Get version
        ObjectVersionHistoryInfo version = new ObjectVersionHistoryInfo
(versionDS.Tables[0].Rows[0]);

        // Roll back
        ObjectVersionManager.RollbackVersion(version.VersionID);

        return true;
    }
}
return false;
}
```

The following example destroys the latest version of the CSS stylesheet.

```
private bool DestroyVersion()
{
    // Get the css stylesheet
    CssStyleSheetInfo stylesheet = CssStyleSheetInfoProvider.GetCssStyleSheetInfo
("MyNewVersionedStyleSheet");
    if (stylesheet != null)
    {
        // Get the latest version
        ObjectVersionHistoryInfo version = ObjectVersionManager.GetLatestVersion
(stylesheet.ObjectType, stylesheet.StyleSheetID);

        if (version != null)
        {
            // Destroy the latest version
            ObjectVersionManager.DestroyObjectVersion(version.VersionID);

            return true;
        }
    }
    return false;
}
```

The following example destroys the whole version history of the CSS stylesheet.

```
private bool DestroyHistory()
{
    // Get the css stylesheet
    CssStylesheetInfo stylesheet = CssStylesheetInfoProvider.GetCssStylesheetInfo
("MyNewVersionedStylesheet");
    if (stylesheet != null)
    {
        // Destroy version history
        ObjectVersionManager.DestroyObjectHistory(stylesheet.ObjectType,
stylesheet.StylesheetID);

        return true;
    }

    return false;
}
```

The following example ensures that the CSS stylesheet has at least one version (if it does not have one, it creates it).

```
private bool EnsureVersion()
{
    // Get the css stylesheet
    CssStylesheetInfo stylesheet = CssStylesheetInfoProvider.GetCssStylesheetInfo
("MyNewVersionedStylesheet");
    if (stylesheet != null)
    {
        // Check if object versioning of stylesheet objects is allowed on current
site
        if (ObjectVersionManager.AllowObjectVersioning(stylesheet))
        {
            // Ensure version
            ObjectVersionManager.EnsureVersion(stylesheet, false);

            return true;
        }
    }

    return false;
}
```

7.17.6.4.3 Object recycle bin

The following example deletes the CSS stylesheet created on the [previous page](#) and moves it to the objects recycle bin.

```
private bool DeleteObject()
{
    // Get the css stylesheet
    CssStylesheetInfo deleteStylesheet =
```

```
CssStyleSheetInfoProvider.GetCssStyleSheetInfo("MyNewVersionedStyleSheet");

    if (deleteStyleSheet != null)
    {
        // Check if restoring from recycle bin is allowed on current site
        if (ObjectVersionManager.AllowObjectRestore(deleteStyleSheet))
        {
            // Delete the css stylesheet
            CssStyleSheetInfoProvider.DeleteCssStyleSheetInfo(deleteStyleSheet);

            return true;
        }
    }

    return false;
}
```

The following example restores the CSS stylesheet deleted by the example above from the objects recycle bin back to the administration interface.

```
private bool RestoreObject()
{
    // Prepare query parameters
    string where = "VersionObjectType = '" + SiteObjectType.CSSSTYLESHEET + "' AND
VersionDeletedByUserID = " + CMSContext.CurrentUser.UserID;
    string orderBy = "VersionDeletedWhen DESC";
    int topN = 1;

    // Get dataset with versions according to the parameters
    DataSet versionDS = ObjectVersionHistoryInfoProvider.GetVersionHistories
(where, orderBy, topN, null);

    if (!DataHelper.DataSourceIsEmpty(versionDS))
    {
        // Get version
        ObjectVersionHistoryInfo version = new ObjectVersionHistoryInfo
(versionDS.Tables[0].Rows[0]);

        // Restore the object
        ObjectVersionManager.RestoreObject(version.VersionID, true);

        return true;
    }

    return false;
}
```

The following example deletes the CSS stylesheet permanently without moving it to the object recycle bin.

```
private bool DestroyObject()
{
    // Get the css stylesheet
```

```
CssStyleSheetInfo destroyStyleSheet =
CssStyleSheetInfoProvider.GetCssStyleSheetInfo("MyNewVersionedStyleSheet");

if (destroyStyleSheet != null)
{
    // Destroy the object (in action context with disabled creating of new
    // versions for recycle bin)
    using (CMSActionContext context = new CMSActionContext())
    {
        // Disable creating of new versions
        context.CreateVersion = false;

        // Destroy the css stylesheet
        CssStyleSheetInfoProvider.DeleteCssStyleSheetInfo(destroyStyleSheet);

        return true;
    }
}

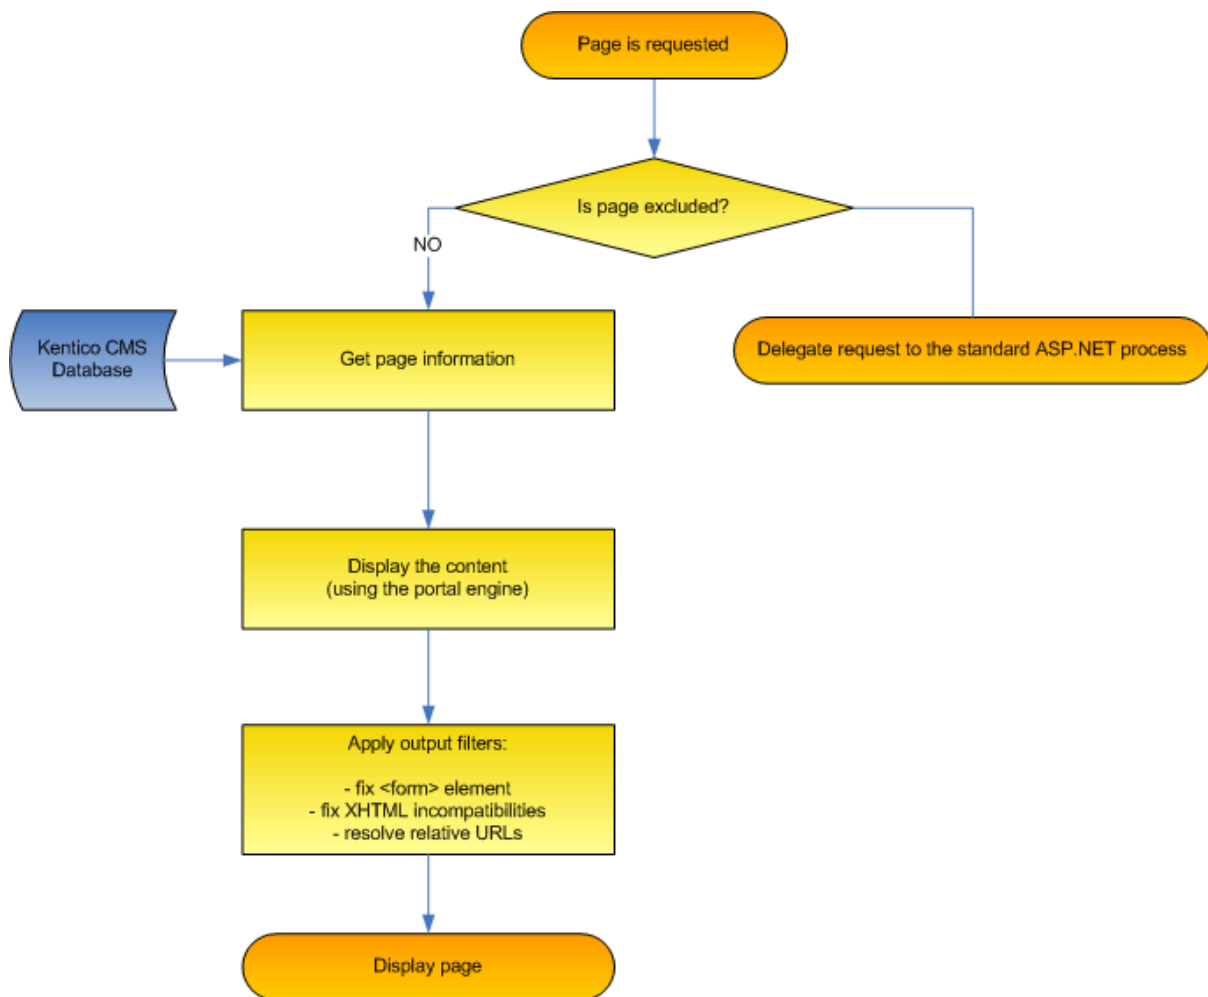

return false;
}
```

7.18 Page processing and URLs

7.18.1 Overview

Kentico CMS processes URLs using a **URL rewriting engine**. This engine ensures the displaying of the correct page based on the required friendly (smart) URL. After the page is processed by the rewriting engine, it is run through output filters that ensure additional changes in the rendered HTML code.

The following figure shows the basic page processing steps:

7.18.2 URL rewriting

Kentico CMS uses a system of friendly URL addresses, which allows you to use URLs like:

<http://www.example.com/products/kentico-cms.aspx>

instead of something like:

<http://www.example.com/products.aspx?id=527>

These friendly or "smart" URLs provide several benefits:

- They are easy to remember and easy to write into the browser address bar.
- They are friendly towards search engines (for more information about this topic, please see the [Search engine optimization](#) chapter).
- They represent a path that shows users where they are located on the website.
- Users can easily send the URL of a document to their friends and they will see the same page with the specific document.

Every document has its own unique URL. If the website's content is available in [multiple languages](#),

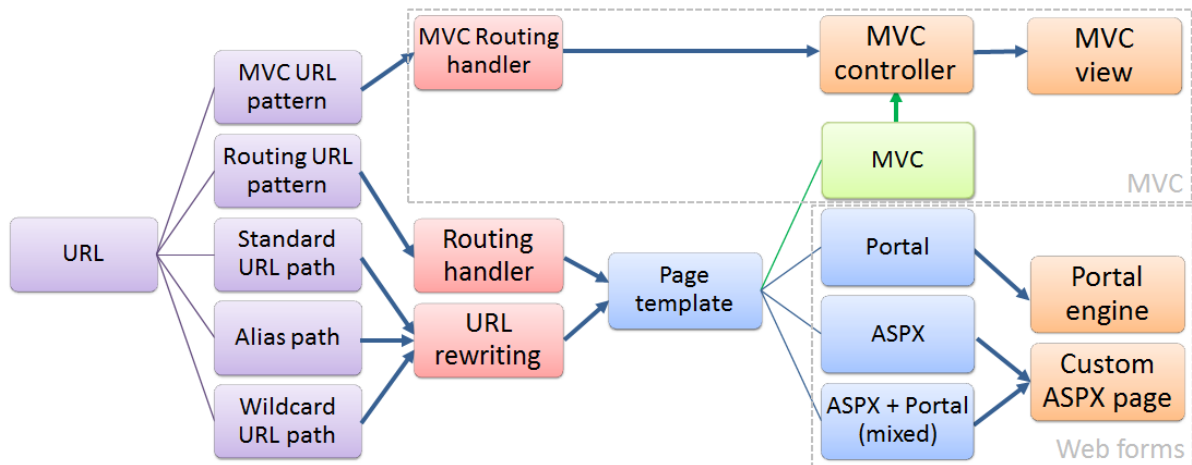

individual language versions of documents are recognized based on a combination of their **alias path** and a URL with a [culture-specific format](#), or through completely custom **URL paths** (if specified).

URL processing

The steps below explain how the system handles a request for the following URL: *http://www.example.com/products/kentico-cms.aspx*

1. After receiving the incoming request, the system looks up the website based on the domain name in the URL (either via the main site domain name or its domain aliases). If none of the currently running websites match the domain name, the *~/cmsmessages/invalidwebsite.aspx* page is displayed instead. If the requested domain name contains a port number that is not found, the corresponding domain name without a port number is checked.
2. The request in this example specifies a standard URL path, so it is passed on to the URL rewriting engine. The most prioritized way to identify standard documents is their **Document URL path**, so the engine first attempts to find a document with a URL path set to */products/kentico-cms*.
3. If there is no document with a matching URL path, the rewriting engine then tries to look up a document with an **Alias path** equal to */products/kentico-cms* (the alias path is generated according to the document's position in the content tree).
4. If a document cannot be found under the given URL or alias path, the system tries to find a document with a **Document alias** set to */products/kentico-cms*.
5. In case all of the steps described above fail to find a matching document for the requested URL, the system does not process the request. The web server returns a 404 HTTP status code and displays the [Page not found error page](#) configured for the website.
6. When the requested document is identified, the URL rewriting engine checks the type of its page template and handles it accordingly:
 - If the page is managed by the [Portal engine](#), the *~/cmspages/portaltemplate.aspx* system page is called, which renders the final output according to the web parts placed on the given template and the content of the particular document.
 - For [ASPX page templates](#), the appropriate template (web form) used to display the document is loaded using a specific internal URL, for example: */products.aspx?aliaspath=/products/kentico-cms*
 - In the case of [MVC templates](#), the system passes on the request to the MVC controller and action specified for the given template, which then renders the page using an appropriate MVC view.

The flow of the entire process for all types of URL requests is shown in the following diagram:

Processing of MVC and Routing URL patterns

If the URL of an incoming request matches the [MVC](#) or Routing pattern defined for a page, the pattern always has priority over other types of URL processing (even if it is set through a document alias).

The rewriting engine evaluates MVC and Routing patterns in the same step of the process, so precedence between the two is not defined. You should always avoid collisions between MVC and Routing patterns.

Excluding URLs from the rewriting engine

If your website uses custom physical pages (*.aspx*, *.html* or any other file types) stored inside the web project directory, you can avoid unnecessary processing by excluding their URLs from the Kentico CMS rewriting engine. When a visitor requests an excluded URL, the system skips all URL rewriting actions and attempts to access the specified page directly. This leads to better performance when loading the given pages and also allows you to prepare your own custom URL rewriting logic.

To disable rewriting for specific pages, go to **Site Manager -> Settings -> URLs and SEO** and enter the matching URL paths into the **Excluded URLs** setting.

- Use URL paths without the website's domain name or virtual directory.
- The paths must always start with a forward slash (/), without the virtual path designator (~).
- Entering a value excludes all URLs that start with the given path, including sub-directories and all possible extensions.
- You can enter multiple URLs separated by semicolons (;).

Sample values:

- **/Custom.aspx** - excludes the *~/Custom.aspx* page stored directly under the website's root.
- **/Custom** - excludes all pages whose URL path starts with */Custom*, for example: *~/Custom.aspx*, *~/Custom2.aspx*, *~/Custom/Page.htm*
- **/Custom;/Static** - excludes all pages whose URL path starts with */Custom* or */Static*.

**Warning!**

Be careful not to exclude the URLs used by the regular documents in the website's content tree. With URL rewriting disabled for a URL, the system always tries to load a matching physical page, which leads to a page not found error in most cases.

7.18.3 Multiple document aliases

In Kentico CMS, it is possible to have an unlimited number of different URLs leading to one document. These can be set in CMS Desk, on the **Properties -> URLs** tab of each document:

- **Document alias** - this is the unique name of the document in the given section of the website. Aliases are used to form the *alias path* of each document, which contains all parent documents up to the root of the site's content tree. The alias path of a document is then used to generate its default URL. For example, if *Media* is the alias of a document, then its URL would be: `<site domain>/<parent document alias path>/Media.aspx`
- **Document URL path** - the fields in this section may be used to specify an alternate URL for the document, regardless of its position in the website hierarchy. For example, if you have the *Standard URL or wildcard Path* type selected and enter `/Medialibrary`, the URL of the document would be the following:
`<domain>/Medialibrary.aspx`

Further URLs can be added to a document through *document aliases*. Aliases do not change how the main URL of a document is generated, they only make it possible to access the given document through other URLs. Document aliases may be created in the following way:

1. Sign in to CMS Desk, select the appropriate document from the content tree and switch to its **Properties -> URLs** tab.
2. Click  **Add new alias** in the **Document aliases** section.

The screenshot shows the 'Properties' window for a document alias in Kentico CMS. The left sidebar has 'URLs' selected. The main content area is divided into several sections:

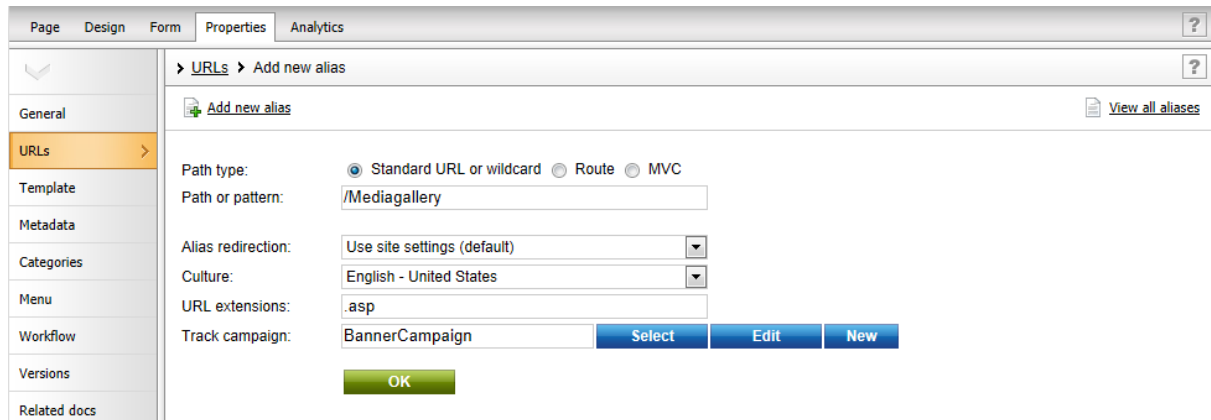

- Alias:** Document alias:
- Document URL path:**
 - Use custom URL path:
 - Path type: Standard URL or wildcard Route MVC
 - Path or pattern:
- Extended properties:**
 - URL extensions:
 - Use custom URL extensions:
- Document aliases:**
 - (circled in red)
 - No data found.

3. It is possible to fill in the following properties for each alias:

- **Path type** - you can choose several different URL types for the alias path. The selection made here determines how the value of the *Path or pattern* field will be processed. The following options are available:
 - **Standard URL or wildcard** - the alias URL will be handled by the standard Kentico CMS rewriting engine. Wildcard URLs can be used here, as described in [Wildcard URLs](#).
 - **Route** - the alias URL will be processed as an ASP.NET Route pattern.
 - **MVC** - requests to the alias URL are handled as requests for an MVC page. See the [MVC development model](#) chapter for more information.
- **Path or pattern** - enter a URL path for the document alias according to the selected *Path type*. For example, if you enter */Mediagallery* as the value, the document will be accessible under the following URL: *<domain>/Mediagallery.aspx*
- **Default controller (MVC only)** - the name of the MVC controller containing the action that should be performed when the alias URL is accessed, without the *Controller* part at the end. For example, if the class is called *NewsMVCController*, enter *NewsMVC*. The system first searches for the specified class in the *CMS.Controllers.<current site code name>* namespace. If it is not found there, the *CMS.Controllers.Global* namespace is searched.
- **Default action (MVC only)** - specifies the action defined within the controller that should be performed when the alias URL is accessed.
- **Alias redirection** - determines how the URL should be handled (redirected) when the document is accessed through this alias (for SEO purposes). The following options are available:
 - **Use site settings (default)** - with this option, the redirection behavior will follow the *Redirect document aliases to main URL* setting specified for the website in *Site Manager -> Settings -> URLs and SEO*.
 - **Redirect to main URL** - if selected, the alias URL will always be redirected to the main URL of the document, i.e. its alias path or custom URL path (if specified).
 - **Do not redirect** - if selected, the alias URL will not be redirected when accessed. This option is recommended if the URL of the alias contains a wildcard.
- **Culture** - sets which culture version of the document should be displayed when the page is accessed through the URL of this alias.
- **URL extensions** - additional supported extensions of the URL. For these to work, you will have to

configure the system as described in [Custom URL extensions and extensionless URLs](#). This field is optional.

- **Track campaign** - visitors who access the document through this alias will be assigned to the selected web analytics [Campaign](#) and tracked accordingly. For example, a special alias may be created for a document and its URL can then be used by links contained in marketing materials such as banners, e-mails etc. This way, the system will monitor how many page views the website receives as a result of the campaign and track the activity of the visitors who arrive as a result. This field is optional.

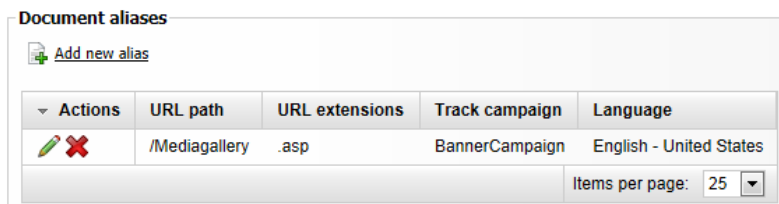

The screenshot shows the 'Add new alias' dialog box in the 'Properties -> URLs' tab. The dialog has a sidebar with 'URLs' selected. The main area contains the following fields and controls:

- Path type:** Radio buttons for 'Standard URL or wildcard' (selected), 'Route', and 'MVC'.
- Path or pattern:** Text input field containing '/Mediagallery'.
- Alias redirection:** Dropdown menu set to 'Use site settings (default)'.
- Culture:** Dropdown menu set to 'English - United States'.
- URL extensions:** Text input field containing '.asp'.
- Track campaign:** Text input field containing 'BannerCampaign', with 'Select', 'Edit', and 'New' buttons to its right.
- OK:** A green button at the bottom center.

Click **OK** to create the alias.

4. Now if you switch back to the **Properties -> URLs** tab of the document, you should see the newly created alias present in the list in the **Document aliases** section, as depicted in the screenshot below. Like this, you can add an unlimited number of aliases.

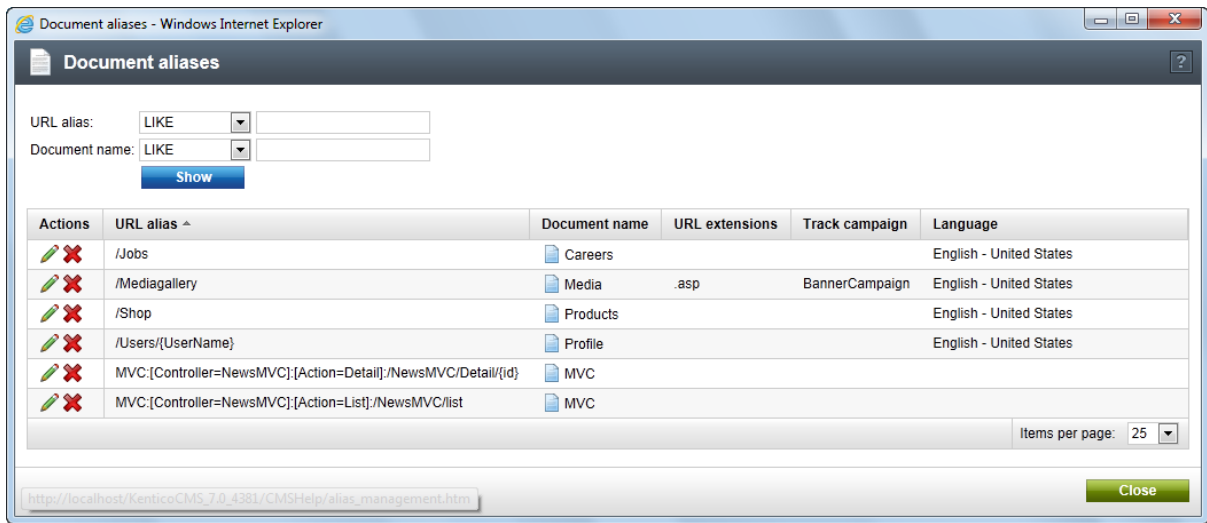

The screenshot shows the 'Document aliases' section with a table of aliases. The table has the following columns: Actions, URL path, URL extensions, Track campaign, and Language. A single alias is listed with the following values:

| Actions | URL path | URL extensions | Track campaign | Language |
|---|---------------|----------------|----------------|-------------------------|
|   | /Mediagallery | .asp | BannerCampaign | English - United States |

At the bottom right of the table, there is a dropdown menu for 'Items per page' set to 25.

5. If you edit () any alias, you can use the  **View all aliases** link at the top right of the page to access a list of all aliases defined on the website (for all documents). The information provided can help you avoid URL collisions when creating new aliases. The **Edit** () and **Delete** () actions are also available here, and through them you can easily manage all aliases and their properties from a single location.

7.18.4 URL format and configuration

Defining URL extensions

Page URLs can use various types of extensions. By default, all URLs end with `.aspx`, for example: `http://www.example.com/products/kentico-cms.aspx`

You can also use **custom extensions**, such as `.htm`, `.html` or any other sequence of characters. Alternatively, you can even use **URLs without extensions**, such as `http://www.example.com/products/kentico-cms`. In this case, you need to configure the system as described in the [Configuration of custom URL extensions](#) chapter.

Forbidden URL characters

Certain characters have special meanings when they are found in a URL, so they cannot be used in values that determine the path to pages (i.e. document aliases and URL paths). By default, the following characters are forbidden:

`\ / : * ? " < > | & % . ' # [] + = , " and the space character.`

If needed, you can add additional forbidden characters by entering them (without any separator) into the **Forbidden URL characters** setting in **Site Manager -> Settings -> URLs and SEO**. Alternatively, a regular expression may be entered as the value of the **Allowed URL characters** setting to precisely specify which characters should be allowed in URLs.

Please note that the default characters listed above will always be forbidden unless you override them through the **CMSForbiddenURLValues** key, which can be added to the `/configuration/appSettings` section of your application's web.config file. For example:

```
<add key="CMSForbiddenURLValues" value="$\/:?*?"<>|&%.'#[ ]+=, " />
```

Through this key, you may either allow some of the default forbidden characters or add new ones. It is recommended to keep the default characters forbidden, since they may prevent certain types of URLs

from working correctly if entered into URL paths.

Forbidden characters are automatically replaced or removed. You can specify the character that is used to replace forbidden characters through the **Forbidden characters replacement** setting in **Site Manager -> Settings -> URLs and SEO**. By default, forbidden characters located at the beginning or end of the path are removed completely and consecutive forbidden characters are only replaced by a single character. If you wish to have each forbidden character replaced individually, you can add the following key to your web.config:

```
<add key="CMSLimitUrlReplacements" value="false" />
```

This preference may also be set specifically for the **Document URL Path** property of documents (and no other URLs) via the key below:

```
<add key="CMSUseLimitReplacementsForUrlPath" value="false" />
```

Advanced character replacement customization

It is also possible to change the character replacement behavior to deal with specific scenarios, such as handling non-ASCII character sets or assigning unique replacement strings for specific characters.

This can be achieved by customizing the process used to convert URLs into a safe format. Please see [Custom handling of URL path values](#) for more information.

Using URL Prefixes

If you need to add a prefix to all URLs on a specific site (e.g. for search engine optimization), you can specify it in the **Site Manager -> Settings -> URLs and SEO -> Default Uri Path Prefix** field. The URLs will then use the following format: `<domain>/<path prefix>/<document URL path>`

For example: `http://www.example.com/myprefix/products/kentico-cms.aspx`

Automatic creation of new document aliases

If you check the **Site Manager -> Settings -> URLs and SEO -> Remember original URLs when moving documents** check-box, new document aliases will automatically be created when a new extension or URL path is set.

Using language prefixes for URLs

If you wish to add a different URL prefix for every document culture version, you can specify it in the **Site Manager -> Settings -> URLs and SEO -> Use language prefix for URLs** field. If you have both language prefixes and standard URL path prefixes enabled, the standard URL prefix always precedes the language prefix in the URL. Please refer to the [Multilingual and international support -> Languages and URLs](#) topic for more details.

URL related settings

The above configuration tasks can be performed in **Site Manager -> Settings -> URLs and SEO**. The following table shows an overview of the available settings:

| URL format | |
|----------------------------------|---|
| Forbidden URL characters | List of additional characters that cannot be used in URLs (document aliases and URL paths). The following characters are forbidden by default: \ / : * ? " < > & % . ' # [] + = , " and the space character. |
| Forbidden characters replacement | Specifies the character that the system uses as a replacement for forbidden characters in URLs. |
| Allowed URL characters | <p>Determines which characters are usable in URLs by means of a regular expression. Any characters not specified are forbidden. If empty, only the characters specified by the Forbidden URL characters setting are prohibited.</p> <p>When allowing special characters in the regular expression, they must be preceded by a backslash (\) as an escape character.</p> <p>Example: Entering <code>a-zA-Z0-9\^</code> as the value only allows alphanumeric characters and the caret symbol (^) to be used in URLs.</p> |
| Friendly URL extension | <p>Specifies the extensions that the system adds to document URLs.</p> <ul style="list-style-type: none"> • Extensions must be preceded by the period character. • You can add multiple extensions separated by semicolons (;). • The first extension is used as the default option when generating links and page URLs. Additional extensions are supported in URLs when accessing documents. • To allow extensionless URLs, enter a semicolon without any extension. <p>Sample value: <code>.aspx;.html;.htm;;</code></p> |
| Files friendly URL extension | <p>Specifies the extension that the system adds to file URLs.</p> <p>Example: <code>getfile/<node alias>/myimage.aspx</code></p> <p>If empty, the file URLs end with no extension: <code>getfile/<node alias>/myimage</code></p> |
| Excluded URLs | Specifies a list of URLs that are excluded from the URL rewriting engine. See Excluding URLs from the rewriting engine for more information. |
| Document URLs | |
| Default URL path prefix | Defines a default URL path prefix that will be used for all URLs of the content pages. Internally, this prefix is rewritten to the <code>urlpathprefix</code> query string parameter. |
| Use name path for URL path | If checked, a document's name path will automatically be copied to its |

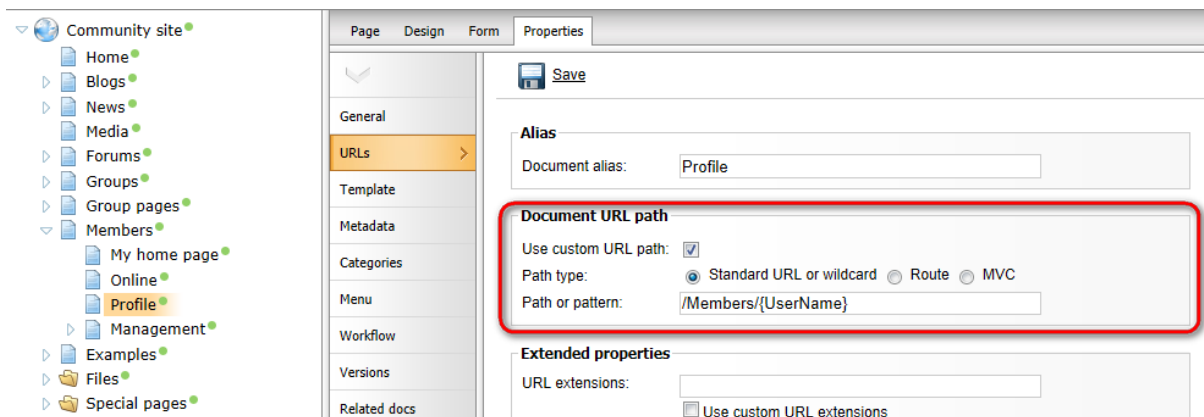

| | |
|--|--|
| | URL path. |
| Use permanent URLs | If enabled, URLs of documents and document attachments will be generated in permanent format. If disabled, friendly URLs will be used. Learn more in the Linking pages and files topic. |
| Remember original URLs when moving documents | Determines if new document aliases should be created when a new document URL path or extension is set. |
| Automatically update document alias | If enabled, the alias of a document is automatically updated to match any changes in the name of the given document in the default culture. Also, the document alias property will not be editable manually. |

Other settings (related to SEO) may also affect the format of URLs. To learn about these, please refer to the [Search engine optimization](#) chapter.

7.18.5 Wildcard URLs

Wildcard URLs provide a way of loading content dynamically depending on the page URL. You can find an example of how this works on the sample Community starter site. The **Members -> Profile** page uses wildcard URLs to display user profiles. As you can see, it is only one single page that can display profiles of various site users.

How is it achieved? If you go to **CMS Desk**, select the **Members -> Profile** page from the content tree and switch to its **Properties** tab, you should see **/Members/{UserName}** in the **Document URL path** field. The **{UserName}** part of the URL is the actual wildcard.

If you type `<domain>/Members/David.aspx` into your browser, the **Members -> Profile** page opens. The system converts the wildcard part of the URL (*David*) into a query string parameter, so that the internal URL actually looks like this: `<domain>/Members/Profile.aspx?username=David`. As you can see, the name of the parameter is taken from the name of the wildcard, while the value is the matching part of the entered URL. The [User public profile](#) web part which is placed on the page recognizes the *username* parameter in the rewritten URL and displays David's profile.

Default wildcard values

It is possible to set default values for wildcards in URLs. To do this, simply use the following format in the URL path: `{<wildcard name>;<Default value>}`. This is useful when you want to have a wildcard in a document's URL path, but expect that it might not always be entered into its URL. The default value

ensures that the URL is always generated with a certain value where the wildcard should be.

To show this on an example, select the **Members** page, switch to its **Properties -> URLs** tab and enter `/Members/{UserName;David}` into the **Document URL path** field and click  **Save**. If you now access the Members page on the live site, you will see that it automatically displays David's profile.

Additionally, the current value of a wildcard is always used as the default value in all other URLs on the given page that contain the same wildcard. For example, imagine a scenario with two documents that use a wildcard in their URL path: the first set to `/Profile/{UserName}` and the other to `/Profile/{UserName}/Details`. When the first page is accessed through the URL `<domain>/Profile/Andy.aspx`, navigation links to the second page will automatically be generated as `<domain>/Profile/Andy/Details.aspx`. The current value is used even for wildcards that have a different default value set in their URL path.

Using wildcard URLs on multi-language sites

The **Document URL path** is unique for each language version of a document. Because of this fact, you may encounter problems when referring to a page using a wildcard URL on multi-lingual sites. Let's explain the situation using the following example:

On the sample **Community Starter site**, the **Members/Profile** page has its Document URL path set to `/Members/{UserName}`. If you created a version of this page in another language, its Document URL path would get changed to `/Members/{UserName}-1` automatically. This happens because the URL path needs to be unique for every document.

Now let's presume that you have the following link leading to the page: `<domain>/Members/David.aspx`. In the original version, it works fine. But if you tried to click the link in the second language version, no profile would be found, because the URL in this language version would be `<domain>/Members/David-1.aspx`. The modification added to the end of the URL path changes the wildcard value representing the user name, which makes it impossible to find a matching user profile.

If you want to keep such links functional in all language versions, you will need to define the `/Members/{UserName}` path via the **Document aliases** section, as described in the [Multiple document aliases](#) topic. When creating the alias, select **(all)** in the **Culture** drop-down list. Before you can do this, you must erase the Document URL path value for both language versions of the document. As it has higher priority, URL paths defined in the Document aliases section would have no effect. The result should look as in the following screenshot:

Save

Alias

Document alias: Profile

Document URL path

Use custom URL path:

Path type: Standard URL or wildcard Route MVC

Path or pattern: /Members/{UserName}

Extended properties

URL extensions:

Use custom URL extensions

Document aliases

[Add new alias](#)

| Actions | URL path | URL extensions | Track campaign | Language |
|---------|---------------------|----------------|----------------|----------|
| | /Members/{UserName} | | | |

Items per page: 25

Please keep in mind that it is not possible to specify *default* wildcard values through document aliases. An alias only makes the page accessible through a given URL, it does not enforce this URL for the document.

Dots in wildcard URLs

You may encounter problems when a string containing a dot "." gets into the wildcard part of a URL. A typical example of this can be found on the **Members -> Profile** page of the sample Community Starter Site.

The page's Document URL path is set to **/Members/{UserName}**. Let's presume that you have the following user name: **jack.smith**. Then the user's profile page would be located at **http://<domain>/Members/jack.smith**. As the last part of the URL after the last dot (*smith* in this case) is understood as a file extension, this URL would produce the 404 error in your browser.

To prevent this, registration on the sample Community Starter Site doesn't allow user names with dots. This is ensured through validation of the **UserName** field in the **Registration form** alternative form of the **User** system table.

If you need to allow dots in user names and use wildcard URLs with user names at the same time, you can do so by removing the validation and setting the page's Document URL path to something like **/Members/{UserName}/Profile**. In this case, the dot would be located in the middle of the URL and the URL should work fine.

7.18.6 Linking pages and files

Creating permanent links to documents (pages)

If you need to create a permanent link to a document, use a URL in the following format:

```
<domain>/getdoc/<document GUID>/<document name><extension>
```

- **<document GUID>** is the globally unique identifier of the document. You can find a document's GUID value in *CMS Desk -> Content -> Properties -> General -> Node GUID*.
- The **<document name>** value may contain any text — it is not used by the system, but allows you to specify the exact URL (e.g. for the purposes of search engine optimization). By default, the system uses the document's name.

Permanent links keep working even if you move the target document to another location.

For example:

```
http://www.example.com/getdoc/016fad52-0d69-46d5-80dc-daec9173c0c7/Products.aspx
```

is the permanent equivalent of:

```
http://www.example.com/company/products.aspx
```

Linking specific language versions of documents

If you need to link to a specific [language version](#) of a document, you use a URL in the following format:

```
<domain>/getdoc/<document GUID>/<document name>/<culture code><extension>
```

For example:

```
http://www.example.com/getdoc/8FG7-84E394-FABD-5678/our-services/fr-fr.aspx
```

Displays the given document in French (if the document is translated). It is an equivalent of:

```
http://www.example.com/company/our-services.aspx?lang=fr-fr
```

Linking attachments

If you need to create a permanent link to a file uploaded as a document attachment, you use a URL in the following format:

```
<domain>/getattachment/<file GUID>/<filename><extension>
```

- The **<file GUID>** is not the same as the document GUID. It is the GUID of the file in the *CMS_Attachment* database table. To find the GUID of an attachment, click the attachment in *CMS Desk -> Content -> Properties -> Attachments* and view the URL.
- The **<file name>** value can contain any text.

For example:

<http://www.example.com/getattachment/763c8921-be94-4610-99b4-25e8d3be5b08/logo.aspx>

You can find information about the query string parameters available for file URLs in [GetFile.aspx parameters](#).

7.18.7 GetFile.aspx parameters

The system uses the **GetFile.aspx** page to retrieve uploaded files from the database. The page is called whenever you use /getdoc, /getattachment or a direct URL based on the alias path of a cms.file document.

GetFile URLs accept the following query string parameters:

| Parameter name | Description | Sample value |
|------------------|---|------------------------------------|
| guid | Attachment GUID value. | |
| nodeguid | Node GUID value. | |
| versionhistoryid | Version history ID of the attachment. It can only be used together with the guid parameter. | |
| width | Resizes the image to a specified width (in pixels). | 100 |
| height | Resizes the image to a specified height (in pixels). | 400 |
| maxsize | Resizes the image to the specified size of the longest side (in pixels). | 500 |
| disposition | Indicates the output disposition of the file.

You can use one of the following disposition values: <ul style="list-style-type: none"> • inline - opens the file in the browser window if possible • attachment - opens the browser's "Save or Open" dialog | inline

or

attachment |

Resizing of images

If your website has the **Resize images according to device profile** setting enabled in **Site Manager -> Settings -> Content -> Content management**, the system may override the **width**, **height** and **maxsize** parameters used in GetFile URLs of image files. When a user views the website on a device that matches a [device profile](#), images automatically *reduce* their maximum side size to the larger of the dimensions set for the given profile.

To configure the dimensions of device profiles:

1. Go to **Site Manager -> Development -> Device profiles**.

2. Edit (✎) a profile.
3. Set the **Preview width** and **Preview height** properties.
4. Click  **Save**.

If you wish to disable device profile resizing for an image, add the **resizemode=1** parameter to the GetFile URL.

7.18.8 Custom handling of URL path values

To ensure that URLs can be processed correctly, the system checks text values for unsafe characters before they are added to the URL path, and makes any necessary changes. This affects fields such as document aliases, document URL paths, forum names, post subjects etc.

By default, the process includes removal of diacritics and replacement of all forbidden characters according to the settings defined for the given site (as described in the [URL format and configuration](#) topic). Characters with diacritics are replaced by the appropriate base character, for example *ü* is converted to *u*.

If you need to change this default behavior in any way, you can customize it by registering and implementing a handler for one or both of the events described below:

- **OnBeforeGetSafeUriPath** - occurs whenever a potentially unsafe text value is added to a part of a URL, e.g. when the document alias field is saved (or filled automatically based on the document's name). This event can be used to customize the final format of URL paths. For example, you can convert characters from an international character set to an equivalent in Latin characters (ASCII) or specify a unique replacement string for particular forbidden characters.
- **OnBeforeRemoveDiacritics** - occurs whenever the system removes diacritics from text. This is one of the default steps performed when creating safe URLs, but the event will also be triggered during many text parsing operations that are not directly related to URLs (e.g. when indexing text for the [Smart search](#)).

These events are members of the **URLHelper** and **TextHelper** classes respectively, which can be found under the **CMS.GlobalHelper** namespace.

The handlers for these events have the source text included as a string parameter passed by reference, so any changes made to it in the code will be reflected in the result.

Both handlers have a *boolean* return value that indicates whether the default functionality should also be performed after the handler is executed. For this reason, it is highly recommended to set the return value to *true* for all but the most extensive customizations.

Important!

Returning a *false* value should only be done if you are sure that your custom handler can take full responsibility for all URL safety or diacritics removal requirements.

Disabling the default system functionality may prevent parts of your website from working correctly, particularly in the case of handlers for the **OnBeforeGetSafeUriPath** event.

Example

The following example demonstrates how you can define handlers for these events.

1. Open your Kentico CMS web project in Visual Studio, expand the **App_Code** folder (or **Old_App_Code** if your project was installed as a web application) and create a new class inside it. It may be placed in a sub-folder if you wish.
2. Edit the new class and add the following references:

[C#]

```
using CMS.SettingsProvider;  
using CMS.SiteProvider;  
using CMS.GlobalHelper;
```

3. Next, delete the default class declaration and its content. Instead, add the following code:

[C#]

```
[URLFormatHandlerLoader]  
public partial class CMSModuleLoader  
{  
    /// <summary>  
    /// Loader module registration.  
    /// </summary>  
    private class URLFormatHandlerLoaderAttribute : CMSLoaderAttribute  
    {  
        /// <summary>  
        /// Called automatically when the application starts.  
        /// </summary>  
        public override void Init()  
        {  
            // Hooks a handler for the OnBeforeGetSafeURLPath event.  
            URLHelper.OnBeforeGetSafeUrlPath +=  
                new URLHelper.OnBeforeGetSafeUrlPathEventHandler  
                (Custom_OnBeforeGetSafeUrlPath);  
  
            // Hooks a handler for the OnBeforeRemoveDiacritics event.  
            TextHelper.OnBeforeRemoveDiacritics +=  
                new TextHelper.OnBeforeRemoveDiacriticsEventHandler  
                (Custom_OnBeforeRemoveDiacritics);  
        }  
    }  
}
```

This extends the **CMSModuleLoader** partial class and defines a new attribute for it. In a private class representing the attribute, you can override the **Init** method, which is executed automatically when the application starts. The method can then be used to assign custom handlers for the events.

4. Add the definition of the **Custom_OnBeforeGetSafeUrlPath** handler under the private class according to the code below:

[C#]

```
static bool Custom_OnBeforeGetSafeUrlPath(ref string url, string siteName,
EventArgs e)
{
    // Replaces all & characters with the word "and".
    url = url.Replace("&", "and");

    // Returns true to indicate that the default URL replacements should also be
    performed (i.e. removing diacritics and forbidden characters).
    return true;
}
```

This code replaces all ampersand (&) characters with the word *and*. For example, this means that a document named *Products & Services* would have its default document alias generated as *Products-and-Services*, which would then be used in its URL. This example is only meant as a simple demonstration. In real-world scenarios, the handler could be much more complex, e.g. when mapping the character set of an international language to appropriate ASCII characters or words.

The **siteName** parameter of the handler contains the code name of the site under which the event occurred. This can be useful if you need to access the forbidden character settings of the given site in your custom code.

5. Next, add the **Custom_OnBeforeRemoveDiacritics** handler as shown below:

[C#]

```
static bool Custom_OnBeforeRemoveDiacritics(ref string text, EventArgs e)
{
    // Replaces German special characters.
    text = text.Replace("ä", "ae" );
    text = text.Replace("ö", "oe" );
    text = text.Replace("ü", "ue" );
    text = text.Replace("Ä", "Ae" );
    text = text.Replace("Ö", "Oe" );
    text = text.Replace("Ü", "Ue" );
    text = text.Replace("ß", "ss" );

    // Returns true to indicate that the default diacritics removal should also be
    performed.
    return true;
}
```

This ensures that the system will use custom replacements for German special characters rather than simply stripping the diacritics and leaving the base character.

Save the file. **Build** your project if it was installed as a web application. The changes will now be applied when creating new URLs and when removing diacritics from text. Please note that this will not

automatically change the aliases and URL paths of existing documents until their current value is changed or saved.

7.18.9 Output filters

The output filters are applied to the HTML code rendered by pages. They make various changes to the code before it is sent to the browser. Output filters do not affect the pages of the Kentico CMS administration interface (CMS Desk and Site Manager).

The following types of output filtering are available:

Form filter

The form filter fixes issue with non-working postbacks on pages that use URL rewriting. It ensures that forms, dialogs and buttons will work correctly on pages managed by Kentico CMS.

URL resolving filter

This filter resolves relative URLs so that they reflect the root URL of the website. For example, `~/mypage1/mypage2.aspx` would be changed to `/mypage1/mypage2.aspx` (if the application is running in the root) or `/VirtualDirectory/mypage1/mypage2.aspx` (when using a virtual directory).

Only URLs inside **src** and **href** attributes are changed.

XHTML filter

The XHTML filter may be used to fix certain types of XHTML incompatibilities. Specifically, the filtering functionality can ensure the following things:

- **Tag attributes** - the attributes of HTML tags are generated in valid XHTML format.
- **JavaScript tags** - the *type* and *language* attributes are included in all `<script>` tags.
- **Enforcing lower case** - all HTML tags and attributes are generated in lower case.
- **Fixing self closing tags** - all HTML elements without closing tags are properly closed, e.g. `
` will be replaced by `
`.
- **Replacing invalid tags** - tags that are not XHTML valid are replaced by appropriate equivalents (`` instead of ``, `` instead of `<i>`).
- **Indentation** - the HTML code of pages is organized into a properly indented, easier to read format.

XHTML errors may also be fixed for the content entered into the [WYSIWYG editor](#) when it is saved. This can be configured globally by adding the **CMSWYSIWYGFixXHTML** key into the `/configuration/appSettings` section of your application's `web.config` file as shown below:

```
<add key="CMSWYSIWYGFixXHTML" value="true" />
```

Supported values are *true* or *false*.

HTML 5 filter

The output filter provides a way to replace tag attributes that are obsolete in HTML5. Such attributes are removed and the system instead assigns CSS classes named in format `<attribute name>_<attribute`

value>. These classes need to be defined in the CSS stylesheet used by the website's pages.

The affected attributes are: *cellpadding*, *cellspacing*, *width*, *height*, *border*, *align*, *valign*

For example:

```
<table cellpadding="2" cellspacing="4">
```

Would be replaced by:

```
<table class="cellpadding_2 cellspacing_4">
```

Converting Tables to Div tags

The output filter may be used to automatically convert `<table>` elements and their child `<tr>` and `<td>` tags to `<div>` elements with appropriate CSS classes assigned (named according to the replaced tag). These classes need to be defined in the CSS stylesheet used by the website's pages.

For example:

```
<table>
  <tr><td>A</td><td>B</td></tr>
</table>
```

Would be replaced by:

```
<div class="table">
  <div class="tr">
    <div class="td">A</div>
    <div class="td">B</div>
  </div>
</div>
```

You may enable or disable this behavior for specific blocks of HTML code by marking them with `class="_divs"` or `class="_nodivs"` attributes. The filter may then be configured to convert only tables designated by the `_divs` class, or all tables except for those marked with `_nodivs` (see the descriptions of the settings below).

Output filter settings

If you do not wish to use the various types of output filters for specific sections of the website (e.g. due to performance reasons), you can disable them through the site settings in **Site Manager -> Settings -> System -> Output filter**.

Individual *Excluded URLs* fields are available for particular filter types. You can disable a certain type of output filter for all pages that start with a specific URL path by entering this path (without the `~` character and extension) into the corresponding field. Multiple URL paths may be added, separated by semicolons (;).

Please note that this only excludes specific URLs, not entire documents. For instance, if you exclude the */Home* URL path, but then access the Home page through a different URL or alias (such as the website root configured to display the Home page), output filtering will still be enabled.

Examples:

- */* - disables the filter for the entire website.
- **/Products** - disables filtering for the Products page under the website root and all other pages whose URL path starts with */Products* (e.g. child documents).
- **/Services/News** - excludes all pages whose URL path starts with */Services* or */News*.
- **/Company.** - by adding the period character (".") after the URL path, you can exclude only one specific page, but not its child documents (this will not work with extensionless URLs).

The following table describes all settings available in the Output filter category:

| General | |
|---------------------------------------|--|
| Excluded output form filter URLs | Specifies the URLs of the pages that should be excluded from the Form output filter. |
| Excluded resolve filter URLs | May be used to disable the URL resolving output filter for specific URL paths. |
| XHTML filter | |
| Excluded XHTML filter URLs | Specifies the URLs that should be excluded from all functionality provided by the XHTML output filter. |
| Excluded XHTML attributes filter URLs | Specifies the URLs that should be excluded from the Tag attribute XHTML filter. |
| Excluded XHTML JavaScript filter URLs | Specifies the URLs that should be excluded from the JavaScript tag XHTML filter. |
| Excluded XHTML lower case filter URLs | Specifies the URLs that should be excluded from the Lower case XHTML filter. |
| Excluded XHTML self close filter URLs | Specifies the URLs that should be excluded from the Self closing tag XHTML filter. |
| Excluded XHTML tags filter URLs | Specify the URLs that should be excluded from the Invalid tag replacement XHTML filter. |
| Excluded HTML5 filter URLs | Specifies the URLs that should be excluded from the HTML5 output filter. |
| Indent output HTML | Indicates if the HTML output of all pages should be processed into a properly indented, easier to read format. This setting is applied to all pages on which the XHTML output filter is enabled. |
| Convert TABLE tags to DIV tags | Determines which tables should be converted to <div> elements by the output filter. This behavior can either be disabled completely, enabled for all tables except for those marked by the _nodivs CSS class, or only enabled for the tables designated through the _divs class. |

The screenshot displays the Kentico CMS 7.0 Settings Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The 'Settings' tab is active, and the 'Output filter' configuration page is shown. The left sidebar lists various settings categories, with 'Output filter' highlighted. The main content area is titled 'Output filter' and contains the following settings:

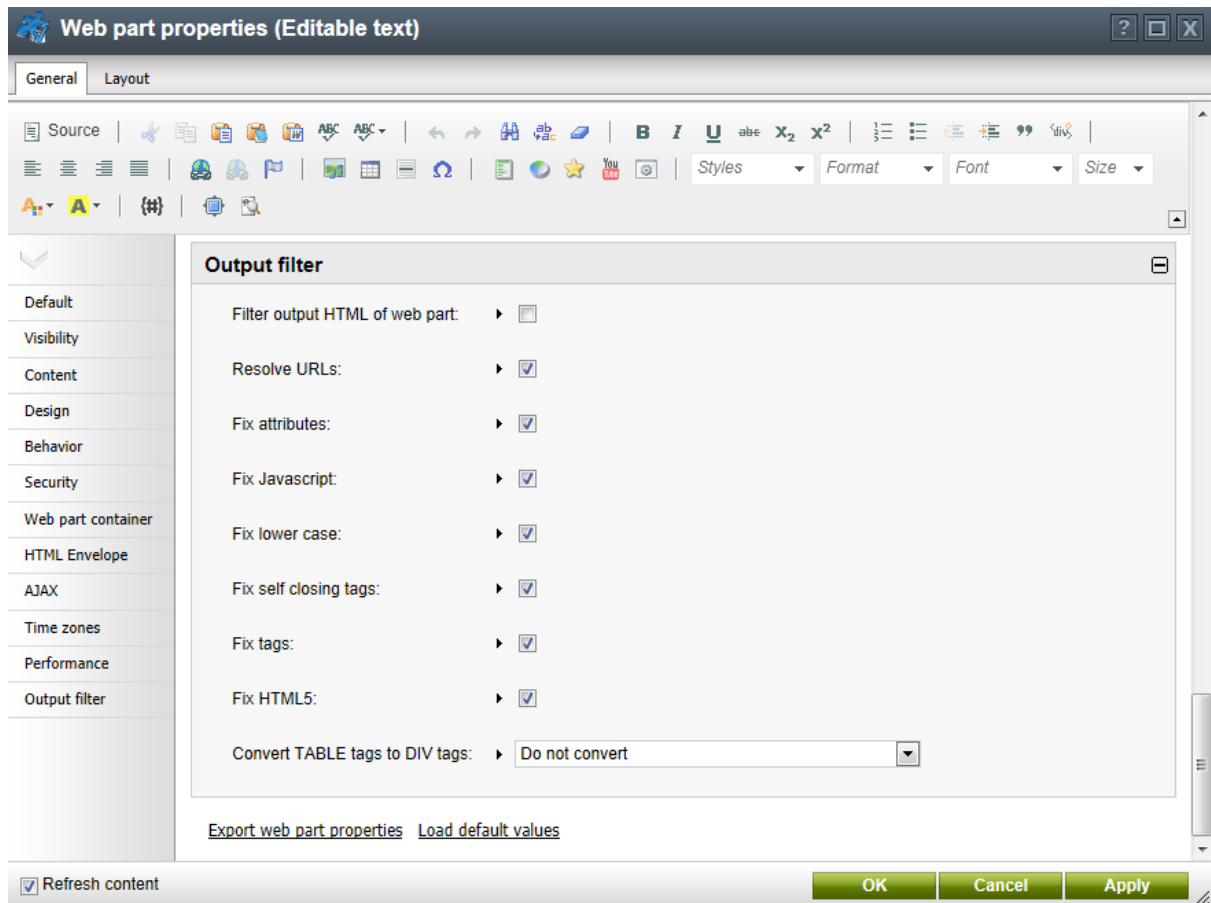

- General**
 - Excluded output form filter URLs:
 - Excluded resolve filter URLs:
- XHTML filter**
 - Excluded XHTML filter URLs:
 - Excluded XHTML attributes filter URLs:
 - Excluded XHTML JavaScript filter URLs:
 - Excluded XHTML lower case filter URLs:
 - Excluded XHTML self close filter URLs:
 - Excluded XHTML tags filter URLs:
 - Excluded HTML5 filter URLs:
 - Indent output HTML:
 - Convert TABLE tags to DIV tags:

Buttons for 'Save' and 'Reset these settings to default' are located at the top of the settings area. A note states: 'These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.' An 'Export these settings' link is at the bottom.

Enabling output filters for specific web part instances

You can enable the output filters separately for the code generated by [Web parts](#). This allows you to filter the output of specific instances of web parts, even if their parent page is excluded from the output filter via the website settings. Output filtering is always used for web parts on pages that are not excluded.

To access these settings, configure (⚙️) the given web part on the **Design** tab of CMS Desk and adjust its **Output filter** properties. This section of properties is available for all web parts.

The configuration options correspond with the types of output filters described in the sections above.

7.18.10 Search engine optimization

7.18.10.1 SEO overview

Search engine optimization (SEO) is a process that attempts to improve the page rank of a website, which determines its organic position in the results of web search engines (such as Google). Being higher in these results benefits the site by naturally attracting more visitors.

While Kentico CMS cannot guarantee by itself that your website will have good search engine optimization, it provides many features that simplify related configuration tasks and make it easier to follow general best practices. Additionally, the system ensures a solid SEO foundation by generating pages with valid, standards compliant output code and URLs in a search engine friendly format.

Tracking search engine traffic

You can use the web analytics module to review the results of your website's SEO. It is possible to monitor user traffic gained from search engines and the activity of web crawlers on your site's pages can also be tracked.

For more information, please refer to the [Monitoring traffic from search engines](#) topic in the **Modules -> Web analytics** chapter of this guide.

Editing the metadata of pages

An important SEO consideration is the metadata of individual pages, which you can edit by selecting the corresponding document in the content tree of CMS Desk and opening its **Properties -> Metadata tab**. Here you can set properties such as the page title or meta description.

See also: [Content management -> Document properties -> Metadata](#)

SEO settings

You can configure most of the SEO functionality of your website in the **Site Manager -> Settings -> URLs and SEO** interface. The settings here are divided into three main sections which are described below.

The screenshot displays the Kentico CMS 7.0 Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The 'Settings' section is expanded to show 'URLs and SEO'. The left sidebar lists various settings categories, with 'URLs and SEO' selected. The main content area is divided into three sections:

- Search engine optimization (SEO):**
 - Google sitemap URL:
 - Google sitemap path:
 - Robots.txt path:
 - Allow permanent (301) redirection:
 - Move ViewState to the end of the page:
 - Use NOFOLLOW for user links:
 - Default replacement document:
- SEO - URLs:**
 - Use URLs with trailing slash:
 - Redirect document aliases to main URL:
 - Redirect invalid case URLs to their correct versions:
 - Redirect documents to main extension:
 - Process domain prefix:
 - Default page:
- SEO - Cultures:**
 - Force domain culture:
 - Use language prefix for URLs:
 - Allow URLs without language prefixes:

Search engine optimization (SEO)

Before search engines can provide results that link users to your website, they need to index the site using web crawlers (robots). The settings in this section allow you to use standard techniques for giving instructions to crawlers. You can also enable several options that help crawlers easily and accurately index the pages on your website.

| | |
|---------------------------------------|---|
| Google sitemap URL | These two settings set up the URL of the website's Google (XML) sitemap and the path of the source document. The sitemap allows you to instruct web crawlers how to index the site's pages. |
| Google sitemap path | |
| Robots.txt path | Specifies the path of the document that generates the website's robots.txt file.

Refer to Managing robots.txt for detailed information about setting up robots.txt content. |
| Allow permanent (301) redirection | If enabled, the system uses permanent (301) redirection instead of standard temporary (302) redirection. This is highly recommended, because it allows web crawlers to properly react to any changes made on your website and pass page rank to the new or main URL. |
| Move ViewState to the end of the page | If enabled, the system places the ViewState field at the end of the output code generated for pages. This helps search engine crawlers process more page content. |
| Use NOFOLLOW for user links | If enabled, the system instructs search engine crawlers not to follow links posted by users on Forums , Message boards or in Blog comments. This is achieved by including the <code>rel="nofollow"</code> attribute in the output code of all such link tags.

This can prevent damage to your website's search ranking caused by user-generated links that lead to unrelated content. The setting can also help stop spammers from passing page rank to other sites. |
| Default replacement document | See the <i>Assigning replacement documents for deleted pages</i> section below. |

Assigning replacement documents for deleted pages:

Removing documents can have a negative effect on your website's traffic. Visitors may find it confusing if pages suddenly become unavailable (e.g. if they have a deleted page bookmarked). Another thing to consider is that deleted pages might be indexed by search engines, which then provide invalid links in their search results until they re-index the site's content.

You can mitigate these problems by setting up other documents as replacements when deleting pages:

1. Select the document that you wish to remove in the CMS Desk content tree and click **Delete**.
 - o The **Delete document** confirmation dialog opens.

2. Check the **Display alternate page when visitors access the deleted document** box.
3. Specify the path of the **Replacement document**.
 - The field loads its default value from the **Default replacement document** setting of the current website, but you can enter a different path for each specific case.
4. Enable or disable the following configuration options:
 - **Copy all paths** - if checked, the website uses the replacement document for all possible URL paths of the deleted document (including any document aliases). If false, the replacement only covers the main URL of the deleted page, i.e. the corresponding document's custom URL path (if one is specified) or alias path.
 - **Include child nodes** - if checked, the website uses the replacement document for all child documents removed along with the deleted page.

Setting a replacement document in the Delete document confirmation dialog

Once you confirm the deletion, the system automatically adds [document aliases](#) to the replacement document. These aliases ensure that the website serves up the replacement page whenever a visitor requests the URLs of the deleted document. When combined with permanent 301 redirection, the replacement aliases also properly inform search engine crawlers about the change in your website's structure.

SEO - URLs

The settings in this section allow you to configure URL rewriting that focuses on avoiding issues with duplicate content, i.e. having the same content available under multiple URLs. Such problems can have a negative effect on search ranking, so it is recommended to set up a unified URL format.

| | |
|------------------------------|---|
| Use URLs with trailing slash | Specifies how the rewriter handles trailing slashes in URLs. Possible options: <ul style="list-style-type: none"> • Leave the URL as is • Always use URLs with a trailing slash • Always use URLs without a trailing slash |
| Redirect document aliases | Enabling this setting ensures that documents always have only one |

| | |
|--|--|
| to main URL | <p>valid URL and other aliases are redirected to this main URL. The main URL of a document is determined either by its alias path, or custom URL path if one is specified.</p> <p>Note: You can override this setting for individual document aliases through their Alias redirection property.</p> <p>For more information about document URLs, see the Multiple document aliases topic.</p> |
| Redirect invalid case URLs to their correct versions | <p>Determines how the system handles the letter case of characters in URLs. Available options:</p> <ul style="list-style-type: none"> • Do not check the URL case • Use the exact URL of each document • Redirect all requests to lower case URLs • Redirect all requests to upper case URLs |
| Redirect documents to main extension | <p>If enabled, the system ensures that all document URLs use the current main extension. The main URL extension is the first one specified in the Friendly URL extension setting. Any URLs with a different extension are automatically redirected to a corresponding URL with the main extension.</p> |
| Process domain prefix | <p>Determines how the rewriter handles the <i>www</i> domain prefix in the website's URLs. You can leave the domain as it was entered or have it rewritten to either always or never include the <i>www</i> prefix.</p> <p>Note: This setting does not apply for IP addresses and top-level domains.</p> |
| Default page | <p>Allows you to redirect (permanent 301) all possible URLs that access the home page of your website to one single URL. Using a unified home page URL is highly recommended, because it prevents the duplicate content problem on your website's most important URL.</p> <p>You can choose from the following options for the home page URL:</p> <ul style="list-style-type: none"> • Not specified - supports all possible home page URLs and does not perform any redirection. • Use domain root - always uses the base URL of the website's domain name. • Use page defined by default alias path - always uses the URL of the document specified by the website's <i>Content -> Default alias path</i> setting. • Use default page URL - always uses the <i>default</i> URL: <code><domain>/default.aspx</code> <p>Important: This setting only works correctly if the website is hosted on IIS 7 or newer, and uses an application pool with an <i>Integrated Managed</i> pipeline mode.</p> |

SEO - Cultures

The options in this section are important when performing search engine optimization of multilingual websites. The following settings allow you to set up unique URLs for different language versions of pages in a search engine friendly format.

| | |
|--------------------------------------|--|
| Force domain culture | <p>If checked, the system generates the domain name in document URLs based on the current content culture. Whenever a user switches to a different language on the website, the URL is redirected to the corresponding domain name.</p> <p>You can assign cultures to domains by editing your site in Site Manager -> Sites:</p> <ul style="list-style-type: none"> • Set the culture of the website's main domain through the Visitor culture property on the General tab. • To define domain names for other languages, create Domain aliases with an appropriately set Visitor culture. <p>Note: You cannot use this option in combination with language prefixes.</p> |
| Use language prefix for URLs | <p>If enabled, the system generates document URLs with language prefixes. A language prefix is a subdirectory inserted into the URL. The name of the prefix matches the culture code (or culture alias) of the content culture selected on the website.</p> <p>Example: <code><domain>/en-US/Home.aspx</code></p> |
| Allow URLs without language prefixes | <p>If enabled, URLs without language prefixes are allowed. Otherwise the system redirects such URLs to a corresponding URL that includes a language prefix.</p> <p>Only applies if Use language prefix for URLs is enabled.</p> |

- [Languages and URLs](#)
- [Multilingual content](#)

7.18.10.2 Google Sitemaps

Kentico CMS allows you to automatically generate sitemaps for your websites according to the Google Sitemap Protocol. Sitemaps help search engines correctly index the content of websites and can have a significant effect on the resulting search ranking.

A sitemap is an XML file that lists the URLs of a website's pages along with additional metadata. Search engine crawlers (robots) use the sitemap data to determine which pages to index and how often to re-index pages. Sitemaps only serve as a *recommendation* and do not guarantee that all crawlers will index your website strictly according to the specified data.

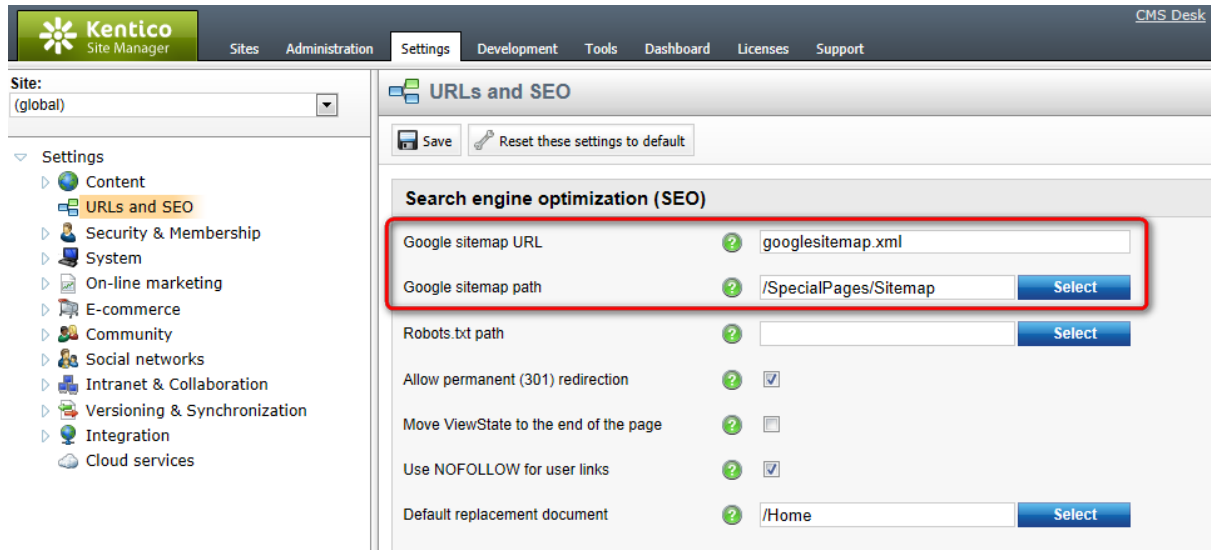

For detailed information about the Sitemap protocol, see <http://www.sitemaps.org/>.

Setting the sitemap URL

You can change the URL of your website's sitemap in **Site Manager -> Settings -> URLs and SEO** through the **Google sitemap URL** setting.

For example, the default value *googlesitemap.xml* means that web crawlers can access the sitemap through the following URL:

<website domain>/googlesitemap.xml

Sitemap-related website settings

Using the .xml extension

If you want to have your sitemap available under a URL with the **.xml** extension, you need to configure your application to handle all types of request extensions:

1. Edit your application's **web.config** file.
2. Find the **system.webServer** section directly under the web.config root (i.e. not under a specific *<location>* element).
3. Add the following attribute to the **<modules>** element:

```
<modules runAllManagedModulesForAllRequests="true" >
```

Defining the sitemap content

The system generates sitemaps for websites based on the documents stored in the content tree.

By **default** the sitemap:

- Only contains pages (documents of the *CMS.MenuItem* type)
- Automatically excludes all pages whose parent document is not in the sitemap (such as pages stored under folders or custom document types)

You can **modify** the content of your website's sitemap by creating a dedicated sitemap document:

1. Add a new *Page (menu item)* document to your website's content tree.
 - You can use the predefined **SEO -> Google Sitemap** page template to quickly create sitemap documents. This template contains the required web part by default.
2. Place the [Google Sitemap \(XML Sitemap\)](#) web part onto the page.
 - Adding this web part stops the page from displaying standard content. Instead, the page returns an XML response with the sitemap data.
 - The web part only generates output when the page is accessed on the live site.
3. Configure the content of the sitemap through the web part's properties.
 - You can limit which documents are included in the sitemap by entering an appropriate **Path expression**.
4. Go to **Site Manager -> Settings -> URLs and SEO**.
5. Enter the path of your sitemap document into the **Google sitemap path** setting.

The sitemap generated according to the configuration of the web part replaces the default sitemap. Search crawlers can access the sitemap either under the main URL specified in the **Google sitemap URL** setting, or directly through the URL of the document containing the *Google Sitemap* web part.

Customizing the default sitemap directly

If you do not wish to use portal engine pages and web parts, you can instead edit the markup of the `~/CMSPages/googlesitemap.aspx` system page. This page generates the default sitemap for websites that have an empty **Google sitemap path** setting.

The **GoogleSitemap** control on the page provides the same configuration options as the *Google Sitemap* web part.

Troubleshooting:

If you encounter problems with pages missing in your sitemap, try checking for the following:

- **Manually excluded documents** - specific documents may be excluded through their [sitemap properties](#) (**Show in sitemap** or **Exclude from search**).
- **Incorrect content filtering** - review the content filtering properties of your *Google Sitemap* web part.
 - If the **Document types** property is empty, the sitemap only loads pages (*CMS.MenuItem* documents). Add the document types that you wish to have in the sitemap. You can use the asterisk (*) wildcard to specify all document types.
- **Broken document hierarchy** - sections of the website may be excluded due to parent documents

missing in the sitemap. To load all documents regardless of the parent-child hierarchy in the content tree, disable the **Hide children for hidden parent** property of the *Google Sitemap* web part.

Configuring sitemap settings for specific pages

By filling in the sitemap properties of documents, you can exclude specific pages from sitemaps or give search crawlers additional details describing how to index pages:

1. Select the document in the content tree of CMS Desk.
2. Open the document's **Properties -> Navigation** tab.
3. Set up the following properties:

| Basic properties | |
|--------------------------|---|
| Show in sitemap | Sitemaps only list documents that have this property enabled. |
| Search & SEO | |
| Exclude from search | <p>Marks the document to be ignored by all forms of search, including search engines.</p> <p>Enabling this checkbox excludes the document from sitemaps by default. However, individual <i>XML Sitemap</i> web parts can override this setting and generate sitemaps including documents that are excluded from search.</p> |
| Sitemap change frequency | <p>Determines the value of the document's <changefreq> tag in the sitemap. This metadata provides a suggestion to search engines about how often they should re-index the page.</p> <p>Choose a value that reflects how frequently the page's content changes.</p> |
| Sitemap priority | <p>Allows you to inform web crawlers which pages you consider to be the most important.</p> <p>The system converts the selected priority to a decimal number between 0 and 1 and adds the number as the value of the document's <priority> tag in the sitemap. Web crawlers only measure the priority in relation to other pages on the website.</p> |

The screenshot shows the 'Properties' tab in the Kentico CMS interface. The left sidebar lists various categories, with 'Navigation' selected. The main area is divided into sections: 'Basic properties', 'Menu actions', and 'Search & SEO'. In the 'Basic properties' section, the 'Show in sitemap' checkbox is checked and highlighted with a red box. In the 'Search & SEO' section, the 'Exclude from search' checkbox is unchecked, and the 'Sitemap change frequency' is set to 'Weekly' and 'Sitemap priority' is set to 'Very high', both of which are also highlighted with a red box.

Setting a document's sitemap properties

If you enter the URL of the sitemap into your browser, you can review the generated XML output. The system automatically creates the required XML structure:

```
<?xml version="1.0" encoding="UTF-8"?>
- <urlset xmlns="http://www.sitemaps.org/schemas/sitemap/0.9" xsi:schemaLocation="http://www.sitemaps.org/schemas/sitemap/0.9
http://www.sitemaps.org/schemas/sitemap/0.9/sitemap.xsd" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
- <url>
  <loc>http://localhost/KenticoCMS_7.0.4456/Home.aspx</loc>
  <lastmod>2012-03-20</lastmod>
  <changefreq>weekly</changefreq>
  <priority>0.9</priority>
</url>
- <url>
  <loc>http://localhost/KenticoCMS_7.0.4456/Products.aspx</loc>
  <lastmod>2012-03-20</lastmod>
</url>
- <url>
  <loc>http://localhost/KenticoCMS_7.0.4456/Products/Smartphones.aspx</loc>
  <lastmod>2012-02-17</lastmod>
</url>
- <url>
  <loc>http://localhost/KenticoCMS_7.0.4456/Products/Laptops-and-Tablets.aspx</loc>
  <lastmod>2011-06-23</lastmod>
</url>
```

XML output of the Google sitemap generated for a Kentico CMS website

- The `<url>` elements represent individual pages.
- The sitemap loads the values of the `<loc>` and `<lastmod>` tags from the data of the corresponding documents.
- The `<changefreq>` and `<priority>` optional tags are added for documents that have values in their **Sitemap change frequency** and **Sitemap priority** properties.

Creating sitemap indexes

A single XML sitemap can only list up to 50 000 pages (URLs). If you need to include more pages, prepare multiple sitemaps and create a sitemap index for your website:

1. Add any number of sitemap documents, each one containing its own [Google Sitemap](#) web part.
2. Separate your website's pages between the sitemaps by configuring the content filtering properties of the web parts.
 - Each sitemap can contain a maximum of 50 000 items.
 - Avoid duplicate content — do not list the same page URLs in multiple sitemaps.
3. Create the index as another document with a *Google Sitemap* web part.
 - Switch the **Sitemap mode** property of the web part to *Sitemap index*.
 - Configure the content filtering properties so that the sitemap index web part loads only the documents representing your sitemaps.
4. Enter the path of your *sitemap index* document into the website's **Google sitemap path** setting.
 - This ensures that crawlers process the sitemap index first.

The sitemap index points search engine crawlers to the other sitemaps, which then provide the lists of page URLs in the usual way.

Customizing the XML format of sitemaps

If you need to override the default XML format of a sitemap or index, you can specify a custom [transformation](#) for the [Google Sitemap](#) web part or *GoogleSitemap* control. This allows you to react to any changes in the Sitemap protocol.

For example, the default **CMS.Root.GoogleSiteMap** transformation uses the following code to define the sitemap structure:

```
<url>
  <%# GetSitemapItem("loc") %>
  <%# GetSitemapItem("lastmod") %>
  <%# GetSitemapItem("changefreq") %>
  <%# GetSitemapItem("priority") %>
</url>
```

The **GetSitemapItem** transformation method generates XML tags according to the sitemap protocol. The method's parameter specifies the type of the tag, and the value is dynamically loaded from the data of the transformed documents.

In the final XML output, the web part automatically encloses the transformed items within either a `<urlset>` or `<sitemapindex>` element depending on the selected **Sitemap mode**.

7.18.10.3 Managing robots.txt

You can give instructions to web crawlers and other robots using the [Robots Exclusion Protocol](#), i.e. a **robots.txt** file. The primary purpose of robots.txt files is to exclude certain pages from search engine indexing. Like with [Sitemaps](#), the provided instructions are only considered as recommendations and may be ignored by some robots.

Creating a robots.txt file for your website

The most direct way to use robots.txt with Kentico CMS is to physically add the text file into the root of your web project. However, this scenario does not allow you to assign different robots.txt files to specific websites (if there are multiple sites running on your installation). Additionally, it may be difficult to access the file system in certain types of hosting environments.

The recommended approach is to create a dedicated document in your site's content tree and make it return the appropriate text response:

1. Create a standard *Page (menu item)* document.
 - o You can use the predefined **SEO -> Robots.txt** page template to quickly implement robots.txt documents.
2. Add a [Custom response](#) web part to the page.
3. Configure (🔗) the *Custom response* web part to generate a valid robots.txt response according to the following steps:
 - a. Set the **Content type** property to *text/plain*.
 - b. Enter an appropriate **Encoding** type, for example *UTF-8*.
 - c. Set the **Status code** of the response to *200*.
 - d. Add the actual robots.txt instructions into the **Content** property, just like you would in a physical text file. This property supports [K# macro expressions](#), so you can dynamically load values from the current system data if needed.

The screenshot shows the 'Web part properties (Custom response)' dialog box with the following configuration:

- Usability:**
 - Enabled:
 - Disable on subpages:
 - Use for document types: [] [Select] [Clear]
 - Use for roles: [] [Add roles] [Clear]
- General:**
 - Content type*: text/plain
 - Encoding*: UTF-8
 - Status code*: 200
 - Content disposition: []
 - Content: User-agent: *
Disallow: /InternalDocs/ [...]

At the bottom left, the 'Refresh content' checkbox is checked. At the bottom right, there are 'OK', 'Cancel', and 'Apply' buttons.

4. Go to **Site Manager -> Settings -> URLs and SEO** and enter the path of your robots.txt document

into the **Robots.txt path** setting.

- You can specify a different value for each site by using the **Site** selector above the settings tree.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The 'Settings' tab is active, and the 'URLs and SEO' section is selected. On the left, a settings tree shows 'Content' > 'URLs and SEO' selected. The main panel shows the 'Robots.txt path' setting with a value of '/SpecialPages/robots' and a 'Select' button. Other settings include 'Remember original URLs when moving documents' (checked), 'Automatically update document alias' (unchecked), 'Google sitemap URL' (googlesitemap.xml), 'Google sitemap path' (/SpecialPages/Sitemap), 'Allow permanent (301) redirection' (checked), 'Move ViewState to the end of the page' (unchecked), 'Use NOFOLLOW for user links' (checked), and 'Default replacement document' (/Home).

The output of the specified document is always available under the standard `<website domain>/robots.txt` URL, regardless of the document's location in the content tree. Compliant web crawlers read the instructions from this URL before processing other pages on the website.

Enabling the .txt extension

To ensure that the `<domain>/robots.txt` URL is available, you need to configure your application to handle all request extensions:

1. Edit your application's **web.config** file.
2. Find the **system.webServer** section directly under the web.config root (i.e. not under a specific `<location>` element).
3. Add the following attribute to the **<modules>** element:

```
<modules runAllManagedModulesForAllRequests="true">
```

Excluding documents manually

You can also configure individual documents to be excluded from search engine listings without the need to prepare a robots.txt file.

1. Select the given document in the CMS Desk content tree.
2. Open the **Properties -> Navigation** tab.
3. Enable the **Exclude from search** property.
4. Click  **Save**.

The system automatically adds the following meta tag to the `<head>` section in the HTML output of such pages:

```
<meta name="robots" content="noindex,nofollow" />
```

This instructs web crawlers not to index the page and to ignore any links in the content.

7.18.11 Document aliases internals and API

7.18.11.1 Overview

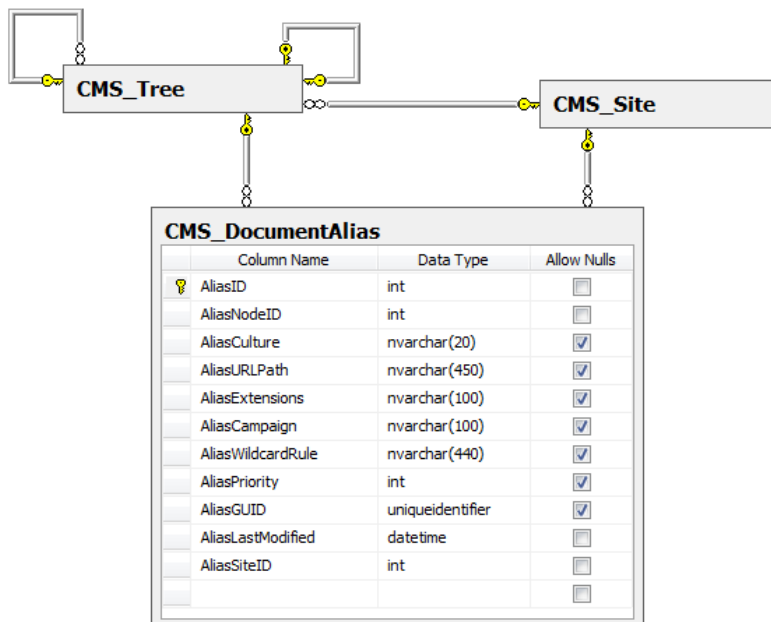

In this chapter, you will learn which [database tables](#) and [API classes](#) are used to manage document aliases. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the related classes, please refer to [Kentico CMS API Reference](#).

7.18.11.2 Database tables

The following database tables are used to store information about document aliases:

- **CMS_DocumentAlias** - contains records representing aliases of documents from the content trees of the sites in the system.

7.18.11.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes for managing document aliases can be found in the **CMS.DocumentEngine** namespace.

CMS_DocumentAlias table API:

- **DocumentAliasInfo** - represents one document alias.
- **DocumentAliasInfoProvider** - provides management functionality for document aliases.

7.18.11.4 API examples

7.18.11.4.1 Overview

These topics show examples of how the API for managing document aliases can be used:

- [Managing document aliases](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Documents\DocumentAliases\Default.aspx.cs**.

The document alias API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.DocumentEngine;
```

7.18.11.4.2 Managing document aliases

The following example creates a document alias.

```
private bool CreateDocumentAlias()
```

```
{
    // Get "Home" document
    TreeNode document = TreeHelper.GetDocument(CMSContext.CurrentSiteName, "/"
Home", CultureHelper.GetPreferredCulture(), true, "CMS.MenuItem", false);

    if (document != null)
    {
        // Create new document alias object
        DocumentAliasInfo newAlias = new DocumentAliasInfo();

        // Set the properties
        newAlias.AliasURLPath = "/MyNewAlias";
        newAlias.AliasNodeID = document.NodeID;
        newAlias.AliasSiteID = CMSContext.CurrentSiteID;

        // Save the document alias
        DocumentAliasInfoProvider.SetDocumentAliasInfo(newAlias,
CMSContext.CurrentSiteName);

        return true;
    }

    return false;
}
```

The following example gets and updates a document alias.

```
private bool GetAndUpdateDocumentAlias()
{
    // Prepare the parameters
    string orderBy = "";
    string where = "AliasURLPath = N'/MyNewAlias'";

    // Get the data
    DataSet aliases = DocumentAliasInfoProvider.GetDocumentAliases(where,
orderBy);
    if (!DataHelper.DataSourceIsEmpty(aliases))
    {
        DocumentAliasInfo updateAlias = new DocumentAliasInfo(aliases.Tables[0]
.Rows[0]);

        // Update the properties
        updateAlias.AliasURLPath = updateAlias.AliasURLPath.ToLower();

        // Save the changes
        DocumentAliasInfoProvider.SetDocumentAliasInfo(updateAlias,
CMSContext.CurrentSiteName);

        return true;
    }

    return false;
}
```

```
}
```

The following example gets and bulk updates document aliases.

```
private bool GetAndBulkUpdateDocumentAliases()
{
    // Prepare the parameters
    string orderBy = "";
    string where = "AliasURLPath = N'/MyNewAlias'";

    // Get the data
    DataSet aliases = DocumentAliasInfoProvider.GetDocumentAliases(where,
orderBy);
    if (!DataHelper.DataSourceIsEmpty(aliases))
    {
        // Loop through the individual items
        foreach (DataRow aliasDr in aliases.Tables[0].Rows)
        {
            // Create object from DataRow
            DocumentAliasInfo modifyAlias = new DocumentAliasInfo(aliasDr);

            // Update the properties
            modifyAlias.AliasURLPath = modifyAlias.AliasURLPath.ToUpper();

            // Save the changes
            DocumentAliasInfoProvider.SetDocumentAliasInfo(modifyAlias,
CMSContext.CurrentSiteName);
        }

        return true;
    }

    return false;
}
```

The following example deletes a document alias.

```
private bool DeleteDocumentAlias()
{
    // Prepare the parameters
    string orderBy = "";
    string where = "AliasURLPath = N'/MyNewAlias'";

    // Get the data
    DataSet aliases = DocumentAliasInfoProvider.GetDocumentAliases(where,
orderBy);
    if (!DataHelper.DataSourceIsEmpty(aliases))
    {
        DocumentAliasInfo deleteAlias = new DocumentAliasInfo(aliases.Tables[0]
.Rows[0]);
    }
}
```

```
// Delete the document alias
DocumentAliasInfoProvider.DeleteDocumentAliasInfo(deleteAlias);

return true;
}

return false;
}
```

7.19 Query string parameters in UI

Query string is a part of a URL that contains parameters and values to be passed to a web application. The query string part of the URL begins with the "?" character followed by the name of the parameter (e.g., culture), the "=" character and a value (e.g., en-US). Individual parameters with values are separated by the "&" character.

In Kentico, you can use the query strings for example for:

- Linking to documents
- Creating links to specific sections of the editing UI

Available query string parameters in the Kentico CMS editing user interface

In Site Manager:

| Parameter | Description | Values | Example |
|-----------|---|-------------------------------------|---|
| section | Selects the section (main tab) in Site Manager. | Code names of Site Manager sections | http://localhost/KenticoCMS/CMSSiteManager/?section=development |

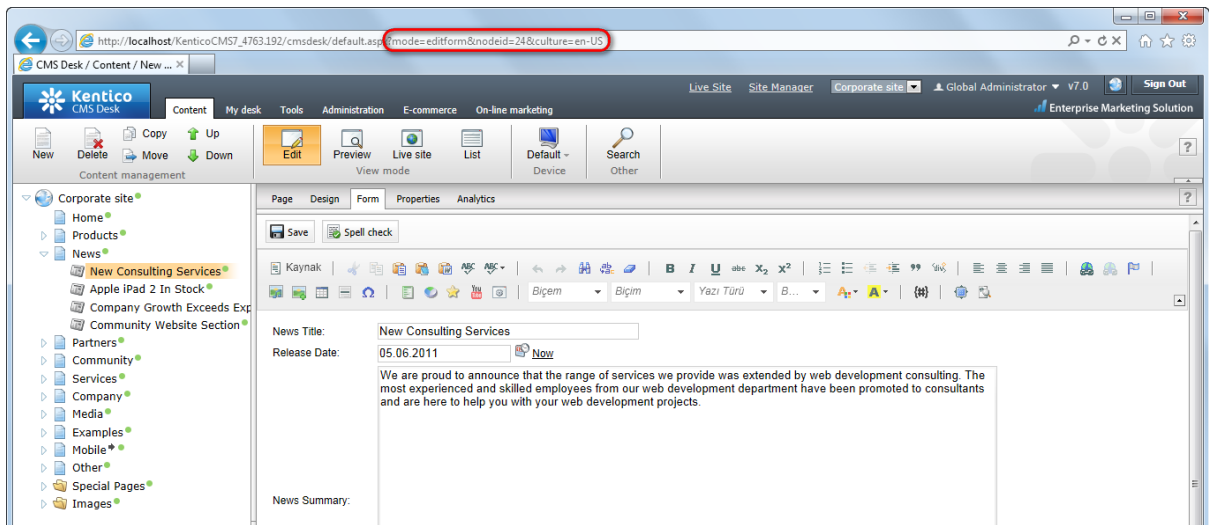

In CMS Desk:

| Parameter | Description | Values | Example |
|--------------|---|--|--|
| section | Selects the section (main tab) in CMS Desk. | Code names of CMS Desk sections | http://localhost/KenticoCMS/CMSDesk/?section=tools |
| nodeid | Selects the document with the specified ID in the currently selected culture. | A node ID number (displayed in CMS Desk -> Edit -> Properties -> General) | http://localhost/KenticoCMS/CMSDesk/?nodeid=24 |
| culture | Changes the current culture. Use in a combination with the <i>nodeid</i> parameter. | Four-letter country codes | http://localhost/KenticoCMS/CMSDesk/?nodeid=7&culture=cs-CZ |
| mode | Selects the View mode or subsections of the Edit mode (Page, Design, Properties, etc.). | <i>edit, preview, livesite, listing, page, wireframe, design, editform, product, masterpage, properties, analytics</i> | http://localhost/KenticoCMS/CMSDesk/?mode=livesite

http://localhost/KenticoCMS/CMSDesk/?nodeid=4&mode=editform |
| device | Sets the device profile. | Code names of device profiles (displayed in Site Manager -> Development -> Device profiles -> Edit (📱) a device) | http://localhost/KenticoCMS/CMSDesk/?device=android_device |
| expandnodeid | Only expands the node with the chosen ID. | A node ID number (displayed in CMS Desk -> Edit -> Properties -> General) | http://localhost/KenticoCMS/CMSDesk/?expandnodeid=7 |

You can also combine these parameters in various ways, for example:

- <http://localhost/KenticoCMS7/CMSDesk/default.aspx?mode=editform&nodeid=24&culture=en-US> - which selects the node with ID = 24 in the US culture and switches into the Form tab of the Edit mode.

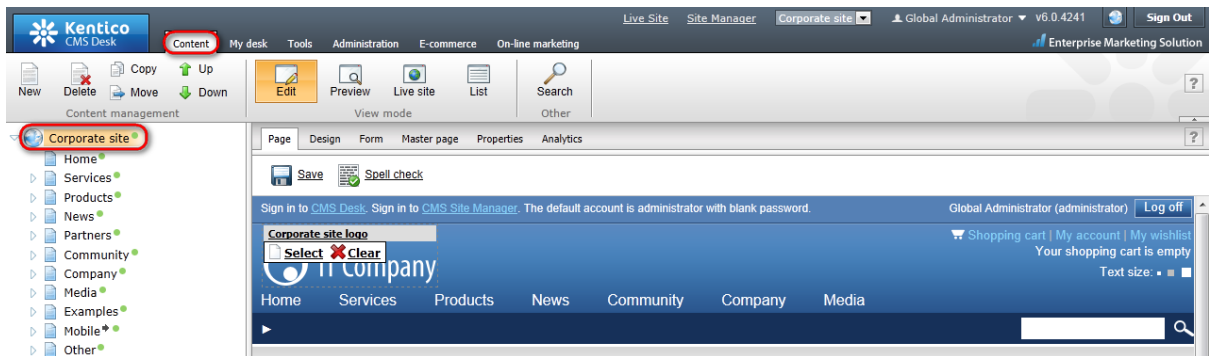

Example of a query string

7.20 Rebranding

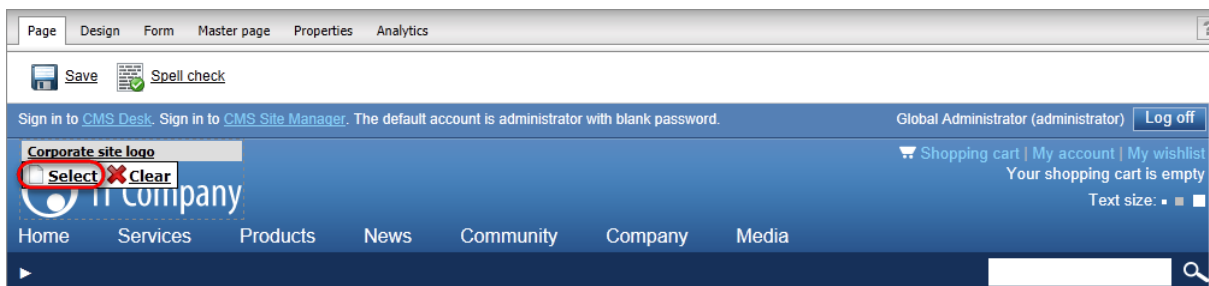

7.20.1 Changing the logo in the header

In this topic, you will learn how to change the header logo on the sample Corporate Site.

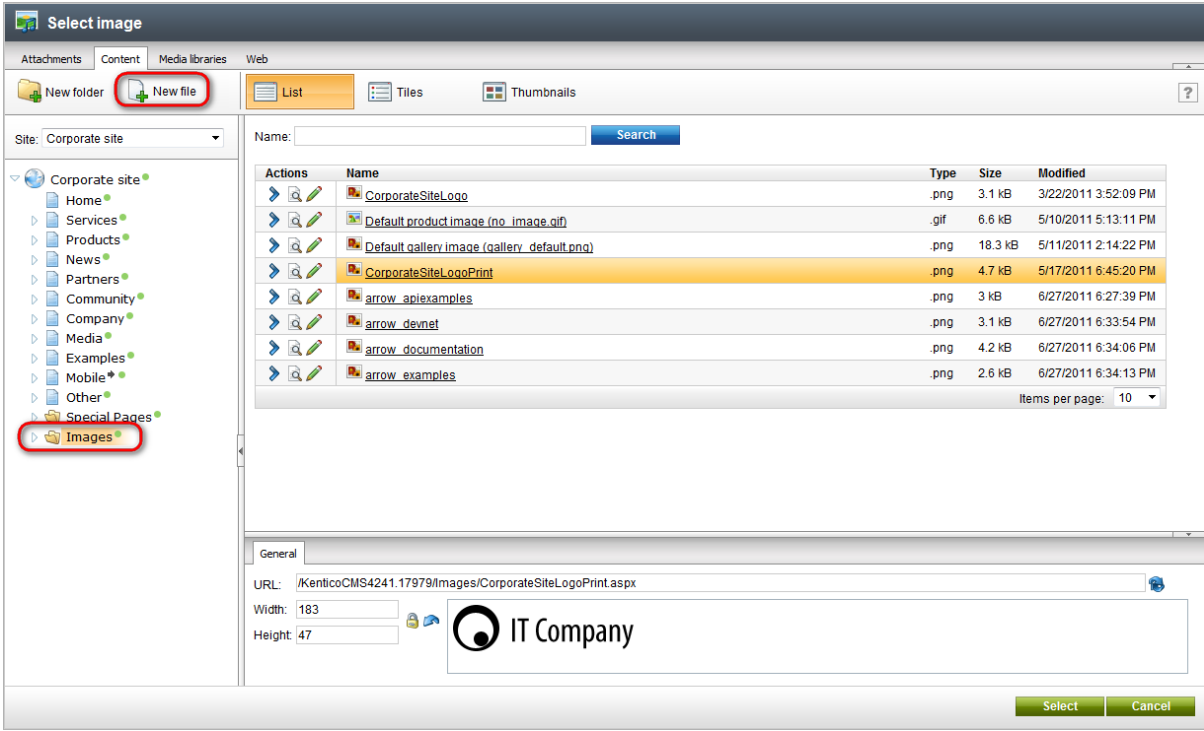

1. Go to **CMS Desk** -> **Content** and select the root of the content tree (**Corporate Site**).

2. On the **Page** tab, click the **Select** button displayed over the logo.

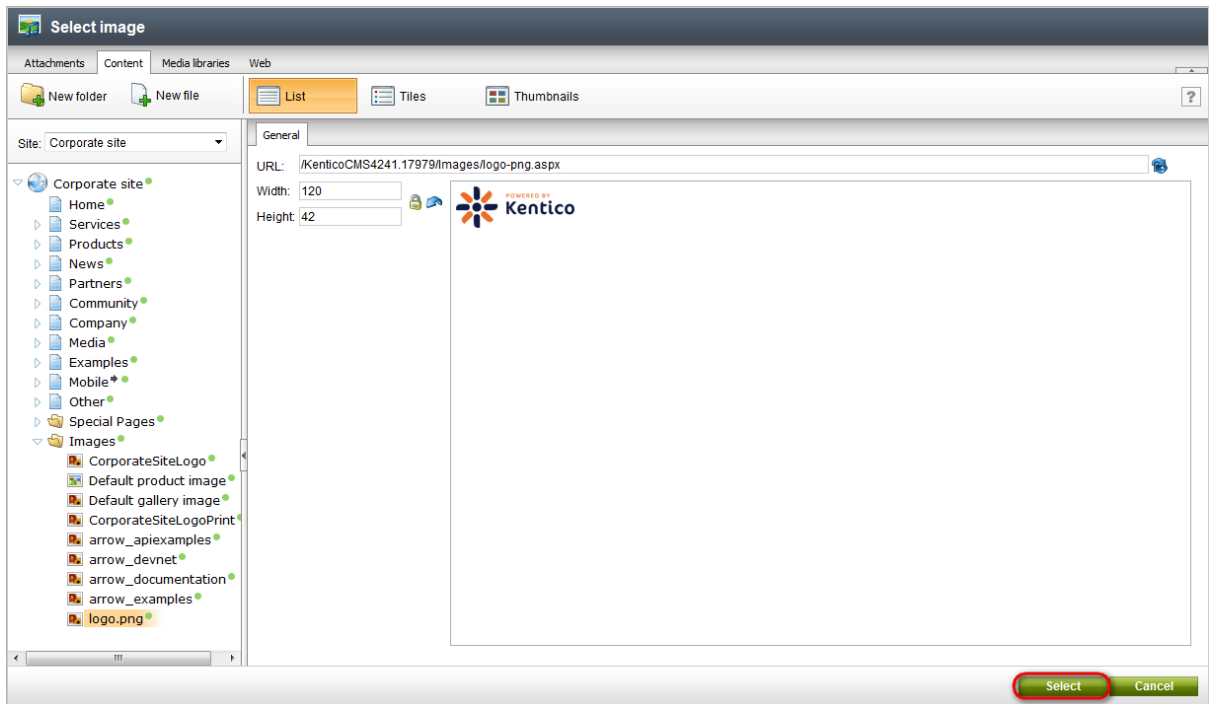

3. In the **Select image** dialog that pops up, select **Images** in the content tree and click the **New file** button above the content tree.

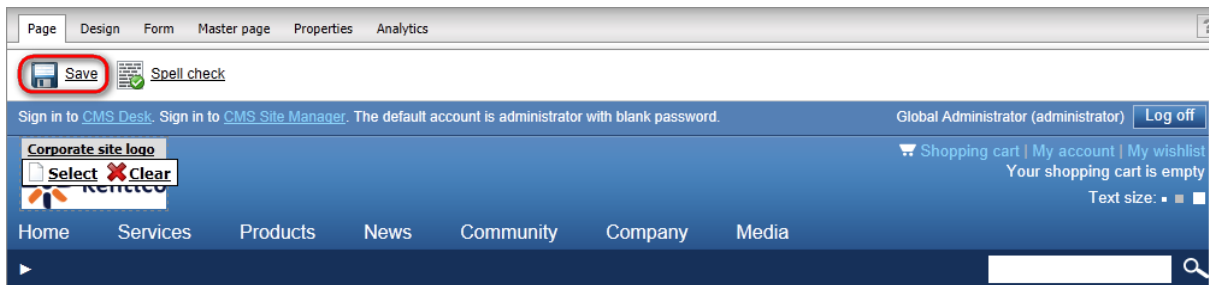

4. Find an image you want to upload and click **Open**.

7. The logo should be added to the Images folder. With the logo selected in the content tree, click **Select**.

8. Now click **Save**.

You've just publish a new logo on your website.

The screenshot shows the homepage of a sample Corporate Site created with Kentico CMS. The top navigation bar includes links for Home, Services, Products, News, Community, Company, and Media. A search bar is located on the right. The main content area features a large banner with the text "Discover Unlimited Website Possibilities!" and a "Learn more" button. Below the banner, there are three columns: a Newsletter sign-up form, a "Welcome to the sample Corporate Site" message with default user name and password information, and a "Latest news" section with a headline "Company Growth Exceeds Expectations".

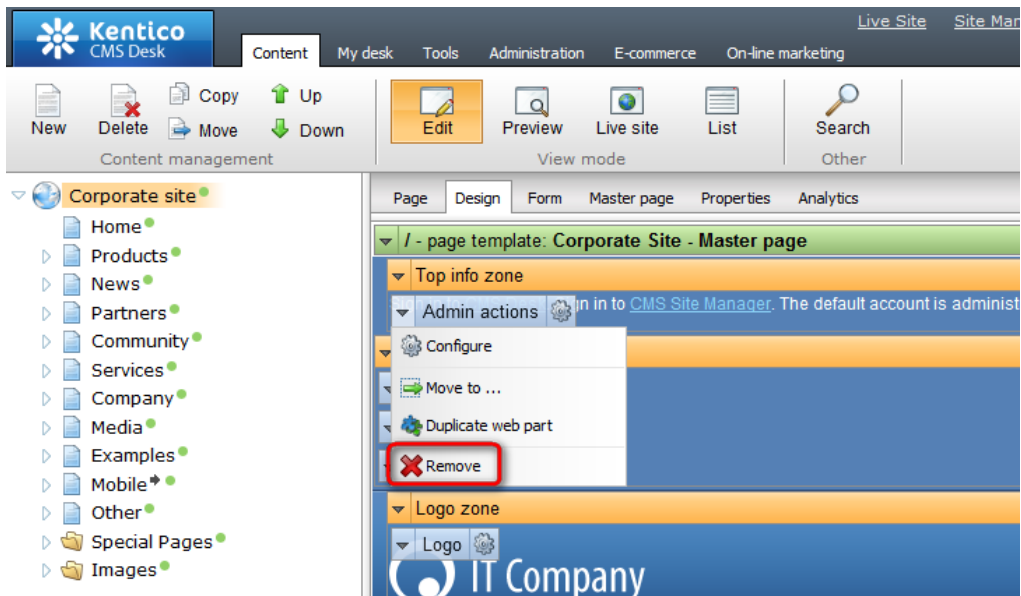

7.20.2 Removing the log-on bar

This topic demonstrates how to remove the links used to log in to the administration interface, which are displayed at the top of the sample Corporate Site by default:

1. Go to **CMS Desk -> Content** and select the root of the content tree (**Corporate Site**).

The screenshot shows the Kentico CMS administration interface. The top navigation bar includes links for My desk, Tools, Administration, E-commerce, and On-line marketing. The "Content" tab is selected. The left sidebar shows the content tree with "Corporate site" selected. The main content area displays the "Corporate site" configuration page, including a "Save" button, a "Spell check" button, and a "Log off" button. The "Admin actions" web part in the "Top info zone" is visible, and the "Remove" option is highlighted.

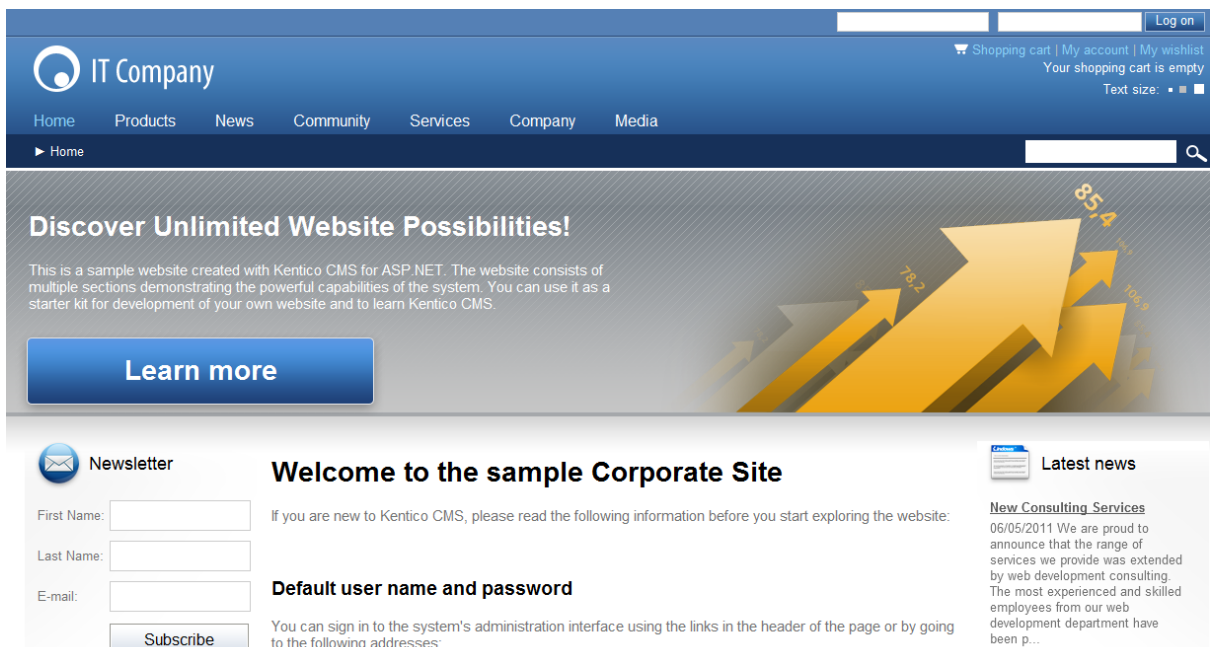

2. Switch to the **Design** tab, right click the **Admin actions** web part in the **Top info zone** and choose the **Remove** option.

3. Click **OK** to remove the links from your website.

If you view the live site, the page will be displayed without the CMS Desk and Site Manager login links.

7.20.3 Changing the CMS Desk and Site Manager logo

The entire design of the administration interface is fully customizable, so it is also possible to change the brand-related logos.

To replace the header logos shown on the top left of CMS Desk or Site Manager, open the **App_ThemesDefault\Images** folder in your Kentico CMS project's directory. The default image files are located inside the *Images.zip* archive, specifically the *Design\Branding* subfolder. To override them, manually create the **Design\Branding** folders outside of the archive directly in the **Images** directory and then add the replacement files containing your own logos into this location. The names of the files must match the names of the default logos in the archive.

The logon page also contains several images that you may wish to replace. This can be done using the same approach as for the header logos, but in this case the folder path that must be created for the replacement files is **Others\LogonForm**. You can check the names of the original files in the corresponding directory inside the *Images.zip* archive.

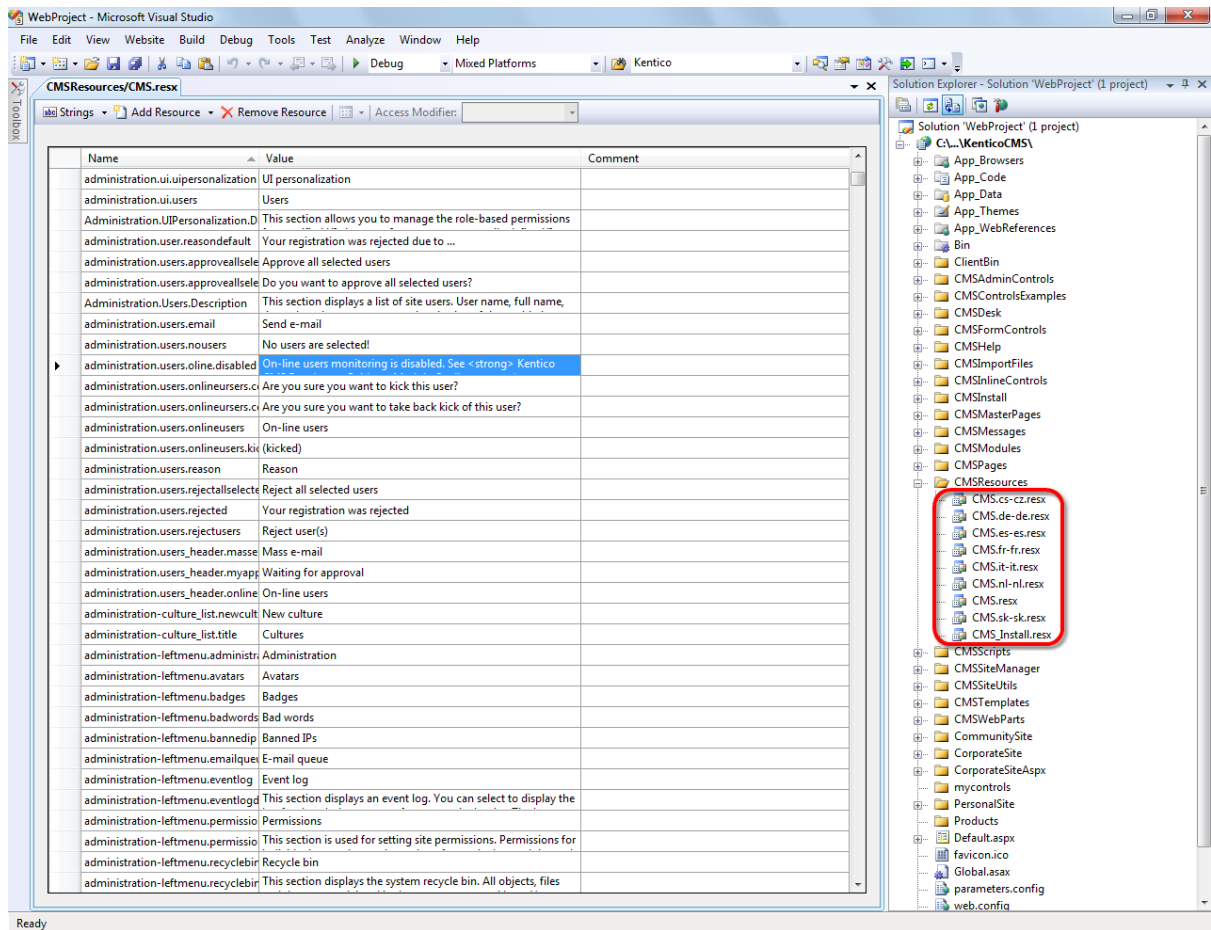

Please note

If you wish to use different image file names or file system paths, you can customize the default stylesheets of the user interface.

These can be found and edited in the project directory, specifically under the **App_ThemesDefault** folder.

7.20.4 Renaming resource strings

While re-branding Kentico CMS, you might need to check all the resource strings in the **.resx** files stored in the **~/CMSResources** folder and replace occurrences of the word **Kentico** with your own brand.

7.21 REST service

7.21.1 Overview

REST is an abbreviation of **Representational state transfer**, which is a style of software architecture designed for distributed systems, typically for the World Wide Web. Kentico CMS has a built-in REST service, which can be used to read, create, update and delete virtually any object or document within the system. These operations are performed by requesting specific URLs. The Kentico CMS REST service can be referred to as RESTful, which means that it supports both directions of data transfer (from and into the system).

To enable the service, certain [Prerequisites](#) need to be met on the machine where the Kentico CMS instance is installed. Once the prerequisites are met, proceed to the [Configuration for REST](#) topic, which describes the required configuration for specific Kentico CMS instances.

Once all the configuration is performed, the REST service should be functional. At this point, you can proceed to the [Data retrieval methods](#) and [Data manipulation methods](#) topics to learn how to work with documents and objects using the REST service. In the [URL parameters](#) topic, you can learn about querystring parameters that can be used to filter data retrieved by GET requests. In the [Retrieved data examples](#) topic, you can find examples of data retrieved from Kentico CMS via the REST service in various formats.

The REST service also supports ODATA browsing by providing service documents with information about data that can be obtained by the service. More information on this can be found in the [ODATA service documents](#) topic.

The Kentico CMS REST service comes with the **Grid for REST service** web part, which can be used to display data obtained from the service in a simple grid. On the sample **Corporate Site**, you can find an example of this web part on the [/Examples/API/REST-service](#) page.

7.21.2 Prerequisites

In order for the Kentico CMS REST service to be functional, you must ensure the following:

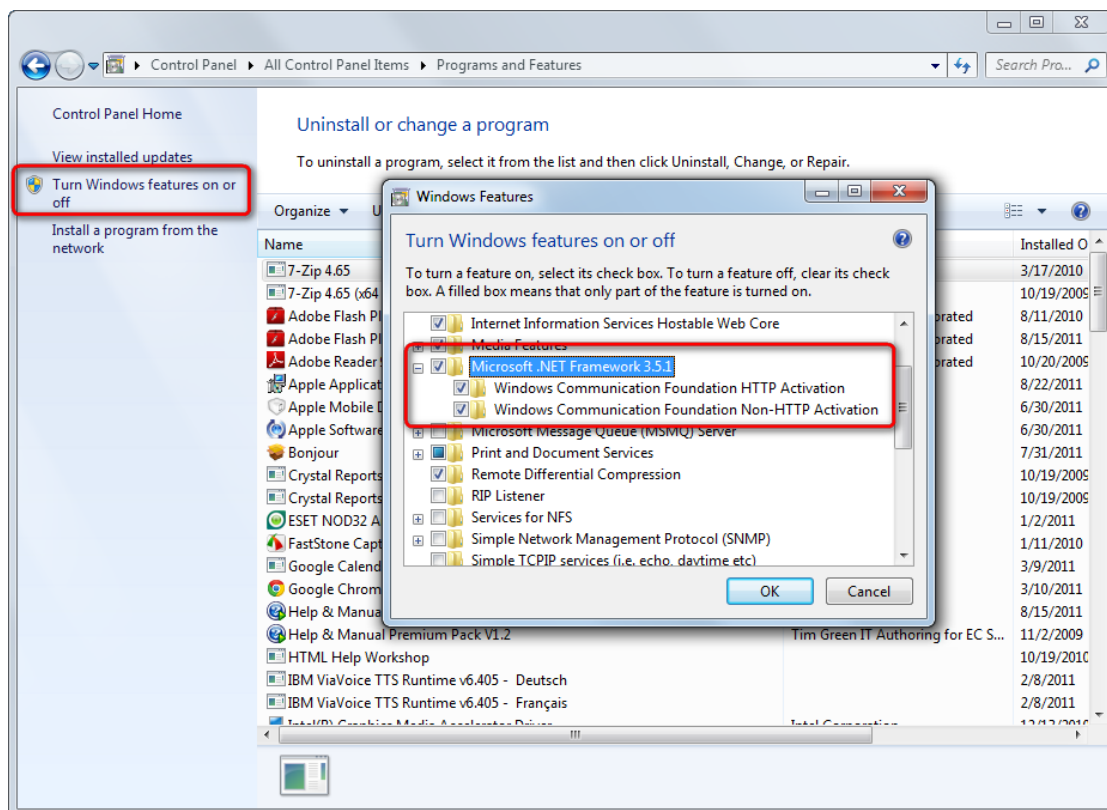

In Windows

Go to **Control Panel -> Programs and Features** and click **Turn Windows features on or off** in the left menu.

Windows 7 / Windows Server 2008

1. Expand the **Microsoft .NET Framework <version>** node in the dialog window.
2. Make sure that both of the following features are installed:

- **Windows Communication Foundation HTTP Activation**
- **Windows Communication Foundation Non-HTTP Activation**

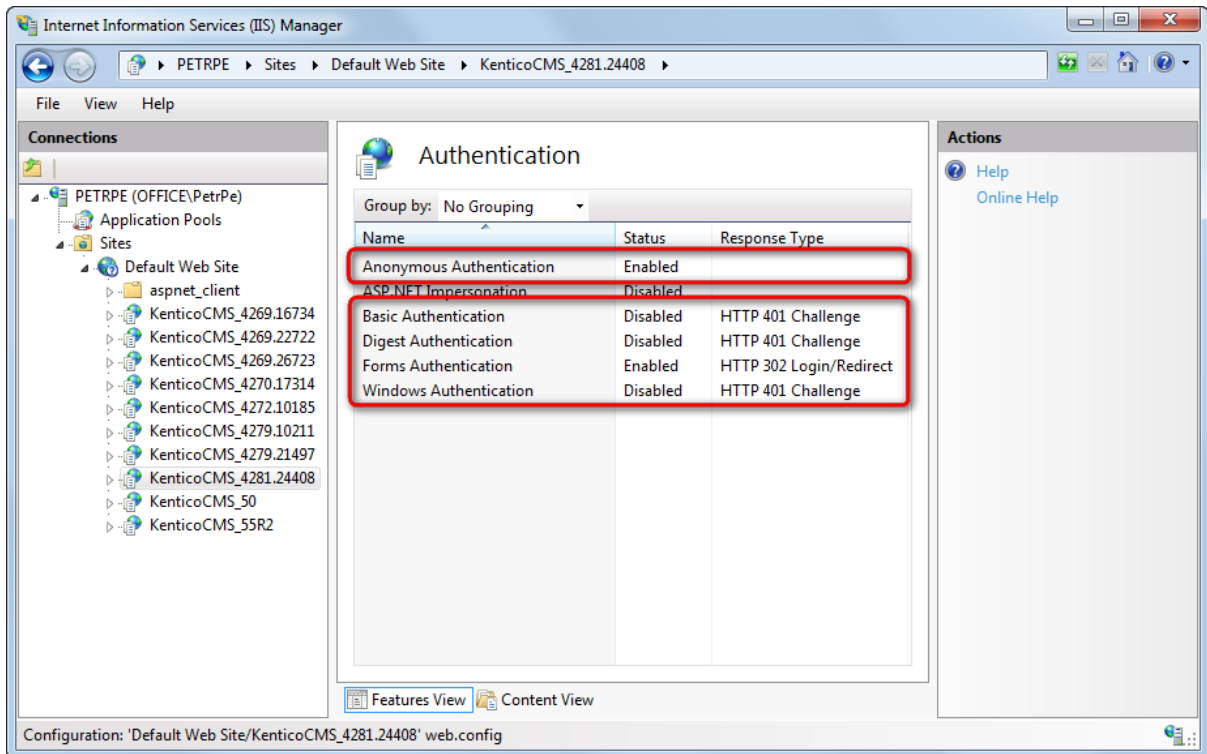

Windows 8 / Windows Server 2012

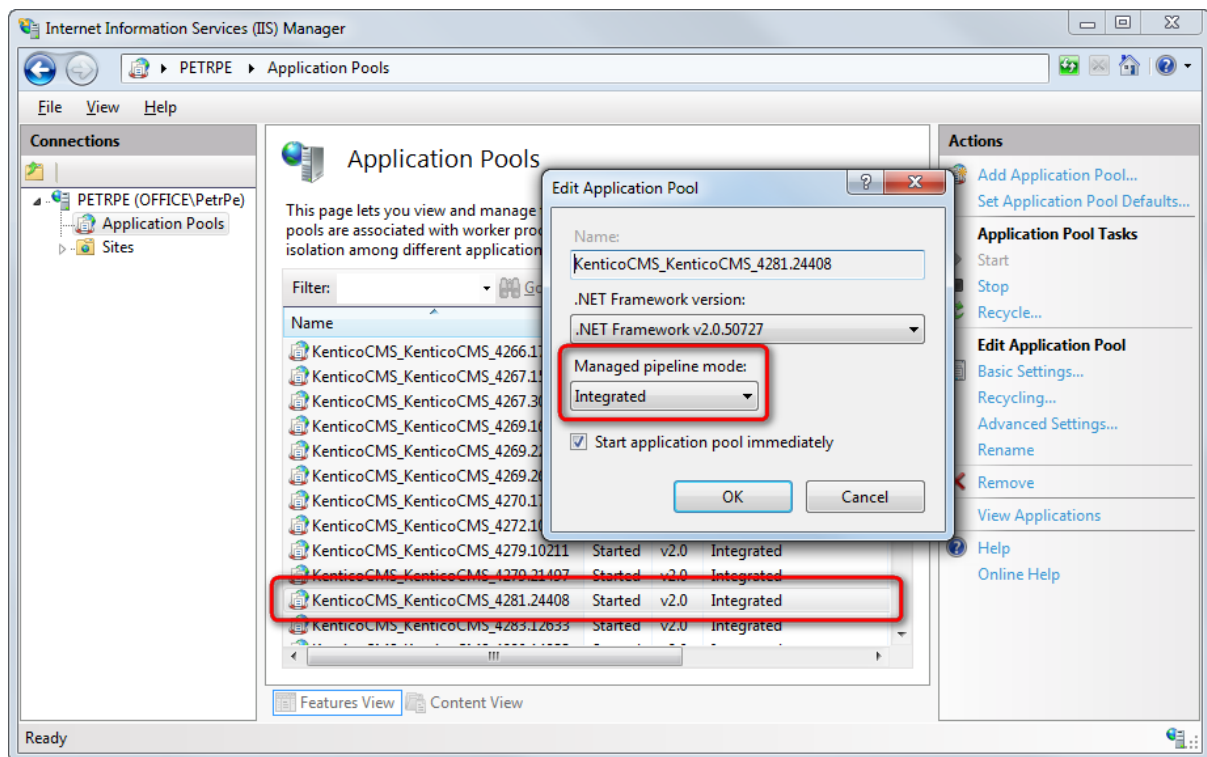

1. Expand the **.NET Framework 4.5 Advanced Services** node.
2. Make sure that the **WCF Services -> HTTP Activation** feature is installed.

In IIS Manager

1. Select the website for which you want REST to be enabled.
2. Open the **Authentication** configuration.
3. Ensure that either **Anonymous**, **Basic** or **Forms** authentication is enabled. No other authentication types are supported.
4. Disable all other types of authentication.

5. Select **Application Pools** in the navigation tree.
6. Double-click the application pool used by your website.
7. Make sure the pool uses **Integrated** Managed pipeline mode.

Once you have these prerequisites met, you can proceed to the [Configuration for REST](#) topic.

7.21.3 Configuration for REST

Once you meet the [pre-requisites](#) for using the REST service, you need to make additional settings on the level of the Kentico CMS instance:

1. Edit your application's **web.config** file, find the **system.webServer** section directly under the root (i.e. not under a specific `<location>` element) and add the following attribute to the **<modules>** element:

```
<modules runAllManagedModulesForAllRequests="true">
```

2. Go to **Site Manager -> Settings -> Integration -> REST** and adjust related settings.

The following settings are available:

| | |
|---------------------|--|
| Service enabled | Enables or disables the Kentico CMS REST service. |
| Service enabled for | Choose if the REST service allows access to objects, documents, or both. |
| Authentication type | Determines which type of authentication the REST service uses. Supported types are Basic and Forms authentication.

Note: You can authenticate REST requests using the hash query string parameter in both modes. |

| | |
|--------------------------------------|--|
| Always check document security | If disabled, security is not checked when accessing published versions of documents. If enabled, security is always checked. |
| Document access is read only | If enabled, the REST service only allows GET requests for documents (documents cannot be modified). |
| Object access is read only | If enabled, the REST service only allows GET requests for objects (objects cannot be modified). |
| Allowed document types | Specifies a list of document types that the REST service is allowed to access. Enter the names of document types separated by semicolons.

If empty, all document types are allowed. |
| Allowed object types | Specifies a list of objects types that the REST service is allowed to access. If empty, all object types are allowed. |
| Generate authentication hash for URL | <p>Click the link to generate an authentication hash for specific REST URLs.</p> <p>Enter the full absolute URL of the REST request, including the protocol, website domain name, virtual directory, REST path, and query string parameters. For example:</p> <pre><i>http://mywebsite.com/rest/content/currentsite/en-us/all/news?format=json</i></pre> <p>The system adds the authentication hash parameter to the URL. You can copy the URL and use it to perform the REST request without any other type of authentication.</p> <p>Restrictions:</p> <ul style="list-style-type: none"> • Only works for GET requests (read only data retrieval) • You cannot use hash parameter authentication for <i>/all</i> object retrieval requests (<i>~/rest/<objecttype>/all</i>). |
| Default encoding | Sets the character encoding that the REST service uses for requests that do not contain a supported <i>Accept-Charset</i> header. |

Additional configuration for large-size data upload

If you are planning to upload large-size data into Kentico CMS through the REST service, it is necessary to specify the required data size limit in the application's *web.config* file. This can be done by adding the following pieces of code into the `<system.serviceModel>` section at the end of the *web.config* file:

1. Insert a `<webHttpBinding>` element into the `<bindings>` sub-section as shown below:

```
<webHttpBinding>
  <!-- Limits set to 10 MB (specified value in bytes) -->
  <binding name="RESTQuotaBinding" maxReceivedMessageSize="10485760"
maxBufferSize="10485760" maxBufferPoolSize="10485760" closeTimeout="00:03:00"
openTimeout="00:03:00" receiveTimeout="00:10:00" sendTimeout="00:03:00">
  <readerQuotas maxDepth="32" maxStringContentLength="10485760"
maxArrayLength="10485760" maxBytesPerRead="10485760" />
  <security mode="None" />
</binding>
</webHttpBinding>
```

Please note that this sample sets all limits to 10 MB. You may need to enter different values according to your specific needs.

2. Then add a `<service>` element under the `<services>` sub-section according to the following:

```
<service name="CMS.WebServices.RESTService">
  <host>
    <baseAddresses>
      <add baseAddress="http://localhost/KenticoCMS/rest" />
    </baseAddresses>
  </host>
  <endpoint address="" bindingConfiguration="RESTQuotaBinding"
binding="webHttpBinding" contract="CMS.WebServices.IRESTService" />
</service>
```

```
</service>
```

The *baseAddress* in the code above only contains a sample value and needs to be replaced with the actual root address of the REST service (depending on your website's domain name).

7.21.4 Authenticating REST requests

Every REST request needs to be authenticated. You can select the **Authentication type** of the REST service in **Site Manager -> Settings -> Integration -> REST**.

Basic authentication

With Basic authentication, you need to specify the username and password through the **Authorization** line in the header of every REST request. The header line consists of:

The authentication type (*Basic*)

The username and password connected by a colon (***username:password***), encoded using the Base64 algorithm

For example:

```
Authorization: Basic UmVzdENsaWVudDpzZWNYZXQ=
```

Note: We strongly recommend using [SSL](#) to protect the authentication credentials in the request headers. See also: [SSL \(HTTPS\) support](#)

Forms authentication

When using [forms authentication](#) of requests, the system identifies users based on the active session and the authentication ticket stored in the .ASPXFORMSAUTH cookie. You can use forms authentication to create a web interface with a login page, and allow users to send REST requests through their browser.

Forms authentication can pose a security threat, because logged in users may unknowingly click links that send malicious REST requests to your site. To protect yourself from such attacks, take the following steps:

1. Immediately after creating the session (i.e. first authentication), you need to set up an **authentication token** by sending a POST request to the following URL:

```
http://<your project URL>/rest/settoken?username=<your user name>&password=<your password>&token=<your authentication token>
```

The authentication token can be an arbitrary string of characters, for example a GUID.

2. Include the authentication token in the HTTP header of every REST request:

```
Cms-Session-Token: <your authentication token>
```

Hash parameter authentication

You can authenticate individual REST requests by adding a hash parameter to the URL. The hash parameter allows you to prepare REST requests that can be executed by unauthenticated users. Requests that contain the hash parameter ignore the other types of authentication — the value of the **Authentication type** setting does not affect hash authentication.

Restrictions:

- Only works for GET requests (read only data retrieval)
- You cannot use hash parameter authentication for *all* [object retrieval requests](#) (*~/rest/<objecttype>/all*). This is an intentional security limitation that protects global data in the system.

Warning

Only use hash parameter authentication for loading data that you want to make publicly available. REST requests with hash authentication can be executed by anyone who obtains the URL (for example by intercepting the web request).

To get the authentication hash for REST requests:

1. Prepare the URL of your REST request in advance.
2. Go to **Site Manager -> Settings -> Integration -> REST**.
3. Click **Generate authentication hash**.
4. Enter the full absolute URL of the REST request, including the protocol, website domain name, virtual directory, REST path, and query string parameters. For example: *http://mywebsite.com/rest/content/currentsite/en-us/all/news?format=json*
5. Click **Authenticate**.

The system adds the authentication hash parameter to the URL. You can copy the URL and use it to perform the REST request without any other type of authentication.

7.21.5 Data retrieval methods

This page contains examples of REST URLs that can be requested to retrieve document or object data from a Kentico CMS instance using the REST service.

Note: The URLs are listed as relative, so if your instance is running at *http://localhost/KenticoCMS*, perform requests listed as *~/rest* in format *http://localhost/KenticoCMS/rest*.

Document retrieval methods

Below, you can find examples of URLs under which object GET requests can be performed to retrieve document data from a Kentico CMS instance. You can also achieve a more detailed specification of retrieved data by appending querystring parameters to the URLs.

See [URL parameters](#) for more information.

- Returns a single document of the given culture on the specified site:
 - `~/rest/content/site/<sitename>/<culture>/document/<aliaspath>`, e.g. `~/rest/content/site/corporatesite/en-us/document/company/careers`
 - `~/rest/content/currentsite/<culture>/document/<aliaspath>`, e.g. `~/rest/content/currentsite/en-us/document/company/careers`
- Returns all documents which start with the specified alias path:
 - `~/rest/content/site/<sitename>/<culture>/all/<aliaspath>`, e.g. `~/rest/content/site/corporatesite/en-us/all/news`
 - `~/rest/content/currentsite/<culture>/all/<aliaspath>`, e.g. `~/rest/content/currentsite/en-us/all/news`
- Returns all child documents of the given document:
 - `~/rest/content/site/<sitename>/<culture>/childrenof/<aliaspath>`, e.g. `~/rest/content/site/corporatesite/en-us/childrenof/news`
 - `~/rest/content/currentsite/<culture>/childrenof/<aliaspath>`, e.g. `~/rest/content/currentsite/en-us/childrenof/news`

Constants for default culture and all cultures

If you want to get documents in the default culture, there is a special constant *defaultculture*, which you can use instead of the culture string. The same applies for all cultures, while the constant is *allcultures* in this case.

Object data retrieval methods

Below, you can find examples of URLs under which object GET requests can be performed to retrieve object data from a Kentico CMS instance. You can also achieve a more detailed specification of retrieved data by appending querystring parameters to the URLs.

See [URL parameters](#) for more information.

Object ID, GUID and code name

In all of the examples below, object ID, object GUID and object code name are interchangeable, i.e. you can use any of them to specify the respective object.

When using code names of site-related objects, the object with the code name assigned to the current site is always returned, unless a site is explicitly specified in

the URL.

- Exposes the service document (for ODATA browsing). The document contains a list of all available object types and URLs under which objects of the type can be accessed:
 - **~/rest**
- Returns all objects of the given object type (both site objects from all sites and global objects):
 - **~/rest/<objecttype>/all**, e.g. *~/rest/cms.emailtemplate/all*

Note

The REST service does not allow */all* object retrieval for requests that use the hash URL parameter for [authentication](#). This is an intentional security limitation that protects global data.

- Returns all objects of the given object type assigned to the current site. If there is no site binding for the given object type, it returns all objects of the given type:
 - **~/rest/<objecttype>**, e.g. *~/rest/cms.country*
 - **~/rest/<objecttype>/currentsite**, e.g. *~/rest/cms.country/currentsite*
- Returns all objects of the given object type assigned to the specified site. If there is no site binding for the given object type, it returns all objects of the given type:
 - **~/rest/<objecttype>/site/<sitecodename>**, e.g. *~/rest/cms.country/site/corporatesite*
- Returns all global objects of the given object type (which are not assigned to any site). If there is no site binding for the given object type, it returns all objects of the given type:
 - **~/rest/<objecttype>/global**, e.g. *~/rest/cms.emailtemplate/global*
- Returns all sites on which the specified object type is available to the currently authenticated user and URLs under which the objects for the particular sites can be retrieved (for ODATA browsing):
 - **~/rest/<objecttype>/site**, e.g. *~/rest/cms.country/site*
- Returns an object of the given type with the specified ID, GUID or code name:
 - **~/rest/<objecttype>/<id>**, e.g. *~/rest/cms.country/271*
- Returns an object of the given type with the specified code name assigned to the current site:
 - **~/rest/<objecttype>/<objectcodename>**, e.g. *~/rest/cms.country/usa*
 - **~/rest/<objecttype>/currentsite/<objectcodename>**, e.g. *~/rest/cms.country/currentsite/usa*

- Returns a global object of the given type with the specified name:
 - `~/rest/<objecttype>/global/<objectcodename>`, e.g. `~/rest/cms.emailtemplate/global/Blog.NotificationToModerators`
- Returns all supported child object types for the given object (only object ID can be used in this URL, not code name or GUID):
 - `~/rest/<objecttype>/<id>/children`, e.g. `~/rest/cms.country/271/children`
- Returns all child objects of the specified object and of the given object type (only object ID can be used in this URL, not code name or GUID):
 - `~/rest/<objecttype>/<id>/children/<childrenobjecttype>`, e.g. `~/rest/cms.country/271/children/cms.state`
- Returns all binding object types supported by the given object (only object ID can be used in this URL, not code name or GUID):
 - `~/rest/<objecttype>/<id>/bindings`, e.g. `~/rest/cms.user/53/bindings`
- Returns all binding objects of the given type of the specified object (only object ID can be used in this URL, not code name or GUID):
 - `~/rest/<objecttype>/<id>/bindings/<bindingobjecttype>`, e.g. `~/rest/cms.user/53/bindings/cms.usersite`
- Returns *TypeInfo* of the given object type:
 - `~/rest/typeinfo/<objecttype>`, e.g. `~/rest/typeinfo/cms.user`
- Evaluates the given [macro expression](#) (without the encapsulating character sequence and with forbidden characters URL-encoded) and serializes the result:
 - `~/rest/macro/<expression>`, e.g. `~/rest/macro/CurrentSite.SiteName`

Custom table and Form data items vs. class definition

When working with [custom tables](#) or [forms](#) via the REST service, you need to use different URLs when you want to specify the table's or form's class definition and when you want to specify the data items stored in the custom table or form.

For **class definition**, you need to use:

- `~/rest/cms.customtable/<customtablecodename>`, e.g. `~/rest/cms.customtable/customtable.sampletable`
- `~/rest/cms.form/<formcodename>`, e.g. `~/rest/cms.form/contactus`

For the actual **data items**, you need to use:

- `~/rest/customtableitem.<customtablecodename>`, e.g. `~/rest/customtableitem.customtable.sampletable`

- `~/rest/bizformitem.bizform.<formcodename>`, e.g. `~/rest/bizformitem.bizform.contactus`

GET request result encoding

Data retrieval (GET) requests return the results encoded using the default server encoding. If you want to get the result in a different encoding, you need to specify the required encoding in the **Accept-Charset** field of the HTTP GET request. If the specified encoding is not available, the default encoding specified in [REST settings](#) is used.

For example:

```
GET http://localhost/CMS/rest/cms.user/administrator HTTP/1.1
User-Agent: Fiddler
Authorization: Basic <enter Base64-encoded <username>:<password> here>
Accept-Charset: utf-8
Host: localhost
Content-Type: text\xml
```

7.21.6 Data manipulation methods

In this topic, you can find examples of REST requests that can be used to manipulate document or object data in a Kentico CMS instance using the REST service. The URLs in this topic are listed as relative, so e.g. if your instance is running at `http://localhost/KenticoCMS`, you would perform a request listed as `~/rest` in format `http://localhost/KenticoCMS/rest`.

Validation of inserted or updated data

Please note that when inserting or updating object data via the REST service, no validation is performed on the side of Kentico CMS. You therefore need to ensure appropriate validation on the side of your application to prevent unwanted behavior.

Document manipulation methods

The following URLs can be requested by the respective type of request in order to manipulate Kentico CMS documents. You can update, delete and insert documents (respectively) using these Http methods. Both XML and JSON formats are supported when performing these requests.

Http POST method

- Creates new document in the given culture, website and alias path location:
 - `~/rest/content/site/<sitename>/<culture>/document/<aliaspath>`, e.g. `~/rest/content/site/corporatesite/en-us/document/news`
 - `~/rest/content/currentsite/<culture>/document/<aliaspath>`, e.g. `~/rest/content/currentsite/en-us/document/news`

Http PUT method

- Updates the specified document:
 - **~/rest/content/site/<siteName>/<culture>/document/<aliaspath>**, e.g. *~/rest/content/site/corporatesite/en-us/document/news*
 - **~/rest/content/currentsite/<culture>/document/<aliaspath>**, e.g. *~/rest/content/currentsite/en-us/document/news*
- Publishes the specified document:
 - **~/rest/content/site/<siteName>/<culture>/publish/<aliaspath>**, e.g. *~/rest/content/site/corporatesite/en-us/publish/news/mynewsitem*
 - **~/rest/content/currentsite/<culture>/publish/<aliaspath>**, e.g. *~/rest/content/currentsite/en-us/publish/news/mynewsitem*
- Performs check-out of the specified document:
 - **~/rest/content/site/<siteName>/<culture>/checkout/<aliaspath>**, e.g. *~/rest/content/site/corporatesite/en-us/check out/news/mynewsitem*
 - **~/rest/content/currentsite/<culture>/checkout/<aliaspath>**, e.g. *~/rest/content/currentsite/en-us/check out/news/mynewsitem*
- Performs check-in of the specified document:
 - **~/rest/content/site/<siteName>/<culture>/checkin/<aliaspath>**, e.g. *~/rest/content/site/corporatesite/en-us/check in/news/mynewsitem*
 - **~/rest/content/currentsite/<culture>/checkin/<aliaspath>**, e.g. *~/rest/content/currentsite/en-us/check in/news/mynewsitem*
- Archives the specified document:
 - **~/rest/content/site/<siteName>/<culture>/archive/<aliaspath>**, e.g. *~/rest/content/site/corporatesite/en-us/archive/news/mynewsitem*
 - **~/rest/content/currentsite/<culture>/archive/<aliaspath>**, e.g. *~/rest/content/currentsite/en-us/archive/news/mynewsitem*
- Moves the specified document to the next workflow step:
 - **~/rest/content/site/<siteName>/<culture>/movetoneststep/<aliaspath>**, e.g. *~/rest/content/site/corporatesite/en-us/movetoneststep/news/mynewsitem*
 - **~/rest/content/currentsite/<culture>/movetoneststep/<aliaspath>**, e.g. *~/rest/content/currentsite/en-us/movetoneststep/news/mynewsitem*
- Moves the specified document to the previous workflow step:
 - **~/rest/content/site/<siteName>/<culture>/movetopreviousstep/<aliaspath>**, e.g. *~/rest/content/site/corporatesite/en-us/movetopreviousstep/news/mynewsitem*
 - **~/rest/content/currentsite/<culture>/movetopreviousstep/<aliaspath>**, e.g. *~/rest/content/*

currentsite/en-us/movetopreviousstep/news/mynewsitem

Http DELETE method

- Deletes the specified document:
 - `~/rest/content/site/<sitename>/<culture>/document/<aliaspath>`, e.g. `~/rest/content/site/corporatesite/en-us/document/news`
 - `~/rest/content/currentsite/<culture>/document/<aliaspath>`, e.g. `~/rest/content/currentsite/en-us/document/news`

Please note

If you specify a *NodeID* and a *DocumentID* is not specified, the operation is considered as new culture version creation. If you want to create a linked document, you have to specify a *NodeLinkedNodeID* in the request.

Examples of document manipulation requests

Below, you can find examples of document manipulation requests. For testing purposes, you can use [Fiddler](#) to send the requests to your web application and see the results.

The following example creates a sample document in the content tree.

```
POST http://localhost/CMS/rest/content/site/CorporateSite/en-us/document/Home
HTTP/1.1
User-Agent: Fiddler
Authorization: Basic <enter Base64-encoded <username>:<password> here>
Host: localhost
Content-Type: text\xml
Content-Length:165

<CMS_MenuItem>
  <NodeClassID><enter class ID here></NodeClassID>
  <DocumentName>Services</DocumentName>
  <DocumentPageTemplateID><enter template ID here></DocumentPageTemplateID>
</CMS_MenuItem>
```

The following example updates the sample document created by the example above.

```
PUT http://localhost/CMS/rest/content/site/CorporateSite/en-us/document/Home/
Services HTTP/1.1
User-Agent: Fiddler
Authorization: Basic <enter Base64-encoded <username>:<password> here>
Host: localhost
Content-Type: text\xml
```

```
Content-Length:81

<CMS_MenuItem>
  <DocumentName>Services MODIFIED</DocumentName>
</CMS_MenuItem>
```

The following example creates a new language version of the document created by the first example in this section.

```
POST http://localhost/CMS/rest/content/site/CorporateSite/cs-cz/document/Home/
Services HTTP/1.1
User-Agent: Fiddler
Authorization: Basic <enter Base64-encoded <username>:<password> here>
Host: localhost
Content-Type: text/xml
Content-Length:103

<CMS_MenuItem>
  <NodeID>51939</NodeID>
  <DocumentName>Services CZ</DocumentName>
</CMS_MenuItem>
```

Object data manipulation methods

The following URLs can be requested by the respective type of request in order to manipulate Kentico CMS objects. You can update, delete and insert objects (respectively) using these Http methods. Both XML and JSON formats are supported when performing these requests.

HTTP POST method URLs

Creates a new object of the specified type.

- `~/rest/<objectType>`, e.g. `~/rest/cms.user`

Creates a new object of the specified type and assigns it to the current website.

- `~/rest/<objectType>/currentsite`, e.g. `~/rest/cms.user/currentsite`

Creates a new object of the specified type and assigns it to the specified website.

- `~/rest/<objectType>/site/<sitename>`, e.g. `~/rest/cms.user/site/corporatesite`

HTTP PUT method

Updates the object of the specified type with the specified ID.

- `~/rest/<objectType>/<id>`, e.g. `~/rest/cms.user/53`

Updates the object of the specified type with the specified code name and assigns it to the specified site.

- `~/rest/<objectType>/site/<sitename>/<objectcodename>`, e.g. `~/rest/cms.user/site/`

corporatesite/administrator

Updates the object of the specified type with the specified code name and assigns it to the current website.

- `~/rest/<objectType>/<currentsite>/<objectcodename>`, e.g. `~/rest/cms.user/currentsite/administrator`

Updates the global object of the specified type with the specified code name.

- `~/rest/<objectType>/global/<objectcodename>`, e.g. `~/rest/cms.user/global/administrator`

HTTP DELETE method

Deletes the object of the specified type with the specified ID.

- `~/rest/<objectType>/<id>`, e.g. `~/rest/cms.user/53`

Deletes the object of the specified type with the specified code name assigned to the specified website.

- `~/rest/<objectType>/site/<sitename>/<objectcodename>`, e.g. `~/rest/cms.user/site/corporatesite/administrator`

Deletes the object of the specified type with the specified code name assigned to the current website.

- `~/rest/<objectType>/<currentsite>/<objectcodename>`, e.g. `~/rest/cms.user/currentsite/administrator`

Deletes the global object of the specified type with the specified code name.

- `~/rest/<objectType>/global/<objectcodename>`, e.g. `~/rest/cms.user/global/administrator`

Examples of object manipulation requests

Below, you can find examples of object data manipulation requests. For testing purposes, you can use e.g. [Fiddler](#) to send the requests to your web application and see the results in the UI.

The following request creates a sample *cms.country* object based on the provided XML definition.

```
POST http://localhost/CMS/rest/cms.country HTTP/1.1
User-Agent: Fiddler
Authorization: Basic <enter Base64-encoded <username>:<password> here>
Host: localhost
Content-Type: text/xml
Content-Length: 271

<data><cms_country><CountryDisplayName>Test Country REST</CountryDisplayName><CountryName>TestCountryREST</CountryName></cms_country><CMS_State><StateDisplayName>Test State 1</StateDisplayName><StateName>TestState1</StateName><StateCode>TST</StateCode></CMS_State></data>
```

The following example updates the sample *cms.country* object created by the example above based on the provided XML data.

```
PUT http://localhost/CMS/rest/cms.country/TestCountryREST HTTP/1.1
User-Agent: Fiddler
Authorization: Basic <enter Base64-encoded <username>:<password> here>
Host: localhost
Content-Type: text/xml
Content-Length: 102

<data><cms_country><CountryDisplayName>Test Country MODIFIED</
CountryDisplayName></cms_country></data>
```

The following request creates a sample *cms.country* object based on the provided JSON definition.

```
POST http://localhost/CMS/rest/cms.country?format=json HTTP/1.1
User-Agent: Fiddler
Authorization: Basic <enter Base64-encoded <username>:<password> here>
Host: localhost
Content-Type: application/json
Content-Length:161

{ "CountryDisplayName": "Test JSON", "CountryName": "TestJSON", "cms.state":
[ { "StateCode": "TST", "StateName": "TestStateJSON", "StateDisplayName": "Test State
JSON" } ] }
```

The following example updates the sample *cms.country* object created by the example above based on the provided JSON data.

```
PUT http://localhost/CMS/rest/cms.country/TestJSON HTTP/1.1
User-Agent: Fiddler
Authorization: Basic <enter Base64-encoded <username>:<password> here>
Host: localhost
Content-Type: application/json
Content-Length:45

{ "CountryDisplayName": "Test JSON MODIFIED" }
```

The following example deletes the sample *cms.country* object created by either of the examples above.

```
DELETE http://localhost/CMS/rest/cms.country/TestCountryREST HTTP/1.1
User-Agent: Fiddler
Authorization: Basic <enter Base64-encoded <username>:<password> here>
Host: localhost
```

Null value macro

In case that you need to specify an empty value in a data manipulation request, you can use the **##null##** macro instead of an actual value. This is particularly useful for non-string fields (e.g. typically

foreign keys) where an empty string value would not produce the desired results.

The following example updates the **Home** page of the sample Corporate Site and ensures that it will not have any user specified in the **Document created by** field.

```
PUT http://localhost/CMS/rest/content/currentsite/en-us/document/home HTTP/1.1
User-Agent: Fiddler
Authorization: Basic <enter Base64-encoded <username>:<password> here>
Host: localhost
Content-Type: text/xml
Content-Length: 271

<CMS_File><DocumentCreatedByUserID>##null##</DocumentCreatedByUserID></CMS_File>
```

7.21.7 URL parameters

This topic contains a list of querystring parameters supported by the REST service. You can append these parameters to the request URLs in order to further specify the behavior of the methods. The information in the parentheses explains the expected data type of the parameter along with its default value (in **bold font**).

General parameters

- **Format** (json/atom10/rss20/xml)
Sets the format of the request data. If specified for PUT/POST requests, this parameter has higher priority than the *Content-Type* parameter in the request header. For example, append *?format=json* to the request URL to use the JSON format.
- **Localize** (string) [**Only available after applying [hotfix 7.0.4 or newer](#)**]
If added to a data retrieval request, the system resolves all [localization expressions](#) inside the returned data. Specify the target language by entering the corresponding *culture code* into the parameter's value. Without this parameter, requests always return localization expressions in unresolved format. The *Localize* parameter is supported by both object and document retrieval requests.

For example, append *?localize=fr-fr* to the request URL to resolve all localization expressions into their French value (or the value in the default [UI culture](#) if the expression is not defined in French).

- **Hash** (string)
Allows you to [authenticate](#) the request without requiring an authentication header or Forms authentication. To generate a valid hash for a request:
 - Go to **Site Manager -> Settings -> Integration -> REST**.
 - Click **Generate authentication hash**.
 - Enter the full absolute URL of the REST request, including the protocol, website domain name, virtual directory, [REST path](#), and query string parameters.
 - Click **Authenticate**.

The system adds the authentication hash parameter to the URL. You can copy the URL and use it to perform the REST request without any other type of authentication.

Object retrieval parameters

You can add the following parameters to object retrieval requests:

- **ObjectData** (true/false)
Indicates whether the request retrieves object data. To load only the metadata of an object, append ? *objectdata=false&metadata=true* to the request URL.
- **MetaData** (true/false)
Determines if the request retrieves the metadata of the object (type, list of properties / columns). To load the metadata, append ? *metadata=true* to the request URL.
- **Binary** (true/false)
Indicates whether the request retrieves binary data (e.g. the data of files uploaded into form fields). Binary data is retrieved in *Base64* format. To include the binary data in the response, append ? *binary=true* to the request URL.
- **Children** (true/false)
Indicates whether to include child objects in the result. To load child objects, append ? *children=true* to the request URL.
- **MaxRelativeLevel** (int, -1 = all levels)
If the *Children* parameter is true, this parameter sets the maximum depth of the exported object tree structure. For example, to load all child objects down to the second level of the object tree, append ? *children=true&maxrelativelevel=2* to the request URL.
- **Bindings** (true/false)
Determines if the retrieved data includes bindings to child objects and sites. Requests only return bindings if the *ObjectData* parameter is true. To load object data with its bindings, append ? *bindings=true* to the request URL.
- **OtherBindings** (true/false)
Determines if the retrieved data includes bindings to other objects (M:N relationships). Requests only return bindings if the *ObjectData* parameter is true. To load object data with bindings to other objects, append ? *otherbindings=true* to the request URL.
- **Metafiles** (true/false)
Determines if the retrieved data includes metafiles attached to the object. To load metafiles, append ? *metafiles=true* to the request URL.
- **Relationships** (true/false)
Determines if the retrieved data includes object relationships. To load relationships, append ? *relationships=true* to the request URL.
- **Categories** (true/false)
Determines if the retrieved data includes the object's category structure (if the object belongs to a category). To load the category structure, append ? *categories=true* to the request URL.
- **Translations** (true/false)
Indicates whether to include a translation table of foreign keys in the result. To load the translation table, append ? *translations=true* to the request URL.

- **Hierarchy** (true/false)

If true, the response data is exported in a hierarchical structure (if false, the children – bindings – parent structure is flat). To export the data in a hierarchical structure, append `?hierarchy=true` to the request URL.

Multiple object retrieval parameters

When retrieving a dataset containing multiple objects, the following parameters allow you to filter the items and change their order:

- **Where** (string, **empty by default**)

SQL WHERE condition for filtering of the dataset. To filter retrieved data using a WHERE condition, append `?where=<text of the condition>` to the request URL.

For example: `~/rest/cms.user?Where=UserIsEditor=1`

- **OrderBy** (string, **empty by default**)

SQL ORDER BY clause for modifying the order of the items in the dataset. Append `?orderby=##default##` to use alphabetical order based on the object display name.

- **Columns** (string, **all columns by default**)

Limits which data columns of the object are retrieved by the request. For example, to load only the `UserName` and `UserID` columns when retrieving users, append `?columns=UserName,UserID` to the request URL. If you add this parameter, the `Binary` parameter is ignored (you can choose whether to include binary columns by enumerating the corresponding columns).

- **TopN** (int, **all records by default**)

SQL TOP N clause for filtering of the dataset. For example, to load only the first 10 retrieved records, append `?topn=10` to the request URL.

- **Offset** (int, **first record by default**)

Sets the number of the first record that the request returns (according to the order of the dataset). This parameter allows you to implement paging of the data. For example, to load data starting from the third item in the dataset, append `?offset=2` to the request URL.

- **MaxRecords** (int, **all record by default**)

Limits the maximum number of retrieved records. You can use this parameter in combination with the `Offset` parameter to load pages containing a specific range of records. For example, to load items 11–20 from the dataset, append `?offset=10&maxrecords=10` to the request URL.

Document retrieval parameters

The following parameters are supported for requests that retrieve document data. You may also use the filtering and ordering parameters listed in the *Multiple object retrieval parameters* section.

- **ClassNames** (string, **all classnames**)

Limits which document types the request returns. Specified as a list of document type code names separated by semicolons. For example, to retrieve only `cms.article` documents, append `?classnames=cms.article` to the request URL.

- **CombineWithDefaultCulture** (true/false)

Indicates if the request should load the default language versions of documents if they do not exist in the specified culture. To load the language culture versions of documents, append `?`

combinewithdefaultculture=true to the request URL.

- **SelectOnlyPublished (true/false)**
Determines if the request loads only documents that are published on the live site. To also retrieve unpublished documents, append *?selectonlypublished=false* to the request URL.
- **Version (published/last)**
Determines if the request returns the document versions that are published on the live site or the latest version that is being edited in CMS Desk (when using [Workflow](#)). To load the latest document versions, append *?version=last* to the request URL.
- **CoupledData (true/false)**
Determines if the request retrieves the data stored in the fields of specific document types (coupled data). To load documents without coupled data, append *?coupleddata=false* to the request URL.

Document deletion parameters

- **DeleteAllCultures (true/false)**
Indicates if the request also deletes all cultural versions of the specified document. To delete all culture versions of a document, append *?deleteallcultures=true* to the request URL.
- **DestroyHistory (true/false)**
Indicates if the request also deletes the document's version history. To delete the version history together with the document, append *?destroyhistory=true* to the request URL.
- **DeleteProduct (true/false)**
Indicates if the request also deletes the e-commerce product associated with the specified product document. To delete e-commerce products along with documents, append *?deleteproduct=true* to the request URL.

7.21.8 Retrieved data examples

In this topic, you can see examples of the same data (all *cms.country* objects) obtained from the REST service in various formats.

XML

In the screenshot below, you can see data of all *cms.country* objects retrieved in [XML](#) format and displayed in Microsoft Internet Explorer. This result was obtained using the following URL: **`~/rest/cms.country`**

```

<?xml version="1.0"?>
- <cms_countries>
  - <cms_country>
    <CountryID>272</CountryID>
    <CountryDisplayName>Afghanistan</CountryDisplayName>
    <CountryName>Afghanistan</CountryName>
    <CountryGUID>12d61676-7541-4a4e-88f6-f02098b637fe</CountryGUID>
    <CountryLastModified>2011-03-06T14:56:42+01:00</CountryLastModified>
  </cms_country>
  - <cms_country>
    <CountryID>273</CountryID>
    <CountryDisplayName>Albania</CountryDisplayName>
    <CountryName>Albania</CountryName>
