RSS 2.0

In the screenshot below, you can see all *cms.country* objects retrieved in [RSS 2.0](#) format and displayed in Microsoft Internet Explorer. This result was obtained using the following URL: `~/rest/cms.country?format=rss20`

Atom 1.0

In the screenshot below, you can see all *cms.country* objects retrieved in [Atom 1.0](#) format and displayed in Microsoft Internet Explorer. This result was obtained using the following URL: `~/rest/cms.country?format=atom10`

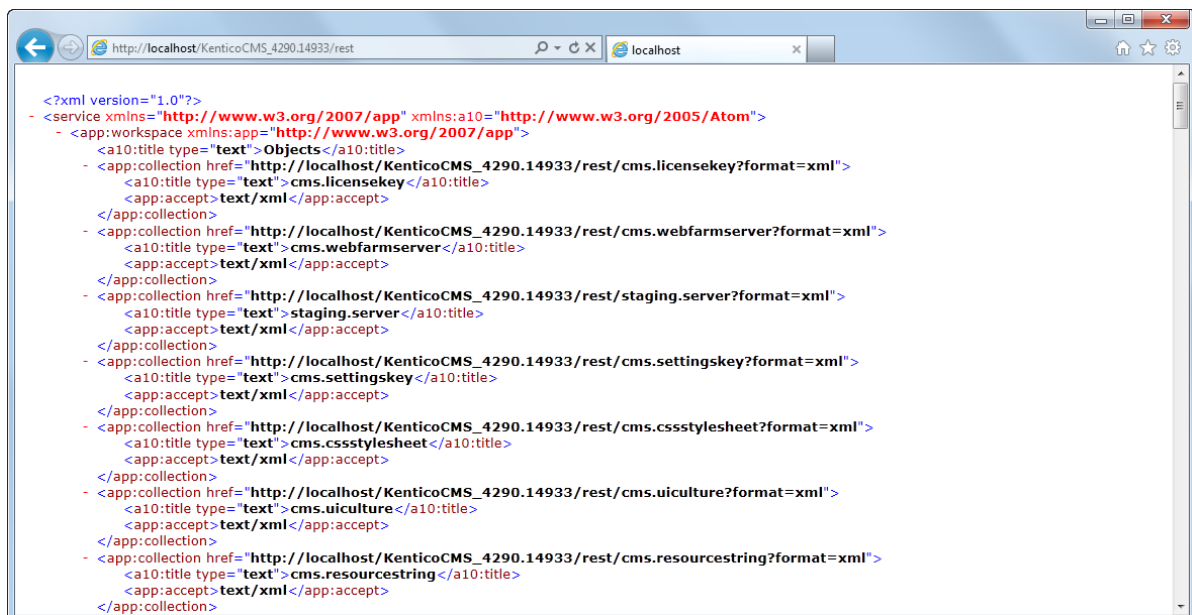

7.21.9 ODATA service documents

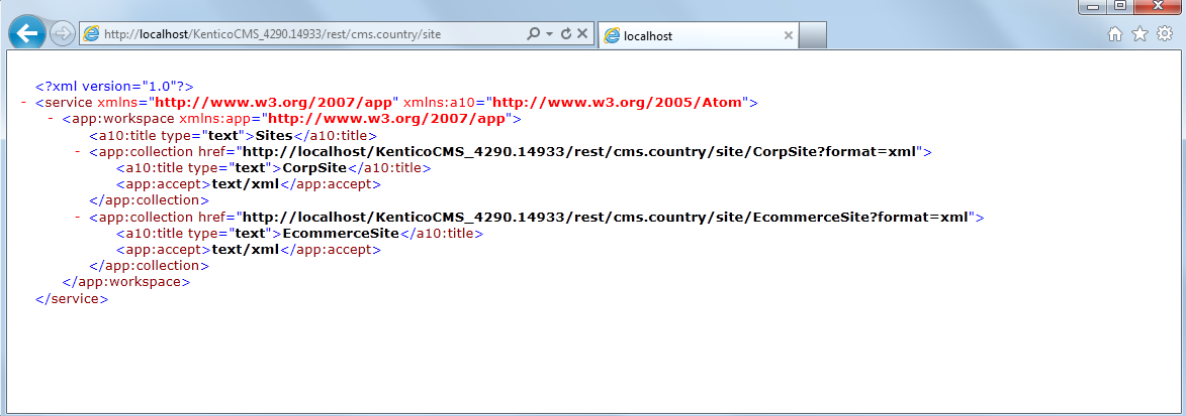

Kentico CMS REST service supports [ODATA](#) by providing service documents in a standard format for ODATA services. The service documents provide information about the types of data available via the REST service and about the URLs under which the data can be accessed.

The service documents are available under the following URLs:

- `~/rest` - exposes the service document. The document contains a list of all available object types and URLs under which objects of the type can be accessed.

- `~/rest/<objecttype>/site` - returns a list of all sites on which the specified object type is available to the currently authenticated user and URLs under which objects from the particular sites can be retrieved.

```
<?xml version="1.0"?>
- <service xmlns="http://www.w3.org/2007/app" xmlns:a10="http://www.w3.org/2005/Atom">
  - <app:workspace xmlns:app="http://www.w3.org/2007/app">
    <a10:title type="text">Sites</a10:title>
    - <app:collection href="http://localhost/KenticoCMS_4290.14933/rest/cms.country/site/CorpSite?format=xml">
      <a10:title type="text">CorpSite</a10:title>
      <app:accept>text/xml</app:accept>
    </app:collection>
    - <app:collection href="http://localhost/KenticoCMS_4290.14933/rest/cms.country/site/EcommerceSite?format=xml">
      <a10:title type="text">EcommerceSite</a10:title>
      <app:accept>text/xml</app:accept>
    </app:collection>
  </app:workspace>
</service>
```

7.22 Scheduler

7.22.1 Overview

The Scheduler allows you to define when specified scheduled tasks should be executed. This is useful when you want some functionality to be performed automatically at a specific time or regularly over a certain time period. The scheduler is leveraged by many of the modules in Kentico CMS to execute tasks necessary for their functionality.

The Scheduler provides various configuration options that determine when scheduled tasks are executed and if they are executed by the application itself or by a dedicated Windows service. In the [Configuring task execution](#) topic, you can learn about these configuration possibilities. The [Installing the Scheduler Windows service](#) topic provides information on how the Windows service can be installed.

While Kentico CMS comes with a number of default scheduled tasks, it is possible to create custom ones to schedule execution of your own code. The [Scheduling custom code](#) topic contains an example of how this can be achieved. To learn about the user interface for management of scheduled tasks and actions that can be performed in it, please refer to the [Scheduled tasks administration](#) topic.

The [Scheduler internals and API](#) sub-chapter provides information about the database tables and classes used by the module and examples of how scheduled tasks can be managed using the API.

7.22.2 Configuring task execution

This topic explains how to configure execution of scheduled tasks.

Configuring execution by the Kentico CMS application or external Windows service

Scheduled tasks can either be executed by the Kentico CMS application itself, or by a dedicated Windows service. Executing tasks using the Windows service is recommended for resource-consuming tasks because their execution by the Windows service does not affect the performance of the Kentico CMS application.

For tasks to be executed by the Windows service, the service needs to be [installed and running](#) and the **Use external service** setting in **Site Manager -> Settings -> System** needs to be enabled. With these pre-conditions met, you can enable the **Use external service** option in each task's editing interface in **Site Manager -> Administration -> Scheduled tasks**. Tasks with the **Use external service** option disabled will still be executed by the application itself. If the **Use external service** setting in **Site Manager -> Settings -> System** is disabled, even tasks with this option enabled are processed by the application itself.

Scheduling reliability

Since task execution by the application runs within the ASP.NET process, tasks will not be executed by the application if it is not running. This happens when the process is recycled without being started again (after a long period of website inactivity).

If you want to run the scheduling reliably, it's recommended to execute these tasks using the Windows service.

If you still wish to have them executed by the application, you need to ensure that your website is always running. You can do that by using some utility or an external service that requests the home page of your website on a regular basis.

Resolving context macros when executing tasks by the Windows service

Tasks that are executed by the Windows service can't resolve macros dependent on application context (e.g. `{%ApplicationPath%}`). This happens due to the fact that the context is not available when tasks are executed outside the application. Therefore, it is recommended to execute such tasks by the application.

Configuring execution intervals

There are two types of settings which determine when tasks should be executed. First, you can configure a time period after which tasks should be **ready for execution**. This can be configured separately for each individual task. Then, you can configure a time period after which the application or the Windows service **checks if there are any tasks ready for execution**. All tasks that are ready for execution during this check are subsequently executed.

Task interval

Individual tasks have a specified time interval after which they should be considered as ready to be executed. This interval is defined separately for each scheduled task by means of the **Task interval** settings in the task's editing interface in **Site Manager -> Administration -> Scheduled tasks**.

Application scheduler interval

The **Application scheduler interval** setting in **Site Manager -> Settings -> System** determines the time interval after which the application checks if there are any tasks ready to be executed. This setting

only applies to tasks that are configured to be executed by the application itself, not by the Windows service. By default, the application performs the check at the end of each standard page request. This means that tasks are executed when user activity on your website generates requests; you can set the minimum time between the checks to any interval. The execution can be completely disabled by setting the value to 0.

Alternatively, the scheduler can be configured to process tasks regularly according to an automatic internal timer, regardless of website activity. In this case, the **Application scheduler interval** sets the precise interval between these checks. The values you are allowed to set range between 0 - 30 seconds, where 0 disables the checks altogether. You can do this by adding the **CMSUseAutomaticScheduler** key into the **/configuration/appSettings** section of your *web.config* file, as shown below.

```
<add key="CMSUseAutomaticScheduler" value="true" />
```

Service scheduler interval

The **Service scheduler interval** setting in **Site Manager -> Settings -> System** determines the time interval after which the Windows service checks if there are any tasks ready to be executed. This setting only applies to tasks that are configured to be executed by the Windows service, not by the application itself. The value sets the precise interval between the checks, the same as when using the automatic scheduler, but with higher reliability and less application load. The values are entered in seconds and the checks and execution can be completely disabled by setting the value to 0. The maximum value of the setting is 30.

Additional low-level settings

Additional low-level scheduler settings can be done by adding the keys listed in the [Scheduler settings](#) section of Appendix B - Web.config parameters.

7.22.3 Installing the Scheduler Windows service

Kentico CMS comes with a dedicated Windows service for execution of scheduled tasks. This service can be used to execute specified tasks — typically the resource-consuming ones — instead of the application itself in order to optimize application performance.

The following text describes how the service can be installed. Please note that a specific configuration is also required for scheduled tasks to be executed by the Windows service. See [Configuring task execution](#) for more details.

Installing and uninstalling the Scheduler Windows service using Kentico CMS Service Manager

The easiest way to install or uninstall the Scheduler Windows service is to use the [Kentico Service Manager](#) utility. The utility can either be launched from Kentico CMS program group in Windows Start menu, or from [Kentico Installation Manager](#), as shown in the screenshot below.

Installing the Scheduler Windows service from the command line

To install the Windows service from the command line, you need to use [Installer Tool \(InstallUtil.exe\)](#), which is a native part of the .NET Framework. The following steps describe installation of the Windows service using the Installer Tool.

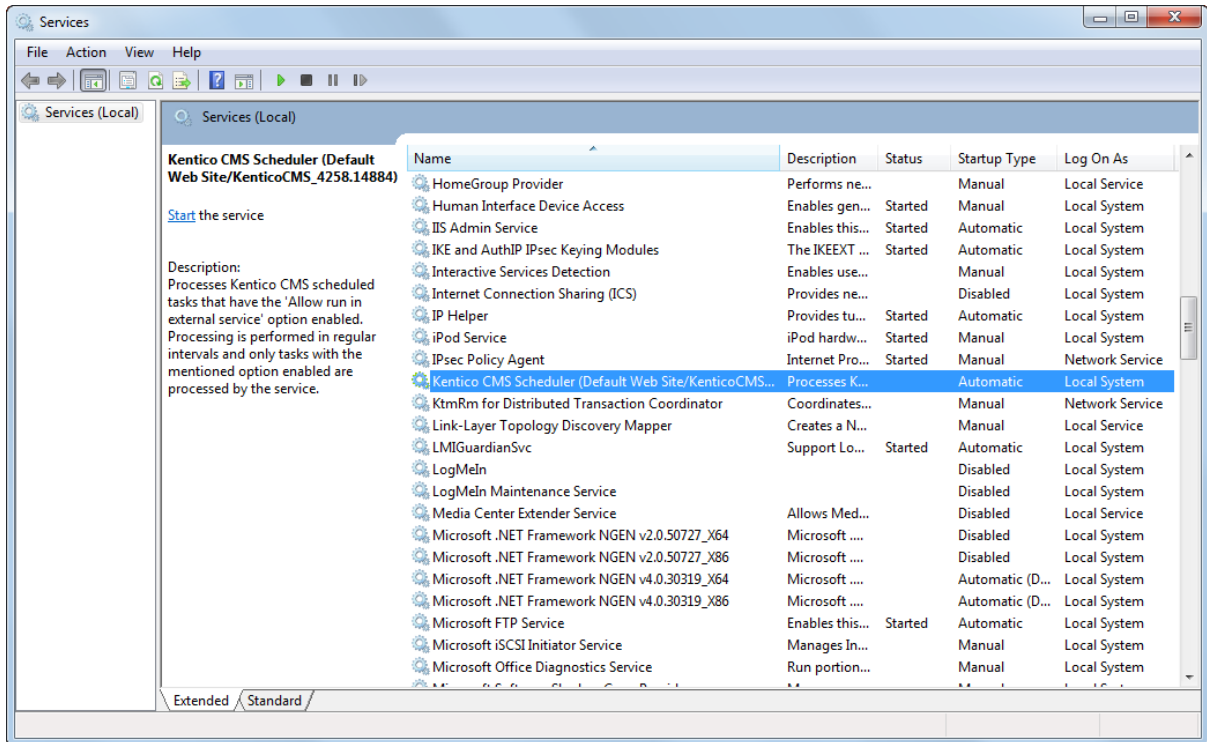

1. Open Windows command line (type *cmd* in the Start menu search box) and navigate to the .NET folder containing *InstallUtil.exe* (e.g. *c:\Windows\Microsoft.NET\Framework64\v4.0.30319*).

2. Execute *InstallUtil.exe* from Windows command line with parameters as shown below. The parameters mean the following:

- **/webpath** - path to the root folder of the Kentico CMS instance for that you want to install the Windows service.
- **second parameter** - path to the *SchedulerService.exe* file in the *Bin* folder inside application root (typically *c:\inetpub\wwwroot\KenticoCMS\bin\SchedulerService.exe*).
- **/LogToConsole** - optional parameter defining if installation progress will be logged to console.
- **/i** - if this parameter is used, the Installer Tool performs installation of the Windows service.

```
InstallUtil.exe /webpath="C:\inetpub\wwwroot\CMS" "c:\inetpub\wwwroot\KenticoCMS\bin\SchedulerService.exe" /LogToConsole=true /i
```

3. To verify that the service is installed successfully, open Services management console (type *services.msc* into the Start menu search box). In the list of installed services, you should see the **Kentico CMS Scheduler (<CMSApplicationName web.config key value>)** service. The service is not running initially. To start it, click the **Start Service** button in the top toolbar, as highlighted in the screenshot below.

Uninstalling the Scheduler Windows service from the command line

Uninstalling the Scheduler Windows service can be performed exactly the same way as described above, while you only need to use the */u* parameter instead of */i* at the end of the command:

```
InstallUtil /webpath="C:\inetpub\wwwroot\CMS" "c:\Program Files (x86)
\KenticoCMS\6.0\Bin\SchedulerService.exe" /LogToConsole=true /u
```

After executing this command, the Scheduler Windows service for the instance of Kentico CMS specified by the */webpath* parameter will be uninstalled.

7.22.4 Scheduled tasks administration

You can configure scheduled tasks in **Site Manager -> Administration -> Scheduled tasks**. The tasks are divided into two tabs:

- **Tasks tab** - here, you can manage, configure and add new scheduled tasks.
- **System tasks tab** - here, you can manage and configure system scheduled tasks. System tasks are temporary tasks created dynamically by the system to ensure its correct internal functionality. You cannot add new tasks under this tab as it contains system tasks only.

The screenshot shows the 'Scheduled tasks' page in the Kentico Administration interface. The 'Tasks' tab is selected, and a table of scheduled tasks is displayed. The table has columns for Actions, Task name, Last run, Next run, Last result, Server name, Executions, and Enabled. Tasks include 'Check bounced e-mails', 'Content publishing', 'Content synchronization', 'Delete old shopping carts', 'SalesForce replication', 'Translations retrieval', and 'Users delete non activated user'.

| Actions | Task name | Last run | Next run | Last result | Server name | Executions | Enabled |
|---------|---------------------------------|----------------------|----------------------|---|-------------|------------|---------|
| | Check bounced e-mails | 8/7/2012 1:08:39 PM | 8/7/2012 2:08:39 PM | Monitoring is not enabled for this site. | | 2 | Yes |
| | Content publishing | 8/7/2012 1:13:55 PM | 8/7/2012 1:14:55 PM | | | 27 | Yes |
| | Content synchronization | 4/4/2012 2:39:56 PM | 4/4/2012 3:39:56 PM | | | 0 | No |
| | Delete old shopping carts | 8/7/2012 12:08:06 PM | 8/8/2012 12:08:06 PM | | | 1 | Yes |
| | SalesForce replication | 8/7/2012 1:08:39 PM | 8/7/2012 2:08:39 PM | SalesForce organization access is not authorized. | | 2 | Yes |
| | Translations retrieval | 4/4/2012 2:39:56 PM | 4/6/2012 2:03:51 PM | | | 0 | No |
| | Users delete non activated user | 8/7/2012 1:08:39 PM | 8/7/2012 2:08:39 PM | | | 2 | Yes |

The **Site** drop-down list at the top is used for selecting a site. If a particular website is chosen, a list of site-specific tasks scheduled for the given site will be displayed in the grid below. Selecting the *(Global)* option allows you to work with tasks that are not related to a specific site. The tasks of the current site can also be edited in **CMS Desk -> Administration -> Scheduled tasks**.

Next to the site selection drop-down list, you can find the following two buttons that may be used to manage the selected site's timer:

- **Restart timer** - restarts the internal scheduling timer. This button is only available when the scheduler is configured to use the internal timer as described in [Configuring task execution](#).
- **Run ASAP** - immediately executes all tasks that are ready to be executed.

New task, available only in **Tasks tab**, allows you to schedule new custom tasks. The process of creating a scheduled task is covered in more detail in the [Scheduling custom code](#) topic. The **Refresh** action updates the information displayed below in the list of tasks. Clicking **Reset executions** clears the execution counter for all tasks and starts it again from 0.

The three action icons on the left of each task serve the following purpose:

- **Edit** - allows the properties of the task (e.g. its execution interval) to be modified.
- **Delete** - removes the scheduled task.
- **Execute** - immediately runs the task. When a task is executed manually, the scheduled time of its next execution is automatically moved forward according to the scheduling interval.

If a icon is displayed in the **Actions column**, it indicates that the task should be executed by the Windows service, but was not executed for a long period of time. This typically happens when the service is not running and notifies you about the fact that it should be started in order for these task to be executed.

7.22.5 Scheduling custom code

The process of scheduling a custom task includes two steps:

- Writing the code that performs the required actions
- [Registering](#) a new scheduled task in the CMS

Writing the task code

You need to define each scheduled task as a class that implements the **CMS.Scheduler.ITask** interface. To integrate this type of class into the application, you can:

- Create a new assembly (Class library) in your web project and include the task class there. In this case, you must add the appropriate references to both the assembly and the main CMS project.
- Define the scheduled task in **App_Code** and load the class via the API. This ensures that the system automatically compiles the task and you do not need to use a separate assembly. The example below uses this approach.

Example

1. Open your web project in Visual Studio and add a new class into the **App_Code** folder (or **Old_App_Code** if the project is installed as a web application). For example, name the class **CustomTask.cs**.

2. Edit the class and add the following references:

[C#]

```
using CMS.EventLog;  
using CMS.Scheduler;
```

3. (Optional) Wrap the class into the **Custom** namespace.

[C#]

```
namespace Custom  
{  
    /// <summary>  
    /// Custom task class.  
    /// </summary>  
    public class CustomTask  
    {  
    }  
}
```

4. Make the class implement the **ITask** interface.

[C#]

```
public class CustomTask: ITask
```

5. Define the **Execute** method in the class:

[C#]

```
/// <summary>
/// Executes the task.
/// </summary>
/// <param name="ti">Info object representing the scheduled task</param>
public string Execute(TaskInfo ti)
{
    string detail = "Executed from '~/App_Code/CustomTask.cs'. Task data:"
        + ti.TaskData;

    // Logs the execution of the task in the event log.
    EventLogProvider.LogInformation("CustomTask", "Execute", detail);

    return null;
}
```

You must always include the **Execute** method when writing a scheduled task. The system calls this method whenever the given task is executed, so it needs to contain all code implementing the required functionality. In this example, the task only creates a record in the application's event log so that you can confirm it is being executed.

- The **TaskInfo** parameter of the method allows you to access the data fields of the corresponding scheduled task object. The sample code adds the content of the **TaskData** field into the details of the event log entry.
- The string returned by the method is displayed in the administration interface as the result of the task's most recent execution. You can leave it as *null* in this case.

Loading App_Code task classes

For tasks added to the *App_Code* folder, you must ensure that the system loads the appropriate class when executing the scheduled task. You can find additional information related to this topic in [Registering custom classes in App_Code](#).

1. Create another class in the **App_Code** folder (or **Old_App_Code** if the project is installed as a web application). For example, name the class **ClassLoader.cs**.
2. Edit the class and add the following reference:

[C#]

```
using CMS.SettingsProvider;
```

3. Delete the default class declaration and its content. Instead, extend the **CMSModuleLoader** partial class and define a new attribute inheriting from *CMS.SettingsProvider.CMSLoaderAttribute*:

[C#]

```
[ClassLoader]
```

```

public partial class CMSModuleLoader
{
    /// <summary>
    /// Attribute class for loading custom classes.
    /// </summary>
    private class ClassLoader : CMSLoaderAttribute
    {
    }
}

```

4. Enter the following code into the **ClassLoader** attribute class:

[C#]

```

/// <summary>
/// Called automatically when the application starts.
/// </summary>
public override void Init()
{
    // Assigns a handler for the OnGetCustomClass event.
    ClassHelper.OnGetCustomClass += ClassHelper_OnGetCustomClass;
}

/// <summary>
/// Gets a custom class object based on the given parameters.
/// </summary>
private void ClassHelper_OnGetCustomClass(object sender, ClassEventArgs e)
{
    if (e.Object == null)
    {
        // Checks the name of the requested class.
        switch (e.ClassName)
        {
            // Gets an instance of the CustomTask class.
            case "Custom.CustomTask":
                e.Object = new Custom.CustomTask();
                break;
        }
    }
}
}

```

In the case of scheduled tasks, the value of the **ClassName** property of the **ClassHelper_OnGetCustomClass** handler's *ClassEventArgs* parameter matches the **Task class name** specified for the given task (*Custom.CustomTask* in this example). The handler checks the class name to identify which specific task is being executed and then passes on an instance of the appropriate class.

Registering new scheduled tasks

1. Go to **Site Manager -> Administration -> Scheduled tasks** and select the **Site** for which you wish to schedule the task (*global* if it should be performed for all sites or affect global objects).

2. Click  **New task** and fill in the properties of the task:

| | |
|-----------------------------|--|
| Task display name | Sets a name for the task that is shown in the administration interface. |
| Task name | Sets a unique name that serves as an identifier for the scheduled task, for example in the API. You can leave the (<i>automatic</i>) option to have the system generate an appropriate code name based on the display name. |
| Task assembly name | Specifies the name of the assembly where the task is implemented.

Enter <i>App_Code</i> for tasks implemented in the <i>App_Code</i> folder. |
| Task class name | Specifies the exact class (including any namespaces) that defines the functionality of the scheduled task.

Enter <i>Custom.CustomTask</i> to load the task class created in the example sections above. |
| Task interval | Sets the time interval between two executions of the task.

This does not ensure that the task will be executed at the exact time, only that it will be considered ready for execution. The precise execution time depends on the general settings of the scheduler. |
| Task data | Additional data provided to the task's class. This field can be accessed from the code of the task, so you may use as a parameter to easily modify the task without having to edit its implementation. |
| Task condition | Allows you to enter an additional macro condition that must be fulfilled in order for the scheduler to execute the task.

You can write any condition according to your specific requirements. For details about available macro options and syntax, refer to the Development -> Macro expressions chapter.

Clicking on the edit icon () opens the Macro condition editor , which allows you to build conditions through a graphical interface. The Clear condition () action removes the current content of the condition field. |
| Task enabled | This field must be enabled in order for the task to be scheduled. |
| Delete task after last run | Indicates if the system should delete the task after its final run (applicable if the task is set to run only once). |
| Run task in separate thread | Indicates if the scheduler should execute the task in a separate thread to improve application performance.

It is not possible to access context data (information about the current page, user, etc.) in the code of tasks that are executed in a separate thread. |
| Use external service | If enabled, the task is processed by the Scheduler Windows service instead of the web application. If the Use external service setting in Site Manager -> Settings -> System is disabled, even tasks with this option enabled are processed by the application itself. Only some of the |

| | |
|--------------------------------|--|
| | <p>default scheduled tasks support this option. The ones that do not have it available in their editing interfaces must be processed by the application itself.</p> <p>You cannot define the task in the <i>App_Code</i> folder if you wish to use the external service. To run a custom task externally, you must add a new assembly to your project and then define the task class there.</p> |
| Run individually for each site | <p>This option is only available for global tasks. If enabled, the scheduler executes the task repeatedly as a site-specific task, once for each running site in the system. The task automatically runs within the context of the corresponding site.</p> <p>This can be useful if you wish to manage a task in a single location instead of creating a separate one for every site.</p> |
| Server name | <p>Sets the name of the web farm server where the task is executed. This field is applicable only if your application is running in a Web farm environment.</p> <p>To add a new task for all web farm servers currently registered in the system, check the Create tasks for all web farm servers box below the field.</p> |
| Use context of user | <p>If the scheduled task needs to access data from the user context in its code (e.g. to check permissions), you can use this property to choose which user is provided. The scheduler always executes the task within the context of the selected user.</p> <p>In most cases, the user context does not affect the functionality of the task, and you can leave the <i>(default)</i> option — the context of a public user is used.</p> |
| Executions | <p>Shows how many times the task has been executed. You can reset this counter back to 0 by clicking Reset.</p> |

Scheduled tasks

Executions: 0 (from) [Reset](#)

3. Click  **Save**.

The task will now be executed regularly according to the specified interval.

Result

To check the result of the sample custom task, go to **Site Manager -> Administration -> Event log** and look for entries with *CustomTask* as their **Source**.

The screenshot shows the Kentico CMS 7.0 Administration interface. The main content area displays the 'Event log' page. The page includes a search bar at the top with the following fields: 'Select site: (all)', 'Type: (all)', 'Source: LIKE', and 'Event code: LIKE'. Below these fields is a 'Time between:' field with 'Now' and 'and' buttons, and a 'Search' button. A 'Display advanced filter' link is also present. The event log table below has the following data:

| Actions | Type | Event time | Source | Event code | User name | IP address | Document name | Site | Machine name |
|---------|------|----------------------|------------|------------|---------------|------------|---------------|------|--------------|
| | I | 8/13/2012 8:35:05 AM | CustomTask | EXECUTE | administrator | ::1 | | | AA-15-PC |
| | I | 8/13/2012 8:34:04 AM | CustomTask | EXECUTE | administrator | ::1 | | | AA-15-PC |

7.22.6 Scheduler internals and API

7.22.6.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used by the Scheduler. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the related classes, please refer to [Kentico CMS API Reference](#).

7.22.6.2 Database tables

The following database tables are used to store scheduler-related information:

- **CMS_ScheduledTask** - contains records representing scheduled tasks and their settings.

| CMS_ScheduledTask | | | |
|-------------------------|------------------|-------------------------------------|--|
| Column Name | Data Type | Allow Nulls | |
| TaskID | int | <input type="checkbox"/> | |
| TaskName | nvarchar(200) | <input type="checkbox"/> | |
| TaskDisplayName | nvarchar(200) | <input type="checkbox"/> | |
| TaskAssemblyName | nvarchar(200) | <input type="checkbox"/> | |
| TaskClass | nvarchar(200) | <input checked="" type="checkbox"/> | |
| TaskInterval | nvarchar(1000) | <input type="checkbox"/> | |
| TaskData | nvarchar(MAX) | <input type="checkbox"/> | |
| TaskLastRunTime | datetime | <input checked="" type="checkbox"/> | |
| TaskNextRunTime | datetime | <input checked="" type="checkbox"/> | |
| TaskProgress | int | <input checked="" type="checkbox"/> | |
| TaskLastResult | nvarchar(MAX) | <input checked="" type="checkbox"/> | |
| TaskEnabled | bit | <input type="checkbox"/> | |
| TaskSiteID | int | <input checked="" type="checkbox"/> | |
| TaskDeleteAfterLastRun | bit | <input checked="" type="checkbox"/> | |
| TaskServerName | nvarchar(100) | <input checked="" type="checkbox"/> | |
| TaskGUID | uniqueidentifier | <input type="checkbox"/> | |
| TaskLastModified | datetime | <input type="checkbox"/> | |
| TaskExecutions | int | <input checked="" type="checkbox"/> | |
| TaskResourceID | int | <input checked="" type="checkbox"/> | |
| TaskRunInSeparateThread | bit | <input checked="" type="checkbox"/> | |
| | | <input type="checkbox"/> | |

The diagram shows two relationships from the CMS_ScheduledTask table to external classes. One relationship connects the TaskResourceID column to the CMS_Resource class. The other relationship connects the TaskSiteID column to the CMS_Site class. Both relationships are represented by lines with a small yellow circle at the end pointing to the class boxes.

7.22.6.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Scheduler can be found in the **CMS.Scheduler** namespace.

CMS_ScheduledTask table API:

- **TaskInfo** - represents one scheduled task.
- **TaskInfoProvider** - provides management functionality for scheduled tasks.

Other classes:

- **SchedulingExecutor** - provides methods for executing scheduled tasks.
- **SchedulingHelper** - provides general functionality and settings for the scheduler.
- **SchedulingTimer** - can be used to manage the internal timer of the scheduler.
- **TaskInterval** - provides management functionality for the time intervals used by scheduled tasks.

7.22.6.4 API examples

7.22.6.4.1 Overview

These topics show examples of how the API of the Scheduler can be used:

- [Managing scheduled tasks](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Administration\ScheduledTasks\Default.aspx.cs**.

The scheduler API examples use the following namespaces:

```
using System;
using System.Data;
using System.Collections;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.Scheduler;
```

7.22.6.4.2 Managing scheduled tasks

The following example creates a scheduled task.

```
private void CreateScheduledTask()
{
    // Create new scheduled task object
    TaskInfo newTask = new TaskInfo();

    // Set the properties
    newTask.TaskDisplayName = "My new task";
    newTask.TaskName = "MyNewTask";
    newTask.TaskAssemblyName = "CMS.WorkflowEngine";
    newTask.TaskClass = "CMS.WorkflowEngine.ContentPublisher";

    // Create interval
    TaskInterval interval = new TaskInterval();

    // Set interval properties
    interval.Period = SchedulingHelper.PERIOD_DAY;
    interval.StartTime = DateTime.Now;
    interval.Every = 2;
```

```
// Add some days to interval
ArrayList days = new ArrayList();
days.Add(DayOfWeek.Monday.ToString());
days.Add(DayOfWeek.Sunday.ToString());
days.Add(DayOfWeek.Thursday.ToString());

interval.Days = days;

newTask.TaskInterval = SchedulingHelper.EncodeInterval(interval);
newTask.TaskSiteID = CMSContext.CurrentSiteID;
newTask.TaskData = "<data></data>";
newTask.TaskEnabled = true;
newTask.TaskNextRunTime = SchedulingHelper.GetNextTime(newTask.TaskInterval,
DateTime.Now, DateTime.Now);

// Save the scheduled task
TaskInfoProvider.SetTaskInfo(newTask);
}
```

The following example gets and updates a scheduled task.

```
private bool GetAndUpdateScheduledTask()
{
    // Get the scheduled task
    TaskInfo updateTask = TaskInfoProvider.GetTaskInfo("MyNewTask",
CMSContext.CurrentSiteID);
    if (updateTask != null)
    {
        // Update the properties
        updateTask.TaskDisplayName = updateTask.TaskDisplayName.ToLower();

        // Save the changes
        TaskInfoProvider.SetTaskInfo(updateTask);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates scheduled tasks.

```
private bool GetAndBulkUpdateScheduledTasks()
{
    // Get the data
    DataSet tasks = TaskInfoProvider.GetAllTasks();
    if (!DataHelper.DataSourceIsEmpty(tasks))
    {
        // Loop through the individual items
        foreach (DataRow taskDr in tasks.Tables[0].Rows)
        {
```

```
        // Create object from DataRow
        TaskInfo modifyTask = new TaskInfo(taskDr);

        // Update the properties
        modifyTask.TaskDisplayName = modifyTask.TaskDisplayName.ToUpper();

        // Save the changes
        TaskInfoProvider.SetTaskInfo(modifyTask);
    }

    return true;
}

return false;
}
```

The following example deletes a scheduled task.

```
private bool DeleteScheduledTask()
{
    // Get the scheduled task
    TaskInfo deleteTask = TaskInfoProvider.GetTaskInfo("MyNewTask",
        CMSContext.CurrentSiteID);

    // Delete the scheduled task
    TaskInfoProvider.DeleteTaskInfo(deleteTask);

    return (deleteTask != null);
}
```

The following example runs a scheduled task.

```
private bool RunTask()
{
    // Get the scheduled task
    TaskInfo runTask = TaskInfoProvider.GetTaskInfo("MyNewTask",
        CMSContext.CurrentSiteID);

    if (runTask != null)
    {
        // Run task
        SchedulingExecutor.ExecuteTask(runTask);

        return true;
    }

    return false;
}
```

7.23 Social networking

7.23.1 Overview

Integration of Facebook, Google+, LinkedIn and Twitter social networks in Kentico CMS offers various features. A summary of features associated with each social network and available web parts and form controls is displayed in the provided table.

| Social network | Feature | Available web parts | Available form controls |
|-----------------|--------------------------------|---------------------------------|-------------------------|
| Facebook | Authentication | Facebook connect logon* | |
| | | Facebook connect required data* | |
| | Company interactions | Facebook activity feed* | |
| | Users interactions | Facebook comments | |
| | | Facebook facepile | |
| | | Facebook like box | |
| | | Facebook like button | |
| | | Facebook send button | |
| | | Facebook recommendations | |
| | | Auto post | |
| Google+ | Company interactions | Google+ activity feed* | |
| | | Google+ badge | |
| | Users interactions | Google+ button | |
| LinkedIn | Authentication | LinkedIn logon* | |
| | | LinkedIn required data* | |
| | Company Interactions | LinkedIn apply with* | |
| | | LinkedIn company insider | |
| | | LinkedIn company profile | |
| | | LinkedIn member profile | |
| | Users interactions | LinkedIn recommend button | |
| | | LinkedIn share button | |
| Twitter | | Twitter feed* | |
| | | Twitter follow button | |
| | | Twitter tweet button | |
| | Auto post | | Twitter auto post* |

* Requires configuration of settings at **Site Manager -> Settings -> Social networks -> Facebook/Google+/LinkedIn/Twitter**.

- **Authentication** - Provides an alternative way for users to log in to your site using their social network accounts.
- **Company interactions** - Provides means for displaying content and information from the company's

social network page.

- **Users interactions** - Provides users with useful buttons and features associated with their social network accounts.
- **Auto post** - Enables content editors to post on social networks through the site UI during the document creation and publishing process.

7.23.2 Autoposting

From Kentico CMS, you can post messages to Facebook and Twitter accounts directly from CMS Desk or the on-site editing interface.

You have the following options how to publish content from within the editing interface to Facebook or Twitter. Each of them is suitable for a different situation.

- If you want to post information about documents of one **specific document type**, either manually, or automatically at the time of publishing, choose [Publishing to Facebook or Twitter using form controls](#).
- If you want to post information about a certain **section of the content tree**, regardless of the document type, choose [Publishing to Facebook or Twitter using a workflow step](#).

In both these cases, you post to the chosen social network from within the interface where you edit a document. You can use macros in the message you post. For example, you can use macros to insert the URL of the document into the message.

Connecting the application to Facebook

Before you can post from Kentico CMS to Facebook, you must authorize the application to use your Facebook account. See [Registering your application](#).

Connecting the application to Twitter

Before you can post tweets from Kentico CMS, you must authorize the application to use your Twitter account.

1. Go to <http://dev.twitter.com> and log in.
2. Create a new application.
3. Navigate to your application's **Settings** and select **Read and Write** under **Application Type -> Access**.
4. Switch back to **Details** and under **Your access token**, create your access token.
5. Paste the following information into Kentico CMS, **Site Manager -> Settings -> Social networks -> Twitter**.
 - Consumer key
 - Consumer secret
 - Access token
 - Access token secret
6. On Twitter, navigate to your application's **Settings** and select **Read and Write** under **Application**

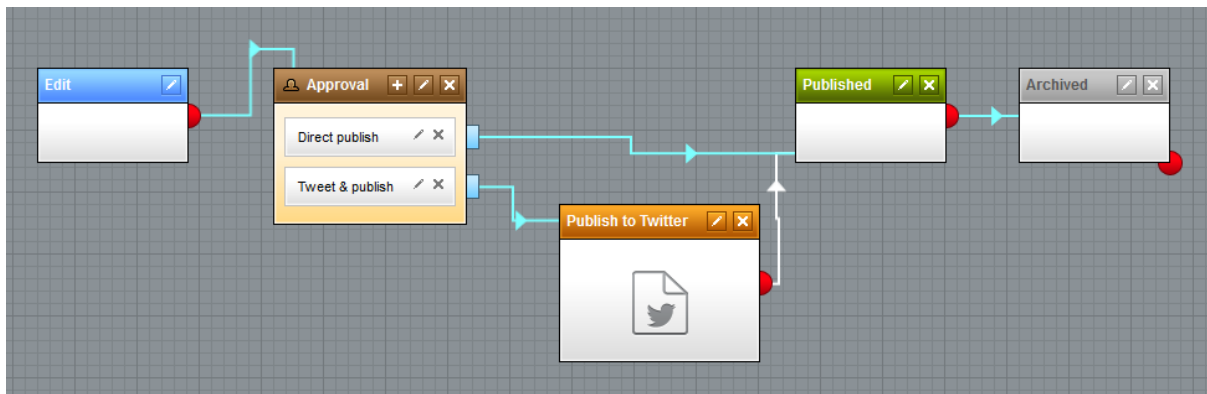

Type -> Access.

The system is now configured to post to Twitter.

Automatic publishing to Facebook or Twitter using a workflow step

You can post messages to social networks as part of a document's workflow process using the Publish to Facebook and Publish to Twitter workflow steps. You can use this approach to automatically publish information about documents in a section of your site's content. If you want to write a message and publish it to social networks directly from the document editing interface, consider [Publishing to Facebook or Twitter using form controls](#).

1. Configure the application for [connecting to Facebook](#) or [connecting to Twitter](#).
2. [Create an advanced workflow](#) with the **Publish to Facebook** or **Publish to Twitter** step.

An example workflow process with publishing to Twitter

3. Set the **Text** of the message which will be automatically posted to Facebook/Twitter in the **Workflow step properties**. You can use macros in the message.
 - For example, *Check out our new blog post at `www.example.com{% GetDocumentURL() %}`.* The resulting URL could then look like this: *`www.example.com/blog/my-latest-blog-post.aspx`*
4. Create a document using this defined workflow.
 - When advancing over the Publish to Facebook/Publish to Twitter step in the workflow, the predefined message will be automatically posted.

Publishing to Facebook or Twitter using form controls

By adding the **Facebook auto post** and **Twitter auto post** form controls to a document type, you can enable editors to post messages to social networks from the document editing interface. You can also allow choosing whether to post the message right away or after the document gets published.

1. Configure the application for [connecting to Facebook](#) or [connecting to Twitter](#).
2. Insert the **Facebook auto post**/**Twitter auto post** form control into the required document type.
 - You can do this in **Site Manager -> Development -> Document types -> Edit** the chosen document type -> **Fields tab -> New attribute (+)**. Choose **Text** as attribute type and choose a sufficient attribute size (at least 140 is recommended).
 - If you plan on using workflow on this document, add "**autopost**" as suffix to the column name.

3. Create a document of the modified type in CMS Desk.
4. Save the document.
5. Type a message into the **Post at Facebook/Post at Twitter** field. You can use macros.
 - Note that the message can be only 140 characters long on Twitter.
6. Click the **Post at Facebook/Post at Twitter** button, or check **Post at Facebook/Twitter after publishing** (if using workflow) and save the document.
 - The system posts your message on a corresponding social network.
 - If the Post after publishing checkbox is on, the system will post your message once you publish the document.

The screenshot displays two sections for social media posting. The top section, titled "Post at Twitter", features a text area containing the message "Check out a new article on www.example.com{% GetDocumentURL() %}". Below the text area is a checkbox labeled "Post at Twitter after publishing" which is checked. To the right of the checkbox is a character count "64/140" and a blue button labeled "Post at Twitter". Below these elements is the text "Tweet wasn't published yet". The bottom section, titled "Post at Facebook", has a similar text area with the same message. It includes a checkbox labeled "Post at Facebook after publishing" which is unchecked. To the right is a blue button labeled "Post at Facebook". Below these elements is the text "Facebook post wasn't published yet".

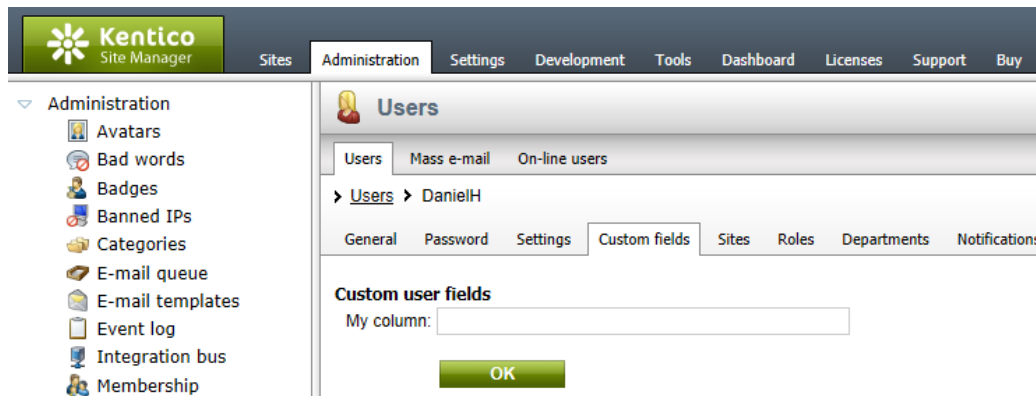

Posting a link to an article to Twitter and Facebook on the Form tab in CMS Desk

7.24 System tables and custom fields

7.24.1 Overview

Kentico CMS allows you to modify some of the system tables and enhance them with custom attributes. You can edit them in **Site Manager -> Development -> System tables**.

If you add a new column to a system table, it is available on the **Custom fields** tab of the corresponding dialog. For example, if you add a custom column to the *CMS_User* table, it will be displayed in **Site Manager -> Administration -> Users -> Edit (✎) user** on the **Custom fields** tab.

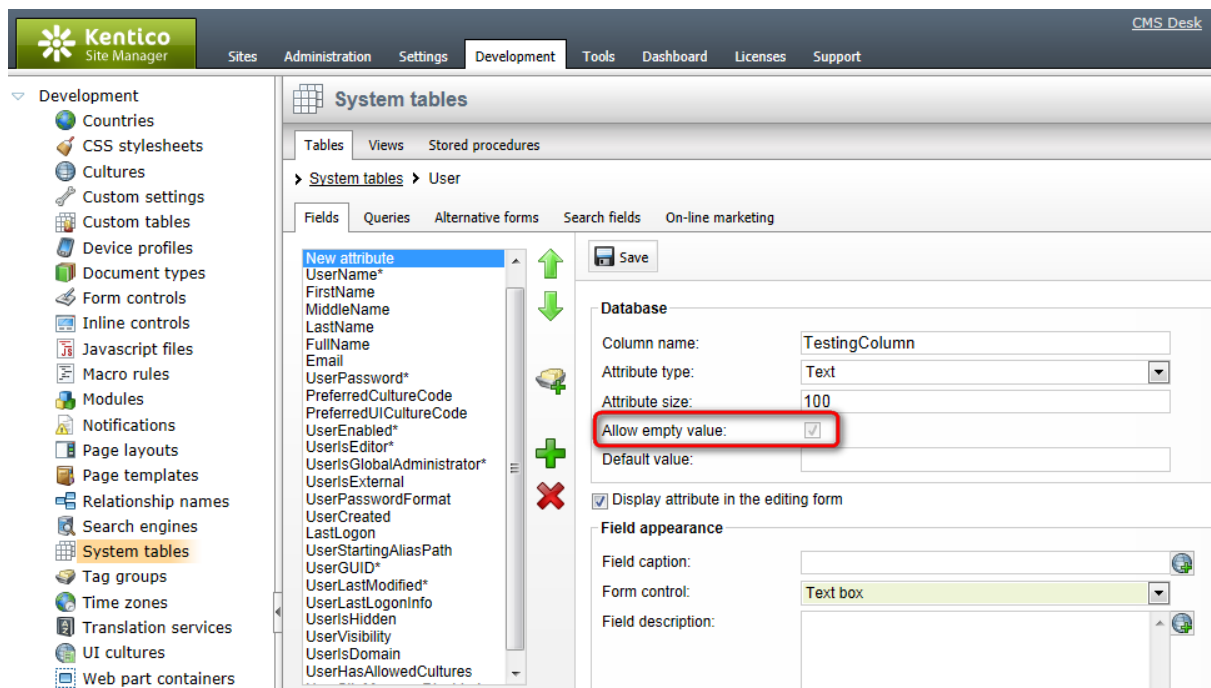

The screenshot shows the 'Users' configuration page in the Kentico Site Manager. The left sidebar lists various administration options like Avatars, Bad words, Badges, etc. The main content area is titled 'Users' and has tabs for 'Users', 'Mass e-mail', and 'On-line users'. Under the 'Users' tab, there's a sub-tab for 'DanielH'. Below that, there are tabs for 'General', 'Password', 'Settings', 'Custom fields', 'Sites', 'Roles', 'Departments', and 'Notifications'. The 'Custom user fields' section is active, showing a text input field labeled 'My column:' and an 'OK' button.

When creating a new field in a system table, the **Allow empty value** property is set to *TRUE* and cannot be edited. This is necessary to ensure that the default system procedures continue to work correctly.

However, you can change this value to *FALSE* to make the field required in [alternative forms](#).

The screenshot shows the 'System tables' configuration page in the Kentico Site Manager. The left sidebar lists various development options like Countries, CSS stylesheets, Cultures, etc. The main content area is titled 'System tables' and has tabs for 'Tables', 'Views', and 'Stored procedures'. Under the 'Tables' tab, there's a sub-tab for 'User'. Below that, there are tabs for 'Fields', 'Queries', 'Alternative forms', 'Search fields', and 'On-line marketing'. The 'New attribute' list is visible, and the 'Allow empty value' checkbox is checked and highlighted with a red box.

If you would like to learn how to add custom data to all documents, please refer to the [Custom document data](#) topic.

7.24.2 Custom document data

In some cases, you may need to add custom data to all documents. In this case, you can use the *NodeCustomData* or *DocumentCustomData* (culture specific) fields in the *CMS_Tree* and

CMS_Document database tables, respectively.

These fields are accessible through the following properties of the document (TreeNode):

- *TreeNode.NodeCustomData*
- *TreeNode.DocumentCustomData*

You can use these values in two ways:

1. You can use them as a single ntext block of text:

[C#]

```
TreeNode.NodeCustomData.Value = "my value";
```

2. You can use them as a collection of custom values that are stored as an XML document:

[C#]

```
TreeNode.NodeCustomData["myproperty1"] = "my value 1";  
TreeNode.NodeCustomData["myproperty2"] = "my value 2";
```

If you would like to learn how to create a new document type or modify fields of an existing one, please refer to the [Document types and transformations](#) chapter in the Development section of this guide.

7.25 Team development

7.25.1 Overview

Development in a team of co-workers can be difficult, as two people might accidentally edit the same object at the same time and unintentionally overwrite each other's work. That's why a developer can lock a certain object for editing (check out) and unlock it (check in) after finishing the edits. When an object is checked out, other developers cannot modify it.

Object locking works similarly as [content locking](#) used for documents. Object locking is, however, used on various objects with modifiable code, such as CSS stylesheets or web part containers. A list of objects that currently support this function can be found in the [Supported object types](#) topic.

You can find the details about object locking, how this feature works and where it can be turned on/off in the [Object locking](#) topic.

All these objects can also be stored in the file system and managed by an external version control system ([Git](#), [Team Foundation Server](#), etc.). More information can be found in the [Deployment and source control](#) topic along with the instructions on how to deploy these objects to another system.

7.25.2 Supported object types

In the following table you can see the object types that support object locking and storing to the disk instead of a database (except for E-mail templates object type which does not support storing to disk).

The **Editing interface** column contains locations within Kentico CMS interface where the particular object type can be edited. If object locking is enabled, then the  **Check out** button (or  **Undo checkout** and  **Check in** buttons, when the object is checked out) is situated above each code editing area.

| Object type | Editing interface |
|---------------------|--|
| CSS stylesheets | <ul style="list-style-type: none"> • Site Manager -> Development -> CSS stylesheets -> Edit () • CMS Desk -> Content -> Edit -> Properties -> General -> Edit a CSS stylesheet • other interfaces containing the stylesheet selector (e.g., when editing a site, department, etc.) |
| E-mail templates* | <ul style="list-style-type: none"> • Site Manager -> Administration -> E-mail templates -> Edit () • CMS Desk -> Administration -> E-mail templates |
| Page layouts | <ul style="list-style-type: none"> • Site Manager -> Development -> Page layouts -> Edit () • CMS Desk -> Content -> Edit -> Design -> Edit layout () |
| Page templates | <ul style="list-style-type: none"> • Site Manager -> Development -> Page templates -> Edit () -> Layout • CMS Desk -> Content -> Edit -> Design -> Edit template -> Layout • other interfaces that allow editing of page templates |
| Transformations | <ul style="list-style-type: none"> • Site Manager -> Development -> Document types -> Edit () -> Transformations -> Edit () • Site Manager -> Development -> Custom tables -> Edit () -> Transformations -> Edit () • web part properties dialogs of web parts that have transformation properties |
| Web part containers | <ul style="list-style-type: none"> • Site Manager -> Development -> Web part containers -> Edit () • CMS Desk -> Content -> Edit -> Design -> Configure () a web part -> Edit a Web part container |
| Web part layouts | <ul style="list-style-type: none"> • Site Manager -> Development -> Web parts -> Edit () -> Layout -> Edit () • CMS Desk -> Content -> Edit -> Design -> Configure () a web part -> Layout |

* Does not support storing to disk.

7.25.3 Object locking

Object locking prevents developers from simultaneously overwriting each other's code modifications of objects. When the feature is enabled, only one developer (or more developers signed in under the same user name) is able to modify a certain object at a time.

Enabling object locking

The object locking feature is disabled by default. You can turn it **on** by checking the **Use check-in/check-out for objects** option in the following location:

Site Manager -> Settings -> Versioning & Synchronization -> Object versioning

- When this option is enabled, then the  **Check out** button (in some cases also the  **Preview** button) is situated next to the  **Save** button. After you click the  **Check out** button, this button disappears and the  **Undo checkout** and  **Check in** buttons appear instead.

- When you disable this option, then only the  **Save** button is present (in some cases also the  **Preview** button).

How object locking works

Common interface for all objects that support this function:

-  **Save** - saves changes made to the object
-  **Check out** - locks an object, so that other users can not modify it at the same time.
-  **Undo checkout** - if versioning is ON: cancels the checkout and discards all changes made to the object (even the changes confirmed by the  **Save** button) and also unlocks the object for other users.
 - if versioning is OFF: discards changes made to the object since the last  **Save** and unlocks the object for other users.
-  **Check in** - saves changes and unlocks the object for other users

If you want to edit an object, for example a CSS stylesheet (see the list of [supported object types](#)), you have to first click the  **Check out** button situated above the code editing area. Until you click this button, the system will not allow you to make any modifications to the object.

When your object is checked out, you can modify it knowing, that you are the only one with this privilege. During the editing process you can save your work by clicking the  **Save** button. Clicking this button also updates the system with any modifications and allows other users to view your changes to the object.

After you finish your edits, you can click the  **Check in** button to confirm your changes and make the object available for other users. Or you can click the  **Undo checkout** button to discard all changes made since the last checkout (even the changes confirmed by the  **Save** button) and also to make the object available for other users.

Global administrator can Undo checkout on any object

There is not time limit or other restriction applied to the length of time for which you can keep an object checked out. Keep in mind though, that a **global administrator** can perform **Undo checkout** on any checked out object in the system.

Creating new versions

Every time you click the  **Save** or  **Check in** button, a new version of the object is created according to the rules specified in the [Using object versioning](#) topic and can be viewed on the objects' **Versions** tab.

Note that if you click the  **Undo checkout** button, the version created by the  **Save** button is discarded. The last version before the checkout is then set as the current version.

Typical scenarios

You want to edit an object:

1. Open the object's editing interface (for example **Site Manager -> Development -> CSS stylesheets -> Edit**  a **Corporate Site**)
 - Notice, that you cannot edit the object at the moment.
2. Click  **Check out**
 - The object is locked for other users. Only you can edit an object when it is checked out.
3. Edit the object
 - You can repeatedly save your work using the  **Save** button.
4. Click  **Check in**
 - The system confirms your modifications and unlocks the object.

You want to create a new object:

1. Click **New** <object> (where <object> can be a CSS stylesheet, page layout, transformation, container or layout)
 - The system displays the new object's dialog with only the  **Save** button available.
2. Type in the object's name and all the required details
3. Edit the object's code
4. Click  **Save**
 - The system saves your new object. According to the setting of option **Keep new object checked out** in **Site Manager -> Settings -> Versioning & Synchronization -> Object versioning** the object stays checked out or not.

You need to edit an object, that is currently checked out by another user:

You have several options, you can:

- wait until the user checks the object back in. You may have to refresh the object's page to see if the object is checked in again.
- contact the user (you can use the built-in interface: **CMS Desk -> My desk -> Messages**).
- ask global administrator to perform **Undo checkout**.

Viewing my checked-out objects

You can view all your currently checked out objects in one place:

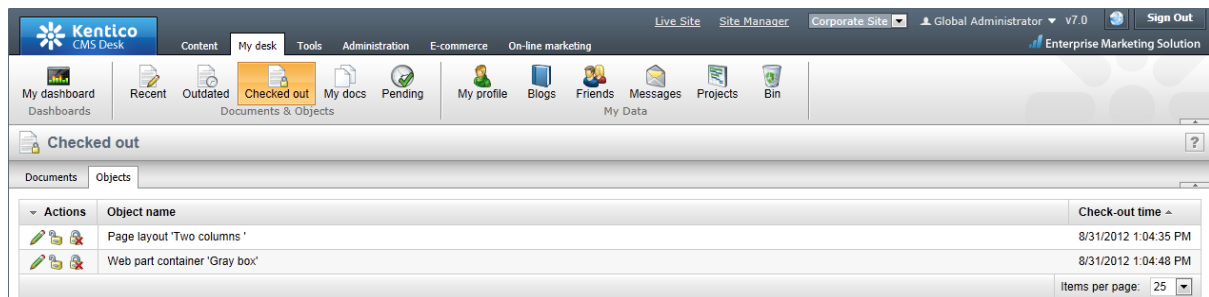

CMS Desk -> My desk -> Checked out -> Objects

Each object's row provides three action buttons:

Edit (✎) - opens a window with the object's editing interface

Check in (📁) - checks the object in (unlocks it)

Undo checkout (🗑️) - discards all changes made to the object since the last checkout and unlocks the object

7.25.4 Deployment and source control

Kentico CMS provides a way to store virtual objects (listed in [Supported object types](#)) on the disk in addition to the database. Having code files on a local disk allows you to prepare your site for deployment, edit code in external editors, or manage objects using a source control system.

You can access the user interface for storing objects in the file system on the following page:

Site Manager -> Administration -> System -> Virtual objects

Deployment mode

To deploy your website to another system:

1. Click the **Store all virtual objects in file system** button.
 - The system saves all virtual objects (page layouts, page template layouts, transformations and web part layouts) on your disk.
 - The target folder is `~/CMSVirtualFiles`.
2. Compile the files in Visual Studio.
 - At this time, you can still edit the code of objects in the Kentico CMS user interface, but any changes will require you to compile the files again.

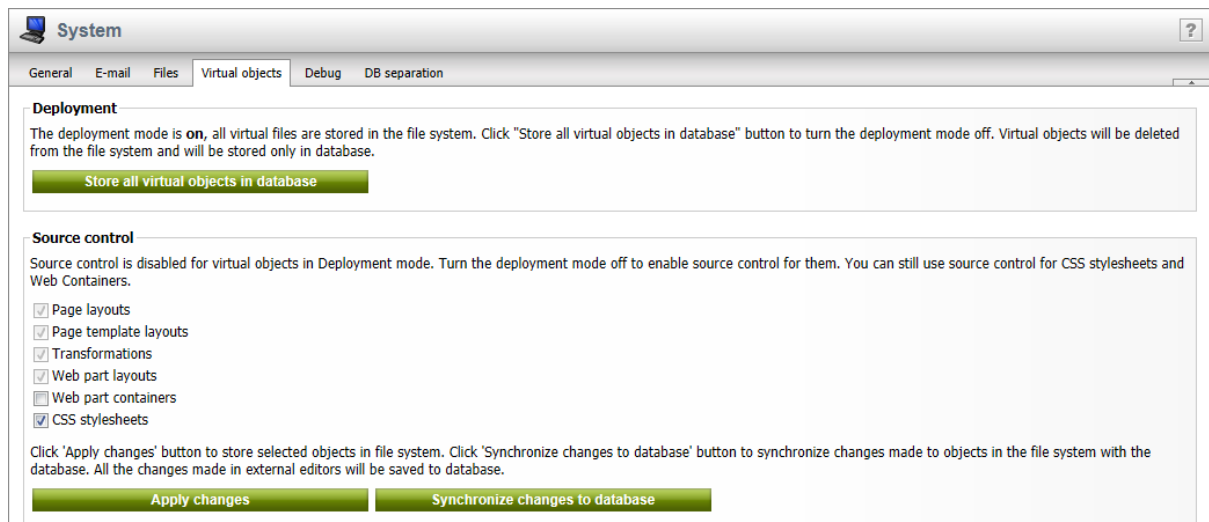

3. Move your website to the target environment.

When deployment mode is **OFF**:

- The location of the objects depends on Source control options.

When the deployment mode is **ON**

- All objects that require compilation are moved into the file system on the local disk. The target folder is `~/CMSVirtualFiles`.
- You can edit the code of objects in the user interface. Changes are saved into the files immediately.
- You can edit the object files in Visual Studio or another external editor.
- To move objects back into the database, click **Store all virtual objects in database** (deletes the files on the disk).
- You can configure the **Source control** options for objects that do not require compilation (Web part containers and CSS stylesheets).

Source control

The options in the **Source control** section allow you to select which objects are stored in the file system, where you can edit the code in external editors, or manage objects using a [source control system](#).

- To store objects in the file system, check the boxes next to the required object types and click **Apply changes**. The files are saved in the `~/CMSVirtualFiles` folder.
- To move objects back into the database, uncheck the corresponding boxes and click **Apply changes**. Checked objects stay in the file system and unchecked objects are moved back into the database.
- Use the **Synchronize changes to database** button to copy the code from the files on the disk into the matching objects in the database.

Source control in Deployment mode

If deployment mode is **ON**, you cannot configure the source control options for objects that require compilation (only for Web part containers and CSS stylesheets).

When using source control, you can still edit the code of objects through the Kentico CMS user interface. If you edit an object, the system displays the code from the corresponding file. Saving the code in the UI writes the data into both the file system and the database.

Using deployment mode/source control on web application projects

When you enable deployment mode or source control on *web application* installations, the system cannot automatically integrate the created files into the Visual Studio project. You need to manually perform the following steps:

1. Edit your project in Visual Studio.
2. Click **Show all files** at the top of the Solution Explorer.
3. Right-click the **CMSVirtualFiles** folder and select **Include in Project**.
4. (For *Deployment mode* only) Right-click the **CMSVirtualFilesWebPartLayouts** folder and select **Convert to Web Application**.
5. Build the **CMSApp** project.

The code files are now integrated in your web application project, and you can edit them in Visual Studio inside the *CMSVirtualFiles* folder.

7.26 UI cultures and localization

7.26.1 Overview

The user interface culture determines the language in which the administration interface is displayed, as well as other factors like numeric and date formats. UI cultures can be managed and added in **Site Manager -> Development -> UI Cultures**. The strings that contain the exact text displayed for specific UI cultures are stored in resource files in the **CMSResources** folder under your web project.

A UI culture can be set for each user in **Site Manager -> Administration -> Users -> edit (🖋)** a user -> **General -> Preferred user interface culture**.

The default UI culture can be set by adding the following key to the `<appSettings>` section of your site's *web.config* file:

```
<add key="CMSDefaultUICulture" value="en-nz" />
```

The value of this key must be a valid culture code as in the example above (*en-nz* represents the **English - New Zealand** culture).

If you wish to change the default UI culture, you also need to rename the `~\CMSResources\CMS.resx` file to **CMS.en-us.resx** and the **CMS.en-nz.resx** file to **CMS.resx**. This is needed because the *CMS.resx* file is used when the (*default*) option is selected as a user's **Preferred user interface**

culture.

When the above mentioned key is used and the CMS.resx file contains the en-nz dictionary, the UI culture will be *en-nz* for users who have their **Preferred user interface culture** set to **(default)**.

Learn more about configuring a multilingual UI the [Configuring multilingual and RTL UI](#).

Multilingual website content

Content of Kentico CMS websites (i.e. documents in the content tree) can also be multilingual. To learn about localization of website content, please refer to the [Content management -> Multilingual content](#) chapter of this guide.

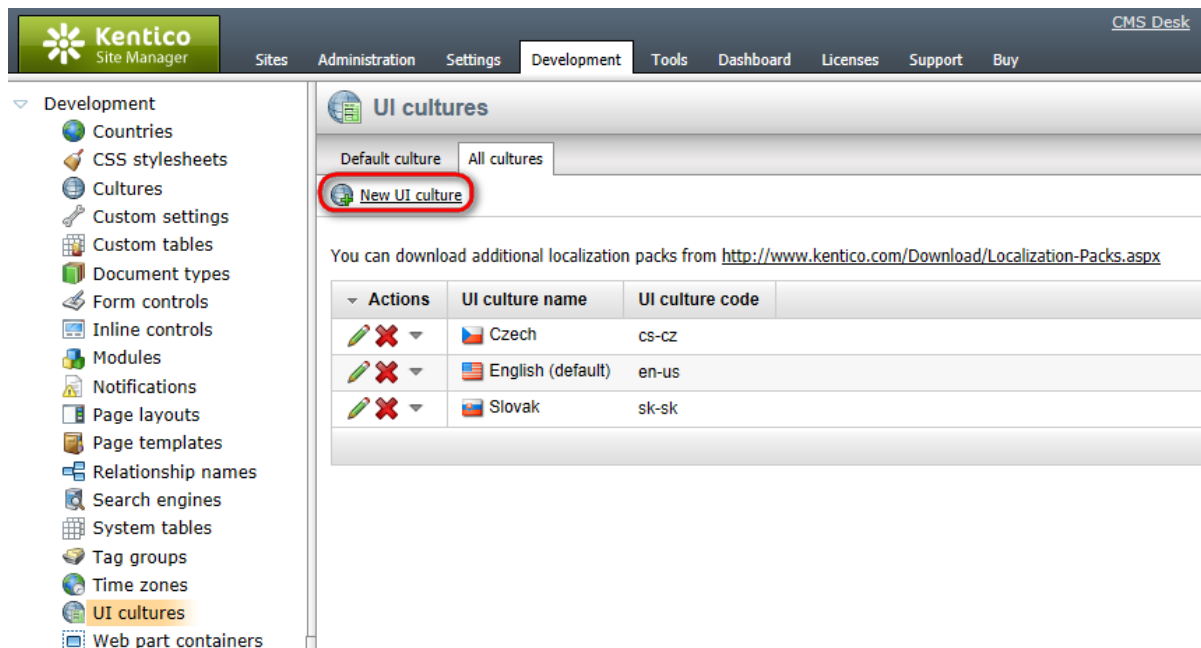

7.26.2 Configuring multilingual and RTL UI

Kentico CMS allows you to manage content in any language, including double-byte (eastern) languages, such as Chinese, and right-to-left languages (such as Hebrew or Arabic). All content is stored and published in UNICODE.

Translating the administration interface

To have the administration interface displayed in a different language or at least with different culture settings (e.g. calendar and numeric format):

1. Go to **Site Manager -> Development -> UI cultures -> All cultures**.
2. Add a  **New UI Culture**.

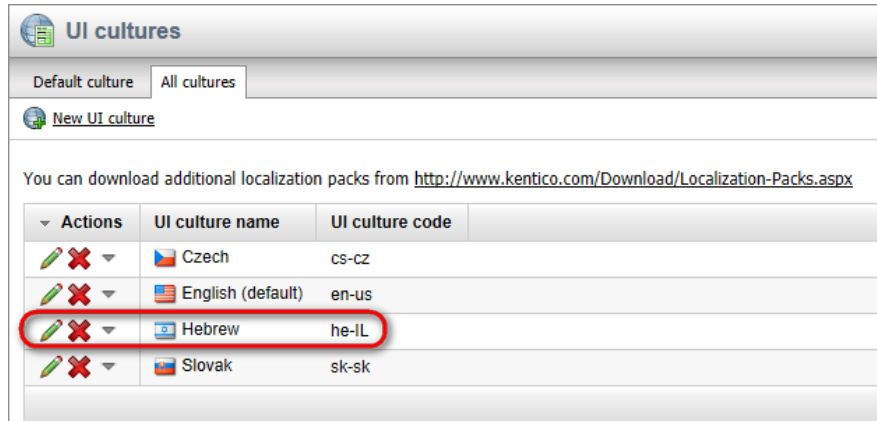

The screenshot shows the Kentico CMS administration interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The left sidebar shows a tree view under 'Development' with various options like 'Countries', 'CSS stylesheets', 'Cultures', etc. The main content area is titled 'UI cultures' and has two tabs: 'Default culture' and 'All cultures'. The 'All cultures' tab is active, and a 'New UI culture' button is highlighted with a red circle. Below the tabs, there is a link to download localization packs: <http://www.kentico.com/Download/Localization-Packs.aspx>. A table lists existing UI cultures:

| Actions | UI culture name | UI culture code |
|---|-------------------|-----------------|
|   | Czech | cs-cz |
|   | English (default) | en-us |
|   | Slovak | sk-sk |

3. Enter the following properties:

- **UI culture name:** Hebrew (example - you can use any other culture)
- **UI culture code:** he-IL (example - you can use any other culture code)

Click **OK**. If you switch back to the **All cultures** tab, the added culture is now shown in the list.

4. Create a copy of the `<web project>\CMSResources\cms.resx` file in the same folder and name it `cms.he-IL.resx` (`cms.<culture code>.resx` in general).

5. You can start translating the strings that are used to display text in the user interface. Localization packs that contain translated resource files are available for some languages and can be downloaded using the link on the **All cultures** tab.

Please note

After modifying a `.resx` file, you need to restart the application to apply the changes to the user interface:

1. Go to **Site Manager -> Administration -> System**
2. Click **Restart application**.

Modifying the default strings

If you want to modify some text in the user interface (including web part dialogs), you can create a **custom.resx** file and store your strings in this file. The key used to identify the string must be the same as in the **cms.resx** file. This procedure allows you to modify the strings without worrying that your changes will be overwritten during an upgrade to a newer version.

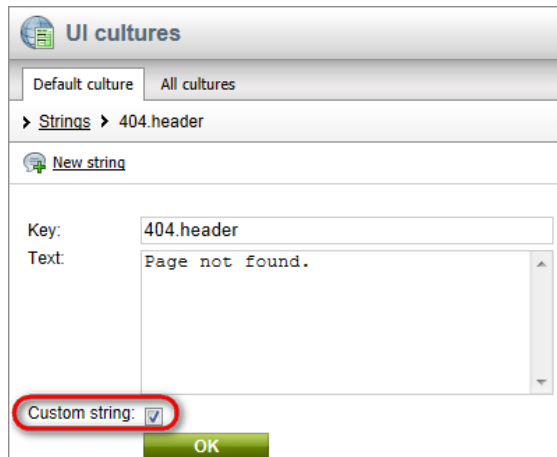

If you need to customize strings in a non-English resource file, your custom file must use a name like **custom.fr-fr.resx** for French.

Adding your own strings

If you need to translate strings used on your website such as form labels, display names of objects or other static text into several languages:

1. Go to **Site Manager -> Development -> UI cultures -> Default culture** and click  **New string**.
2. Enter the following properties:
 - **Key:** 404.header (example - you can use any other key name)
 - **Text:** Page not found. (example - you can use any other text)

Please be sure to check the **Custom string** check box in this case, so that the string will automatically be exported with your website.

UI cultures

Default culture All cultures

Strings > 404.header

New string

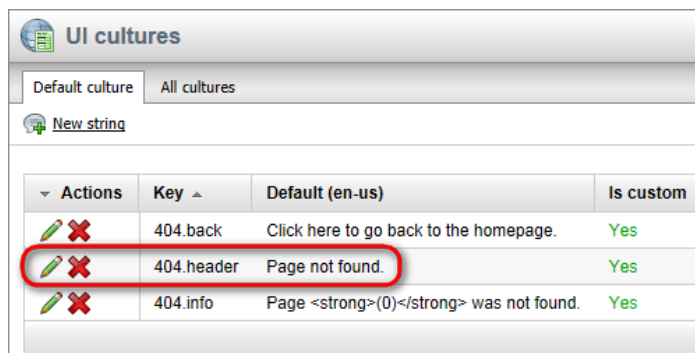

Key: 404.header

Text: Page not found.

Custom string:

OK

Click **OK**. A new string in the default culture is now displayed in the list.

UI cultures

Default culture All cultures

New string

| Actions | Key | Default (en-us) | Is custom |
|---|------------|--|-----------|
|   | 404.back | Click here to go back to the homepage. | Yes |
|   | 404.header | Page not found. | Yes |
|   | 404.info | Page (0) was not found. | Yes |

3. To translate the newly created custom string into the desired language, switch to the **All cultures** tab and choose to **Edit** () the corresponding UI culture. A list of strings in the default language will be displayed.

UI cultures

Default culture All cultures

> UI cultures > Hebrew

Strings General

New string

| Actions | Key | Default (en-us) | Translated | Is custom |
|---------|------------|---|---|-----------|
| | 404.back | Pro návrat na domovskou stránku klikněte zde. | Click here to go back to the homepage. | Yes |
| | 404.header | Page not found. | | Yes |
| | 404.info | Page (0) was not found. | Stránka (0) nebyla nalezena. | Yes |

4. **Edit** () the custom string created in step 1 and translate it into the desired language using the **Text** field of the string. Do not forget to check the **Custom string** check box and click **OK**. When you to edit this particular UI culture again, the string is now displayed with its translation.

UI cultures

Default culture All cultures

> UI cultures > Hebrew

Strings General

New string

| Actions | Key | Default (en-us) | Translated | Is custom |
|---------|------------|---|---|-----------|
| | 404.back | Pro návrat na domovskou stránku klikněte zde. | Click here to go back to the homepage. | Yes |
| | 404.header | Page not found. | Stránka nenalezena. | Yes |
| | 404.info | Page (0) was not found. | Stránka (0) nebyla nalezena. | Yes |

You can create a new string in both the default and currently edited UI culture at the same time by using **New string** on this tab.

3. The resource string and its translation are now created and stored in the database. Please see the [Localization expressions](#) topic to see how you can insert localized strings into text fields throughout the interface of the CMS. If you need to retrieve the value of a resource string in your custom code, you can use the **CMS.GlobalHelper.ResHelper.GetString** method.

Resource string priority

When looking for a localized strings, the system uses the following priority:

1. database (Site Manager -> Development -> UI Cultures)
2. custom.resx
3. cms.resx

If there are duplicate strings with the same key in all three sources, the system will use the one stored in the database.

To change the priorities, you can add the following key to your web.config:

```
<add key="CMSUseSQLResourceManagerAsPrimary" value="false" />
```

When this key is added, the priorities are as follows:

1. custom.resx
2. cms.resx
3. database (Site Manager -> Development -> UI Cultures)

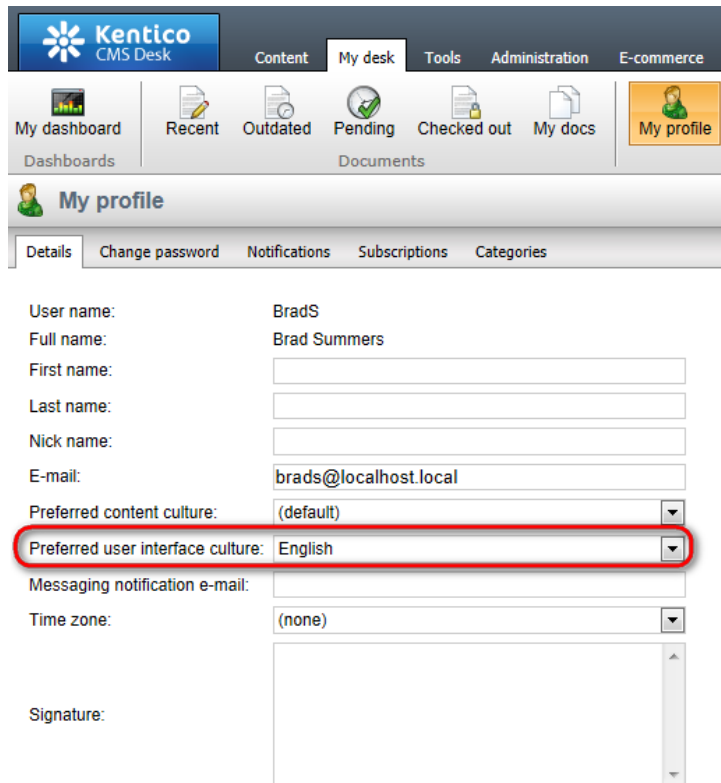

Applying a culture to the user interface

The user interface can be set to a specific culture for each user in the system. To do this, go to **CMS Desk / Site Manager -> Administration -> Users**, edit (✎) the given user and select the required value from the **Preferred user interface culture** drop-down list on the **General** tab.

The screenshot shows the 'Users' administration page in Kentico CMS. The breadcrumb is 'Users > Mia'. The 'General' tab is selected, showing a form for user 'Mia Lee'. The form includes fields for User name, Full name, First name, Middle name, Last name, and E-mail. Below these are checkboxes for 'Enabled', 'Is editor', 'Is global administrator', 'Is external user', 'Is domain user', and 'Is hidden'. At the bottom, there are two dropdown menus for 'Preferred content culture' and 'Preferred user interface culture', both currently set to '(default)'. Other fields include 'Created' (11/8/2011 9:47:01 AM), 'Last logon' (N/A), 'Last logon information', and 'Starting alias path'. An 'OK' button is at the bottom.

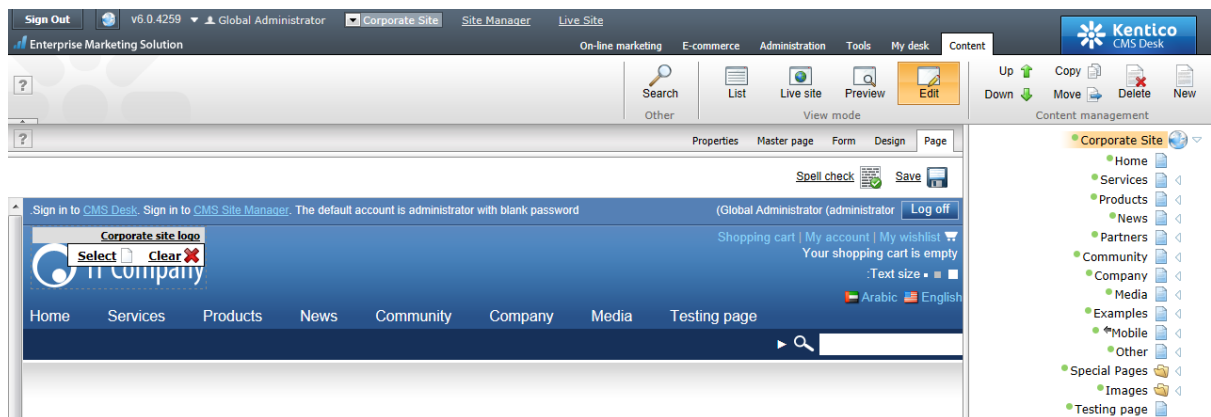

Users may also select their own user interface culture by going to **My Desk -> Account -> Details** and

setting the **Preferred user interface culture**.

The screenshot shows the 'My profile' page in the Kentico CMS Desk. The user's name is BradS (Brad Summers) with email brads@localhost.local. The 'Preferred content culture' is set to '(default)'. The 'Preferred user interface culture' is set to 'English', which is highlighted with a red circle. Other fields include 'Messaging notification e-mail' and 'Time zone' (set to '(none)').

When the user signs out and then back in, the user interface will be displayed according to the new culture settings and with translated strings (once the translation is complete).

The culture of the user interface can also be selected for the current user by clicking the **Change UI culture** button located on the top right of the **CMS Desk** or **Site Manager** main header.

This selection also changes the **Preferred user interface culture** setting of the given user.

7.26.3 RTL languages

If the website is displayed in language that uses right-to-left direction of written text (typically arabic languages), the RTL CSS class is automatically assigned to the <body> element of all pages (<body class="RTL">). You may need to add right-to-left specific CSS style modifications to the stylesheet.

RTL in UI culture vs. content culture

The **user interface direction** (RTL or LTR) is driven by the **preferred UI culture** of the current user. The **content direction** is driven by the **preferred (content) culture** of the current user.

Example:

Original LTR style:

```
.xxx
{
text-align: left;
float: left;
border-right: solid 1px #cccccc;
}
```

RTL style:

```
.RTL .xxx
{
text-align: right;
float: right;
border-right: none;
border-left: solid 1px #cccccc;
}
```

Adding culture-specific fonts

If your culture uses specific fonts that are not available in the WYSIWYG editor, you need to configure it:

1. Open file <web project>\CMSAdminControls\CKeditor\config.js in notepad.
2. Add your font names on the following line:

```
CKConfig.FontNames = 'Arial;Comic Sans MS;Courier New;Tahoma;Times New Roman;
Verdana';
```

3. Save the file.
4. Clear the cache of your web browser (Internet Explorer: Tools -> Internet Options -> General -> Delete

files..., check the "delete all off-line content" box and click OK).

5. Close the browser and sign in to Kentico CMS Desk again. Now you should see the new font(s) in the WYSIWYG editor's font list.

7.26.4 Localization expressions

If you need to supply a localized value into a field or text area where localization expressions are supported, you can use expressions in the following formats:

| Format | Description | Sample Value |
|--|--|--|
| Basic format:

<code>{ \$key\$ }</code> | Displays value of the resource string with the specified key. Strings can be viewed and edited in Site Manager -> Development -> UI Cultures or in the <code>.resx</code> files under the CMSResources folder. | <code>{ \$myform.firstname\$ }</code> |
| In-place localization:

<code>{ \$=default_string
culture_code=translation
culture_code=translation etc.\$ }</code> | Displays the strings defined in the expression.

On the left, you can see an example that displays <i>Hallo</i> for German culture, <i>Ciao</i> for Italian and <i>Hello</i> for all other cultures (default value). | <code>{ \$=Hello de-de=Hallo it-it=Ciao\$ }</code> |

See also: [Development -> Macro expressions](#)

Localization dialogs

Fields in the Kentico CMS interface that contain the display names or descriptions of objects provide a more user friendly way to handle localization. This is achieved using action buttons and dialogs that allow you to insert resource strings and edit their text and translations directly from the given section of the UI.

To add a resource string to a field where this functionality is supported:

1. Click the **Localize** (🌐) button.

Display name: 

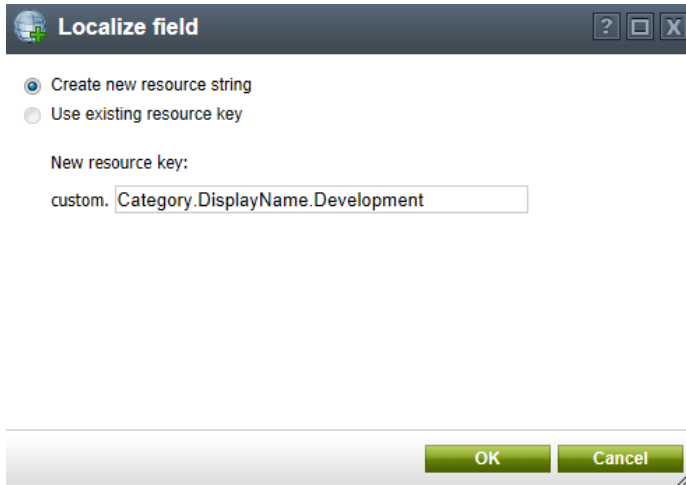

Code name:

Parent category:

Description: 

Enabled:

2. A dialog opens where you can create a new string or select an existing one for the field.

Localize field

Create new resource string
 Use existing resource key

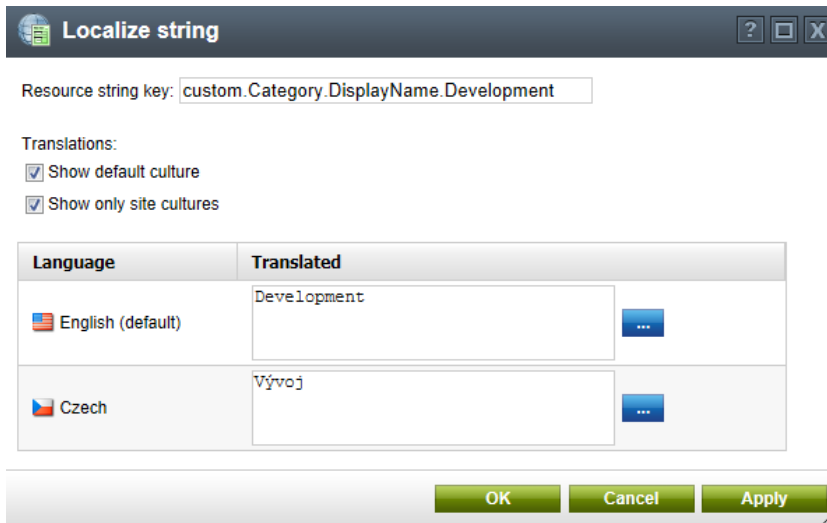

New resource key:
custom.

OK Cancel

3. Edit the text of the resource string for individual cultures. You can use machine [translation services](#) to assist with the translation (if there are any configured for your application).

All cultures specified on the **Site Manager -> Development -> UI cultures -> All cultures** tab are available. If the **Show only site cultures** box is checked, only cultures assigned to the currently active site are visible. The **Show default culture** option can be used to ensure that the default UI culture configured for your installation of Kentico CMS is always displayed.

Please keep in mind that modifying the resource string assigned to a particular field also affects all other occurrences of the same string.

Localize string

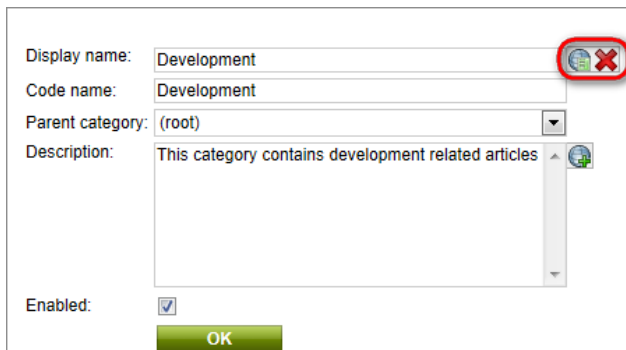

Resource string key:

Translations:
 Show default culture
 Show only site cultures

| Language | Translated |
|---|--|
|  English (default) | <input type="text" value="Development"/>  |
|  Czech | <input type="text" value="Vývoj"/>  |

OK Cancel Apply

4. Click **OK** to confirm any changes made to the resource string.

Display name: Development

Code name: Development

Parent category: (root)

Description: This category contains development related articles

Enabled:

OK

5. Save the form by clicking  **Save** at the top of the page to confirm that the string should be inserted into the field (some forms may use an **OK** confirmation button instead).

The field is now localized and it displays its value according to the current culture settings. You can edit the text of the resource string at any time by clicking the **Localize other languages** () button. If you wish to remove the localization string from a field, click the **Remove localization** () action.

Please note

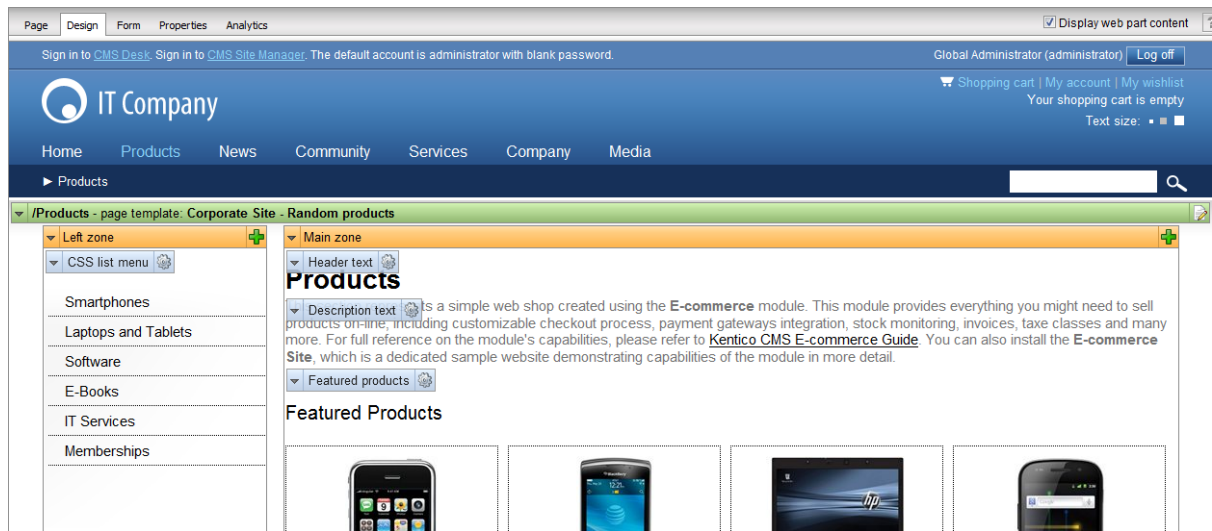

Resource strings created using localization dialogs are always stored in the database. The dialogs cannot be used to interact with strings contained in resource files (*.resx*) under the **CMSResources** folder.

7.27 Web parts

7.27.1 Overview

Web parts represent web page components that provide a combination of content and functionality. They are the basic building blocks of [portal engine](#) page templates. All web parts are registered as objects in the system and may be configured in various ways. More information can be found in the [Web part management](#) topic.

Using existing web parts, users with the appropriate permissions (**Design web site** from the **Module** -> **Design** permission matrix) can build or modify the structure of pages directly from a browser through the **CMS Desk** -> **Content** -> **Edit** -> **Design** interface. Individual web parts added onto a specific page are called web part *instances*. Each instance must be inserted into a specific web part zone, as defined by the layout of the given page's template.

To learn more about working with instances of web parts, please see the [Using and configuring web parts](#) topic in the **Portal engine development model** chapter.

From a developer's point of view, a web part is a user control (.ascx file) that inherits from an appropriate base class. You can easily create your own web parts according to the instructions in the [Developing web parts](#) topic.

A default Kentico CMS installation contains many built-in web parts. You can find complete documentation on all these web parts and their configuration options in the [Kentico CMS Web Parts](#) reference. In some cases however, you may find it necessary to change the behavior, design or functionality of one of them. The [Modifying web parts](#) sub-chapter covers several approaches how this can be done.

Also of interest may be [Widgets](#), which work in a way similar to web parts. They are however intended for various types of users without website design permissions (such as content editors) and may also be used to allow personalization by users.

7.27.2 Web part management

Web parts can be managed in **Site Manager -> Development -> Web parts**. Here you can see all available web parts organized into categories in a tree structure.

Each web part can be configured through the following properties on the **General** tab:

- **Display name** - name of the web part displayed to users in the administration interface (e.g. in the web part toolbar or selection dialog).
- **Code name** - this name serves as a unique identifier for the web part.
- **Category** - here you can choose the category of the web part catalog where the web part will be placed.
- **Type** - sets the type of the web part, which affects its behavior and properties. Different web part types are also marked with different colors and icons on the *Design* tab of *CMS Desk*. The following web part types are available:
 - **Standard** - typical web parts displaying some content.
 - **Data source** - do not display any content, only provide data to be displayed by another connected web part. More information related to data sources is available in the [Data source web parts](#)

sub-chapter.

- **Filter** - can be connected to a data source and enables users to limit the range of the data provided by it.
- **Placeholder** - used for the *General -> Layout -> Page placeholder* web part, which specifies an area where the content of sub-pages should be displayed.
- **Invisible** - are not displayed on the page at all and usually perform some type of background task.
- **Basic** - basic web parts without partial caching and AJAX UpdatePanel support.
- **Layout** - these web parts can be used to generate a specific layout for page content by defining additional web part zones. For more information, please see the [Layout web parts](#) sub-chapter.
- **Widget only** - these web parts are only intended to serve as base templates for widgets and are not available in the web part selection dialog on the *Design* tab of *CMS Desk*. Please keep in mind that changing a web part that is already on some page template to this type will not remove it or prevent it from functioning.
- **Wireframe** - special type of web parts used when defining [wireframe](#) schematics for pages. They are only for internal purposes and are not displayed on the live site. Wireframes can be created for pages on the *Wireframe* tab in the *Edit* mode of *CMS Desk*, either for dedicated wireframe documents or other document types that contain a wireframe definition.
- **File name** - contains a relative path to the user control that implements the web part. The path starts from the `~/CMSWebParts/` folder. It is recommended to organize web part source files on the file system in a way that matches the web part category structure. Example: `Search/cmscompletesearchdialog.ascx`
- **Description** - a text description of the web part that will be displayed in the selection catalog and as a tooltip in the web part toolbar.
- **Thumbnail** - used to upload an image that will represent the web part in the selection catalog and web part toolbar.
- **Skip initial configuration** - if checked, new instances of this web part will be placed directly onto the page without opening the property configuration dialog. This can be convenient, particularly in the case of web parts that are typically used with their default property values.

The screenshot shows the Kentico CMS Desk interface with the 'Web parts' configuration dialog open for an 'Abuse report' web part. The dialog is divided into several sections:

- General:**
 - Display name: Abuse report
 - Code name: AbuseReport
 - Category: Abuse report
 - Type: Standard
 - File name: AbuseReport/AbuseReport.ascx (with 'Select' and 'Clear' buttons)
 - Description: Allows users to write and submit reports concerning website abuse.
- Thumbnail:**
 - Actions: Edit, Delete, Add
 - Update: Refresh
 - File name: abuse_report.png
 - Size: 3.1 kB
- Skip initial configuration:**
- OK:** A green button to confirm the configuration.

The background shows the 'Web parts' selection catalog with a tree view of categories like 'All web parts', 'Abuse report', 'Articles', 'Attachments', etc.

Web part properties

Since web parts often need to provide a wide range of functionality in order to cover different possible scenarios or preferences, their behavior can be configured through properties. A web part's properties are defined on the **Properties** tab and handled in the code of its source file.

The values of these properties can then be set for individual web part instances through the **Web part properties** dialog, which is displayed when a web part is added to a page or configured in CMS Desk. The user interface of each visible property is based on an object called a *form control*. This allows you to select from a large variety of built-in web part property types and provides almost unlimited customization options. Please see the [Development -> Form controls](#) chapter to learn more.

All standard web parts have the following **default properties**. These properties are loaded automatically when the web part is defined and their default values can be specified on the **System properties** tab. If you wish to modify more than the default value of one of these properties, such as its behavior and settings (e.g. for it not to be displayed in the web part configuration dialog) you can do so by overriding it on the **Properties** tab and configuring it differently.

Default

- **Web part control ID** - serves as an identifier for the web part. This ID must be unique within the context of each page template. The value of this property may only contain alphanumeric characters and the underscore character (_). It is recommended to keep the ID short to minimize the total size of the page's output code.
- **Web part title** - title of the web part displayed on the *Design* tab of CMS Desk and in [On-site editing](#) mode. If empty, the value of the *Web part control ID* property is used for this purpose.

Visibility

- **Visible** - indicates if the web part should be displayed.
- **Hide on subpages** - indicates if the web part should be hidden on sub-pages. If checked, the web part will not be displayed on documents that inherit the web part from a parent document.
- **Show for document types** - contains a list of document types on which the web part should be displayed. If the currently selected document uses the page template containing the web part, but its type is not specified by this property, the web part will be hidden. The document types in the list must be specified by their code names and separated by semicolons (;). If empty, the web part will be displayed on all document types.
- **Display to roles** - contains a list of roles to which the web part should be displayed. This may be used to implement documents with specific functionality for different types of users. The roles in the list must be specified by their code names and separated by semicolons (;). If empty, the web part will be displayed to all users.

Web part container

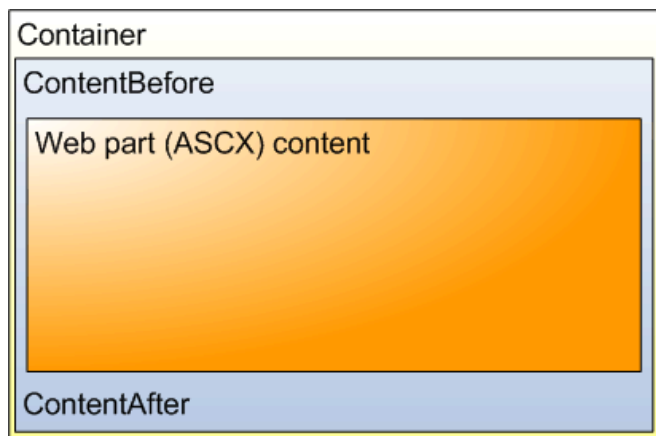

- **Web part container** - specifies the name of the [Web part container](#) (box) to be displayed around the web part. Only the containers defined in *Site Manager -> Development -> Web part containers* can be used. The currently selected container can be edited directly by using the **Edit** button.
- **Container title** - sets a title for the container. This title is displayed only if the `{%ContainerTitle%}` macro is used in the code of the container.
- **Container CSS class** - CSS class used for the web part's container. Applied only if the `{%ContainerCSSClass%}` macro is used as the value of a *Class* attribute somewhere in the code of the container.
- **Container custom content** - may be used to pass a text parameter to the specified web part container. Applied only if the `{%ContainerCustomContent%}` macro is used in the code of the container.

- **Hide container on subpages** - if enabled, the container will not be displayed around the web part on child documents that inherit it through visual inheritance. For example, this allows you to add a container for a master page only.

HTML Envelope

- **Content before** - HTML content placed before the web part. Can be used to display a header or add some encapsulating code, such as `<div>` or `<table>` elements to achieve the required layout.
- **Content after** - HTML content placed after the web part. Can be used to display a footer or close the tags contained in the *ContentBefore* value, such as `</div>` or `</table>` elements.

The structure of a web part, its content before/after sections and container is as follows:

Containers, unlike the *ContentBefore* and *ContentAfter* sections, are re-usable for other web part instances and may contain dynamically inserted values of web part properties.

AJAX

- **Use update panel** - indicates if an AJAX UpdatePanel container should be used for the web part. More information can be found in the [AJAX support](#) topic.

Time zones

- **Time zone** - specifies the type of time zone used for the content of the web part. The following types are available:
 - **Inherit** - inherits the time zone settings from the Page placeholder web part used to display the page template containing this web part (typically the one on the master page).
 - **Server** - server time zone settings will be used by the web part.
 - **Web site** - website time zone settings will be used by the web part.
 - **User** - time zone settings of individual users will be used by the web part.
 - **Custom** - some other time zone will be used based on the selection done in the *Custom time zone* property.
- **Custom time zone** - may be used to assign a custom time zone specifically for the content of this web part. If selected, the time zone will be used regardless of current user or website time zone settings.

Performance

- **Disable view state** - indicates if view state should be disabled for the web part.
- **Disable macros** - if checked, macros contained in the values of the web part's properties will no longer be resolved.
- **Partial cache minutes** - sets the number of minutes for which the output HTML code of the web part should remain cached. This process is similar to full-page caching, but only for the code of the web part specifically. If left empty or set to 0, partial caching will not be used for the web part.
- **Partial cache dependencies** - contains a list of cache keys on which the partial cache of the web part depends. When the specified cache items change, the partial cache of the web part is deleted. Each line may only contain a single item. If the *Use default cache dependencies* box is checked, the default dependencies will be used, which include all possible object changes that could affect the specific web part.

Output filter

- **Filter output HTML of web part** - if checked, the output code generated by the web part is processed by the [output filters](#) enabled through the properties below.
- **Resolve URLs** - indicates if the output filter should remove the "~" character in relative URLs and replace it with the root URL of the website (including the application's virtual directory if applicable).
- **Fix attributes** - if checked, the filter ensures that all attributes of HTML tags are in valid XHTML format.
- **Fix Javascript** - if checked, the filter ensures that the *type* and *language* attributes are included in all `<script>` tags.
- **Fix lower case** - if checked, the filter ensures that all HTML tags and attributes are generated in lower case.
- **Fix self closing tags** - if checked, the filter ensures that all HTML elements without closing tags are properly closed, e.g. `
` will be replaced by `
`.
- **Fix tags** - if checked, the filter replaces tags that are not XHTML valid with appropriate equivalents (`` instead of ``, `` instead of `<i>`).
- **Fix HTML5** - if checked, the filter replaces attributes that are obsolete in HTML5 with CSS classes named in format `<attribute name>_<attribute value>`. These classes need to be defined in the CSS stylesheet used by the page or specific web part. The affected attributes are: *cellpadding*, *cellspacing*, *width*, *height*, *border*, *align*, *valign*
- **Convert TABLE tags to DIV tags** - if enabled, `<table>` elements and their child `<tr>` and `<td>` tags are automatically converted to `<div>` elements with CSS classes assigned, named according to the replaced tag. These classes need to be defined in the CSS stylesheet used by the page or specific web part.

Web part layouts

Layouts allow you to customize the appearance of a web part or add further content into it. You may create or edit a web part's layouts on its **Layouts** tab. Designers can choose which layout they wish to use for each specific instance of the web part. More information and an example can be found in the [Modifying web parts -> Customizing web part layout](#) topic.

Web part CSS styles

You can define any CSS classes needed to correctly display a web part by editing it in on the **CSS** tab. If the styles require any files (such as images), you can add them on the **Theme** tab. This stylesheet will then be automatically requested on all pages where the given web part is placed (in addition to the website or page-specific stylesheet). For more information about page component CSS styles, please see the [Development -> CSS stylesheets and design -> CSS for page components](#) topic.

If you need to ensure that a certain CSS class is applied to the content of a web part, there are several options. You can simply use a container or the *Content before / after* properties to enclose the web part into a HTML element containing the appropriate class. Alternatively, you may define a new property for any web part using the **Column name** *CssClass* and **Attribute type** *Text*. Entering the name of a CSS class from your stylesheet as this property's value will automatically wrap the given web part instance into a <Div> element applying the specified class.

Web part documentation

You can add your own documentation to a web part on the **Documentation** tab. If you wish to document specific properties, you need to fill in the **Field description** on the **Properties** tab.

To generate full web part documentation in a printable format, enter `<website URL>/CMSPages/Dialogs/documentation.aspx?allwebparts=true` into your browser. It is recommended to use FireFox for correct formatting and page breaking.

7.27.3 Developing web parts

In cases where the web parts included in Kentico CMS by default do not meet the requirements of your specific scenarios, it is possible to develop new ones and register them in the system. This way, you can add any type of custom content or functionality to your pages through the portal engine.

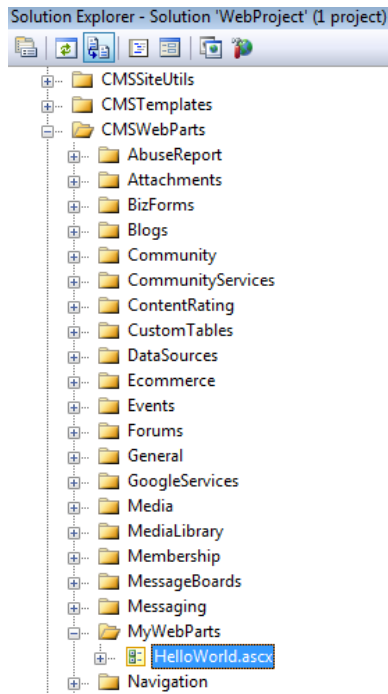

All web parts are implemented as user controls. Standard web parts must inherit the **CMSAbstractWebPart** class from the **CMS.PortalControls** namespace. An exception to this rule are web parts that provide content editable on the Page tab of CMS Desk and in [On-site editing](#) mode (such as the default *Editable text* and *Editable image*), which need to inherit from the **CMSAbstractEditableWebPart** class instead.

Example

The following example will guide you through the process of creating a very simple "Hello world" web part that displays a label and a button. When the button is clicked, the current time will be displayed by the label.

Creating the web part's code files

1. Open the web project in Visual Studio (or Visual Web Developer) using the **WebProject.sln** (or **WebApp.sln**) file or using **File -> Open -> Web site...** in Visual Studio.
2. Right-click the **CMSWebParts** folder in the **Solution Explorer** window and choose **New Folder**. Name the folder **MyWebParts**.
3. Right-click the **MyWebParts** folder and choose **Add New Item**.
4. Create a new **Web User Control** named **HelloWorld.ascx**.

5. In the **Control** declaration, enter the full relative path of the control's code behind file into the **CodeFile** attribute (**CodeBehind** attribute on web application installations).

```
<%@ Control Language="C#" AutoEventWireup="true" CodeFile="~/CMSWebParts/MyWebParts/HelloWorld.ascx.cs" Inherits="CMSWebParts_MyWebParts_HelloWorld" %>
```

6. Switch to the **Design** view and drag the following controls onto the form from the toolbox:

- **Button**
- **Label**

7. Double-click the Button control and add the following code to the **Button1_Click** method:

[C#]

```
Label1.Text = DateTime.Now.ToString();
```

[VB.NET]

```
Label1.Text = DateTime.Now.ToString()
```

8. Add the following line to the beginning of the code:

[C#]

```
using CMS.PortalControls;
```

[VB.NET]

```
Imports CMS.PortalControls
```

9. Change the following line:

[C#]

```
public partial class CMSWebParts_MyWebParts_HelloWorld : System.Web.UI.UserControl  
to  
public partial class CMSWebParts_MyWebParts_HelloWorld : CMSAbstractWebPart
```

[VB.NET]

```
Partial Class CMSWebParts_MyWebParts_HelloWorld  
    Inherits System.Web.UI.UserControl  
to  
Partial Class CMSWebParts_MyWebParts_HelloWorld  
    Inherits CMSAbstractWebPart
```

This ensures that the user control inherits from the correct base class and behaves as a web part.

10. Add the following code to the **Page_Load** method:

[C#]

```
Button1.Text = (string)this.GetValue("ButtonText");
```

[VB.NET]

(Visual Basic.NET doesn't create the **Page_Load** method automatically, so you need to add the whole method:)

```
Protected Sub Page_Load(ByVal sender As Object, ByVal e As System.EventArgs)
    Handles Me.Load
        Button1.Text = CType(My.GetValue("ButtonText"), String)
End Sub
```

This code sets the button text to the value configured for the web part through its **ButtonText** property in Kentico CMS Desk (this property will be defined later in the example). Please notice the use of the **GetValue** method (inherited from the parent class), which allows you to dynamically load values of the web part's properties. The method's parameter must match the *Column name* of the property that you wish to retrieve.

11. Save all changes. If your Kentico CMS project was installed as a web application, you must **Build** the project.

Registering the web part in the system

1. Open **Site Manager -> Development -> Web parts**.
2. Select the root of the tree (*All web parts*) and click  **New category**.
3. Enter *My web parts* into the **Category display name** field, *MyWebParts* into the **Category name** field and click  **Save**.
4. Select the new category and click  **New web part**.
5. Choose to **Create a new web part** and enter the following values:
 - **Display name:** Hello world
 - **Code name:** HelloWorld
 - **File path:** ~/CMSWebParts/MyWebParts/HelloWorld.ascx
 - **Generate the code files:** false (the web part's source files were prepared in the previous steps, so there is no need to generate them)
6. Click  **Save**.
7. Switch to the **Properties** tab and add () the following property:
 - **Column name:** ButtonText
 - **Attribute type:** Text
 - **Attribute size:** 100
 - **Field caption:** Button text
 - **Form control:** Text box

8. Click **Save**.

Adding an instance of the web part to a page

1. Switch to **CMS Desk**.
2. Create a new **blank page** using the **Simple** layout (or any other layout) under the root and switch to the **Design** tab.
3. Click **Add web part** () in the upper right corner of the web part zone and choose to add the **Hello world** web part:

IT Company

Shopping cart | My account | My wishlist
Your shopping cart is empty
Text size: ■ ■ ■

Blank page Home Services Products News Community Company Media

Blank page

/Blank page - page template: ad-hoc

zoneLeft

HelloWorld

Label

4. The Web part properties dialog of the **HelloWorld** web part will be displayed. Set the value of the **Button text** field to: *Hello world!*

Web part properties (Hello world)

Refresh content **OK** **Cancel** **Apply**

5. Click **OK**.

Now switch to the **Live site** mode using the button in the main toolbar. You will see the button with text *Hello world!* When you click it, the label displays the current date and time:

You have learned how to create a simple web part. Please keep in mind that in many cases, it may be easier to achieve your goal by altering or extending one of the default web parts rather than developing an entirely new one. The [Modifying web parts](#) sub-chapter covers several ways how this can be done.

Tip: Displaying content in web parts

You can also use Kentico CMS Controls in your web parts (in the code of their ASCX control) to display content from Kentico CMS in a customized format.

Storing files related to web parts

If your web part consists of several files (such as other ASCX controls, images, js scripts, etc.), you should place these files in a sub-folder under the folder where your main web part ASCX file is placed. If the code name of the web part is **MyWebPart**, the sub-folder's name must be **MyWebPart_Files**. This will ensure that the additional files are included in the web part's export package and imported correctly when you move your website or distribute the web part to other developers.

Initializing Kentico CMS controls in your custom web parts

If you are using Kentico CMS controls in your web parts, it is recommended to initialize their properties using a combination of the **OnContentLoaded** and **SetupControl** methods. This is the way it is handled in all Kentico CMS web parts. You can view the code of any of the web parts located in `<project folder>/CMSWebParts` and use it as an example.

If you are using standard .NET controls or third party controls, this can be handled in the **PageLoad** method.

If a problem occurs (e.g. on postback), try loading the control dynamically. This can be achieved by converting the web part to a standard control and loading using the **General -> User control** web part).

Error message "The control collection cannot be modified during DataBind, Init, Load, PreRender or Unload phases."

If you get this error message you may need to modify the code of your web part, so that it doesn't display any content on the Design tab - for example:

[C#]

```
using CMS.PortalEngine;

public override void OnContentLoaded()
{
    base.OnContentLoaded();
    if ((this.PagePlaceholder.ViewMode == ViewModeEnum.Design)
```

```
    || (this.HideOnCurrentPage) || (!this.IsVisible))  
    {  
        this.Repeater1.DataSourceID = "";  
        this.CMSRepeater1.StopProcessing = true;  
    }  
}
```

7.27.4 Modifying web parts

7.27.4.1 Modifying web parts

If you need to modify the behavior of a standard web part, you may choose from the following options, depending on your goals and requirements:

1. You only need to set a web part's properties dynamically in your code

You can create a user control, add the given web part to it and write additional code. See the [Setting web part properties dynamically in your code](#) topic.

2. You need to modify the design (layout) of a web part

You can use the custom web part layouts described in the [Customizing web part layout](#) topic.

3. You need to modify the code of a web part

You need to create a copy of a standard web part as described in the [Modifying the code of standard web parts](#) topic.

4. You need to create a specialized version of a web part with different default property values

You can use [Web part inheritance](#) to easily create a derived web part.

7.27.4.2 Setting web part properties dynamically in your code

In some cases, you may need to set the values of web part properties in your code, depending on some particular business rules. In such case, you need to create a new ASCX user control and place the original web part onto this user control. In the user control code, you can implement your custom logic and set the properties appropriately.

Example:

The following example shows how you can dynamically set the **WHERE condition (WhereCondition)** property of the **Repeater** web part based on if the current user is or is not authenticated. It uses the standard *News* document type with a custom boolean type field: **Show to public users (ShowToPublicUsers)**.

1. Open the web project in **Visual Studio**.

2. Create a **New folder** under the project root called *CMSSGlobalFiles* (if it doesn't already exist). This location will ensure that your user controls can be exported along with the site when it is deployed to the

live server.

3. Create a new **Web User Control** under the **MSGlobalFiles** folder and name it **NewsRepeater.ascx**.

4. Switch to the **Design** tab and drag and drop **CMSWebParts/Viewers/Documents/cmsrepeater.ascx** from the Solution Explorer onto your user control. You could alternatively use the CMSRepeater server control, but this is not the purpose of this example. Set its properties like this:

- **ID:** RepeaterWebPart1
- **ClassNames:** cms.news (document types)
- **Path:** /news/%
- **TransformationName:** cms.news.preview
- **SelectedItemTransformationName:** cms.news.default

5. Now add the following to the code behind of your user control inside the **MSGlobalFiles_NewsRepeater** class:

[C#]

```
protected void Page_Init(object sender, EventArgs e)
{
    if (CMS.CMSHelper.CMSContext.CurrentUser.IsPublic())
    {
        // public user - show only public news
        this.RepeaterWebPart1.WhereCondition = "ShowToPublicUsers = 1";
        this.RepeaterWebPart1.ReloadData();
    }
}
```

This will set the **WhereCondition** property value dynamically depending on whether the current user is signed in. **Save** all changes. If your Kentico CMS project was installed as a web application, you must **Build** the project.

6. Go to **Site Manager -> Development -> Document types -> News**, add a **New attribute (+)** on the **Fields** tab and set its properties as shown below:

- **Attribute name:** ShowToPublicUsers
- **Attribute type:** Boolean (Yes/No)
- **Field caption:** Show to public users
- **Field type:** Check box

7. Go to **CMS Desk -> Content**, choose **Home**, switch to the **Design** tab and add (+) a new **General -> User control** web part to the *Main* zone. Set the **User control virtual path** property value to: *~/MSGlobalFiles/NewsRepeater.ascx*

8. Edit some news document in the **/News** section of the website on the **Form** tab and check the **Show to public users** checkbox.

9. **Sign out** and view the home page. You should see only news items that you marked as **Show to public users**.

You have learned how to dynamically set web part properties based on your custom logic.

7.27.4.3 Customizing web part layout

Layouts allow you to customize the appearance of web parts or add content. Web part layouts are custom skins that replace the HTML code and ASPX markup of the web part.

- Each web part has its own list of layouts.
- You can select a different layout for every instance of the web part.

To select the layout for specific web part instances:

1. Go to CMS Desk.
2. Edit the document containing the web part instance on the **Design** tab.
3. Configure (ⓘ) the web part instance.
4. Switch to the **Layout** tab of the web part configuration dialog.
5. Select an existing layout or write a *(New)* layout.
 - The *(Default)* layout uses the markup of the web part's source file.

You can also manage the layouts of web parts in **Site Manager -> Development -> Web parts** by editing web parts on the **Layout** tab.

Requirement

The **Control** declaration in the markup of the web part's [user control file](#) must contain the **full relative path** to the code behind file in the **CodeFile** attribute (**CodeBehind** attribute on web application installations). For example:

```
<%@ Control Language="C#" AutoEventWireup="true"
Inherits="CMSWebParts_Navigation_cmslistmenu"
CodeFile="~/CMSWebParts/Navigation/cmslistmenu.ascx.cs" %>
```

Do not remove controls from the layout

Keep all of the default controls inside the code of web part layouts to ensure that web parts work correctly. If you need to hide any of the controls, add the **Visible="False"** attribute.

Note: Your custom web part layouts may not work after upgrading to a new version of Kentico CMS (if the controls in the web part's markup changed). Please test your website carefully after upgrading, and update your custom layouts according to the controls in the default layout if necessary.

Example: Customizing the Newsletter subscription dialog

In this example, we will customize the newsletter subscription dialog layout. The standard layout looks like this (when no user is logged on):

Go to **CMS Desk -> Content** and navigate to the **Examples -> Web parts -> Newsletters -> Newsletter subscription** page (if you're using the sample Corporate Site).

Switch to the **Design** tab and configure (🔍) the **Newsletter subscription** web part. Click the **Layout** tab and choose (*New*) from the drop-down list. Fill in the following values:

- **Display name:** Narrow layout
- **Code name:** NarrowLayout

Then enter the following **Layout code**:

Please note: If you installed the Kentico CMS project as a web application, you need to rename the **CodeFile** attribute on the first line to *CodeBehind* for the code example to be functional.

```
<%@ Control Language="C#" AutoEventWireup="true"
Inherits="CMSWebParts_Newsletters_NewsletterSubscriptionWebPart" CodeFile="~/
CMSWebParts/Newsletters/NewsletterSubscriptionWebPart.ascx.cs" %>

<%@ Register Src="~/CMSFormControls/Inputs/SecurityCode.ascx"
TagName="SecurityCode" TagPrefix="cms" %>

<asp:Panel ID="pnlSubscription" runat="server" DefaultButton="btnSubmit"
CssClass="Subscription">
  <asp:Label runat="server" ID="lblInfo" CssClass="InfoMessage"
  EnableViewState="false"
  Visible="false" />
  <asp:Label runat="server" ID="lblError" CssClass="ErrorMessage"
  EnableViewState="false"
  Visible="false" />
  <div class="NewsletterSubscription">
    <table cellpadding="0" cellspacing="0" border="0" class="Table">
      <asp:PlaceHolder runat="server" ID="plcFirstName">
        <tr>
          <td>
            <cms:LocalizedLabel ID="lblFirstName" runat="server"
            AssociatedControlID="txtFirstName"
            EnableViewState="false" />
          <br />
          <asp:TextBox ID="txtFirstName" runat="server"

```

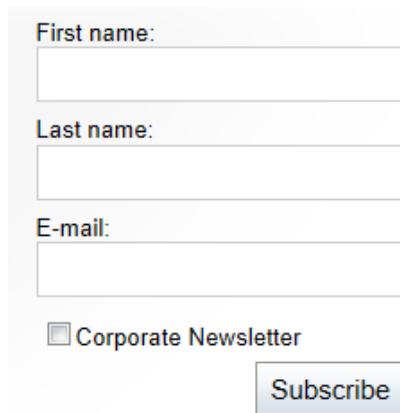

```

        CssClass="SubscriptionTextbox"
            MaxLength="200" />
    </td>
</tr>
</asp:Placeholder>
<asp:Placeholder runat="server" ID="plcLastName">
    <tr>
        <td>
            <cms:LocalizedLabel ID="lblLastName" runat="server"
AssociatedControlID="txtLastName"
                EnableViewState="false" />
            <br />
            <asp:TextBox ID="txtLastName" runat="server"
        CssClass="SubscriptionTextbox"
            MaxLength="200" />
        </td>
    </tr>
</asp:Placeholder>
<asp:Placeholder runat="server" ID="plcEmail">
    <tr>
        <td>
            <cms:LocalizedLabel ID="lblEmail" runat="server"
AssociatedControlID="txtEmail"
                EnableViewState="false" />
            <br />
            <asp:TextBox ID="txtEmail" runat="server"
        CssClass="SubscriptionTextbox"
            MaxLength="400" />
        </td>
    </tr>
</asp:Placeholder>
<asp:Placeholder runat="server" ID="plcNwsList">
    <tr>
        <td>
            <asp:CheckBoxList runat="server" ID="chklNewsletters"
        CssClass="NewsletterList" />
        </td>
    </tr>
</asp:Placeholder>
<asp:Placeholder runat="server" ID="plcCaptcha">
    <tr>
        <td>
            <cms:LocalizedLabel ID="lblCaptcha" runat="server"
AssociatedControlID="scCaptcha"
                EnableViewState="false" />
            <br />
            <cms:SecurityCode ID="scCaptcha"
GenerateNumberEveryTime="false" runat="server" />
        </td>
    </tr>
</asp:Placeholder>
<asp:Placeholder ID="pnlButtonSubmit" runat="server">
    <tr>
        <td align="right">
            <cms:LocalizedButton ID="btnSubmit" runat="server"
OnClick="btnSubmit_Click"
                CssClass="SubscriptionButton"
            EnableViewState="false" />
        </td>
    </tr>

```

```
        </tr>
    </asp:Placeholder>
    <asp:Placeholder ID="pnlImageSubmit" runat="server">
        <tr>
            <td align="right">
                <asp:ImageButton ID="btnImageSubmit" runat="server"
OnClick="btnSubmit_Click"
                EnableViewState="false" />
            </td>
        </tr>
    </asp:Placeholder>
</table>
</div>
</asp:Panel>
```

Click **OK**. When you look at the page now, you will see that the dialog looks like this (when no user is logged on):

First name:

Last name:

E-mail:

Corporate Newsletter

Layout styles

You can define any CSS classes used within the layout code by clicking the [Add CSS styles](#) link below the layout editor and adding the styles into the **CSS styles** field. If the styles require additional files (such as images), you can add them on the **Theme** tab, which is available when editing the layout in **Site Manager -> Development -> Web parts**.

For more information about page component CSS styles, please see the [Development -> CSS stylesheets and design -> CSS for page components](#) topic.

7.27.4.4 Modifying the code of standard web parts

This topic explains how you can create a copy of a standard web part and customize its behavior by modifying its code.

The following example uses the [Forms -> On-line form](#) web part as its base. It shows how you can send a custom e-mail when a form is submitted and display a confirmation message. Please note that this is only for demonstration purposes. There is a much easier way to set up notifications or autoresponders for on-line forms through the built-in functionality of the [Forms](#) module.

1. Create a copy of the *On-line form* web part in Kentico CMS. Go to **Site Manager -> Development -> Web parts** and select the **Forms -> On-line form** web part from the tree. Click the  **Clone web part** action and enter the following values:

- **New object display name:** Form with custom e-mail
- **New object code name:** FormWithEmail

- **Clone web part to category:** Forms
- **Clone web part files:** yes (checked)
- **Cloned web part file name:** BizForms/formwithemail.ascx

Click **Clone**. The system creates a copy of the existing web part and its code files (ASCX and CS) using the specified names.

2. Open the web project in Visual Studio using the **WebProject.sln** (or **WebApp.sln**) file and edit **~/CMSWebParts/BizForms/formwithemail.ascx**.

Important!

If you installed Kentico CMS as a web application, the clone's code files will not be visible right away, since they are not included in the project. In this case:

1. Click **Show all files** at the top of the Solution Explorer.
2. Right-click the **formwithemail.ascx** file in the BizForms folder.
3. Select **Include in Project**.

3. Switch to the **Design** tab and drag and drop a **Label** control onto the page. Set its **ID** to *lblConfirmationMessage* and clear its **Text** property.

4. Edit the code behind file and locate the **viewBiz_OnAfterSave** handler, which is executed every time the form is saved. Insert the following code after the default content of the method:

[C#]

```
void viewBiz_OnAfterSave(object sender, EventArgs e)
{
    ...

    // Creates a new e-mail message.
    CMS.EmailEngine.EmailMessage msg = new CMS.EmailEngine.EmailMessage();

    msg.From = "mail@localhost.local"; // Enter any valid e-mail address.
    msg.Recipients = "mail@localhost.local"; // Use a valid e-mail address that
you can access.
    msg.Subject = "Custom form e-mail";
    msg.Body = "The value of the FirstName field: "
        + CMS.GlobalHelper.ValidationHelper.GetString(
            viewBiz.BasicForm.GetDataValue("FirstName"), "N/A");
}
```

```
// Sends out the custom e-mail notification.
CMS.EmailEngine.EmailSender.SendEmail(msg);

// Sets the confirmation message shown in the label.
lblConfirmationMessage.Text = "The e-mail has been sent.";
}
```

This code creates a new e-mail message, sends it out and adds text into the confirmation label. You can notice how the content of the e-mail dynamically retrieves a field value from the current form by using the **BasicForm.GetDataValue(string fieldName)** method, which may be called through the corresponding property of the BizForm control. Fill in valid e-mail addresses into the code to be able to try out the example.

Save all changes. Remember to **Build** the project if it is installed as a web application.

5. Go to **CMS Desk -> Content**, choose the **Home** page, switch to the **Design** tab and add the **Form with custom e-mail** web part to the *Main zone* zone. Set the **Form name** property to the **Contact Us** form using the **Select** button. This form should be available by default if you are working with the sample Corporate Site, and it includes the **FirstName** field used in the custom code.

6. Finally, open the live site and view the Home page. Enter some values into the form and submit it. You will see the additional confirmation message ("The e-mail has been sent.") and the specified address will receive the e-mail.

You have seen how to create a customized version of a standard web part. Using the same approach, you can modify the ASPX markup or code behind of any of the default web parts in order to alter their functionality to fit your specific requirements.

7.27.4.5 Web part inheritance

Web part inheritance allows you to create a web part that has the same properties and uses the same code as the original web part, but has different default property values. It means you can create a specialized web part from a general one.

For example: You can create a news list web part inherited from the Repeater web part that will display a list of news by default. The default values can later be modified to any other value, but the inherited (specialized) web part allows you to do things faster.

How to create an inherited web part

1. Go to **Site Manager -> Development -> Web parts**, select the **Listings and viewers** category and click  **New web part**.

2. Choose **Inherit from an existing web part** and enter the following values:

- **Display name:** Custom news list
- **Code name:** CustomNewsList
- **Inherit from:** Listings and viewers/Documents/Repeater

Click  **Save**.

3. Switch to the **Properties** tab of the newly created web part. Here you can see the properties of the parent web part and you can override their default values by clearing the **Inherited** box and entering a new default value. Enter the following default values:

- **Path:** /%
- **Document types:** cms.news
- **ORDER BY expression:** NewsReleaseDate
- **Transformation:** cms.news.preview
- **Selected item transformation:** cms.news.default

Click  **Save**.

Web parts > News > News list

General Properties System properties Layout CSS Theme Documentation

 Save

Content

Path: Text Inherited

Data source name: Text Inherited

Content filter

Document types: Text Inherited

Category name: Text Inherited

Combine with default culture: Text Inherited

Culture code: Text Inherited

Maximum nesting level: Integer Inherited

ORDER BY expression: Text Inherited

Select only published: Boolean Inherited

Select top N documents: Integer Inherited

Site name: Text Inherited

WHERE condition: Text Inherited

Columns: Text Inherited

Filter out duplicate documents: Boolean Inherited

Filter name: Text Inherited

Transformations

Transformation: Text Inherited

Alternating transformation: Text Inherited

Selected item transformation: Text Inherited

4. Go to **CMS Desk**, choose the **Home** page in the content tree and switch to the **Design** tab. Add the News list web part to the page. It will now display all site news without any additional configuration.

7.27.4.6 Adding custom code to web parts (obsolete)

Obsolete feature

This feature is now obsolete. If you need to customize the behavior of some web part, please clone the web part and customize it.

If you still need to use this feature (for backward compatibility), you need to enable it by adding the following parameter to your web.config file, to the **appSettings** section:

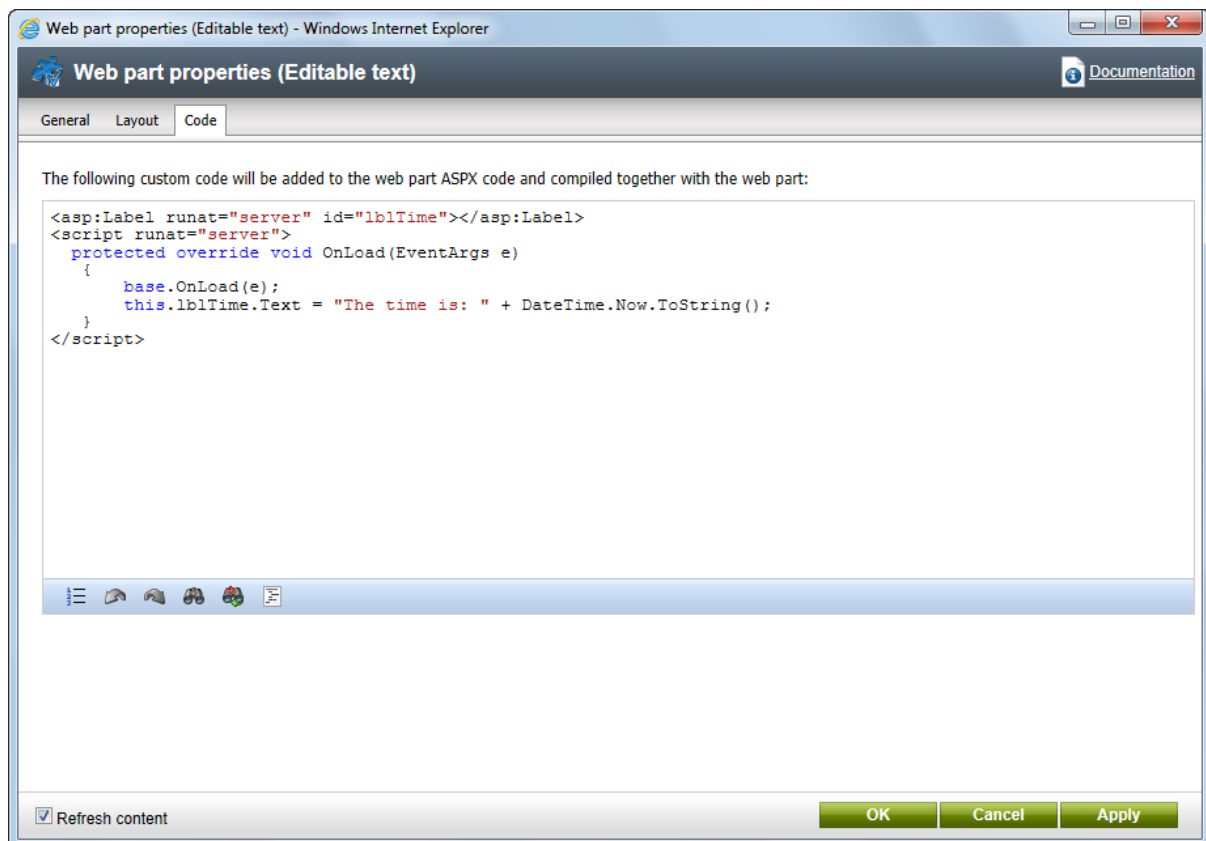

```
<add key="CMSShowWebPartCodeTab" value="true" />
```

Limitations when using the Code tab

If you add custom code on the Code tab, you will not be able to pre-compile the website and you will not be able to use the website in a medium trust environment. If this is an issue for you, you can use the alternative solutions described in this chapter.

If you need to modify the behavior or enhance the functionality of some web part only on a single page template, you can add custom code on the **Code** tab:

The following code displays the current date and time below the current web part:

[C#]

```
<asp:Label runat="server" id="lblTime"></asp:Label>
<script runat="server">
    protected override void OnLoad(EventArgs e)
    {
        base.OnLoad(e);
        this.lblTime.Text = "The time is: " + DateTime.Now.ToString();
    }
</script>
```

Programming language

Please note: You can only use the programming language in which the web part is written. If the web part was written in C#, you can use only C# here.

The following code sample sets the **WhereCondition** property of the web part dynamically at run-time:

[C#]

```
<script runat="server">
public override void OnContentLoaded()
{
    this.SetValue("WhereCondition", "NewsTitle LIKE '%News%'");
    base.OnContentLoaded();
}
</script>
```

Calling the original method from the inherited class

If you override some method of the web part, please be sure to always also call the original method (using `base.Method` in C# or `MyBase.Method` in VB). If you omit this, the web part may not work properly.

7.27.4.7 Web part binding (obsolete)

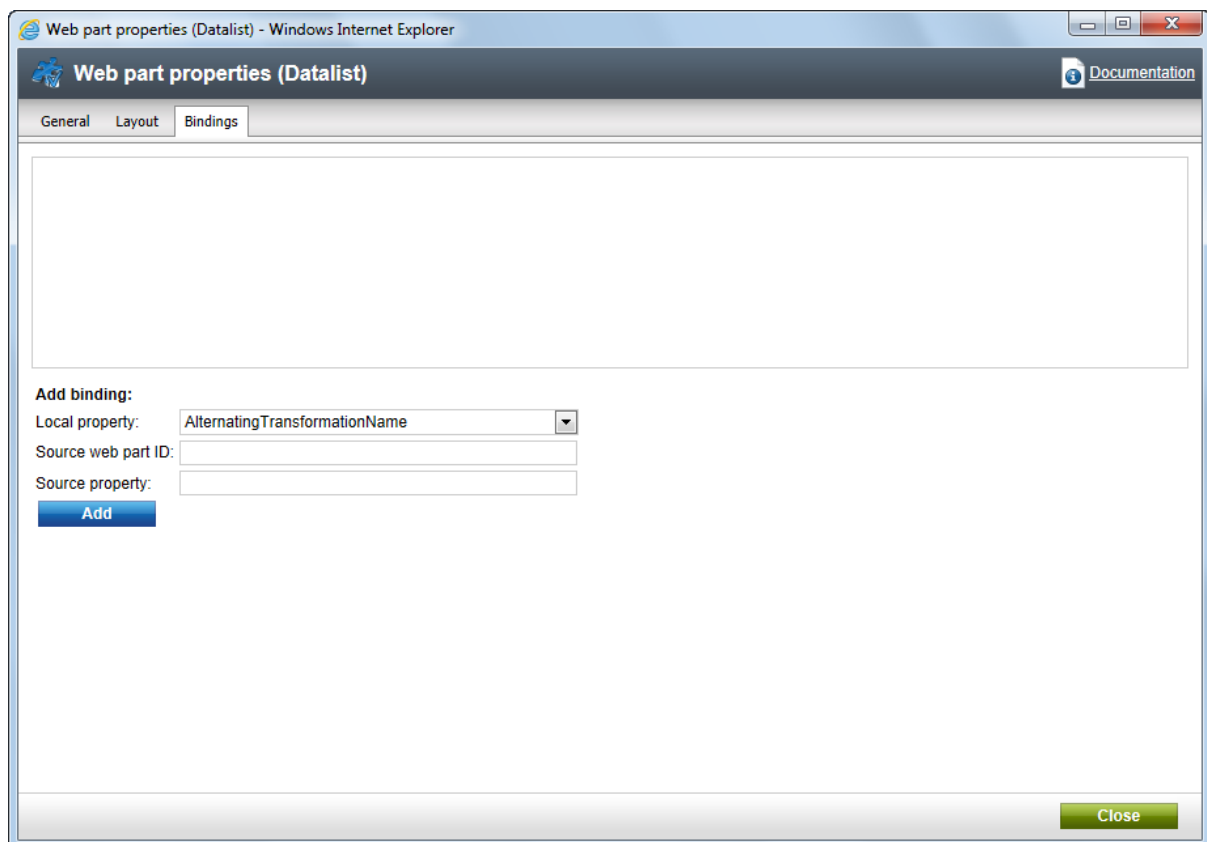

Obsolete feature

This feature is now obsolete. If you need to bind the behavior of a web part to another web part value, please use URL parameters or create a user control that contains both web parts and write custom code that will ensure the communication between the web parts (as described in [Setting web part properties dynamically in your code](#)).

If you need to use this feature for backward compatibility, you need to add the following parameter to your web.config file, to the **appSettings** section:

```
<add key="CMSShowWebPartBindingTab" value="true" />
```

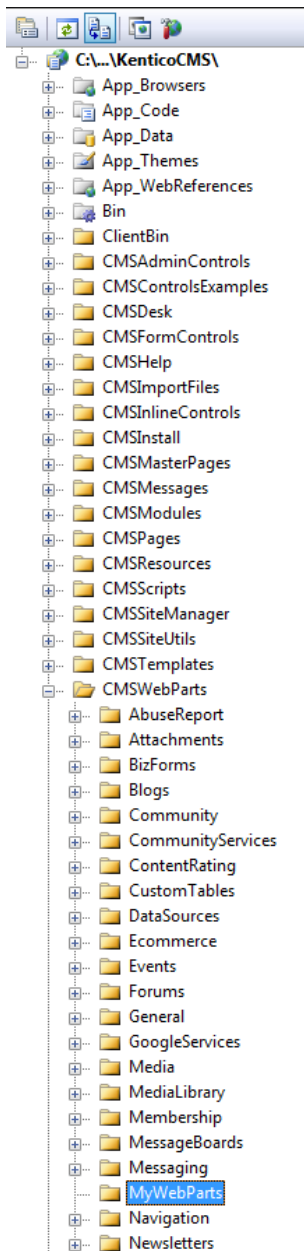

Web part binding allows you to connect two web parts. For example: you can have a web part containing a drop-down list with countries. When some value is selected, it is provided to another web part that displays a list of company offices in the selected country. You can manage web part binding on the **Binding** tab:

Example - creating a product selection dialog with drop-down list and product list

In this example, we will create two web parts - selector and viewer and bind their properties so that the product viewer reflects the product selector status.

1. Open the CMS project in Visual Studio and create a new folder **MyWebParts** under the **CMSWebParts** folder in the Solution Explorer:

2. Create a new user control (ASCX) under **MyWebParts** folder and call it **ProductSelector.ascx**. Switch to its HTML source and paste the following code:

```
<asp:DropDownList ID="DropDownList1" runat="server"
    OnSelectedIndexChanged="DropDownList1_SelectedIndexChanged" AutoPostBack="true">
    <asp:ListItem Value="Under">Under 500</asp:ListItem>
    <asp:ListItem Value="Over">Over 500</asp:ListItem>
</asp:DropDownList>
```

Switch to the code behind and add the following code to the beginning of the code:

[C#]

```
using System;
using CMS.PortalControls;
using CMS.GlobalHelper;
using CMS.DocumentEngine;
using CMS.CMSHelper;
using CMS.ExtendedControls;
```

Change the class inheritance like this:

[C#]

```
public partial class CMSWebParts_MyWebParts_ProductSelector : CMSAbstractWebPart
```

Add the following code inside the page class:

[C#]

```
protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
{
    this.SetValue("PriceRange", this.DropDownList1.SelectedValue.ToString());
    this.ReloadConsumers();
}
```

Please note that you need to set the new value of the web part property **PriceRange** and call the **ReloadConsumers** method.

3. Create a new user control (ASCX) under **MyWebParts** folder and call it **ProductViewer.ascx**. Switch to its HTML source and paste the following code:

```
<%@ Register Assembly="CMS.Controls" Namespace="CMS.Controls" TagPrefix="ccl" %>
<ccl:CMSRepeater ID="CMSRepeater1" runat="server" EnableViewState="true"
TransformationName="CorporateSite.Transformations.ProductList"
SelectedItemTransformationName="CMS.Smartphone.Default" Path="/%"
ClassNames="CMS.Smartphone">
</ccl:CMSRepeater>
```

The **CMSRepeater** control will display the product list.

Switch to the code behind and add the following code to the beginning of the code:

[C#]

```
using System;
using CMS.PortalControls;
using CMS.GlobalHelper;
```

```
using CMS.DocumentEngine;  
using CMS.CMSHelper;  
using CMS.ExtendedControls;
```

Change the class inheritance like this:

[C#]

```
public partial class CMSWebParts_MyWebParts_ProductViewer : CMSAbstractWebPart
```

Add the following code inside the page class:

[C#]

```
public override void OnContentLoaded()
{
    base.OnContentLoaded();
    SetupControl();
}
/// <summary>
/// Reloads data on request
/// </summary>

public override void ReloadData()
{
    base.ReloadData();
    this.SetupControl();
    this.CMSRepeater1.ReloadData(true);
}

/// <summary>
/// Initializes the control properties
/// </summary>

protected void SetupControl()
{
    if ((this.PagePlaceholder.ViewMode == CMS.PortalEngine.ViewModeEnum.Design) ||
        (this.HideOnCurrentPage) || (!this.IsVisible))
    {
        // Stop processing in Design mode and if the control is invisible
        this.CMSRepeater1.StopProcessing = true;
    }

    else
    {
        // set CMSRepeater properties according to the selected value (price
        range)
        string priceRange = ValidationHelper.GetString(this.GetValue
        ("PriceRange"), "Under");
        if (priceRange == "Over")
        {
            this.CMSRepeater1.WhereCondition = "SKUPrice > 500";
        }

        else
        {
            this.CMSRepeater1.WhereCondition = "SKUPrice <= 500";
        }
    }
}
```

4. Save the changes and go to **Site Manager -> Development -> Web parts**. Create a new category called **My Web Parts** and add a new web part:

- **Display name:** Product selector
- **Code name:** ProductSelector
- **File path:** MyWebParts/ProductSelector.ascx

5. Create another new web part:

- **Display name:** Product viewer
- **Code name:** ProductViewer
- **File path:** MyWebParts/ProductViewer.ascx

... and then switch to the **Properties** tab and create a new property:

- **Attribute name:** PriceRange
- **Attribute type:** Text
- **Attribute size:** 100
- **Allow empty value:** yes
- **Display attribute in the editing form:** no

6. Go to CMS Desk, create a new blank page and call it **Product list**.

7. Switch to the **Design** tab and add the **Product selector** web part to the page. Leave all its properties at the default values.

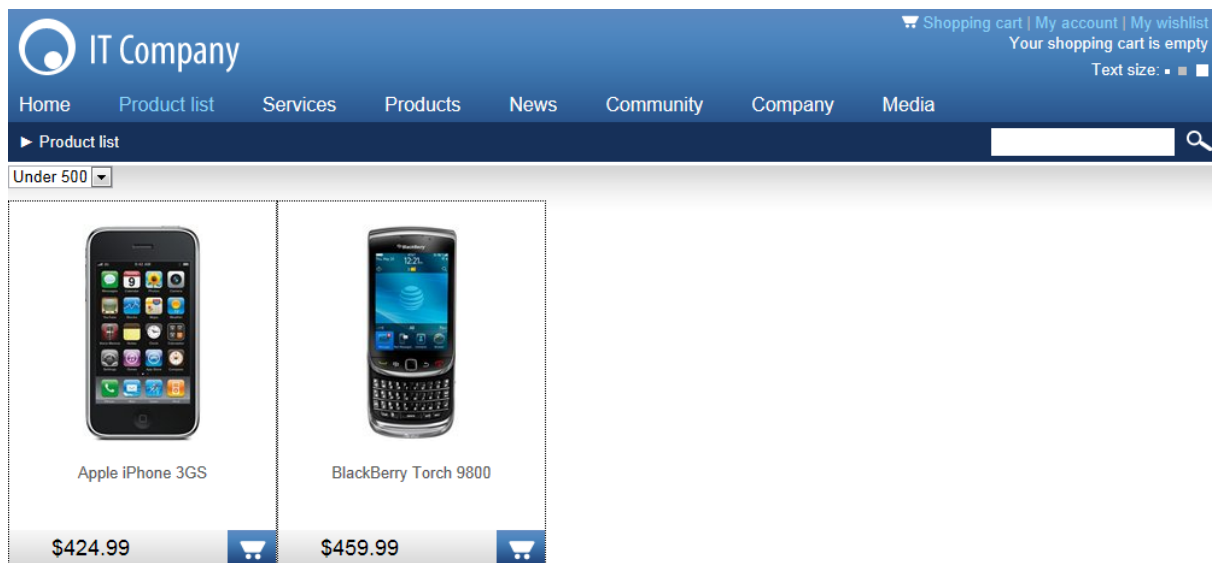

8. Next, add the **Product viewer** web part, set the following properties on the **General** tab:

- **Content before:** <div class="Product list">
- **Content after:** </div>

and on the **Binding** tab, add a new web part binding using the following values:

- **Local property:** PriceRange
- **Source web part ID:** ProductSelector
- **Source property:** PriceRange

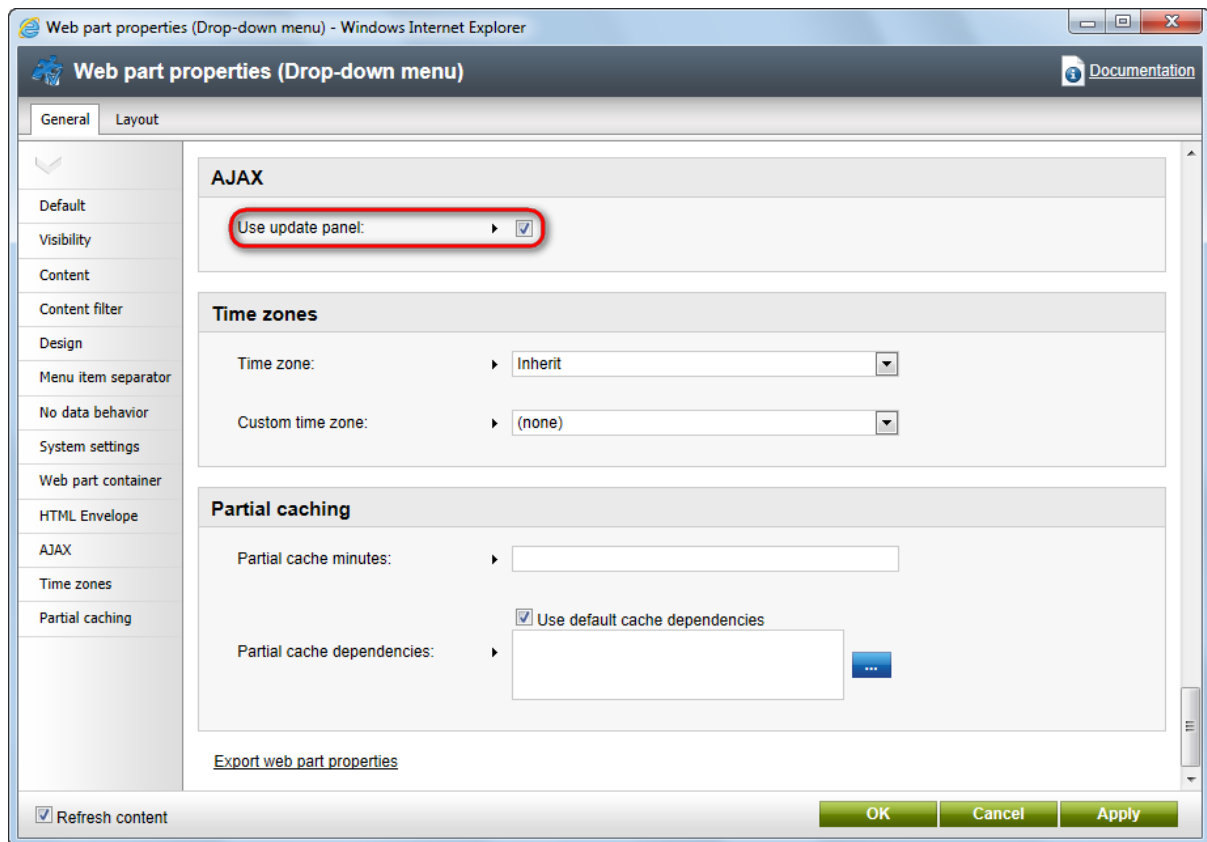

9. Go to the **Live site** mode and see the page. It should look like this:

When you change the drop-down list value, the product list below is automatically updated.

7.27.5 AJAX support

Your web parts can use the UpdatePanel, which wraps the web part into an AJAX UpdatePanel control. This can easily be done by enabling the **Use update panel** property of any web part.

No further modifications are necessary, but the following rules should be followed:

1. If the web part uses any dynamically loaded controls, their ID must be defined:

Incorrect:

```
Control ctrl = this.LoadControl("~/MyControl.ascx");  
if (ctrl != null)  
{  
    Controls.Add(ctrl);  
}
```

Correct:

```
Control ctrl = this.LoadControl("~/MyControl.ascx");  
if (ctrl != null)
```

```
{  
    ctrl.ID = "myControl";  
    Controls.Add(ctrl);  
}
```

2. When requesting `PostBackEventReference`, use Kentico's custom function instead of the default one:

Incorrect:

```
this.Page.ClientScript.GetPostBackEventReference(this, "");
```

Correct:

```
CMS.ExtendedControls.ControlsHelper.GetPostBackEventReference(this, "");
```

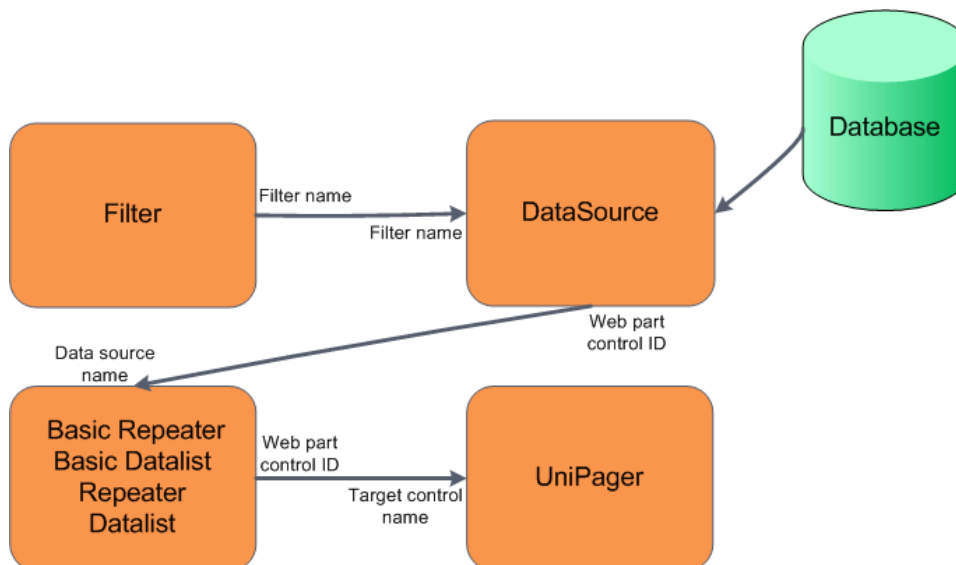

7.27.6 Data source web parts

7.27.6.1 Using Data source web parts

Data source web parts retrieve data from the database (or other sources) and send it to be displayed by other connected web parts. This allows you to distribute the following functions between multiple web parts:

- Loading data
- Displaying and formatting data
- Allowing users to filter the displayed data
- Paging

The diagram below shows how to link together a data source and other types of components. You can place these web parts anywhere on the same page without any change in functionality.

The line captions show which properties connect the web parts. The properties at the beginning and end of each line must have identical values.

Many listing web parts contain a built-in data source. For example, the default [Repeater](#) and [Datalist](#) provide their own data source for loading documents. If you wish to connect a separate data source to these web parts, the type of the data source web part must match the internal data source (e.g. the [Repeater](#) web part can only display data from a [Documents data source](#)).

To display items from any type of data source, use the [Basic repeater](#) or [Basic datalist](#). These web parts do not load data on their own and require a connected data source web part to work correctly.

Example

The following example demonstrates the data source concept in practice. It creates a group of interconnected web parts that load product documents, display them on the website and also provide filtering and paging functionality for the data.

1. Sign in to CMS Desk and edit the sample *Corporate site*.
2. Create a new **Page (menu item)** document under the **Products** section. Choose the **Create a blank page** option in the page template selection dialog.
3. Add the **Products data source** web part to the web part zone on the page. Leave the default values for all of the web part's properties.
4. Add the **Basic repeater** web part to the same web part zone. Set the following properties:
 - **Data source name:** ProductsDataSource (this is the default ID of the *Products data source* web part)
 - **Transformation name:** CMS.Product.Default (this is a basic transformation for formatting product data)

The screenshot shows the Kentico CMS 7.0 Developer's Guide interface. The left sidebar displays a tree view of the site structure, including 'Corporate Site', 'Home', 'Products', 'Data source example', 'Smartphones', 'Laptops and Tablets', 'Software', 'E-Books', 'IT Services', 'Memberships', 'Donations', 'News', 'Partners', 'Community', 'Services', 'Company', 'Media', 'Examples', 'Mobile', 'Other', 'Special Pages', and 'Images'. The main content area shows a page titled 'IT Company' with a navigation menu (Home, Products, News, Community, Services, Company, Media) and a breadcrumb trail 'Products > Data source example'. The page content displays a 'BasicRepeater' web part with the following details:

- name: /Products/Data source example
- Price: \$150.00
- Description: Web development in today's fast changing on-line environment requires deep knowledge and extensive experience. project you have already started, we have the solution for you. Our team of professional consultants is here to help you simple static presentations to enterprise-level web applications. With their help, no problem remains unsolved!
- Photo:
- Product name: Apple iPad 2
- Price: \$510.99

Basic repeater displaying products loaded from the connected data source web part

5. Add the **Product filter** web part to the same web part zone. Set the following property of the filter web part:

- **Filter name:** ProductFilter

This filter allows users to limit which products the page displays based on various criteria.

6. If you inserted the product filter web part using the zone's **Add web part (+)** action, the system automatically adds the filter to the bottom of the zone. In this case, scroll down to the filter web part and move it above the repeater:

- Right-click the web part.
- Hover over **Move to** and click **Up**.

7. Configure () the properties of the *Products data source* web part and type the filter's name

(*ProductFilter*) into the **Filter name** property.

- This connects the filter to the data source. The data source web part now loads a limited set of items according to the current filter settings.

8. Add the **Universal pager** web part to the zone with the following properties:

- **Target control name:** BasicRepeater
- **Page size:** 5
- **Group size:** 5
- **Pager layout transformation:** CMS.PagerTransformations.General-PagerLayout

This web part connects to the repeater and separates the displayed data into multiple shorter pages. Paging can be useful when displaying a large number of records.

Result

You can try out the functionality of the page by switching to **Live site** mode.

For example, use the filter to display only products that have the *Featured Status* and sort the items by price from high to low.

The screenshot shows a web application interface for 'IT Company'. The top navigation bar includes 'Home', 'Products', 'News', 'Community', 'Services', 'Company', and 'Media'. The 'Products' menu is expanded to show 'Data source example'. Below this, there are filter controls: 'Status: Featured', 'Manufacturer: (all)', and 'Only in stock' (checkbox). The 'Sorting' dropdown is set to 'By price: high to low', and a 'Filter' button is highlighted with a red box. The product list shows one item: 'Product name: Apple MacBook Pro MC723LL/A' and 'Price: \$2199.00'. Below the product details, there is a paragraph of text: 'We couldn't leave fast enough alone. The new 15-inch model brings quad-core power to quad-core Intel Core i7 processor — with Turbo Boost speeds up to 3.4GHz and up to 8l Pro models to run applications up to twice as fast as their top-of-the-line predecessors.'

The pager below the data ensures that the list only includes up to 5 products and allows users to switch between pages.

Description:

Surf the web in style with multi-window browsing, a smooth video playback. We've transformed the local portfolio, view your friend's status, and more. Have rays or wipe away the droplets of water.

7.27.6.2 Problems with XML data sources

The [XML data source](#) web part provides data from an XML file specified by its **XML URL** property. It uses the [Dataset.ReadXml\(\)](#) method to read the XML files. This method may separate data from the source XML file into more than one dataset table. In these cases, you need to specify which dataset table the web part should use through the **Table name** property.

Unfortunately, you cannot explicitly determine how the data source organizes XML data into tables. You can find out which table contains the data that you require using the **Debug** function in **Visual Studio**.

If the datasource separates the data into multiple tables and the **Table name** property is not specified appropriately, the web part does not provide any data.

In some cases, the data that you wish to load may be separated into multiple dataset tables. You cannot use the **Table name** property to specify more than one table, so the only way to resolve this issue is to modify the source XML structure (if possible).

7.27.6.3 Developing Data source web parts

When developing custom data source web parts, you need to create two separate user controls:

1. The first control ensures the loading of the data that will be provided by the data source. This control must inherit from **CMSBaseDataSource** (found in the *CMS.Controls* namespace).
2. The second user control contains the first control in its markup and serves as the source file for the actual web part. Must inherit from **CMSAbstractWebPart**.

Example

This example shows how to create a custom data source web part that provides user data from the CMS.

Open your web project in Visual Studio and create two user controls according to the sections below.

Warning

The code is only for demonstrational purposes. Set the values of the *Inherits* attribute in the user control declarations and the class names according to the name and location of your controls.

DataSourceControl.ascx

Leave the ASCX markup of the first user control empty.

DataSourceControl.ascx.cs

The **OnInit** override and **DataFilter_OnFilterChanged** handler method are needed to manage connected filters. If you are not planning to use filters with the data source web part, you do not need to implement these methods.

[C#]

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Web;
using System.Web.UI;
using System.Web.UI.WebControls;
using System.Data;

using CMS.Controls;
using CMS.SiteProvider;

/// <summary>
/// User data source. Loads all users according to a specified where condition.
/// </summary>
public partial class CMSGlobalFiles_DataSourceControl : CMSBaseDataSource
{
    #region "Properties"

    /// <summary>
    /// Gets or sets the data source.
    /// </summary>
    public override object DataSource
    {
        get
        {
            return mDataSource ?? (mDataSource = base.GetDataSource());
        }
        set
        {
            mDataSource = (DataSet)value;
        }
    }

    #endregion

    #region "Methods"

    /// <summary>
    /// Assigns a handler for the 'OnFilterChanged' event if there is a filter
    /// attached to the data source.
    /// </summary>
    protected override void OnInit(EventArgs e)
```

```
{
    if (SourceFilterControl != null)
    {
        SourceFilterControl.OnFilterChanged += new ActionEventHandler
(DataFilter_OnFilterChanged);
    }

    base.OnInit(e);
}

/// <summary>
/// Handles the OnFilterChanged event.
/// </summary>
void DataFilter_OnFilterChanged()
{
    // Clears the old data
    InvalidateLoadedData();

    // Raises the change event.
    this.RaiseOnFilterChanged();
}

/// <summary>
/// Loads the data provided by the datasource.
/// </summary>
protected override object GetDataSourceFromDB()
{
    // Initializes the data properties according to the filter settings.
    if (SourceFilterControl != null)
    {
        SourceFilterControl.InitDataProperties(this);
    }

    // Loads the data. The WhereCondition and OrderBy properties are inherited
from the parent class.
    DataSource = UserInfoProvider.GetFullUsers(WhereCondition, OrderBy);
    return DataSource;
}

#endregion
}
```

DataSourceWebPart.ascx

Warning: If your Kentico CMS project was installed as a web application, you need to rename the *CodeFile* property on the first line to *Codebehind*.

```
<%@ Control Language="C#" AutoEventWireup="true"
CodeFile="DataSourceWebPart.ascx.cs"
Inherits="CMSTestingSite_APIExamples_Controls_DataSourceWebPart" %>

<%@ Register src="DataSourceControl.ascx" tagname="DataSourceControl"
tagprefix="cms" %>
```

```
<cms:DataSourceControl ID="srcUsers" runat="server" />
```

DataSourceWebPart.ascx.cs

[C#]

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Web;
using System.Web.UI;
using System.Web.UI.WebControls;

using CMS.PortalControls;
using CMS.GlobalHelper;

public partial class CMSGlobalFiles_DataSourceWebPart : CMSAbstractWebPart
{
    /// <summary>
    /// Gets or sets the value of the WhereCondition web part property.
    /// </summary>
    public string WhereCondition
    {
        get
        {
            return ValidationHelper.GetString(this.GetValue("WhereCondition"),
            "");
        }
        set
        {
            this.SetValue("WhereCondition", value);
            srcUsers.WhereCondition = value;
        }
    }

    /// <summary>
    /// Gets or sets the value of the OrderBy web part property.
    /// </summary>
    public string OrderBy
    {
        get
        {
            return ValidationHelper.GetString(this.GetValue("OrderBy"), "");
        }
        set
        {
            this.SetValue("OrderBy", value);
            srcUsers.OrderBy = value;
        }
    }

    /// <summary>
    /// Gets or sets the value of the FilterName web part property.

```

```
/// </summary>
public string FilterName
{
    get
    {
        return ValidationHelper.GetString(this.GetValue("FilterName"), "");
    }
    set
    {
        this.SetValue("FilterName", value);
        srcUsers.SourceFilterName = value;
    }
}

/// <summary>
/// Content loaded event handler.
/// </summary>
public override void OnContentLoaded()
{
    base.OnContentLoaded();
    SetupControl();
}

/// <summary>
/// Initializes the properties of the internal data source control.
/// </summary>
protected void SetupControl()
{
    if (this.StopProcessing)
    {
        // Does nothing if the web part is disabled
    }
    else
    {
        this.srcUsers.WhereCondition = this.WhereCondition;
        this.srcUsers.OrderBy = this.OrderBy;

        // Sets the inner data source's name according to the web part's 'Web
part control ID' property.
        // This allows listing web parts to connect to the inner control.
        // The identifier property is named 'FilterName' because data sources
inherit the property from
        // a base class shared with filter objects.
        this.srcUsers.FilterName = (string)this.GetValue("WebPartControlID");

        // Connects the attached filter, as specified by the 'Filter name'
property of the web part
        this.srcUsers.SourceFilterName = this.FilterName;
    }
}
}
```

If your Kentico CMS project was installed as a web application, you must **Build** the project.

Registering the web part

Register the **DataSourceWebPart.ascx** control as a new web part in Kentico CMS via the **Site Manager -> Development -> Web parts** interface. For details about this process, see the [Developing web parts](#) topic.

1. Type *Custom user data source* as the web part's **Display name**.
2. Set the **Type** of the web part to *Data source* on the **General** tab.
3. On the **Properties** tab, define the following properties for the web part:

- **Column name:** OrderBy
- **Attribute type:** Text
- **Attribute size:** 500
- **Allow empty value:** yes (checked)
- **Field caption:** SQL Order by clause
- **Form control:** Order by

- **Column name:** WhereCondition
- **Attribute type:** Text
- **Attribute size:** 500
- **Allow empty value:** yes (checked)
- **Field caption:** SQL Where condition
- **Form control:** Where condition

- **Column name:** FilterName
- **Attribute type:** Text
- **Attribute size:** 200
- **Allow empty value:** yes (checked)
- **Field caption:** Filter name
- **Form control:** Text box

Result

The custom data source web part is now ready and you can try out its functionality.

Go to **CMS Desk**, create a new page and place the following web parts into its design:

| Web part | Instructions |
|-------------------------|--|
| Custom user data source | Type <i>UsersFilter</i> into the Filter name property. |
| Users filter | Leave the default property values. The Web part control ID is set to <i>UsersFilter</i> by default, which connects the filter to the custom data source. |
| Basic repeater | <ol style="list-style-type: none"> 1. Enter the ID of the Custom user data source web part into the Data source name property: <i>CustomUserDataSource</i> 2. Set an appropriate Transformation name for displaying users, for example: <i>Community.Transformations.MembersList</i> |

The page display a list of all users in the system. You can modify the list by configuring the *SQL Where condition* and *SQL Order by clause* properties of the data source. Visitors can dynamically narrow down the list directly on the page using the connected filter.

7.27.6.4 Developing custom filters

Filters are components that allow users to modify the data loaded and displayed by other website components. Filters provide two types of functionality:

- Limiting the range of items displayed in a list
- Changing the order of items in a list

Kentico CMS comes with a built-in set of filters for various types of data, but you can also create custom filters to fulfill specific requirements.

1. Implement filters as *user controls* that inherit from one of the following base classes:

- **CMSAbstractDataFilterControl** - works with document data sources
- **CMSAbstractMenuFilterControl** - works with navigation web parts
- **CMSAbstractQueryFilterControl** - works with custom table and query data sources

Select the appropriate base class according to the type of data that you need to filter. You can find these base classes in the **CMS.Controls** namespace.

Note

If you are connecting a **CMSAbstractQueryFilterControl** filter to a data source with a custom query, the query must contain the **##WHERE##** and **##ORDERBY##** expressions. When applied, the filter replaces the expressions with dynamically generated SQL code.

Query example:

```
SELECT ##TOPN## ##COLUMNS## FROM View_CONTENT_MenuItem_Joined
WHERE (##WHERE##) ORDER BY ##ORDERBY##
```

2. Add the filter control onto your website through the **Filter** web part.
 - You need to specify the path to the .ascx file in the **Filter control path** property.
3. Attach the filter web part to the data source web part of the matching type.

You can also use custom filters anywhere in your code as standard user controls, for example on ASPX templates or in other web parts. All necessary properties, such as the **FilterName** used to connect with the data source, are inherited from the base class.

Example

The example below demonstrates how to develop a custom filter. This sample filter works with *product documents*. It supports filtering according to product departments and allows the selection of several options that determine the order in which products are displayed. You can create filters for all types of

documents or other objects using the same approach.

1. Open the web project in Visual Studio and create a **New folder** under the root called *CMSSGlobalFiles* (if it doesn't already exist).
 - o The content of this folder can be exported along with your site when it is deployed to the live server.
2. Add a new **Web User Control** named *CustomProductFilter.ascx* into the **CMSSGlobalFiles** folder and modify it to contain the following code:

```
<%@ Control Language="C#" AutoEventWireup="true"
CodeFile="CustomProductFilter.ascx.cs"
Inherits="CMSSGlobalFiles_CustomProductFilter" %>
|
<table cellpadding="2">
  <tr>
    <td>
      <cms:LocalizedLabel ID="lblDepartment" runat="server" Text="Product
department" DisplayColon="true">
    </cms:LocalizedLabel>
    </td>
    <td>
      <cms:LocalizedDropDownList ID="drpDepartment" runat="server" Width="180" >
    </cms:LocalizedDropDownList>
    </td>
  </tr>
  <tr>
    <td>
      <cms:LocalizedLabel ID="lblOrder" runat="server" Text="Order by"
DisplayColon="true">
    </cms:LocalizedLabel>
    </td>
    <td>
      <cms:LocalizedDropDownList ID="drpOrder" runat="server" Width="180" >
    </cms:LocalizedDropDownList>
    </td>
  </tr>
  <tr>
    <td colspan="2">
      <cms:LocalizedButton ID="btnFilter" runat="server" Text="Apply Filter" />
    </td>
  </tr>
</table>
```

This creates the design of the filter's user interface. As you can see, it is composed of localized labels, drop-down lists and a button arranged in a simple table layout. Alternatively, it is possible to use a CSS-based layout applied through HTML elements (e.g. <div>, , etc.).

When developing a filter for actual live deployment, it may be preferable to enter the captions of the child controls using localization strings through the **ResourceString** property, rather than directly as **Text**.

3. Switch to the code behind file of the user control, add the references shown below and set the control to inherit from the appropriate base class. This example uses the **CMSAbstractDataFilterControl** class, since the filter is intended for use with a document data source.

[C#]

```
using System;
using System.Data;
using System.Collections.Generic;
using System.Web;
using System.Web.UI;
using System.Web.UI.WebControls;

using CMS.Controls;
using CMS.GlobalHelper;
using CMS.Ecommerce;

public partial class CMSGlobalFiles_CustomProductFilter :
CMSAbstractDataFilterControl
{
    ...
}
```

4. Add the following methods into the user control class:

[C#]

```
/// <summary>
/// Setup the inner child controls
/// </summary>
private void SetupControl()
{
    // Hide the filter if StopProcessing is enabled
    if (this.StopProcessing)
    {
        this.Visible = false;
    }

    // Initialize only if the current request is NOT a postback
    else if (!RequestHelper.IsPostBack())
    {
        // Loads product departments as filtering options
        InitializeDepartments();

        // Initialize the order by drop-down list
        IntializeOrder();
    }
}

/// <summary>
/// Ensures that the ordering options are loaded into the order by drop-down list
/// </summary>
private void IntializeOrder()
{
    // Initialize options
    this.drpOrder.Items.Add(new ListItem("Price - Ascending", "priceAsc"));
}
```

```

        this.drpOrder.Items.Add(new ListItem("Price - Descending", "priceDesc"));
        this.drpOrder.Items.Add(new ListItem("Product name", "name"));
    }

    /// <summary>
    /// Loads all existing product departments as filtering options into the
    /// department drop-down list
    /// </summary>
    private void InitializeDepartments()
    {
        // Get all product departments
        DataSet departments = DepartmentInfoProvider.GetDepartments("",
            "DepartmentDisplayName", 0, "DepartmentID, DepartmentDisplayName");

        // Check if there are any product departments
        if (!DataHelper.DataSourceIsEmpty(departments))
        {
            // Binds departments to the drop-down list
            this.drpDepartment.DataSource = departments;
            this.drpDepartment.DataTextField = "DepartmentDisplayName";
            this.drpDepartment.DataValueField = "DepartmentID";

            this.drpDepartment.DataBind();

            // Adds the default '(all)' value
            this.drpDepartment.Items.Insert(0, new ListItem("(all)", "##ALL##"));
        }
    }
}

```

These methods ensure that the correct filtering options are loaded into the child drop-down lists.

5. Define the **SetFilter()** method as shown below:

[C#]

```

    /// <summary>
    /// Generates a WHERE condition and ORDER BY clause based on the current filtering
    /// selection
    /// </summary>
    private void SetFilter()
    {
        string where = null;
        string order = null;

        // Generate a WHERE condition based on the selected product department
        if (this.drpDepartment.SelectedValue != null)
        {
            int departmentId = ValidationHelper.GetInteger
            (this.drpDepartment.SelectedValue, 0);

            if (departmentId > 0)
            {
                where = "SKUDepartmentID = " + departmentId;
            }
        }
    }
}

```

```
    }

    // Apply the selected ordering direction
    if (this.drpOrder.SelectedValue != "")
    {
        switch (this.drpOrder.SelectedValue)
        {
            case "priceAsc":
                order = "SKUPrice";
                break;

            case "priceDesc":
                order = "SKUPrice Desc";
                break;

            case "name":
                order = "SKUName";
                break;
        }
    }

    if (where != null)
    {
        // Set where condition
        this.WhereCondition = where;
    }

    if (order != null)
    {
        // Set orderBy clause
        this.OrderBy = order;
    }

    // Raise the filter changed event
    this.RaiseOnFilterChanged();
}
```

The custom filter control dynamically generates a WHERE condition and ORDER BY statement based on the current filter selection, which is then used to set the value of the **WhereCondition** and **OrderBy** members inherited from the base class. These members are read by the data source to which the filter is attached and inserted into the SQL query used to load data. Remember that the filter must inherit from the appropriate base class according to the type of the used data source.

6. Add two more methods that override the handlers of the **Init** and **PreRender** events:

[C#]

```
/// <summary>
/// Init event handler
/// </summary>
protected override void OnInit(EventArgs e)
{
    // Create child controls
    SetupControl();
}
```

```

    base.OnInit(e);
}

/// <summary>
/// PreRender event handler
/// </summary>
protected override void OnPreRender(EventArgs e)
{
    // Check if the current request is a postback
    if (RequestHelper.IsPostBack())
    {
        // Apply the filter to the displayed data
        SetFilter();
    }

    base.OnPreRender(e);
}

```

The handlers ensure that the appropriate private methods (defined previously in the example) are called during the correct stages of the page life cycle.

When the *Apply Filter* button is clicked, a postback occurs, which triggers the **SetFilter()** method during the **PreRender** event and the filter is applied to the displayed data. Notice the use of the **CMS.GlobalHelper.RequestHelper.IsPostBack()** method in the conditions. The **SetFilter()** method is only called when the current page request is a postback and the child controls are initialized only when this is not the case.

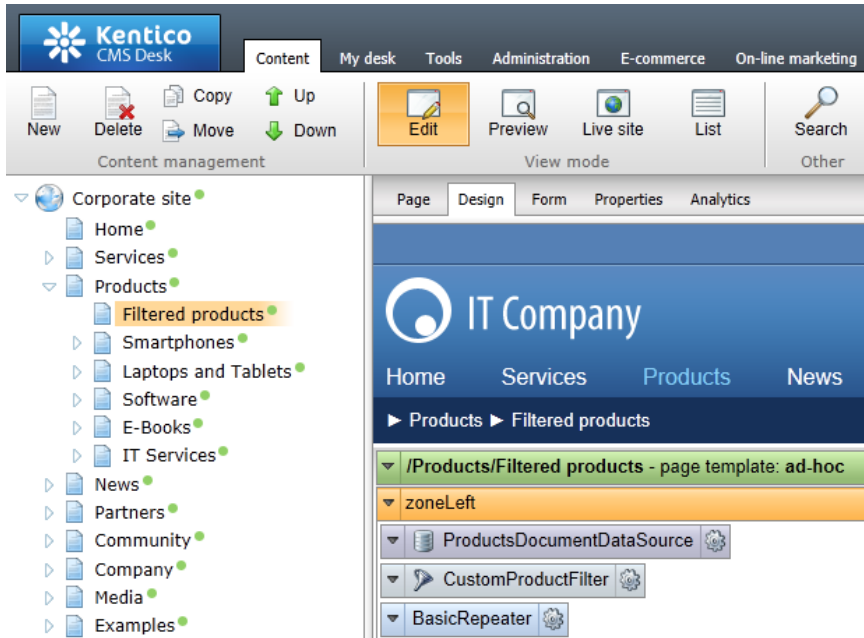

Result

The filter control is now finished and you can try out its functionality. It is recommended to test the filter on the **Corporate** or **E-commerce** sample sites, since they already contain examples of product documents.

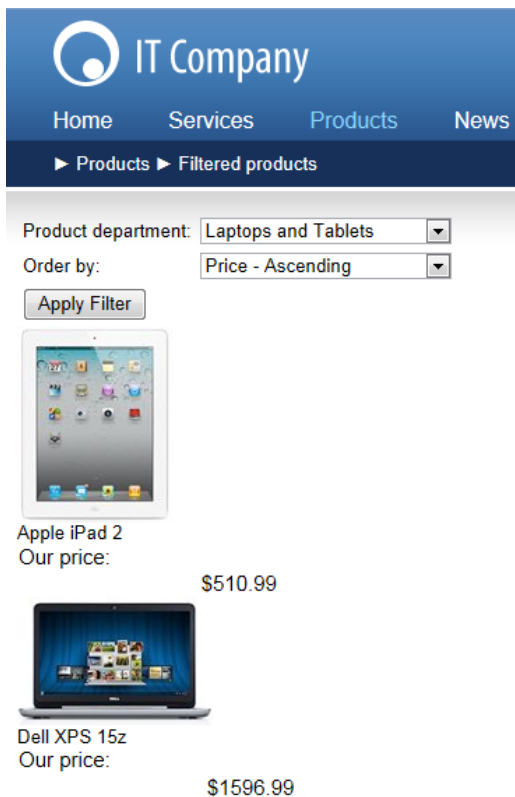

Go to **CMS Desk**, create a new page and place the following web parts into its design:

| Web part | Instructions |
|-----------------------|---|
| Documents data source | <ol style="list-style-type: none"> 1. Configure the web part to load product documents. 2. Fill in the Filter name property (e.g. <i>CustomProductFilter</i>). <p>Note: You can alternatively use the <i>Products data source</i> web part for this purpose.</p> |
| Filter | <ol style="list-style-type: none"> 1. Assign a Filter name that matches the data source (<i>CustomProductFilter</i>). 2. Enter the path of the .ascx file implementing your custom filter into the Filter control path property (<i>~/CMSGlobalFiles/CustomProductFilter.ascx</i>). |
| Basic repeater | <ol style="list-style-type: none"> 1. Enter the ID of the Documents data source web part into the Data source name property. 2. Set an appropriate Transformation name, for example: <i>Ecommerce.Transformations.Product_SimplePreview</i> |

You can find more information about how this type of web part combination works in [Using Data source web parts](#).

If you view the page in **Live site** mode, it displays a list of products with the custom filter shown above. You can filter the products by their department and change the order in which they are displayed.

7.27.7 Layout web parts

7.27.7.1 Overview

Layout web parts are special types of web parts that allow users to define and modify the structure of [portal engine page templates](#) without the need to write or edit the code of the template's page layout. Each layout web part contains one or more child zones that are arranged in a specific way. The layout can be configured just like a standard web part using properties or even directly on the **Design** tab of CMS Desk.

Using this approach, it is possible to simply create a new page with one web part zone (e.g. using the **Create a blank page** option when adding a page to the content tree in **CMS Desk**) and then add the appropriate layout web part to separate the page into further zones as required.

In addition to defining flexible web part zones, some layout web parts also provide special functionality, such as collapsible page sections, zones with a fixed position or graphical interfaces that allow users to select which zone's content should be displayed. The following layout web parts (found under the **Layout** category) are delivered with Kentico CMS by default:

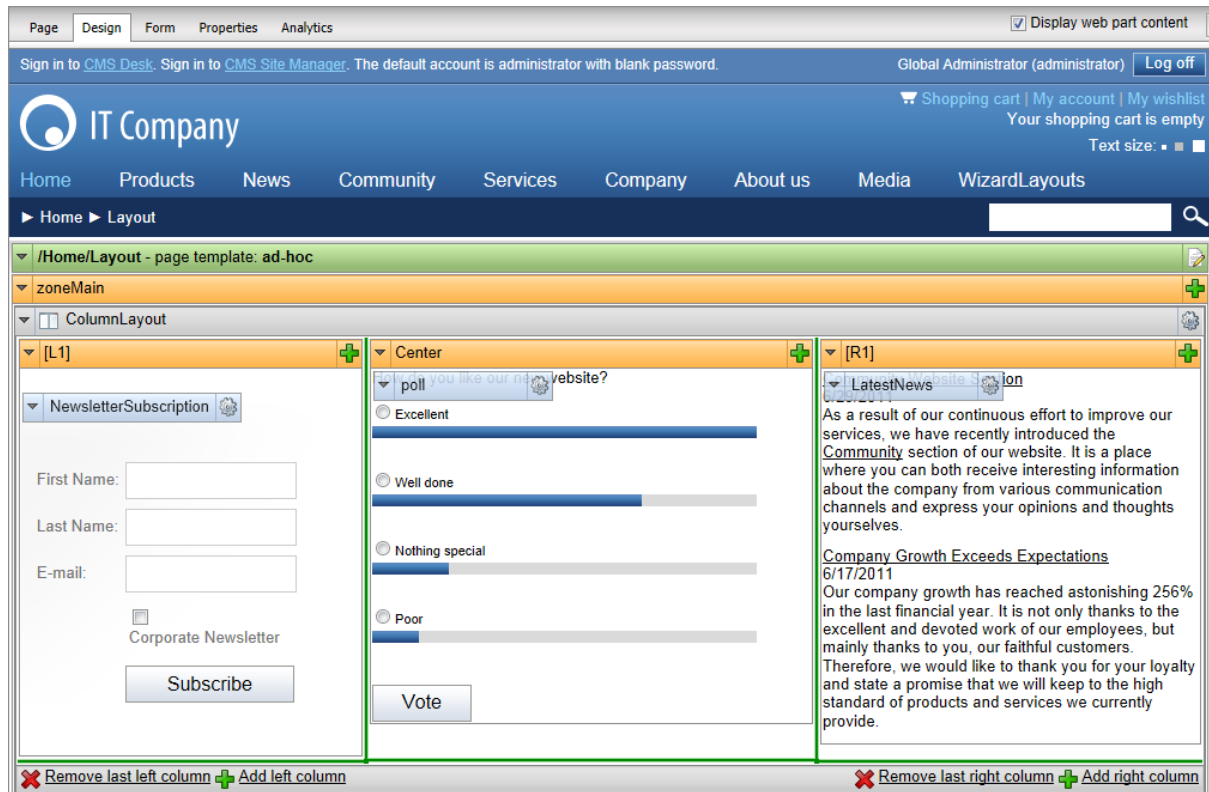

- **Accordion layout** - provides a layout divided into multiple panes that can be expanded or collapsed. Each pane defines a separate web part zone and users can click on the pane headers to select which one should be displayed.
- **Collapsible panel** - generates a web part zone inside a panel that can be collapsed or expanded by users.
- **Columns layout** - provides a CSS-based column layout for content. Each column defines a separate web part zone.
- **Rows layout** - provides a row layout for content. Each row contains a separate web part zone.
- **Table layout** - provides a table layout for content. Each cell in the table defines a separate web part zone.
- **Tabs layout** - creates an AJAX tab layout. The content of each tab can be added through a separate web part zone. Users can then click on the tabs to select which content should be displayed.
- **Web part zone** - adds a single web part zone to the page that can be used to group multiple web parts or assign additional formatting to them. The zone may also be configured to display its content at a fixed location on the screen that moves along with page scrolling.
- **Zones with effect** - provides a list of elements that define separate web part zones and allows additional JavaScript effects (e.g. using jQuery) to be applied to the content displayed by the zones. The scripts used to generate the effects must be specified through the web part's properties.
- **Wizard layout** - provides a layout divided into multiple steps. The wizard displays one step at a time and allows users to navigate through them in consecutive order. The content of each step is defined in its own web part zone. The layout may generate two additional zones as a header and footer for the wizard. It is also possible to separately add the header content of the wizard and the buttons used to move between steps through the *Wizard header* and *Wizard buttons* web parts.

For additional details about individual web parts, please refer to the [Kentico CMS Web Parts](#) reference.

If you wish to use a layout that cannot be achieved by the built-in web parts, it is possible to create new layout web parts or customize existing ones to fulfill the given requirements. Please refer to the [Developing layout web parts](#) topic to find an example of how a custom layout web part can be created and additional information about how web parts of this type work internally.

Editing the content of layout web parts

To add or edit the content of the zones generated by a layout web part, view the given page on the **Design** tab of CMS Desk. You can manage the zones inside the layout like any other standard web part zones and add the required web parts.

The screenshot displays the CMS Desk interface in Design mode. The top navigation bar includes tabs for Page, Design, Form, Properties, and Analytics. The main content area shows a layout web part titled '/Home/Layout - page template: ad-hoc'. This layout is divided into three columns: [L1], Center, and [R1]. The [L1] column contains a NewsletterSubscription web part with input fields for First Name, Last Name, and E-mail, and a Subscribe button. The Center column contains a poll web part titled 'How do you like our new website?' with radio buttons for Excellent, Well done, Nothing special, and Poor, and a Vote button. The [R1] column contains a LatestNews web part with a title and a text block. The interface also shows options to remove or add columns.

All default layout web parts have the **Allow design mode** property. If it is enabled, additional zone management actions will be available directly on the **Design** tab. This makes it possible to dynamically resize individual layout zones as necessary by dragging the green lines on the borders, as can be seen in the screenshot above. Layouts composed of multiple zones also allow designers to directly add or remove the sections that form the layout (columns, tabs etc.).

Once the layout web part and all of its child web parts are added and configured properly, the entered content will be displayed normally on the live site using the specified page structure.

If a layout web part is deleted while it still has some content in its child zones, the given web parts will remain saved in the template definition. You can use this fact to recover a layout if it is deleted accidentally. Simply add the layout web part again and its child content will automatically be inserted. For this reason, it is recommended to remove all child web parts contained in layout before deleting it, if you wish to permanently remove it from the page.

Adding layouts as widgets

It is also possible to add layouts to a page as [Widgets](#). This can be used to give

editors or other users without design permissions additional flexibility when it comes to arranging page content. The zones generated by a layout widget will automatically match the type of the parent zone.

These layout widgets may also be placed onto [Dashboards](#) to help users organize their content. When adding content into a layout on a dashboard page, it is necessary to drag and drop new widgets from their default location to the appropriate zone generated by the layout, since it is not possible to add widgets into specific dashboard zones directly.

7.27.7.2 Developing layout web parts

Even though Kentico CMS is delivered with multiple layout web parts that may be used out-of-the-box, it is also possible to customize them or develop completely new web parts to define layouts that exactly match your specific requirements.

The development process is similar as with standard web parts, but there are several important differences. All layout web parts must inherit from the **CMSAbstractLayoutWebPart** base class (rather than the standard *CMSAbstractWebPart*), which can be found in the **CMS.PortalControls** namespace. The most important members inherited from this base class that can be used to implement the layout are described in the example below.

Example

The following example demonstrates how a custom layout web part can be developed. For the sake of simplicity, this sample layout will only provide a single web part zone with a configurable width and height. It is only intended for demonstration purposes and not for practical use. For further inspiration, you can view the code of the more advanced built-in layout web parts found in the **~/CMSWebParts/Layouts** folder of your web project.

1. Open the web project in Visual Studio, right click the **CMSWebparts/Layouts** folder and select **Add New Item**. Now create a **Web User Control** named *CustomZone.ascx*.

2. Next, edit the control's code behind file. Add references, set the control to inherit from the appropriate base class and define two properties according to the following code:

[C#]

```
using CMS.PortalControls;
using CMS.GlobalHelper;
using CMS.PortalEngine;

public partial class CMSWebParts_Layouts_CustomZone : CMSAbstractLayoutWebPart
{
    /// <summary>
    /// Property used to access the value of the Width property of the web part.
    /// </summary>
    public string Width
    {
        get
        {
```

```
        return ValidationHelper.GetString(this.GetValue("Width"), "");
    }
    set
    {
        this.SetValue("Width", value);
    }
}

/// <summary>
/// Property used to access the value of the Height property of the web part.
/// </summary>
public string Height
{
    get
    {
        return ValidationHelper.GetString(this.GetValue("Height"), "");
    }

    set
    {
        this.SetValue("Height", value);
    }
}
}
```

The **Width** and **Height** public properties are used to handle the corresponding properties of the web part object that will be defined later in the example. The properties use the string type, since the width/height is assigned as a CSS style text value.

3. Add the following private method to the class:

[C#]

```
/// <summary>
/// Adds the layout's web part zone and envelope.
/// </summary>
private void insertZone()
{
    // Stores the Width and Height properties of the layout as a CSS style value.
    string style = null;

    // Width of the zone.
    if (!String.IsNullOrEmpty(Width))
    {
        style += " width: " + Width + ";";
    }

    // Height of the zone.
    if (!String.IsNullOrEmpty(Height))
    {
        style += " height: " + Height + ";";
    }

    // Adds a DIV element that will encapsulate the layout's web part zone.
    Append("<div");
}
```

```

    // Defines the DIV element's id attribute used to identify the zone's envelope
    in Design mode.
    if (IsDesign)
    {
        Append(" id=\"", ShortClientID, "_zoneEnvelope");
    }

    // Defines the style attribute of the zone's envelope.
    if (!String.IsNullOrEmpty(style))
    {
        Append(" style=\"", style, "\"");
    }

    Append(">");

    // Adds the web part zone.
    CMSWebPartZone zone = AddZone(this.ID + "_zone", this.ID);

    Append("</div>");
}

```

The following members inherited from the base class are used:

- **Append(params string[] text)** - this method is a fundamental tool used to build the output code that defines the web part layout. When the method is called, the content of its parameters is added to the end of the current layout code. Any number of string parameters may be specified.
- **AddZone(string id, string title)** - creates a new web part zone, adds it to the layout and passes it back as the return value. If the layout is added as a widget, this method automatically ensures that the zones in the layout are created as widget zones of the same type as the parent zone.
- **IsDesign** - true if the web part is currently being viewed on the *Design* tab of CMS Desk.

The *InsertZone()* method is used to define the web part zone that will be displayed in the layout and surrounding code that allows its width and height to be configured. It will be called later by the code added in the next step of the example.

4. Every layout web part must override the **PrepareLayout()** virtual method, which is where the output code of the layout is generated. Use the following code to add the method:

[C#]

```

/// <summary>
/// Builds the output code that will generate the desired layout on the page.
/// </summary>
protected override void PrepareLayout()
{
    // Starts building the layout code.
    StartLayout();

    // Wraps the layout into a table with additional content if the web part is
    edited in Design mode.
    if (IsDesign)
    {
        Append("<table class=\"LayoutTable\" cellspacing=\"0\">");
    }
}

```

```
if (this.ViewMode == ViewModeEnum.Design)
{
    Append("<tr><td class=\"LayoutHeader\" colspan=\"2\">");

    // Adds a header container.
    AddHeaderContainer();

    Append("</td></tr>");
}

Append("<tr><td>");

// Calls the private method that adds the web part zone.
insertZone();

// Closes the Design mode table.
if (IsDesign)
{
    Append("</td>");

    // Generates dynamic resizers for the zone if the Allow design mode
    property of the web part is enabled.
    if (AllowDesignMode)
    {
        // Adds a horizontal resizer.
        Append("<td class=\"HorizontalResizer\" onmousedown=\"",
GetHorizontalResizerScript("zoneEnvelope", "Width"), " return false;\">&nbsp;</
td></tr><tr>");

        // Adds a vertical resizer.
        Append("<td class=\"VerticalResizer\" onmousedown=\"",
GetVerticalResizerScript("zoneEnvelope", "Height"), " return false;\">&nbsp;</
td>");

        // Adds a combined horizontal and vertical resizer to the corner where
        both resizer types intersect.
        Append("<td class=\"BothResizer\" onmousedown=\"",
GetHorizontalResizerScript("zoneEnvelope", "Width"), " ", GetVerticalResizerScript
("zoneEnvelope", "Height"), " return false;\">&nbsp;</td>");
    }

    Append("</tr></table>");
}

// Saves the current status of the layout code and ensures that it is rendered
on the page.
FinishLayout();
}
```

The following members inherited from the base class are used:

- **StartLayout()** - initializes the building of the layout code. You may start using the *Append()* method only after this method is called.
- **GetHorizontalResizerScript(string elementId, string widthPropertyName)** - returns a script that adds the functionality of a dynamic width resizer. The first parameter is used to specify the ID of the element that will be resized and the second sets the property that will be modified when the width is

changed via the resizer.

- **GetVerticalResizerScript(string elementId, string heightPropertyName)** - returns a script that adds the functionality of a dynamic height resizer. The parameters work the same way as for the horizontal resizer.
- **FinishLayout()** - this method finalizes the layout code of the web part. It must always be used as the last modification of the layout (i.e. once it is called, the *Append()* method will no longer work correctly).

As you can see, the method added in this step initializes the layout code, calls the method created in the previous step and then finalizes the output. In addition, it adds a table element around the web part zone, which is displayed only when the layout web part is viewed in design mode. If the **Allow design mode** property of the web part is enabled, this table also includes elements that can be dragged with the mouse to directly resize the layout's zone. It is not necessary to define the **AllowDesignMode** property for the control, since it is automatically inherited from the **CMSAbstractLayoutWebPart** base class.

Save the changes. If your Kentico CMS project was installed as a web application, you must also **Build** the project.

5. Next, register the web part in the system. Go to **Site Manager -> Development -> Web parts**, select the **Layouts** category and click  **New web part**. Choose to **Create a new web part** and enter the following values:

- **Display name:** Custom zone layout
- **Code name:** CustomZone
- **File path:** ~/CMSWebParts/Layouts/CustomZone.ascx
- **Generate the code files:** false

Click  **Save** and you will be redirected to the web part's **General** tab. Here, select the *Layout* option from the **Type** drop-down list and click  **Save** again. All layout web parts must use this type in order to function correctly.

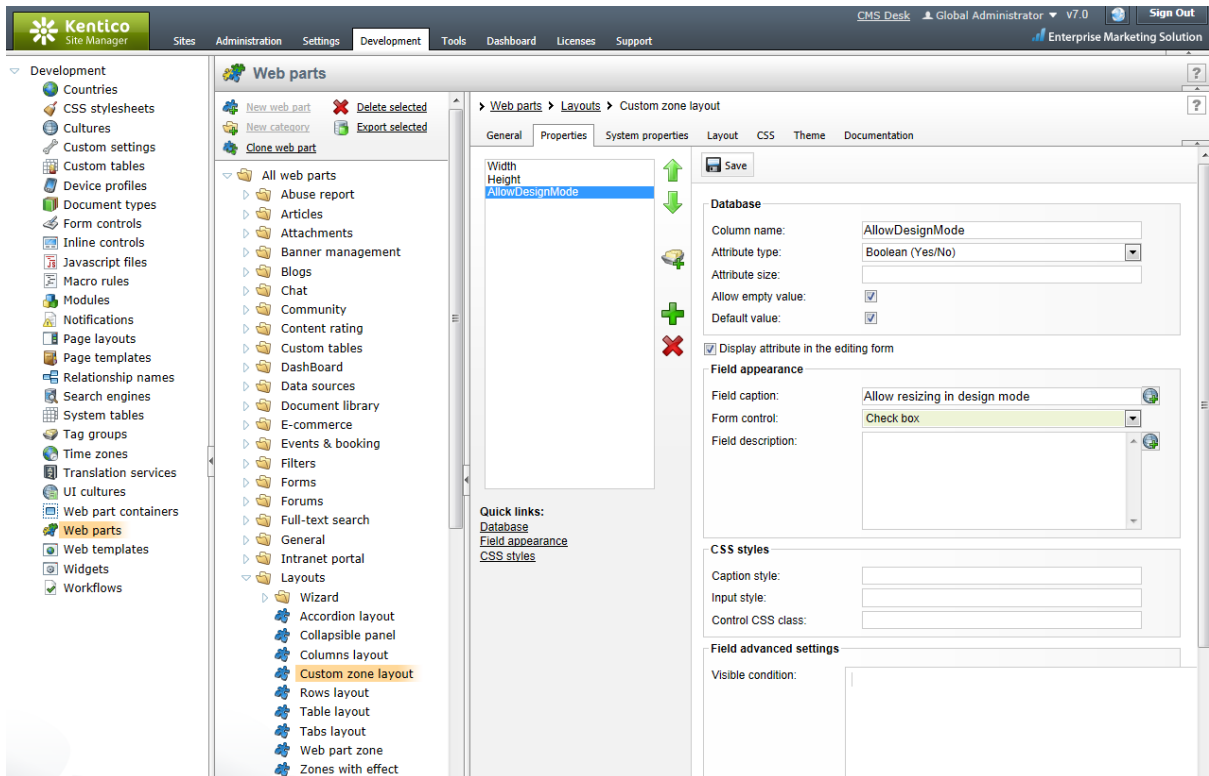

6. Switch to the **Properties** tab and add  three properties according to the information below. Click  **Save** for each property before moving on to the next one.

- **Column name:** Width
- **Attribute type:** Text
- **Attribute size:** 100
- **Allow empty value:** yes (checked)
- **Field caption:** Zone width
- **Form control:** Text box

- **Column name:** Height
- **Attribute type:** Text
- **Attribute size:** 100
- **Allow empty value:** yes (checked)
- **Field caption:** Zone height
- **Form control:** Text box

- **Column name:** AllowDesignMode
- **Attribute type:** Boolean (Yes/No)
- **Allow empty value:** yes (checked)
- **Default value:** yes (checked)

- **Field caption:** Allow resizing in design mode
- **Form control:** Check box

These properties will be available in the web part's configuration dialog. They are handled by the corresponding properties in the code of the user control implementing the web part.

7. The custom layout web part is now complete and ready to be used. You can try out its functionality by adding it onto one of your pages in CMS Desk.

You can use a similar approach (with more advanced layout code) to implement a custom web part to generate any required layout.

7.27.8 Web part containers

7.27.8.1 Containers overview

Containers are used as "boxes" for web parts. They consist of content that is displayed before and after the web part which means they are used as an envelope for web part content. They have three advantages over the **Content before** and **Content after** web part properties:

- They are re-usable for any number of web part instances.
- They can contain a title and dynamically inserted values of the enclosed web part's properties.
- They are objects in the system, which means they can be [Exported and Imported](#).

Containers may be assigned not only to web parts, but also [widgets](#) and entire web part zones.

The containers can be managed in **Site Manager -> Development -> Web part containers**. The following properties are available when editing (✎) or creating a web part container:

- **Display name** - the name of the container displayed to users in lists and selectors.
- **Code name** - a string identifier for the container that can be used by developers in the API and URLs. Unless there is a reason to set a particular value, you can leave the default (*automatic*) option, and the system will generate an appropriate code name.
- **HTML code** - this editor allows you to enter the HTML content that will be placed around the web

part. The position of the actual web part content is represented in the code by a placeholder, so you can add both opening and closing elements.

- **CSS styles** - this field becomes available if you click the [Add CSS styles](#) link. Here you can define any CSS classes used within the code of the container. The specified styles will be loaded on any page where the given container is used.

In the case of existing web part containers that are already placed somewhere on the website, you can use the **Preview** mode for convenient editing. This allows you to inspect the live site appearance of a container directly while working with its code. Please see the [Design preview](#) topic for additional details about the preview.

The **HTML code** field can contain dynamically loaded values of the enclosed web part's properties. You can insert them using expressions in the following format:

{%PropertyName%}

You will most often use the following expression to insert the container title:

{%ContainerTitle%}

These macro expressions are resolved even if macro resolving is disabled for the particular web part instance (through the **Disable macros** property).

Defining CSS styles

There are two locations where CSS classes used by the web part container can be defined:

- **In the general site stylesheet** - all CSS classes are stored in one file, but exporting the container to a site that uses a different stylesheet is more difficult.
- **In the CSS styles property of the container** - styles are stored separately for every container, which requires an additional resource request, but containers are automatically exported (including staging) with their CSS classes to other sites or Kentico CMS instances.

A stylesheet request link similar to the following will be added to the <head> element of any page that contains web part containers with styles defined in their **CSS styles** property:

```
<link href="/KenticoCMS/CMSPages/GetCSS.aspx?_containers=1;14" type="text/css" rel="stylesheet"/>
```

The value of the **_containers** URL parameter is dependent on the containers used on the page, the example above is for a page that contains the *Black box* and *Orange box* containers (identified by their *ContainerID* values).

If [CSS minification](#) is enabled, the request will use the following format instead:

```
<link href="/KenticoCMS/CMSPages/GetResource.ashx?_containers=1;14" type="text/css" rel="stylesheet"/>
```

Storing files related to web part containers

If your web part container code requires any additional files, such as images used by the classes defined in the **CSS styles** property, they must be stored in the `~/App_Themes/Components/Containers/<container code name>` folder so they can be exported/imported along with the container.

The content of this folder can be managed directly from the administration interface at **Site Manager -> Development -> Web part containers** by editing (✎) the given container and switching the **Theme** tab.

If the used CSS classes are defined in the site stylesheet, any accompanying files should be stored in the `~/App_Themes/<stylesheet code name>` folder.

For more information about page component CSS styles, please see the [Development -> CSS stylesheets and design -> CSS for page components](#) topic.

Using web part containers

Containers are assigned to web parts, widgets or zones simply by configuring (⚙️) them and selecting a container through the **Web part container** property. The web part container editing form mentioned above can also be accessed directly from the **Web part properties** dialog by creating a container using the **New** button or modifying the selected one via **Edit**.

Web part properties (Repeater)

General | Layout

Web part container

Web part container: Corporate site - List box content **Edit** **New**

Web part container title:

Container CSS class:

Container custom content: ...

Hide container on subpages:

HTML Envelope

Here's an example of a web part **without a container**:

[Remote Management](#)

In this blog post, I will share some remarks regarding communication between our former New York Office and the newly setup London Office.

[Expanding to Europe](#)

In this blog post, I will try to share some of my impressions of the recent expansion of our operations to the Old Continent.

03/21/2011
[2 comment\(s\)](#)

Please see the [Creating web part containers](#) topic for a step-by-step guide on how a new container can be defined.

7.27.8.2 Creating web part containers

The following is an example of how a new web part container can be defined:

1. Go to **Site Manager -> Development -> Web part containers**.
2. Click  **New container**.
3. Enter the following values:
 - **Display name:** Blue box
 - **HTML code:**

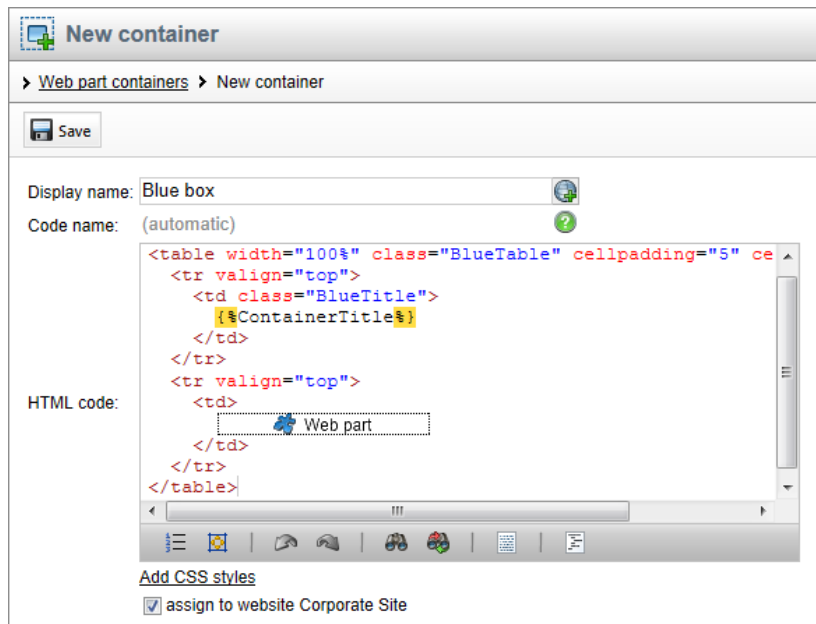

```
<table width="100%" class="BlueTable" cellpadding="5" cellspacing="0">
  <tr valign="top">
    <td class="BlueTitle">
      {%ContainerTitle%}
    </td>
  </tr>
  <tr valign="top">
    <td>
      ?
    </td>
  </tr>
</table>
```

Working with the web part placeholder

The "?" character in the code above will determine the position of the web part placeholder when you paste it into the **HTML code** field.

If you ever need to set a container's HTML code using the API or in the database, you do not have to worry about the placeholder character, because the content before and after the placeholder is stored separately in two fields: **ContainerTextBefore** and **ContainerTextAfter**.

4. Click the [Add CSS styles](#) link and define the used CSS classes in the newly displayed field:

```
.BlueTable
{
  border: 1px solid #4a62e4;
}

.BlueTitle
{
  background-color: #4a62e4;
  font-weight: bold;
  color: white;
}
```

5. Click  **Save** to create the new container.

6. Switch to the **Sites** tab and click the **Add sites** button to assign the new container to the website where you wish to use it.

7. Go to **CMS Desk** and edit any page on the **Design** tab. **Configure**  any web part and set its properties according to the following:

- **Web part container:** Blue box
- **Container title:** My web part with a container

8. View the page in **Live site** mode. The web part will be surrounded by a blue border and it will have the specified title.

7.27.9 Web parts internals and API

7.27.9.1 Overview

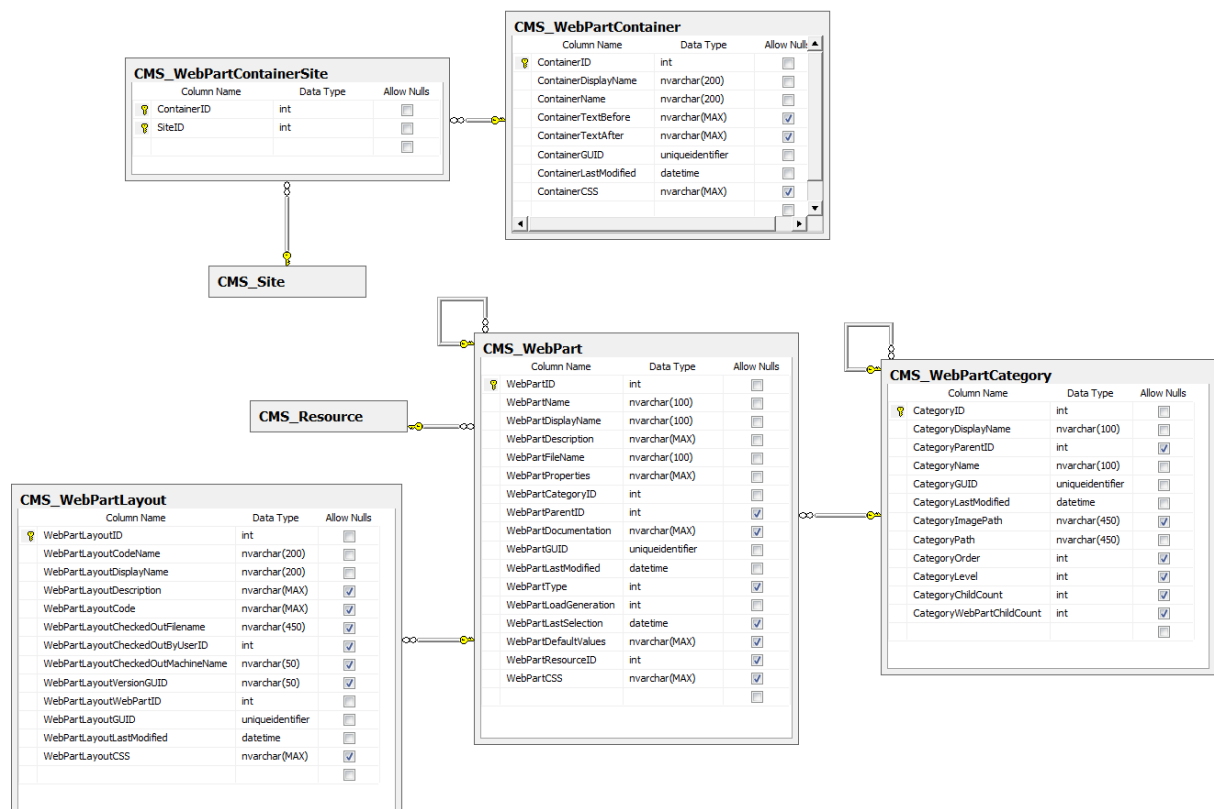

In this chapter, you will learn which [database tables](#) and [API classes](#) are used to manage web parts. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the related classes, please refer to [Kentico CMS API Reference](#).

7.27.9.2 Database tables

The following database tables are used to store information about web parts:

- **CMS_WebPartCategory** - contains records representing web part categories.
- **CMS_WebPart** - contains records representing web parts and their properties.
- **CMS_WebPartLayout** - stores custom layouts for web parts.
- **CMS_WebPartContainer** - contains records representing web part containers.
- **CMS_WebPartContainerSite** - stores relationships between web part containers and sites. Each entry in this table indicates that a specific container may be used on a given site.

Web part instance storage

Data about the content of zones on individual page templates, including web parts and their property configuration, is stored in XML format in the **PageTemplateWebParts** column of the **CMS_PageTemplate** table.

7.27.9.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes for managing web parts can be found in the **CMS.PortalEngine** namespace.

CMS_WebPartCategory table API:

- **WebPartCategoryInfo** - represents one web part category.
- **WebPartCategoryInfoProvider** - provides management functionality for web part categories.

CMS_WebPart table API:

- **WebPartInfo** - represents one web part.
- **WebPartInfoProvider** - provides management functionality for web parts.

CMS_WebPartLayout table API:

- **WebPartLayoutInfo** - represents a custom layout for a specific web part.
- **WebPartLayoutInfoProvider** - provides management functionality for web part layouts.

CMS_WebPartContainer table API:

- **WebPartContainerInfo** - represents one web part container.
- **WebPartContainerInfoProvider** - provides management functionality for web part containers.

CMS_WebPartContainerSite table API:

- **WebPartContainerInfo** - represents a relationship between a web part container and a site.
- **WebPartContainerInfoProvider** - provides management functionality for container-site relationships.

Other classes:

- **WebPartInstance** - represents a single instance of a web part.
- **WebPartZoneInstance** - represents an instance of a web part zone.

7.27.9.4 API examples

7.27.9.4.1 Overview

These topics show examples of how the API for managing web parts can be used:

- [Managing web part categories](#)
- [Managing web parts](#)
- [Managing web part layouts](#)
- [Managing web part containers](#)
- [Web part containers and sites](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Development\Webparts\Default.aspx.cs**.

The web part API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.PortalEngine;
```

7.27.9.4.2 Managing web part categories

The following example creates a web part category.

```
private bool CreateWebPartCategory()
{
    WebPartCategoryInfo root =
    WebPartCategoryInfoProvider.GetWebPartCategoryInfoByCodeName( "/" );

    if (root != null)
    {
        // Create new web part category object
        WebPartCategoryInfo newCategory = new WebPartCategoryInfo();

        // Set the properties
        newCategory.CategoryDisplayName = "My new category";
        newCategory.CategoryName = "MyNewCategory";
        newCategory.CategoryParentID = root.CategoryID;

        // Save the web part category
```

```
        WebPartCategoryInfoProvider.SetWebPartCategoryInfo(newCategory);

        return true;
    }

    return false;
}
```

The following example gets and updates a web part category.

```
private bool GetAndUpdateWebPartCategory()
{
    // Get the web part category
    WebPartCategoryInfo updateCategory =
    WebPartCategoryInfoProvider.GetWebPartCategoryInfoByCodeName("MyNewCategory");
    if (updateCategory != null)
    {
        // Update the properties
        updateCategory.CategoryDisplayName = updateCategory.CategoryDisplayName.ToLo

        // Save the changes
        WebPartCategoryInfoProvider.SetWebPartCategoryInfo(updateCategory);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates web part categories.

```
private bool GetAndBulkUpdateWebPartCategories()
{
    // Prepare the parameters
    string where = "CategoryDisplayName LIKE N'My new category%'";

    // Get the data
    DataSet categories = WebPartCategoryInfoProvider.GetCategories(where, null);
    if (!DataHelper.DataSourceIsEmpty(categories))
    {
        // Loop through the individual items
        foreach (DataRow categoryDr in categories.Tables[0].Rows)
        {
            // Create object from DataRow
            WebPartCategoryInfo modifyCategory = new WebPartCategoryInfo(categoryDr)

            // Update the properties
            modifyCategory.CategoryDisplayName =
            modifyCategory.CategoryDisplayName.ToUpper();

            // Save the changes
        }
    }
}
```

```
        WebPartCategoryInfoProvider.SetWebPartCategoryInfo(modifyCategory);
    }

    return true;
}

return false;
}
```

The following example deletes a web part category.

```
private bool DeleteWebPartCategory()
{
    // Get the web part category
    WebPartCategoryInfo deleteCategory =
    WebPartCategoryInfoProvider.GetWebPartCategoryInfoByCodeName("MyNewCategory");

    // Delete the web part category
    WebPartCategoryInfoProvider.DeleteCategoryInfo(deleteCategory);

    return (deleteCategory != null);
}
```

7.27.9.4.3 Managing web parts

The following example creates a web part.

```
private bool CreateWebPart()
{
    // Get parent category for web part
    WebPartCategoryInfo category =
    WebPartCategoryInfoProvider.GetWebPartCategoryInfoByCodeName("MyNewCategory");

    if (category != null)
    {
        // Create new web part object
        WebPartInfo newWebpart = new WebPartInfo();

        // Set the properties
        newWebpart.WebPartDisplayName = "My new web part";
        newWebpart.WebPartName = "MyNewWebpart";
        newWebpart.WebPartDescription = "This is my new web part.";
        newWebpart.WebPartFileName = "whatever";
        newWebpart.WebPartProperties = "<form></form>";
        newWebpart.WebPartCategoryID = category.CategoryID;

        // Save the web part
        WebPartInfoProvider.SetWebPartInfo(newWebpart);

        return true;
    }
}
```

```
    }  
    return false;  
}
```

The following example gets and updates a web part.

```
private bool GetAndUpdateWebPart()  
{  
    // Get the web part  
    WebPartInfo updateWebpart = WebPartInfoProvider.GetWebPartInfo("MyNewWebpart");  
    if (updateWebpart != null)  
    {  
        // Update the properties  
        updateWebpart.WebPartDisplayName =  
updateWebpart.WebPartDisplayName.ToLower();  
  
        // Save the changes  
        WebPartInfoProvider.SetWebPartInfo(updateWebpart);  
  
        return true;  
    }  
    return false;  
}
```

The following example gets and bulk updates web parts.

```
private bool GetAndBulkUpdateWebParts()  
{  
    // Prepare the parameters  
    string where = "WebPartName LIKE N'MyNewWebpart%'";  
  
    // Get the data  
    DataSet webparts = WebPartInfoProvider.GetWebParts(where, null);  
    if (!DataHelper.DataSourceIsEmpty(webparts))  
    {  
        // Loop through the individual items  
        foreach (DataRow webpartDr in webparts.Tables[0].Rows)  
        {  
            // Create object from DataRow  
            WebPartInfo modifyWebpart = new WebPartInfo(webpartDr);  
  
            // Update the properties  
            modifyWebpart.WebPartDisplayName =  
modifyWebpart.WebPartDisplayName.ToUpper();  
  
            // Save the changes  
            WebPartInfoProvider.SetWebPartInfo(modifyWebpart);  
        }  
    }  
}
```

```
        return true;
    }

    return false;
}
```

The following example deletes a web part.

```
private bool DeleteWebPart()
{
    // Get the web part
    WebPartInfo deleteWebpart = WebPartInfoProvider.GetWebPartInfo("MyNewWebpart");

    // Delete the web part
    WebPartInfoProvider.DeleteWebPartInfo(deleteWebpart);

    return (deleteWebpart != null);
}
```

7.27.9.4.4 Managing web part layouts

The following example creates a web part layout.

```
private bool CreateWebPartLayout()
{
    // Get the web part
    WebPartInfo webpart = WebPartInfoProvider.GetWebPartInfo("MyNewWebpart");
    if (webpart != null)
    {
        // Create new web part layout object
        WebPartLayoutInfo newLayout = new WebPartLayoutInfo();

        // Set the properties
        newLayout.WebPartLayoutDisplayName = "My new layout";
        newLayout.WebPartLayoutCodeName = "MyNewLayout";
        newLayout.WebPartLayoutWebPartID = webpart.WebPartID;
        newLayout.WebPartLayoutCode = "This is the new layout of MyNewWebpart
webpart.";

        // Save the web part layout
        WebPartLayoutInfoProvider.SetWebPartLayoutInfo(newLayout);

        return true;
    }

    return false;
}
```

The following example gets and updates a layout.

```
private bool GetAndUpdateWebPartLayout()
{
    // Get the web part layout
    WebPartLayoutInfo updateLayout =
    WebPartLayoutInfoProvider.GetWebPartLayoutInfo("MyNewWebpart", "MyNewLayout");
    if (updateLayout != null)
    {
        // Update the properties
        updateLayout.WebPartLayoutDisplayName =
        updateLayout.WebPartLayoutDisplayName.ToLower();

        // Save the changes
        WebPartLayoutInfoProvider.SetWebPartLayoutInfo(updateLayout);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates layouts.

```
private bool GetAndBulkUpdateWebPartLayouts()
{
    // Prepare the parameters
    string where = "WebPartLayoutCodeName LIKE N'MyNewLayout%'";

    // Get the data
    DataSet layouts = WebPartLayoutInfoProvider.GetWebPartLayouts(where, null);
    if (!DataHelper.DataSourceIsEmpty(layouts))
    {
        // Loop through the individual items
        foreach (DataRow layoutDr in layouts.Tables[0].Rows)
        {
            // Create object from DataRow
            WebPartLayoutInfo modifyLayout = new WebPartLayoutInfo(layoutDr);

            // Update the properties
            modifyLayout.WebPartLayoutDisplayName =
            modifyLayout.WebPartLayoutDisplayName.ToUpper();

            // Save the changes
            WebPartLayoutInfoProvider.SetWebPartLayoutInfo(modifyLayout);
        }

        return true;
    }

    return false;
}
```

The following example deletes a web part layout.

```
private bool DeleteWebPartLayout()
{
    // Get the web part layout
    WebPartLayoutInfo deleteLayout =
    WebPartLayoutInfoProvider.GetWebPartLayoutInfo("MyNewWebpart", "MyNewLayout");

    // Delete the web part layout
    WebPartLayoutInfoProvider.DeleteWebPartLayoutInfo(deleteLayout);

    return (deleteLayout != null);
}
```

7.27.9.4.5 Managing web part containers

The following example creates a web part container.

```
private void CreateWebPartContainer()
{
    // Create new web part container object
    WebPartContainerInfo newContainer = new WebPartContainerInfo();

    // Set the properties
    newContainer.ContainerDisplayName = "My new container";
    newContainer.ContainerName = "MyNewContainer";
    newContainer.ContainerTextBefore = "<div class=\"myNewContainer\">";
    newContainer.ContainerTextAfter = "</div>";

    // Save the web part container
    WebPartContainerInfoProvider.SetWebPartContainerInfo(newContainer);
}
```

The following example gets and updates a container.

```
private bool GetAndUpdateWebPartContainer()
{
    // Get the web part container
    WebPartContainerInfo updateContainer =
    WebPartContainerInfoProvider.GetWebPartContainerInfo("MyNewContainer");
    if (updateContainer != null)
    {
        // Update the properties
        updateContainer.ContainerDisplayName =
        updateContainer.ContainerDisplayName.ToLower();

        // Save the changes
        WebPartContainerInfoProvider.SetWebPartContainerInfo(updateContainer);

        return true;
    }
}
```

```
    return false;
}
```

The following example gets and bulk updates containers.

```
private bool GetAndBulkUpdateWebPartContainers()
{
    // Prepare the parameters
    string where = "ContainerName LIKE N'MyNewContainer%'";
    string orderBy = "";
    int topN = 0;
    string columns = "";

    // Get the data
    DataSet containers = WebPartContainerInfoProvider.GetContainers(where,
        orderBy, topN, columns);
    if (!DataHelper.DataSourceIsEmpty(containers))
    {
        // Loop through the individual items
        foreach (DataRow containerDr in containers.Tables[0].Rows)
        {
            // Create object from DataRow
            WebPartContainerInfo modifyContainer = new WebPartContainerInfo
            (containerDr);

            // Update the properties
            modifyContainer.ContainerDisplayName =
            modifyContainer.ContainerDisplayName.ToUpper();

            // Save the changes
            WebPartContainerInfoProvider.SetWebPartContainerInfo(modifyContainer);
        }

        return true;
    }

    return false;
}
```

The following example deletes a web part container.

```
private bool DeleteWebPartContainer()
{
    // Get the web part container
    WebPartContainerInfo deleteContainer =
    WebPartContainerInfoProvider.GetWebPartContainerInfo("MyNewContainer");

    // Delete the web part container
    WebPartContainerInfoProvider.DeleteWebPartContainerInfo(deleteContainer);
}
```

```
    return (deleteContainer != null);  
}
```

7.27.9.4.6 Web part containers and sites

The following example assigns a web part container to a site.

```
private bool AddWebPartContainerToSite()  
{  
    // Get the web part container  
    WebPartContainerInfo container =  
    WebPartContainerInfoProvider.GetWebPartContainerInfo("MyNewContainer");  
    if (container != null)  
    {  
        int containerId = container.ContainerID;  
        int siteId = CMSContext.CurrentSiteID;  
  
        // Save the binding  
        WebPartContainerSiteInfoProvider.AddContainerToSite(containerId, siteId);  
  
        return true;  
    }  
  
    return false;  
}
```

The following example removes a container from a site.

```
private bool RemoveWebPartContainerFromSite()  
{  
    // Get the web part container  
    WebPartContainerInfo removeContainer =  
    WebPartContainerInfoProvider.GetWebPartContainerInfo("MyNewContainer");  
    if (removeContainer != null)  
    {  
        int siteId = CMSContext.CurrentSiteID;  
  
        // Delete the binding  
        WebPartContainerSiteInfoProvider.RemoveContainerFromSite  
(removeContainer.ContainerID, siteId);  
  
        return true;  
    }  
  
    return false;  
}
```

7.28 Widgets

7.28.1 Overview

Widgets introduce support for the personalization of pages. This feature allows users and editors to edit the structure of page templates. The personalized settings are saved within the system and can be invoked from the live site by authorized users or through the CMS Desk interface in the case of website editors and administrators.

From a designer's point of view, widgets are the basic building blocks of page templates in the same way as [Web parts](#). Like web parts, they are placed into zones, which must be configured to contain a certain type of widgets. For more information about web development basics, such as page templates, please refer to the [Web development overview -> Portal engine development model](#) chapter of this guide. Widgets may also be used on pages based on ASPX page templates as long as they contain the appropriate zones and are configured as described in [ASPX page template development model -> Adding portal engine functionality to ASPX templates](#).

There is a predefined set of widgets included in the default Kentico CMS installation. A description of these widgets and their properties can be found in the [Kentico CMS Widgets](#) reference. Because all widgets are based on existing web parts, you can also add your own widgets. Widgets can be created and managed at **Site Manager -> Development -> Widgets**. The details are given in the [Developing widgets](#) topic.

As mentioned above, widgets provide the same functionality as ordinary web parts. However, users with the appropriate permissions can modify the properties of widgets and their placement on the web page, add and remove widgets from their pages and so on. Users are divided into four different groups according to the possible ways they can use widgets:

- [Site developers/Administrators](#) - define the placement of widget zones and their default content, select the web part properties that should be available when configuring widgets and manage all available widgets.
- [Page editors](#) - define the content of widget zones created on page templates by the site developers/administrators.
- [Group administrators](#) - define the content of widget zones located on the pages of their group via the live site.
- [Website users](#) - customize the content of widget zones on personalizable pages via the live site.

Widgets can additionally be added directly into editable text areas as described in the [Inline widgets](#) topic. Dashboards in the administration interface also utilize widgets as customization components. Please refer to the [Modules -> Dashboards](#) chapter for detailed information.

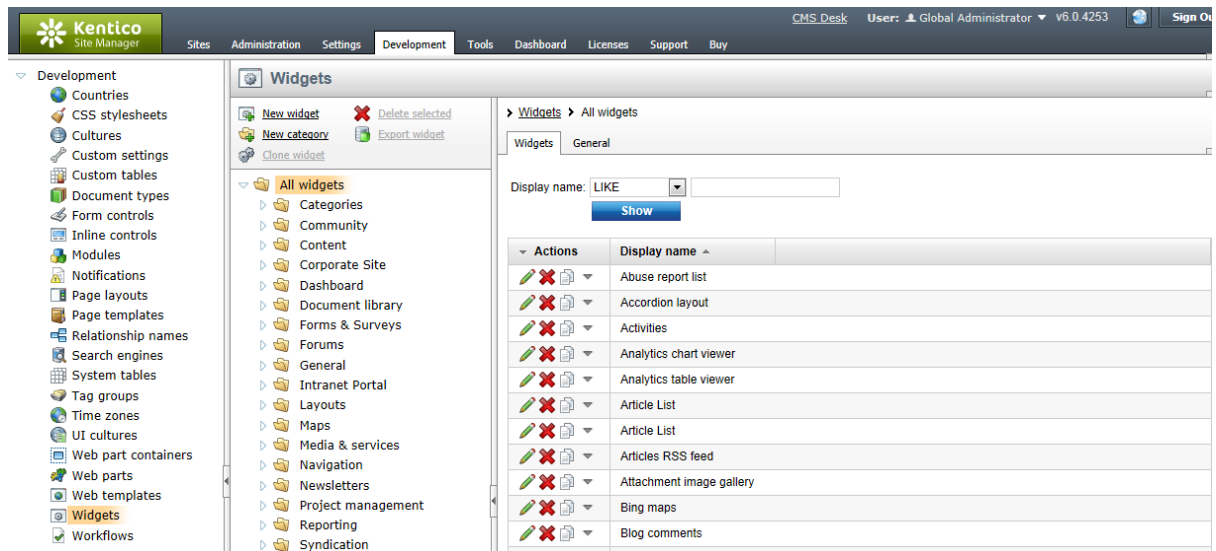

Security issues, such as the definition of where individual widgets can be used and permissions for different types of roles are discussed in the [Security](#) topic.

The [Widget internals and API](#) sub-chapter provides information about the database tables and classes used by widgets and examples of how widgets can be managed using the API.

7.28.2 Developing widgets

This topic leads you through the process of creating a widget. As a site developer, you can create your own widgets. Every widget is based on an existing web part, so if you require a widget with completely new custom functionality, you need to [develop](#) the appropriate web part first.

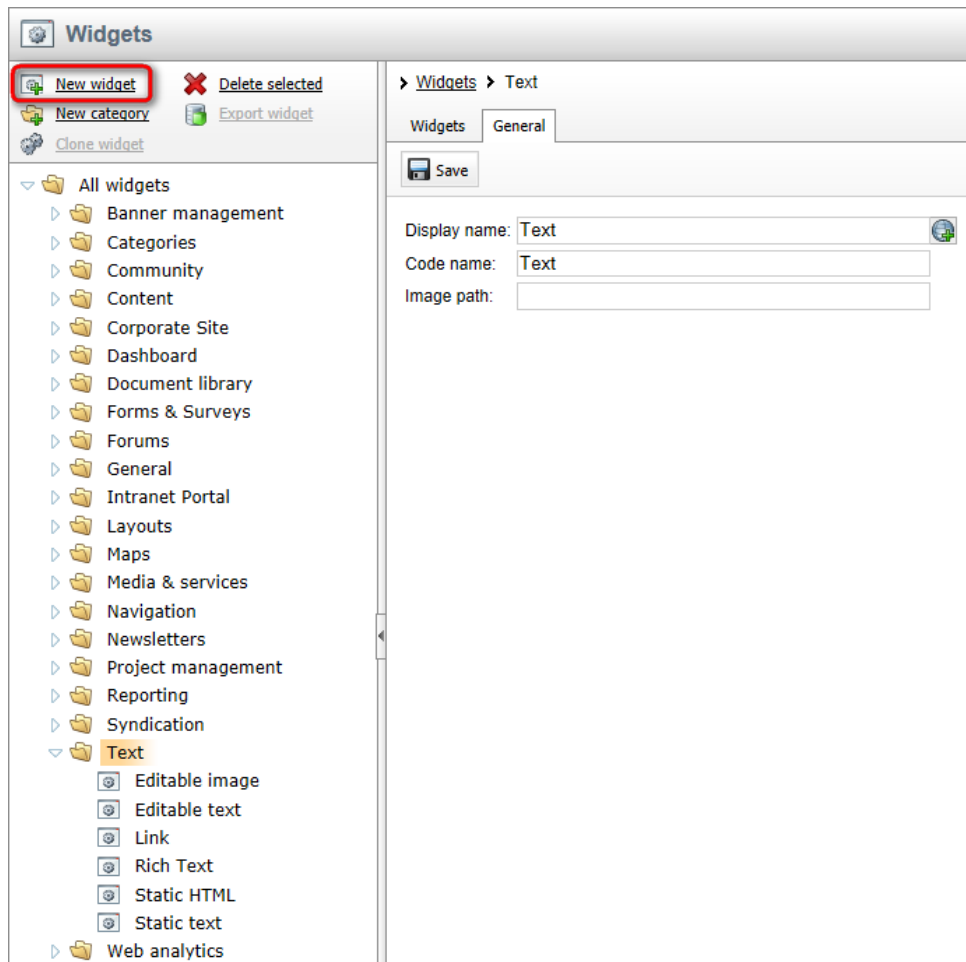

1. As mentioned above, it is not possible to create a widget without a reference to a web part. To start, switch to **Site Manager** -> **Development** -> **Widgets** to access the administration interface where widgets can be created. You should see a screen similar to the following one.

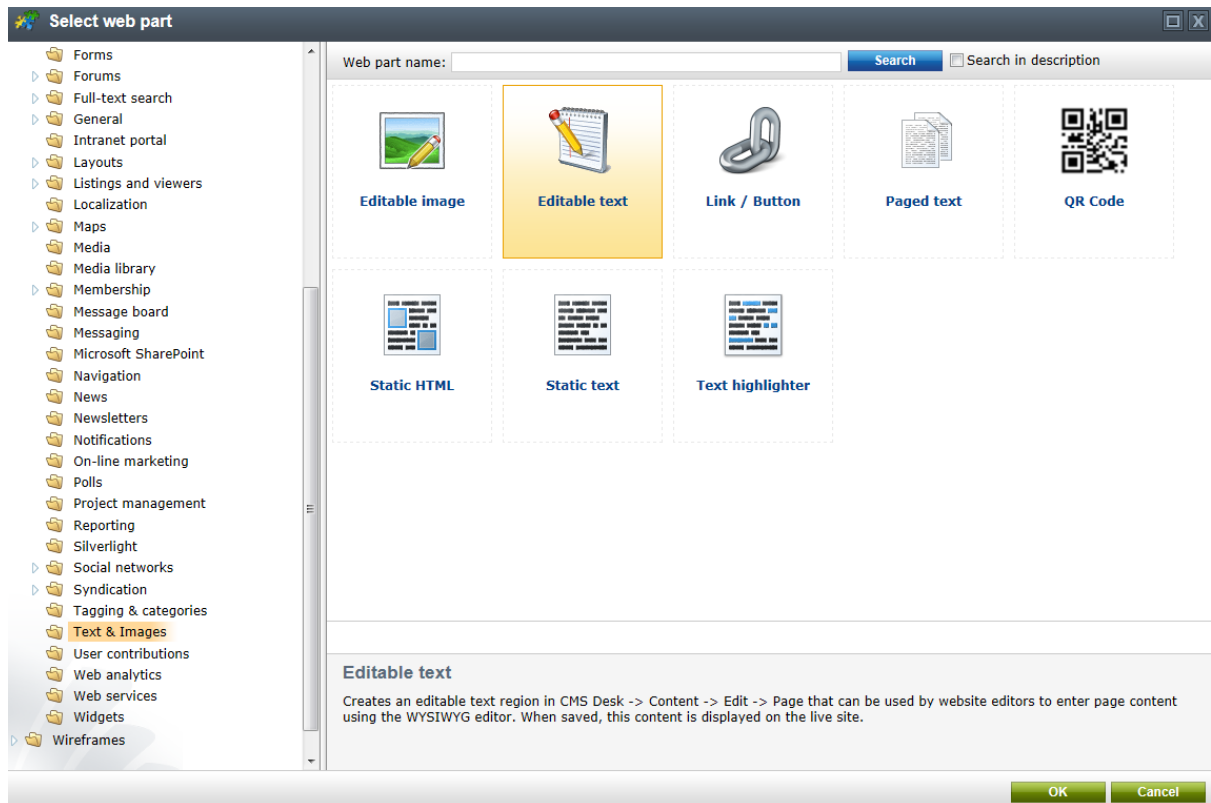

2. Widgets are grouped into categories. It is important to note that categories are used for the sake of organization only. The category under which a given widget is stored has no influence on who can use or modify the widget.

Clicking on a node causes the selected category to open and all widgets stored within that category are listed. You can also change the **Display** and **Code name** of a category on the **General** tab. The **Image path** property sets the path to the image that will be used as the category's icon in the **Add widget** dialog (the recommended image size is 16x16px).

Now select the category where the new widget should be stored, for example **Text**, and click the **New widget** link. Alternatively, you can create the new widget under any folder and change its location later when the properties of the widget are defined.

3. A dialog opens, where you can select the web part that will be used as a template for the new widget. In the example below, the **Editable text** web part from the **Text & Images** category is selected. Click the **OK** button to confirm the selection.

4. A new widget has just been created. You can manage widgets using the actions above the tree. A new widget can be created based on an existing one using **Clone widget**. If you wish to add a new category, use **New category**.

To delete a selected widget or an entire category (except the *All widgets* category), click **Delete selected**. Please bear in mind that when a widget is deleted, it is not automatically removed from page templates. Therefore, when pages containing a deleted widget are to be displayed, an error message will be displayed instead of the missing widget.

The example below shows the effect of deleting the **Social bookmarking** widget without removing it from the page templates.

A selected widget can also be exported by clicking on **Export widget**. For details regarding export see [Exporting single objects](#).

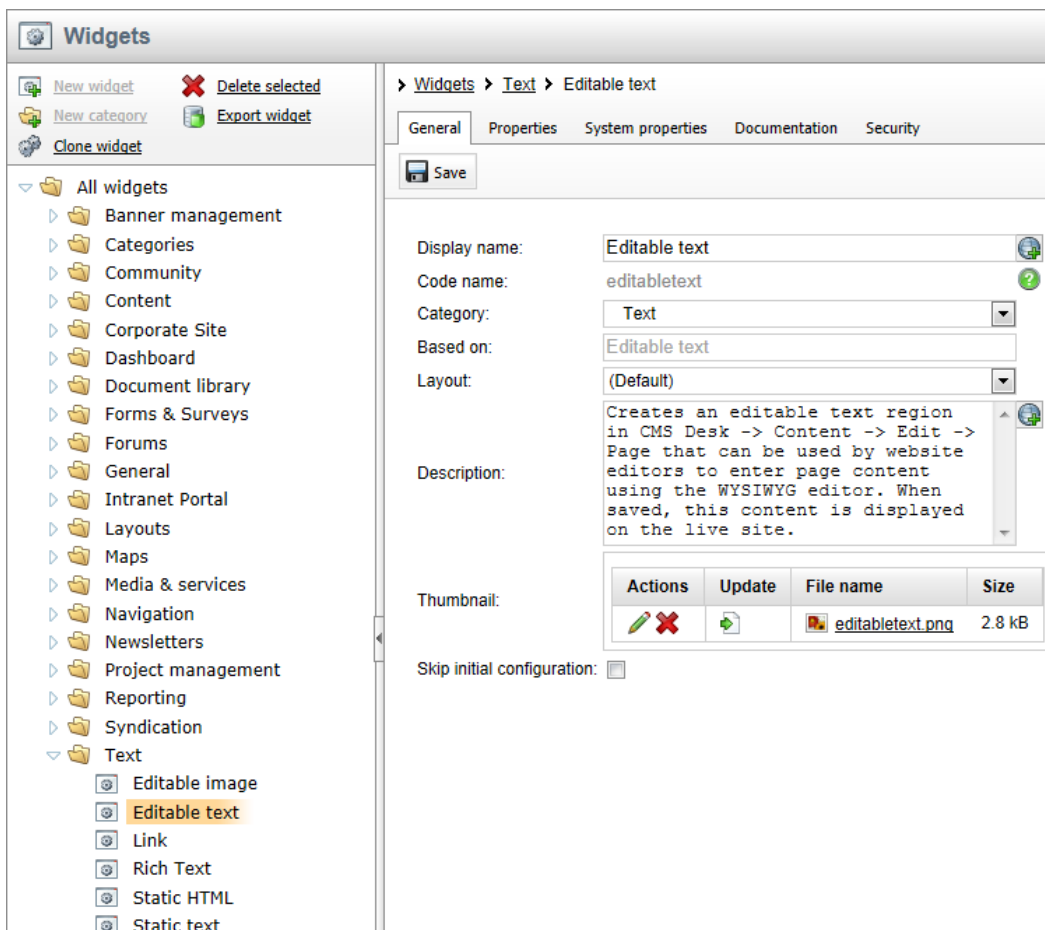

5. For each selected widget there are five tabs available. On the **General** tab there are all the basic settings:

- **Display name** - sets a name for the widget that will be used in the administration interface and widget selection dialog.
- **Code name** - sets a name that will serve as a unique identifier for the widget.
- **Category** - shows the category to which the widget belongs. You can change it here by selecting a

new category from the drop-down list.

- **Based on** - displays the name of the parent web part that the widget is derived from.
- **Layout** - allows you to choose one of the layouts defined for the parent web part. The selected layout will be applied to all instances of the widget across all sites. A layout may be used to modify the widget's appearance or design and even add further content into it. If you wish to use a different layout for certain instances of the same widget, you can make a clone of the widget for this purpose and have it use the alternative layout. For more information about web part layouts and how they can be created, please see the [Customizing web part layout](#) topic.
- **Description** - a text description that is displayed in the widget selection dialog and in widget documentation.
- **Thumbnail** - sets the image used as a graphical representation in the widget selection dialog.
- **Skip initial configuration** - if enabled, new instances of the widget will be added directly to the page without opening the property configuration dialog. This can make the widget easier to use and helps save time, particularly in the case of widgets that are usually left with their default property values.

Perform any changes required and click the  **Save** button.

The screenshot shows the 'Widgets' configuration window. On the left is a tree view of widget categories, with 'Text' expanded to show 'Editable text' selected. The main area shows the configuration for 'Editable text' under the 'General' tab. The breadcrumb path is 'Widgets > Text > Editable text'. A 'Save' button is visible at the top left of the configuration area. The configuration fields include:

- Display name:** Editable text
- Code name:** editabletext
- Category:** Text
- Based on:** Editable text
- Layout:** (Default)
- Description:** Creates an editable text region in CMS Desk -> Content -> Edit -> Page that can be used by website editors to enter page content using the WYSIWYG editor. When saved, this content is displayed on the live site.
- Thumbnail:** A table showing the widget's thumbnail image:

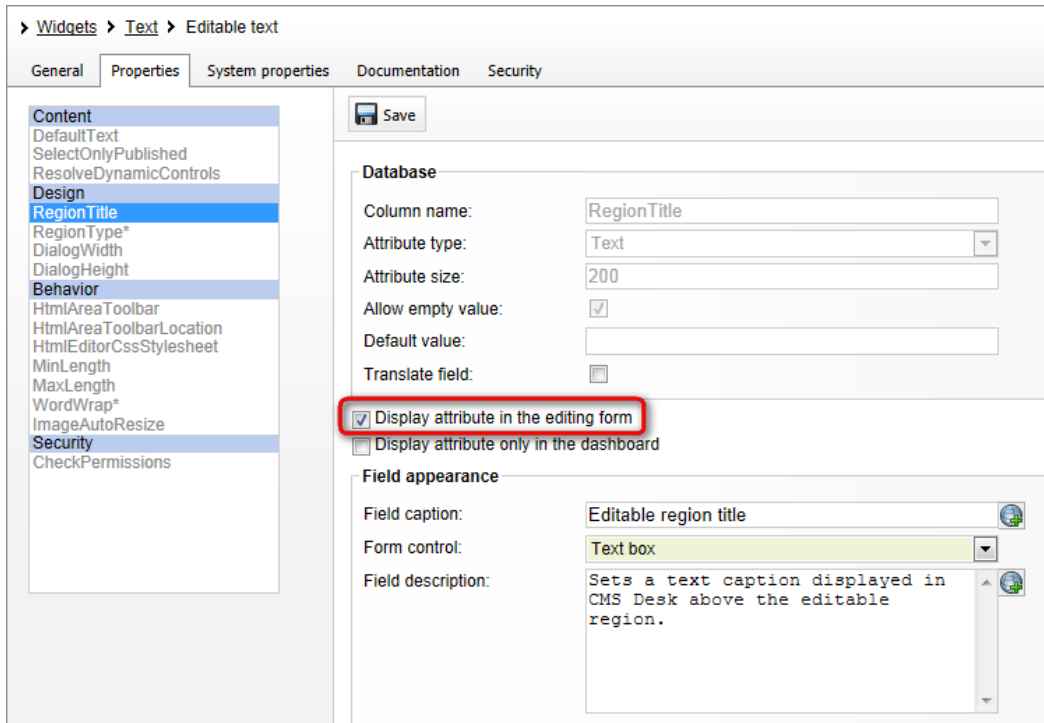

| Actions | Update | File name | Size |
|---|---|------------------|--------|
|   |  | editabletext.png | 2.8 kB |
- Skip initial configuration:**

6. The **Properties** tab includes all the properties taken from the parent web part.

- Using the **Display attribute in the editing form** checkbox, you can choose if a given property should be available in the widget configuration dialog. You can notice that all properties are hidden by default.

- If the **Display attribute only in the dashboard** box is also checked, the property is only accessible when configuring the widget on one of the dashboard sections located in the CMS administration interface.

Changes must be confirmed by clicking  **Save**.

The screenshot shows the configuration interface for the 'Editable text' widget. The 'Properties' tab is selected, and the 'Database' section is expanded. The 'Display attribute in the editing form' checkbox is checked and highlighted with a red box. The 'Field appearance' section shows the 'Form control' set to 'Text box'.

7. The **System properties** tab contains the general properties that all widgets and web parts have in common. Their default values can be modified by clearing the **Inherited** checkbox and entering the desired value into the appropriate field. All changes must be confirmed by clicking  **Save**.

» Widgets » Text » Editable text

| | Allowed for |
|--|-------------------------------------|
| This widget can be used in group zones | <input type="checkbox"/> |
| This widget can be used in editor zones | <input checked="" type="checkbox"/> |
| This widget can be used in user zones | <input type="checkbox"/> |
| This widget can be used in dashboard zones | <input type="checkbox"/> |
| This widget can be used as inline widget | <input type="checkbox"/> |
| Authenticated users | <input checked="" type="radio"/> |
| Global Admin only | <input type="radio"/> |
| Authorized roles | <input type="radio"/> |

Please select the authorized roles (available only when you select the "Authorized roles" option above):

Site: ▼

| | Allowed for |
|------------------------------|--------------------------|
| Authenticated users | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> |
| CMS Community administrators | <input type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> |
| CMS Desk Administrators | <input type="checkbox"/> |
| CMS Editors | <input type="checkbox"/> |
| CMS Readers | <input type="checkbox"/> |

9. Once all settings are configured as needed, the widget is ready to be used on the website's pages.

7.28.3 Using widgets

Users can perform widget-related actions depending on their role on the website:

- [Site developers and administrators](#) - can determine which zones are widget zones (and their type) and which ones are standard (static) web part zones, and also define the default content of these zones. These tasks can be done in **CMS Desk -> Content -> Design**. They can also manage widgets in the administration interface in **Site Manager -> Development -> Widgets**. This includes developing new widgets, determining where and by whom they can be used and selecting the properties which should be personalizable (editable by users).
- [Page editors](#) - can define the content of Editor widget zones created on page templates by the site developers/administrators. This is accessible through **CMS Desk -> Content -> Edit -> Page**.
- [Group administrators](#) - can define the design of Group administrator widget zones on group page templates. Group administrators can add or remove widgets and set their properties just like page editors. This customization can be done on the live site.
- [Website users](#) - authenticated users of the website can customize the content of widget zones on personalizable pages on the live site. They can add or remove widgets and configure the widget properties. Only pages with templates that contain User widget zones can be personalized in this way.

Site developers, administrators and page editors can also use inline widgets. Please refer to the [Inline widgets](#) chapter for more details.

Another place where users can customize page content using widgets is on the dashboards located in the administration interface of Kentico CMS. Dashboard pages are based on special types of page templates and their widget functionality is very similar to that of User widget zones. More detailed information about widgets on dashboards can be found in the [Modules -> Dashboards -> Managing dashboard content](#) topic.

Site developers/Administrators

The site developers make the decisions regarding the layout of page templates. This also includes the decision whether a zone will be defined as a web part zone (static) or widget zone (customizable).

To change a web part zone into a widget zone, go to **CMS Desk -> Content -> Design**, expand the menu of the selected web part zone (▼) and click on the  **Properties** item.

Using the **Web zone part properties** dialog you can define the **Widget zone type** property. The following options are available:

- **None** - a standard web part zone is used.
- **User personalization** - the zone will be a widget zone and website users will be able to personalize it on the live site. The zone will be marked with the *User zone* (👤) icon.
- **Customization by page editor** - the zone will be a widget zone and website editors will be able to customize it. The zone will be marked with the *Editor zone* (🔧) icon.
- **Customization by group administrator** - the zone will be a widget zone and group administrators of the group that owns the page will be able to customize it. The zone will be marked with the *Group*

administrator zone (👤) icon.

Please bear in mind that changing the widget zone type removes all current web parts or default widgets placed in that zone.

The screenshot shows the 'Web part zone properties' dialog box. The 'Default' section includes a 'Zone title' text box, a 'Disable view state' checkbox, and a 'Widget zone type' dropdown menu. The dropdown menu is highlighted with a red box and shows four options: 'None', 'User personalization', 'Customization by page editor' (selected), and 'Customization by group administrator'. The 'Visibility' section includes a 'Visible' checkbox, a 'Hide on subpages' checkbox, a 'Show for document types' dropdown with 'Select' and 'Clear' buttons, and a 'Display to roles' dropdown with 'Add roles' and 'Clear' buttons. At the bottom, there is a 'Zone container' section with a 'Refresh content' checkbox and 'OK', 'Cancel', and 'Apply' buttons.

Having defined the zone as a widget type zone, you can now add widgets. Simply click on the **Add widget** (+) button on the right side of the zone.

You can select any widget available for the given type of widget zone (User, Editor, Group administrator).

A **Widget properties** dialog opens (unless the given widget is configured to skip it), where you can change any properties available for customization. Click **OK** to add the widget.

Refresh page

This way, developers can define the default content of widget zones. It is up to the users to personalize these zones further as described in the remaining sections of this topic.

Page editors

As a page editor, you can add, modify or delete any widget placed in editor type widget zones. This can be used to allow editors to quickly customize pages beyond simply entering content into static page templates.

To add a widget, just click on the **Add widget** (+) button in the top left corner of an editor widget zone.

+ Add widget X Reset to default

+ Add new article

Example article

Edit Delete

Cascading Style Sheets (CSS)

Edit Delete

You can modify the properties of any widget placed in an editor zone by clicking the **Configure widget** (🔧) button. You can also delete widgets using the **Delete widget** (🗑️) button. To move widgets between zones, hover over **Drag widget** (👉) and drag the widget to the desired place.

Group administrators

Group administrators (members of the group who are assigned to a group role that can manage the group) have basically the same options as page editors. They can personalize those pages that belong to their group that contain group administrator widget zones by adding, deleting and configuring widgets in these zones. This is done on the live site, as group administrators won't necessarily have access to the **CMS Desk -> Edit** interface. Other website users who have access to the group pages will be able to see the widgets, but won't be able to manage them.

For specific information about groups, please see the [Modules -> Groups](#) chapter of this guide.

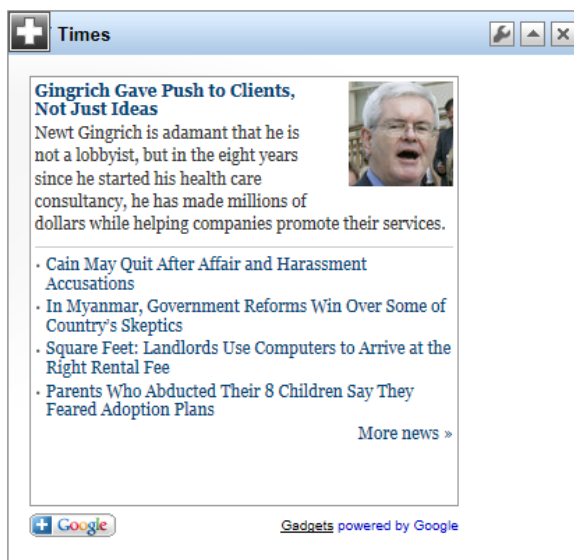

Note

Group ownership of a document can be configured in **CMS Desk -> Edit -> Properties** through the **Owned by group** field.

Website users

Authenticated website users can manipulate user widget zones on the live site and thus personalize their pages. A common use is placing user widget zones onto the home page, so that users can create their own personalized version of it.

In order to add a widget to a user widget zone on the live site, click on the **Add widget** (➕) button in the top left corner of the zone.

Any widget can be configured by clicking on the **Configure widget** (🔧) button. You can also delete

widgets using the **Delete widget** (✖) button. To move widgets between zones or to different positions, click anywhere on the header of the given widget and drag it to the desired location. Any widget can be minimized using the **Minimize** (▢) button, or restored using the **Maximize** (▢) button.

Widget actions web part

You can place the [Widget actions](#) web part onto pages containing widget zones to allow users to:

- Add widgets
- Reset all widget zones to their default content

The web part only works with the type of widget zone specified in its **Widget zone type** property. When a user clicks the **Add widget** button, the web part places the widget into the zone specified by the **Widget zone** property. Users can drag the widget into another zone if the default placement is not suitable.

Tip

When creating pages with *editor* widget zones, you can enable the **Use main menu** property of the Widget actions web part. This causes the web part to display the action buttons on the main edit menu of the **Page** tab in CMS Desk, instead of in the page content.

Using macros in widget properties

For security reasons, the system does *not* resolve [macro expressions](#) entered by users into the properties of widget instances. However, you can pre-set macros as the default values of widget properties:

1. Go to **Site Manager -> Development -> Widgets**.
2. Select the given widget in the tree catalog and open the **Properties** tab.
3. Enter the required macro expression into the **Default value** field of the appropriate property.
4. Disable the **Display attribute in the editing form** option for the property.
5. Click  **Save**.

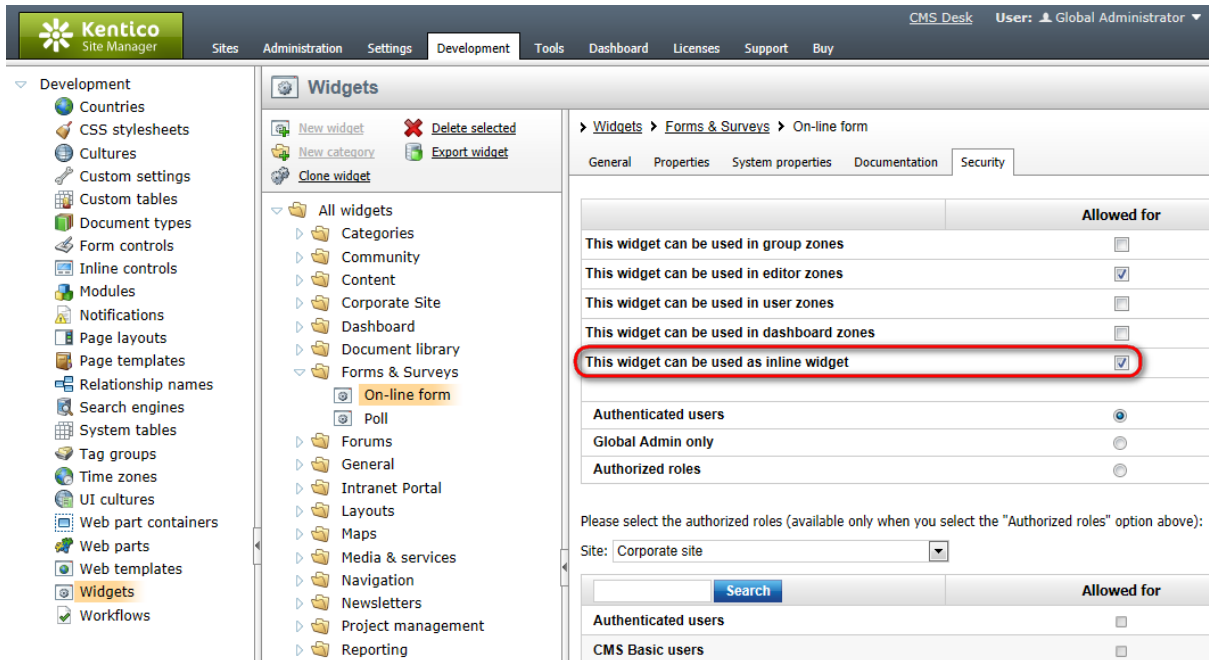

When the website renders a page containing the widget, the system resolves the macro and dynamically inserts the return value into the property.

7.28.4 Inline widgets

Inline widgets allow administrators and content editors to add widgets directly into the text of a page. These widgets are not contained in any widget zones, so they cannot be customized on the live site. Their main purpose is to give content editors, who do not have **Design** permissions, the option of customizing editable regions using widgets.

Inserting inline widgets into text

Inline widgets can be inserted into text by using the **Insert/Edit widget** () button on toolbar of the [WYSIWYG editor](#). This opens the same selection dialog as when adding a widget to a widget zone. Only widgets that are allowed to be used inline can be selected. This option can be configured when editing a widget on its **Security** tab in **Site Manager -> Development -> Widgets**.

The screenshot shows the Kentico Site Manager interface. The left sidebar lists various development tools, with 'Widgets' selected. The main area displays the 'Widgets' configuration page for an 'On-line form' widget. The 'Security' tab is active, showing a table of permissions. The 'This widget can be used as inline widget' checkbox is checked and highlighted with a red circle.

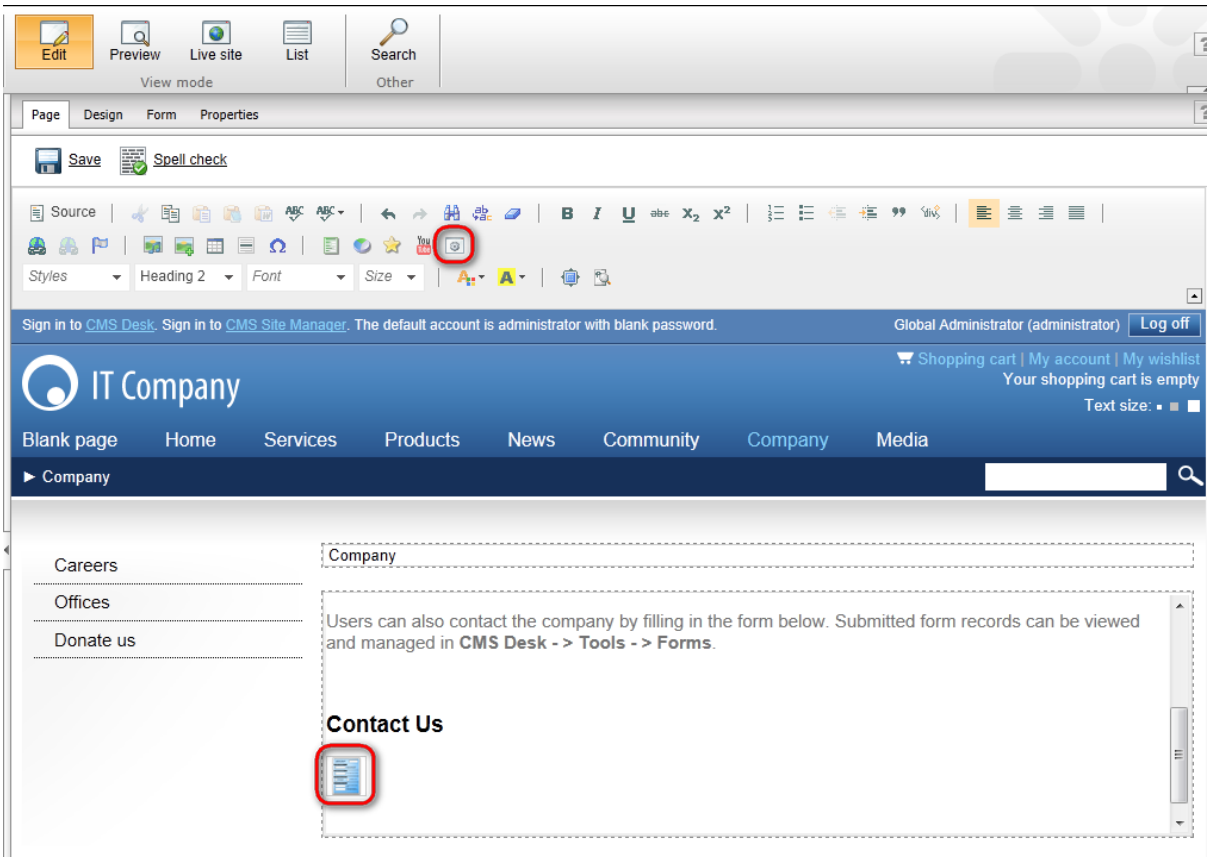

| | Allowed for |
|--|-------------------------------------|
| This widget can be used in group zones | <input type="checkbox"/> |
| This widget can be used in editor zones | <input checked="" type="checkbox"/> |
| This widget can be used in user zones | <input type="checkbox"/> |
| This widget can be used in dashboard zones | <input type="checkbox"/> |
| This widget can be used as inline widget | <input checked="" type="checkbox"/> |
| Authenticated users | <input checked="" type="radio"/> |
| Global Admin only | <input type="radio"/> |
| Authorized roles | <input type="radio"/> |

Please select the authorized roles (available only when you select the "Authorized roles" option above):
 Site: Corporate site

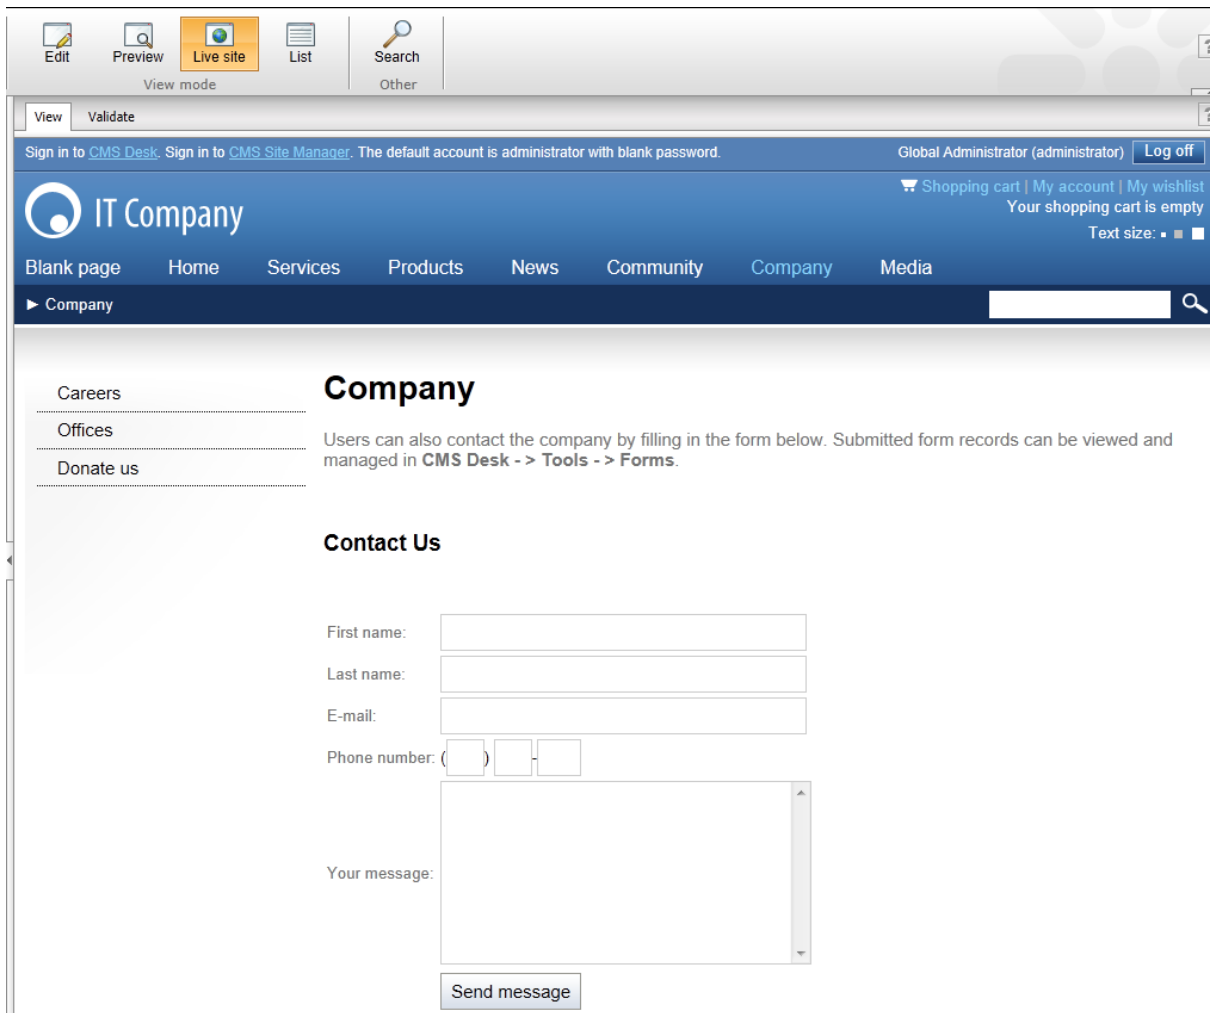

| | Allowed for |
|---------------------|--------------------------|
| Authenticated users | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> |

After you select the desired widget, the **Widget properties** dialog opens, where you can configure any of the widget's available properties. Once inserted into the text, an inline widget is represented by a placeholder image on the **Edit** tab of **CMS Desk** and is displayed fully on the **Preview** tab and the live site. Remember to  **Save** the page once you are done.

The following images show an example of using an inline widget to add a form into text:

The Form is displayed fully on the **Live site**:

Configuring inline widgets

There are three different ways to open an inline widget's properties dialog:

- Double-click its placeholder image in the text
- Right-click its placeholder image in the text and select **Properties**
- Select its placeholder image in the text and click the **Insert/Edit widget** button (🔗) on the WYSIWYG editor toolbar

7.28.5 Security

When a new widget is created from an existing web part, all the attributes are hidden in the editing form by default. It is up to the widget creator to select the attributes which should be available for customization using the check boxes on the **Properties** tab.

The security options are defined on the **Security** tab when selecting a widget from the content tree in **Site Manager -> Development -> Widgets**. By default, all widgets are forbidden for all zone types and are allowed for authorized roles only. However, no authorized role is selected by default. It is up to the developers to allow a widget for specific types of zones and users.

The screenshot shows the 'Security' tab for a 'Rich Text' widget. The left sidebar lists various widget categories, with 'Text' expanded to show 'Rich Text' selected. The main panel has tabs for 'General', 'Properties', 'System properties', 'Documentation', and 'Security'. Below the tabs is a table with columns for permissions and 'Allowed for'.

| | Allowed for |
|--|-------------------------------------|
| This widget can be used in group zones | <input checked="" type="checkbox"/> |
| This widget can be used in editor zones | <input checked="" type="checkbox"/> |
| This widget can be used in user zones | <input type="checkbox"/> |
| This widget can be used in dashboard zones | <input type="checkbox"/> |
| This widget can be used as inline widget | <input type="checkbox"/> |
| Authenticated users | <input type="radio"/> |
| Global Admin only | <input type="radio"/> |
| Authorized roles | <input checked="" type="radio"/> |

Please select the authorized roles (available only when you select the "Authorized roles" option above):

Site: Corporate Site

| | Allowed for |
|------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> |
| CMS Community administrators | <input checked="" type="checkbox"/> |
| CMS Designers | <input checked="" type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> |
| CMS Editors | <input type="checkbox"/> |
| CMS Readers | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> |

Widgets can be allowed for the following locations:

- **In group, editor or user zones** - the widget may be used in the respective type of widget zone.
- **In dashboard zones** - the widget may be used as a component on dashboards.
- **As inline widget** - the widget can be inserted into editable text regions via the WYSIWYG editor.

In addition, the permissions of a widget must also be set for one of the following types of users:

- **Authenticated users** - all logged in users are allowed to use the widget.
- **Global Admin only** - only users designated as global administrators are allowed to use the widget.
- **Authorized roles** - only members of the roles selected in the section below are allowed to use the widget.

Please keep in mind that changing the security settings will only affect new widgets. If a user was allowed to add a widget and an administrator later removes this permission, the user can still see the widget on their page. However, once deleted, the widget cannot be added back to the page without allowing it on the **Security** tab of that particular widget.

7.28.6 Widgets internals and API

7.28.6.1 Overview

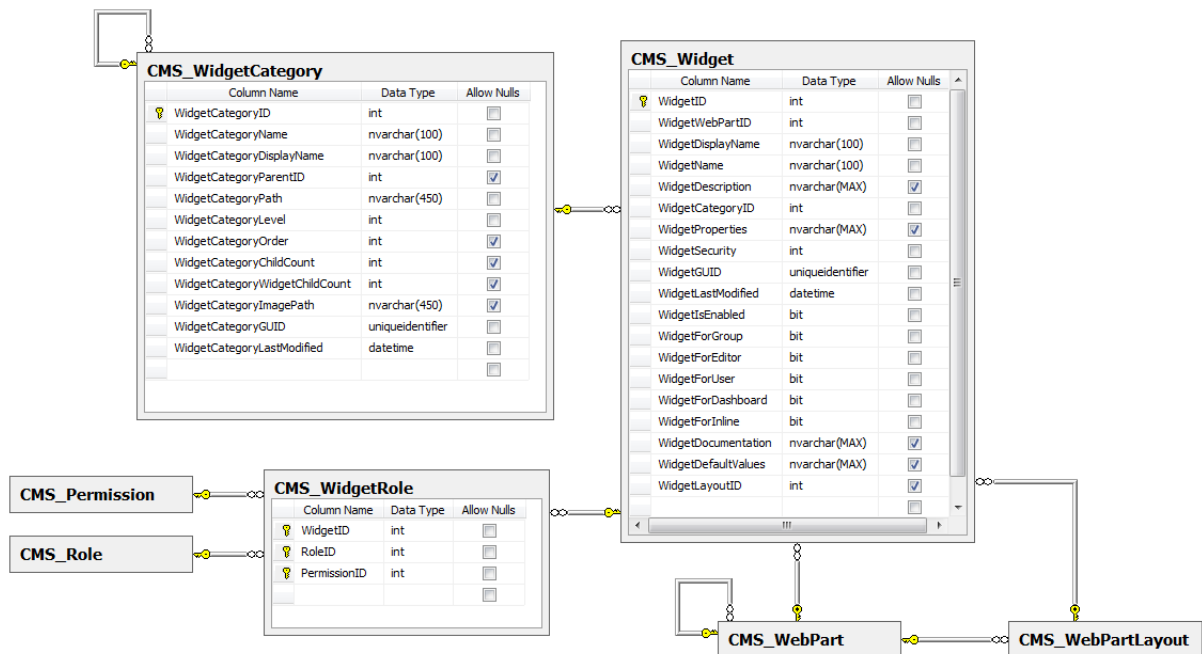

In this chapter, you will learn which [database tables](#) and [API classes](#) are used to manage widgets. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the related classes, please refer to [Kentico CMS API Reference](#).

7.28.6.2 Database tables

The following database tables are used to store information about widgets:

- **CMS_WidgetCategory** - contains records representing widget categories.
- **CMS_Widget** - contains records representing widgets and their configuration.
- **CMS_WidgetRole** - stores relationships between widgets and roles. Each entry in this table indicates that a specific widget can be used by users in a given role.

Widget instance storage

Data about widget instances and their configuration is also stored in the database, but the location depends on the type of the widget.

The content of zones on page templates, including default widgets and their property configuration, is stored in XML format in the **PageTemplateWebParts** column of the **CMS_PageTemplate** table. Widget instances placed onto individual documents by page editors are stored using the same format in the **DocumentWebParts** column of the **CMS_Document** table.

The data about widget instances contained in personalized user and dashboard widget zones, which depends on the current context (user and site), is saved in the **CMS_Personalization** table.

Inline widgets are saved as control macro expressions within the text content of the document onto which they are placed. For standard editable regions on pages, this content is stored in the **DocumentContent** column of the **CMS_Document** table. If the inline widget is inserted into a document field via the **Form** tab of **CMS Desk**, it will be saved in the table that stores documents of the given type (e.g. **CONTENT_News** for news documents).

7.28.6.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes for managing widgets can be found in the **CMS.PortalEngine** namespace.

CMS_WidgetCategory table API:

- **WidgetCategoryInfo** - represents one widget category.
- **WidgetCategoryInfoProvider** - provides management functionality for widget categories.

CMS_Widget table API:

- **WidgetInfo** - represents one widget object.
- **WidgetInfoProvider** - provides management functionality for widgets.

CMS_WidgetRole table API:

- **WidgetRoleInfo** - represents a relationship between a widget and a role.
- **WidgetRoleInfoProvider** - provides management functionality for widget-role relationships.

CMS_Personalization table API:

- **PersonalizationInfo** - represents a personalized version of a page for a specific site and user.
- **PersonalizationInfoProvider** - provides management functionality for personalization objects.

Other classes:

- **WebPartInstance** - can be used to represent a single instance of a widget.
- **WebPartZoneInstance** - represents an instance of a web part (widget) zone.

7.28.6.4 API examples

7.28.6.4.1 Overview

These topics show examples of how the API for managing widgets can be used:

- [Managing widget categories](#)
- [Managing widgets](#)
- [Managing widget security](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Development\Widgets\Default.aspx.cs**.

The widget API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.PortalEngine;
using CMS.FormEngine;
```

7.28.6.4.2 Managing widget categories

The following example creates a widget category.

```
private void CreateWidgetCategory()
{
    // Create new widget category object
    WidgetCategoryInfo newCategory = new WidgetCategoryInfo();

    // Set the properties
    newCategory.WidgetCategoryDisplayName = "My new category";
    newCategory.WidgetCategoryName = "MyNewCategory";

    // Save the widget category
    WidgetCategoryInfoProvider.SetWidgetCategoryInfo(newCategory);
}
```

The following example gets and updates a widget category.

```
private bool GetAndUpdateWidgetCategory()
{
    // Get the widget category
    WidgetCategoryInfo updateCategory =
    WidgetCategoryInfoProvider.GetWidgetCategoryInfo("MyNewCategory");
    if (updateCategory != null)
    {
        // Update the properties
        updateCategory.WidgetCategoryDisplayName =
        updateCategory.WidgetCategoryDisplayName.ToLower();

        // Save the changes
        WidgetCategoryInfoProvider.SetWidgetCategoryInfo(updateCategory);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates widget categories.

```
private bool GetAndBulkUpdateWidgetCategories()
{
    // Prepare the parameters
    string where = "WidgetCategoryName LIKE N'MyNewCategory%';
    string orderBy = "";
    int topN = 0;
    string columns = "";

    // Get the data
    DataSet categories = WidgetCategoryInfoProvider.GetWidgetCategories(where,
    orderBy, topN, columns);
    if (!DataHelper.DataSourceIsEmpty(categories))
    {
        // Loop through the individual items
        foreach (DataRow categoryDr in categories.Tables[0].Rows)
        {
            // Create object from DataRow
            WidgetCategoryInfo modifyCategory = new WidgetCategoryInfo(categoryDr);

            // Update the properties
            modifyCategory.WidgetCategoryDisplayName =
            modifyCategory.WidgetCategoryDisplayName.ToUpper();

            // Save the changes
            WidgetCategoryInfoProvider.SetWidgetCategoryInfo(modifyCategory);
        }

        return true;
    }

    return false;
}
```

```
}
```

The following example deletes a widget category.

```
private bool DeleteWidgetCategory()
{
    // Get the widget category
    WidgetCategoryInfo deleteCategory =
    WidgetCategoryInfoProvider.GetWidgetCategoryInfo("MyNewCategory");

    // Delete the widget category
    WidgetCategoryInfoProvider.DeleteWidgetCategoryInfo(deleteCategory);

    return (deleteCategory != null);
}
```

7.28.6.4.3 Managing widgets

The following example creates a widget.

```
private bool CreateWidget()
{
    // Get parent web part and category for widget
    WebPartInfo webpart = WebPartInfoProvider.GetWebPartInfo("AbuseReport");
    WidgetCategoryInfo category = WidgetCategoryInfoProvider.GetWidgetCategoryInfo
    ("MyNewCategory");

    // Widgets cannot be created from an inherited web part
    if ((webpart != null) && (webpart.WebPartParentID == 0) && (category != null))
    {
        // Create new widget object
        WidgetInfo newWidget = new WidgetInfo();

        // Set the properties from the parent web part
        newWidget.WidgetName = "MyNewWidget";
        newWidget.WidgetDisplayName = "My new widget";
        newWidget.WidgetDescription = webpart.WebPartDescription;

        newWidget.WidgetProperties = FormHelper.GetFormFieldsWithDefaultValue
        (webpart.WebPartProperties, "visible", "false");

        newWidget.WidgetWebPartID = webpart.WebPartID;
        newWidget.WidgetCategoryID = category.WidgetCategoryID;

        // Save new widget
        WidgetInfoProvider.SetWidgetInfo(newWidget);

        return true;
    }
}
```

```
    return false;
}
```

The following example gets and updates a widget.

```
private bool GetAndUpdateWidget()
{
    // Get the widget
    WidgetInfo updateWidget = WidgetInfoProvider.GetWidgetInfo("MyNewWidget");
    if (updateWidget != null)
    {
        // Update the properties
        updateWidget.WidgetDisplayName = updateWidget.WidgetDisplayName.ToLower();

        // Save the changes
        WidgetInfoProvider.SetWidgetInfo(updateWidget);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates widgets.

```
private bool GetAndBulkUpdateWidgets()
{
    // Prepare the parameters
    string where = "WidgetName LIKE N'MyNewWidget%'";
    string orderBy = "";
    int topN = 0;
    string columns = "";

    // Get the data
    DataSet widgets = WidgetInfoProvider.GetWidgets(where, orderBy, topN,
columns);
    if (!DataHelper.DataSourceIsEmpty(widgets))
    {
        // Loop through the individual items
        foreach (DataRow widgetDr in widgets.Tables[0].Rows)
        {
            // Create object from DataRow
            WidgetInfo modifyWidget = new WidgetInfo(widgetDr);

            // Update the properties
            modifyWidget.WidgetDisplayName =
modifyWidget.WidgetDisplayName.ToUpper();

            // Save the changes
            WidgetInfoProvider.SetWidgetInfo(modifyWidget);
        }
    }
}
```

```
        return true;
    }

    return false;
}
```

The following example deletes a widget.

```
private bool DeleteWidget()
{
    // Get the widget
    WidgetInfo deleteWidget = WidgetInfoProvider.GetWidgetInfo("MyNewWidget");

    // Delete the widget
    WidgetInfoProvider.DeleteWidgetInfo(deleteWidget);

    return (deleteWidget != null);
}
```

7.28.6.4.4 Managing widget security

The following example assigns a specific role to a widget (the widget will be usable by users belonging to the given role).

```
private bool AddWidgetToRole()
{
    // Get role, widget and permission object
    RoleInfo role = RoleInfoProvider.GetRoleInfo("CMSDeskAdmin",
CMSContext.CurrentSiteID);
    WidgetInfo widget = WidgetInfoProvider.GetWidgetInfo("MyNewWidget");
    PermissionNameInfo permission =
PermissionNameInfoProvider.GetPermissionNameInfo("AllowedFor", "Widgets", null);

    // If all exist
    if ((role != null) && (widget != null) && (permission != null))
    {
        // Add role to widget
        WidgetRoleInfoProvider.AddRoleToWidget(role.RoleID, widget.WidgetID,
permission.PermissionId);

        return true;
    }

    return false;
}
```

The following example removes the relationship between a specific role and a widget.

```
private bool RemoveWidgetFromRole()
{
    // Get role, widget and permission object
    RoleInfo role = RoleInfoProvider.GetRoleInfo("CMSDeskAdmin",
CMSContext.CurrentSiteID);
    WidgetInfo widget = WidgetInfoProvider.GetWidgetInfo("MyNewWidget");
    PermissionNameInfo permission =
PermissionNameInfoProvider.GetPermissionNameInfo("AllowedFor", "Widgets", null);

    // If all exist
    if ((role != null) && (widget != null) && (permission != null))
    {
        // Remove role from widget
        WidgetRoleInfoProvider.RemoveRoleFromWidget(role.RoleID, widget.WidgetID,
permission.PermissionId);

        return true;
    }

    return false;
}
```

The following example sets the security level for a widget (allows it to be used by all authenticated users).

```
private bool SetSecurityLevel()
{
    // Get widget object
    WidgetInfo widget = WidgetInfoProvider.GetWidgetInfo("MyNewWidget");

    // If widget exists
    if (widget != null)
    {
        // Set security access type
        widget.AllowedFor = SecurityAccessEnum.AuthenticatedUsers;

        WidgetInfoProvider.SetWidgetInfo(widget);

        return true;
    }

    return false;
}
```

7.29 Wireframing

7.29.1 Overview

When creating or redesigning a website, you can plan out its structure, appearance, and functionality using wireframe schematics. Wireframes allow you to build approximate representations of pages directly in the site's content tree. CMS Desk users can view the wireframes and use them as a visual

guide while developing the website. Preparing wireframes is much easier and quicker than implementing real pages.

Topics:

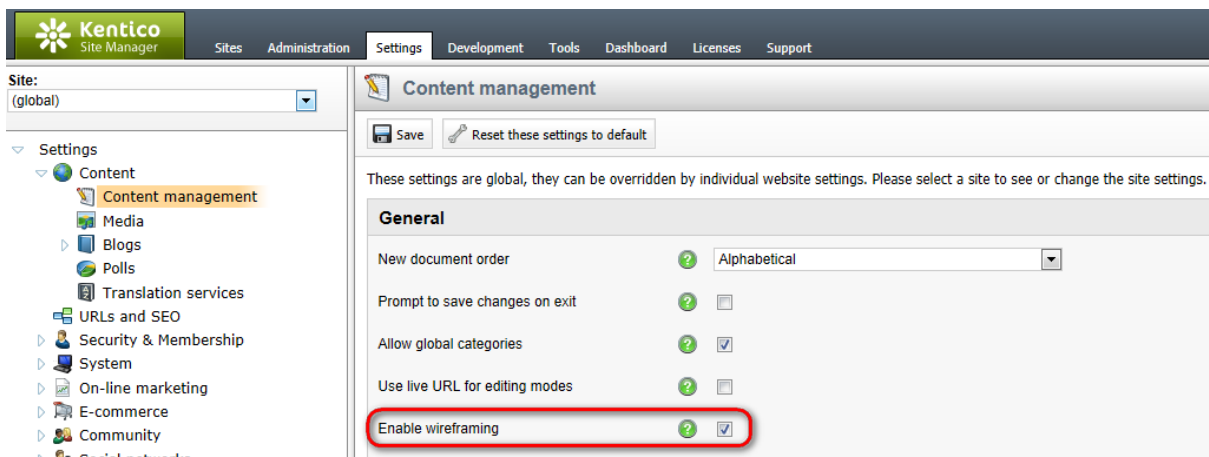

- [Managing wireframes](#)
- [Setting up wireframe templates](#)
- [Configuring content inheritance](#)
- [Developing wireframe components](#)
- [Security](#)

7.29.2 Managing wireframes

Users create, edit and view wireframes in the **CMS Desk** -> **Content** interface, directly in the content tree alongside the website's pages and other documents.

Enabling wireframes

Administrators can enable or disable wireframing for specific websites (or globally) through the **Enable wireframing** setting in **Site Manager** -> **Settings** -> **Content** -> **Content management**.

Enabling wireframing in the global settings

The system displays all existing wireframes even if this setting is disabled. However, users cannot make any modifications or create new wireframes.

Creating dedicated wireframe documents

The *Wireframe* (CMS.Wireframe) document type allows you to add wireframes into the website's content tree. The only purpose of wireframe documents is to provide visual guides in CMS Desk. They are not actual pages and the system does not include them in the website's navigation or sitemap. Visitors cannot access wireframe documents on the live site.

1. Add a [new document](#) in the CMS Desk content tree and select the **Wireframe** document type.
2. Type a name for the wireframe document into the **Page name** field.
3. Choose a [page template](#) for the wireframe. Click  **Save**.
4. Design the [content](#) of the wireframe schematic on the document's **Wireframe** tab.
5. (Optional) Open the **Form** tab and configure the properties of the wireframe:
 - **Comments** - allows you to type any required notes, such as a description of the wireframe or instructions for other users.
 - **Exclude from search** - by default, wireframe documents are ignored by all forms of search (both the [Smart search](#) module and the SQL search). Uncheck the box to enable search for the wireframe.
 - **Inherit content** - here you can set the wireframe's [content inheritance](#) options.

Users can now view the wireframe in the content tree and make further modifications if needed.

Combining wireframes with standard documents

The system allows you to integrate wireframes into documents of any other type. This can be useful in various scenarios, for example if you are creating an actual page (document) based on a wireframe or when using wireframes to plan a new design for existing pages.

- **Converting a dedicated wireframe to another document type**

Warning: This process is irreversible. You cannot convert combined documents back to dedicated wireframe-only documents.

1. Select the source wireframe document in the content tree and open the **Form** tab.
2. Click  **Convert to another document type** in the header actions.
3. Select the target document type. The wireframe must be placed under a document that supports the new document type as a child. For example, pages cannot be placed under wireframe documents by default.
4. Choose a template (for pages) or enter values into the form fields of the new document type.
5. Click  **Save**.

The document keeps the original wireframe definition on the **Wireframe** tab, but otherwise behaves exactly like a new document of the specified type. Users may refer to the wireframe at any time.

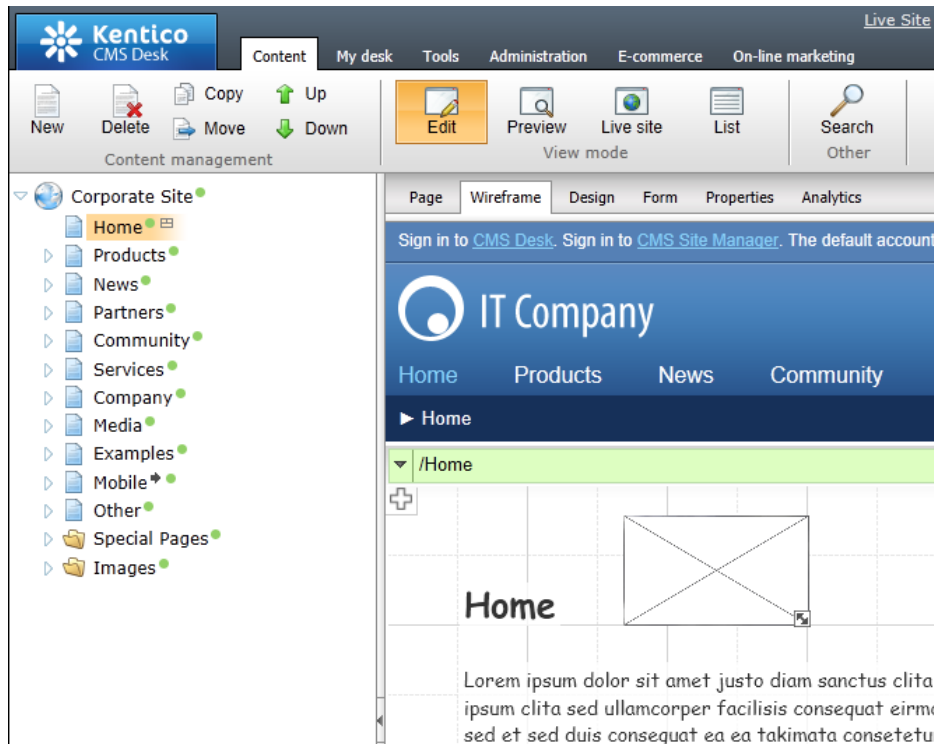

- **Inserting a wireframe into an existing document**

1. Select the document in the content tree and use one of the following options:
 - Switch to the **Properties -> General** tab, scroll down to the **Advanced** section and click **Add wireframe to this page**.
 - Right-click the page template header on the **Design** tab and select **Add wireframe to this page** in the context menu.

2. Choose a [template](#) for the wireframe.
3. Click  **Save**.

The document gains the **Wireframe** tab in addition to the standard content editing and configuration interface. Inserting a wireframe into a page does not affect its live site appearance in any way.

The result of these procedures is a combined document with both regular content and a wireframe.

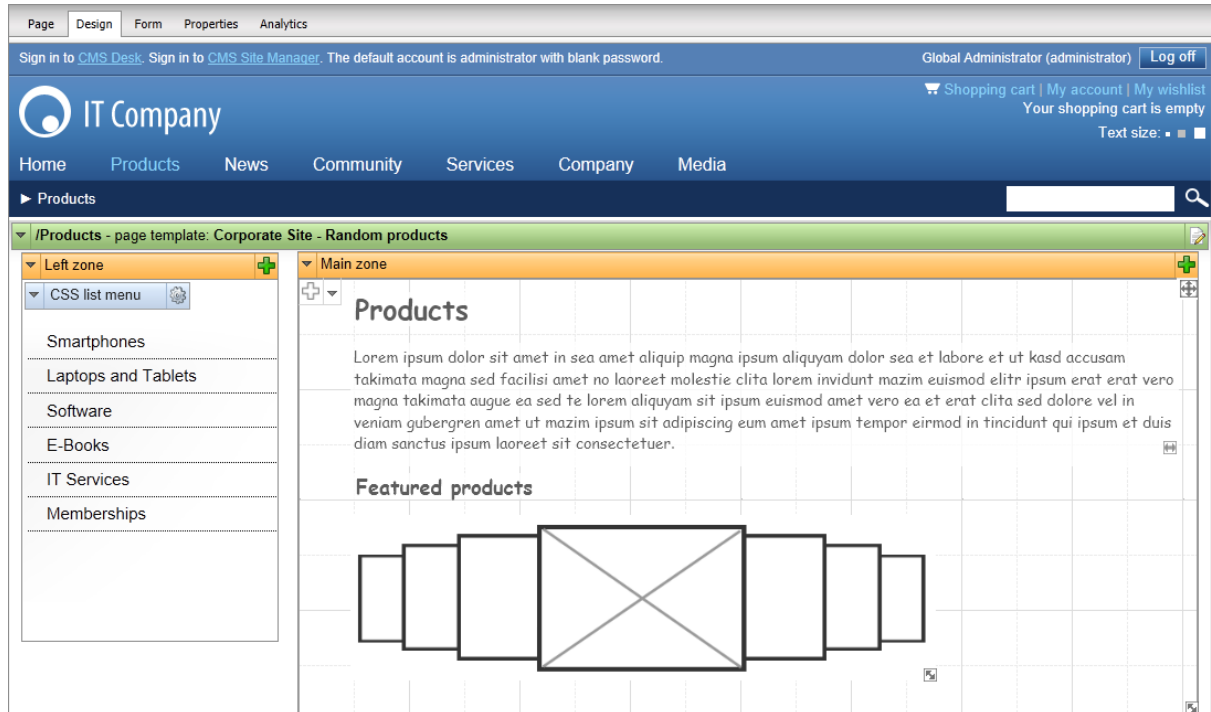

Wireframe inserted into the Home page

- You can manage the wireframe content of combined documents on the **Wireframe** tab, just like for dedicated wireframe documents.
- The system displays a status icon (Ⓜ) next to documents that contain a wireframe. You can disable this icon in **Site Manager -> Settings -> Content -> Content management** via the **Display wireframe icon** setting.
- To configure the [content inheritance](#) settings of the document's wireframe or enter comments, go to **Properties -> Wireframe** instead of the **Form** tab.
- There are several ways to delete the document's wireframe if you no longer need it:
 - Open the **Properties -> General** tab, scroll down to the **Advanced** section and click  **Remove wireframe**.
 - Right-click the page template header on the **Design** or **Wireframe** tab and select **Remove wireframe** in the context menu.
 - Click **Remove wireframe** on the **Properties -> Wireframe** tab.

Adding wireframes to the main page design

You can also place wireframes directly into the content of regular pages by adding the [Wireframe area](#) web part into a zone on the **Design** tab. This defines a sub-section of the page that works just like the *Wireframe* tab. You can use this approach to create wireframes for specific zones on pages that are already partially implemented.

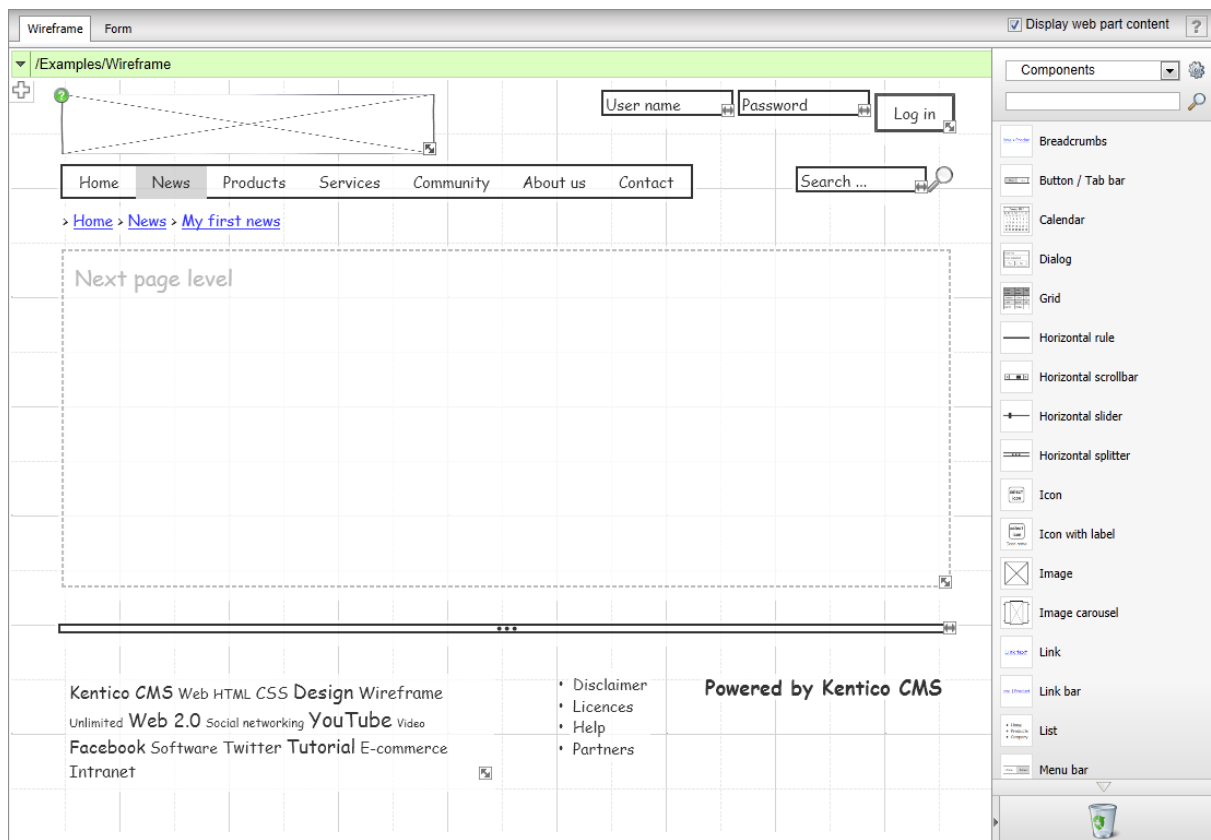

Wireframe area placed inside a standard web part zone on the Design tab

Such pages do not display their wireframe content on the live site, but users can view the wireframe components while editing the document in CMS Desk and in [preview mode](#).

Defining wireframe content

To edit a wireframe, select the corresponding document in the CMS Desk content tree and open the **Wireframe** tab. The wireframe displays a grid, where you can place any number of components. Wireframe components are a special type of [web parts](#). Kentico CMS contains a set of [default wireframing components](#) and you can also [develop](#) your own. When users add content to a wireframe, the system stores it on the assigned [template](#).

Note: Wireframes do not support [workflow](#). Dedicated wireframes always behave as unpublished documents.

Wireframe tab overview, including the web part toolbar

Adding components

You can add components (web parts) onto the wireframe by dragging items from the web part toolbar. To choose which components are offered in the toolbar, select a sub-category in the drop-down list. You can also filter the items by entering their name (or its part) into the search textbox (🔍). Alternatively, click the  button in the corner of the wireframe zone and choose a specific component through the **Select web part** dialog.

Web part toolbar settings

Every user may configure the toolbar according to their preferences. There are four available positions and the toolbar can also be completely disabled.

To configure the toolbar settings, click the **Settings** (⚙️) icon next to the category selector. The same options are also in **CMS Desk -> My Desk -> My profile -> Details**, so even users who have disabled their toolbar can change them.

Editing content

Double-click components to quickly modify their primary content. Depending on the type of the component, you can edit text, select an image, or specify a color. Some components have multiple editable sections.

Editing the options displayed by a menu component

When editing text values, you can use the following formatting syntax:

- **[a]Text[/a]** - displays the text as a standard hyperlink
- **[i]Text[/i]** - displays the text in italics
- **[b]Text[/b]** - makes the text bold
- **[u]Text[/u]** - underlines the text
- **[d]Text[/d]** - displays the text as a disabled element (grayed out)
- **{color:Red}Text{color}** - displays the text in red. You can apply any other CSS styles in format: `{cssProperty:Value}Text{cssProperty}`
- **\n** - inserts a line break (for values that have a single-line editing field)

Multiple formatting tags may be applied to the same text.

You can also insert various types of elements into the text by adding transformation expressions:

| Element | Text expression | Output |
|---------------------------|--|-------------------------------------|
| Checkbox (checked) | [x] | <input checked="" type="checkbox"/> |
| Checkbox (unchecked) | [] | <input type="checkbox"/> |
| Radio button (selected) | (o) | <input checked="" type="radio"/> |
| Radio button (unselected) | () | <input type="radio"/> |
| Minus icon | [-] | <input type="button" value="-"/> |
| Plus icon | [+] | <input type="button" value="+"/> |
| Up arrow | [^] | <input type="button" value="▲"/> |
| Down arrow | [v] | <input type="button" value="▼"/> |
| Up/down icon (spinner) | [^v] | <input type="button" value="↕"/> |
| Left arrow | [<] | <input type="button" value="◀"/> |
| Right arrow | [>] | <input type="button" value="▶"/> |
| Directory icon | [dir] | <input type="button" value="📁"/> |
| File icon | [file] | <input type="button" value="📄"/> |
| Document icon | [doc] | <input type="button" value="📑"/> |
| Indentation space | [_] | |
| | The number of underscore characters determines the indentation size. | |

For example: []

Moving components

You can relocate components by dragging them to any position in the grid. Some components with advanced functionality must be moved using a special drag icon (☒). If a component extends beyond the borders of the grid after being relocated, the wireframe increases the grid dimensions to fit the component. You can disable automatic zone resizing by holding down the CTRL key while dragging, which crops the component if necessary (i.e. hides the sections that do not fit into the zone).

Grouping wireframe components

To create a group of multiple components that you can move as a single unit:

1. Add the **Wireframe area** component from the **Layouts** sub-category.
2. Place the required components into the new sub-section of the grid.
3. Drag the Wireframe area to relocate the entire section.

Resizing items

You can dynamically change the dimensions of many types of wireframe components by dragging the arrow icon in their bottom right corner.

Advanced actions

Right-click components to access their context menu:

- **Configure** - allows you to set the component's web part properties. The available properties depend on the particular component. All wireframe web parts have the *Comments* property, which allows you to enter annotations or any other notes. The component displays the comment in the grid as the tooltip of an additional help icon (🗉).
- **Bring forward** - moves the component to the foreground of the wireframe, in front of all other components that occupy the same space.
- **Send backward** - moves the component to the background, behind other components that share the same space.
- **Duplicate web part** - creates an exact copy of the component in the wireframe.

Removing components

There are two ways to delete components from the wireframe:

- Right-click the component and select **Remove** in the context menu.
- Drag the component into the "trash bin" area (🗑️) on the web part toolbar.

7.29.3 Setting up wireframe templates

The system stores the content of wireframes on page templates. Wireframe templates are standard [portal engine page templates](#). Each template is defined by a [layout](#), which contains one or more zones

representing separate wireframe grids. Individual zones save the content, positions, and configuration of the wireframe components that users place onto the grid.

When creating a new wireframe, users must always assign a template. There are two kinds of wireframe templates:

- **Ad-hoc** - every wireframe has its own unique ad-hoc page template. To start with a blank ad-hoc template when creating a new wireframe, choose the *Create a blank page* option in the template selection dialog. The system automatically deletes ad-hoc templates if their associated wireframe is removed.
- **Re-usable** - allow you to store predefined wireframe content. Individual wireframes cannot use these templates directly. When a user selects a re-usable template for a new wireframe, the system automatically creates an ad-hoc copy of the template for the given wireframe. This allows users to modify the wireframe without changing the default content of the re-usable template.

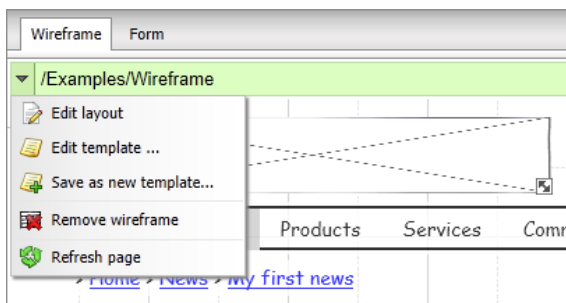

Note

[Combined documents](#) with both standard page content and a wireframe have two separate templates assigned — one for the wireframe and the other for the actual page. These two templates are completely unrelated.

To manage the template of a wireframe:

1. Select the wireframe document in the CMS Desk content tree and open the **Wireframe** tab.
2. Right-click the green template header at the top of the wireframe grid and choose one of the template-related options in the context menu:

- **Edit layout** - allows you to modify the [layout code](#) of the wireframe's template.
- **Edit template ...** - opens a new window where you can configure the properties of the template.
- **Save as new template...** - allows you to save the current template as a new re-usable page template, which users can then select when creating wireframes.

Page template context menu on the Wireframe tab

Creating a re-usable wireframe template

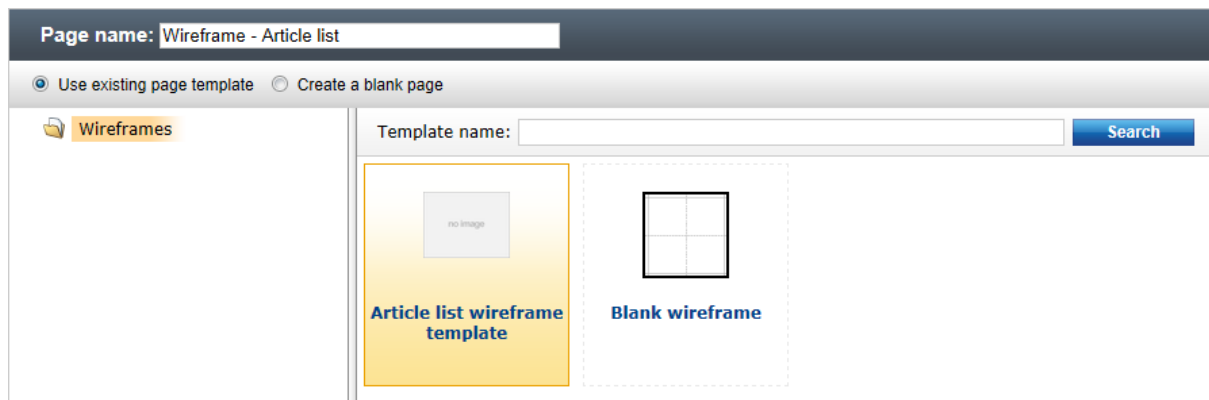

By preparing custom templates, you can store frequently used patterns of wireframe content. Users can then select an appropriate template as a starting point for new wireframes, instead of building each wireframe completely from scratch.

1. Go to **Site Manager -> Development -> Page templates**.
2. Select the **Wireframes** category and click  **New template** above the catalog tree.
3. Enter a name and description for the template and click  **Save**.

The template's **General** tab opens:

- The **Template type** must be set to *Portal page* for wireframe templates. This is the default option for new templates.
 - The **Clone as ad-hoc for new documents** checkbox does not affect the behavior of wireframe templates. The system always clones templates as ad-hoc when creating wireframes, even if this setting is disabled for the assigned template.
4. Switch to the **Layout** tab and enter the template's [layout code](#). Include at least one wireframe zone.
 5. Open the **Design** tab and define the template's [wireframe content](#).
 6. On the **Sites** tab, add all websites for which you wish to make the template available.

Users can now select the new template from the catalog when creating wireframes on the specified sites.

Selecting the custom template for a new wireframe

Changing the wireframe template default category

By default, all wireframes must use templates from the *Wireframes* category. To allow templates from another category:

1. Go to **Site Manager -> Development -> Document types**.
2. Edit the **Wireframe** (CMS.Wireframe) document type.
3. On the **General** tab, select a different category in the **Root page template category** property.
4. Click  **Save**.

When creating wireframes, users can now select templates from the specified category and its sub-categories.

Wireframe template layouts

You can create layouts for wireframe templates in the same way as [standard portal page layouts](#). The only difference is that you need to define the web part zones in the layout as wireframe zones. You can do this by including an additional attribute according to the selected **Layout type**.

- With **ASCX** type layouts, zones are inserted as controls. To designate a zone as a wireframe grid, add the `WireFrame="true"` property to the corresponding control:

```
<cms:CMSWebPartZone runat="server" ZoneID="zoneA" Wireframe="true" />
```

- In the case of **HTML** layouts, web part zones are represented by special macro expressions. Wireframe zones must have the `(Wireframe>true` parameter in addition to their `(id)`:

```
{^ WebPartZone | (id)zoneA | (Wireframe>true ^}
```

You can combine standard web part zones and wireframes zones within a single template layout.

7.29.4 Configuring content inheritance

Like regular pages, wireframes provide support for [master pages](#) and [visual inheritance](#). This allows them to display content from parent documents in addition to their own specific components. Content inheritance offers several advantages, such as viewing wireframes within the exact context of the website and being able to manage shared wireframe content in a single location.

To configure the inheritance preferences for dedicated *Wireframe* documents:

1. Select the wireframe document in the content tree in CMS Desk.
2. Open the **Form** tab.
3. Select one of the options in the **Inherit content** section.

| | |
|----------------------------|--|
| Use page template settings | The content inheritance is determined by the settings of the wireframe's template .

To manage the template's configuration:

1. Switch to the Wireframe tab.
2. Right-click the green template header at the top of the wireframe grid and select  Edit template .
3. Set the Inherit content property on the General tab of the Page template properties dialog. |
| Do not inherit any content | The wireframe does not inherit any content from parent documents in the content tree. |
| Inherit only master page | The wireframe inherits content from the first master page above the |

| | |
|-------------------------|--|
| | document in the content tree. If there are multiple master pages, the wireframe only inherits from the closest one in the hierarchy. |
| Select inherited levels | You can select exactly from which parent documents the wireframe inherits via the checkboxes below. |

Wireframe Form

Save Spell check Convert to another document type

Document name: Wireframe

Comments: This wireframe represents a master page.

Inherit content:

- Use page template settings
- Do not inherit any content
- Inherit only master page
- Select inherited levels

Root

Examples

Wireframe inheritance options

4. Click **Save**.

Wireframe inheritance for combined documents

For [combined documents](#) that have both standard content and a wireframe definition, you can find the inheritance settings on the **Properties -> Wireframe** tab instead.

The wireframe inheritance is completely separate from the content inheritance configured for the actual page (on the *Properties -> Template* tab). They do not affect each other in any way and you can set them up differently.

There are two possible types of inheritance for wireframes:

- Nesting within parent wireframes
- Loading content from portal engine pages through standard visual inheritance

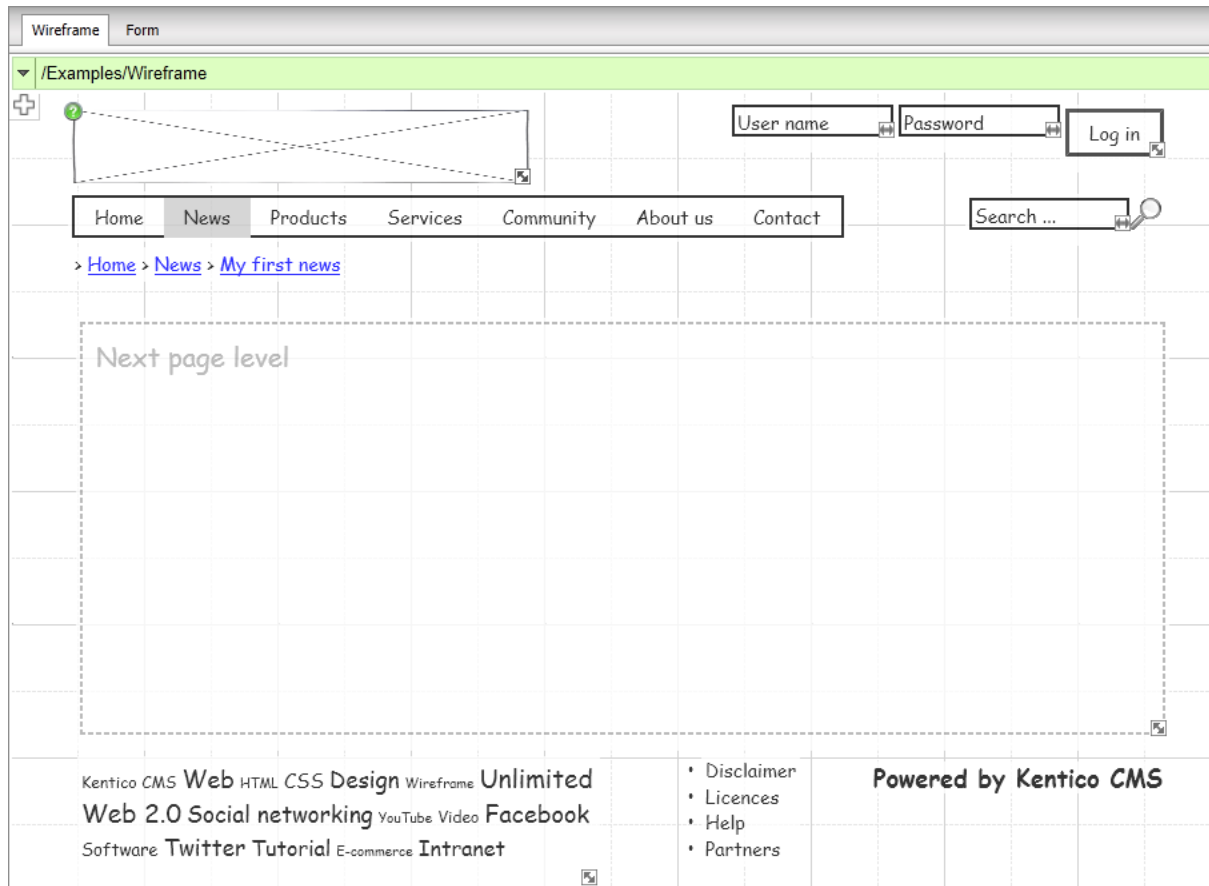

Wireframe nesting

In most cases, real websites utilize some form of content inheritance. Wireframes can accurately represent pages with inheritance by loading content from parent wireframes in the content tree. The

system then displays the child wireframe inside a designated area within the content of the parent.

To set up a wireframe inheritance scenario on your website:

1. Create the wireframe representing the parent page. Inheritance works for both dedicated *Wireframe* documents and wireframes inserted into a different document type.
2. Add the **Next page level** component from the *Wireframes/Layouts* web part category to the parent wireframe.

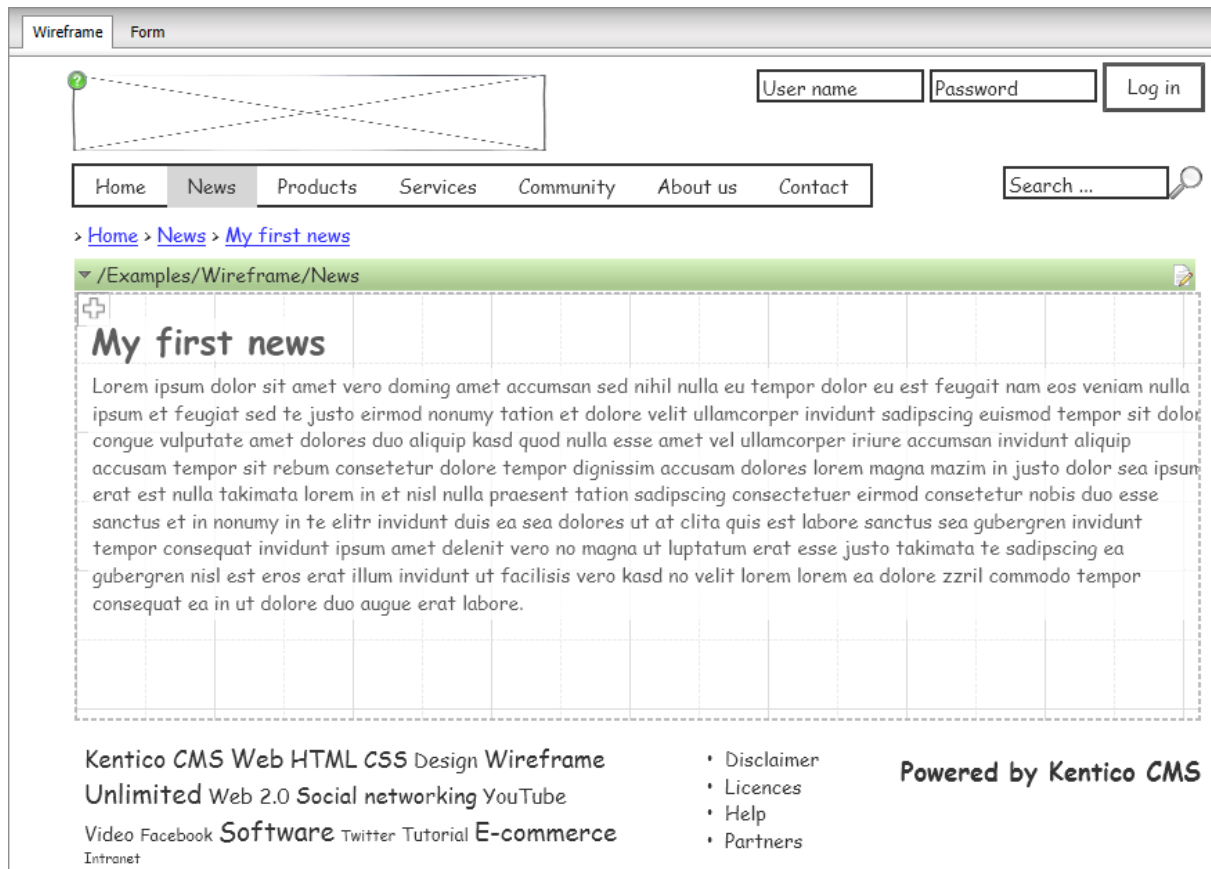

Example of the Next page level component on a parent wireframe

The **Next page level** component must always be placed on parent wireframes. It defines an area inside the grid that serves as a placeholder for the content of child wireframes. You can resize the area to any required dimensions.

3. Create any number of wireframe documents under the parent. The child wireframes do not need to be located directly on the level below the parent. You can skip levels when inheriting content.
4. Open the **Form** (or **Properties -> Wireframe**) tab of the child wireframe documents and configure the **Inherit content** preferences to include the required parents.

Users can customize the child wireframes only in the exact area defined by the **Next page level** component. The wireframe displays the remaining components from the parent around this area as fixed content.

Child wireframe with inherited content

Inheriting content from standard pages

The second type of inheritance allows wireframes to load web content from parent portal engine pages. By displaying wireframes within the actual pages of the current website, you can create accurate visual representations.

Requirements:

- The parent cannot have a wireframe definition of its own, because wireframe-to-wireframe inheritance has a higher priority.
- The [Page placeholder](#) web part must be placed on the parent page, otherwise the system is not able to display the content of child documents correctly (including wireframes).

Example:

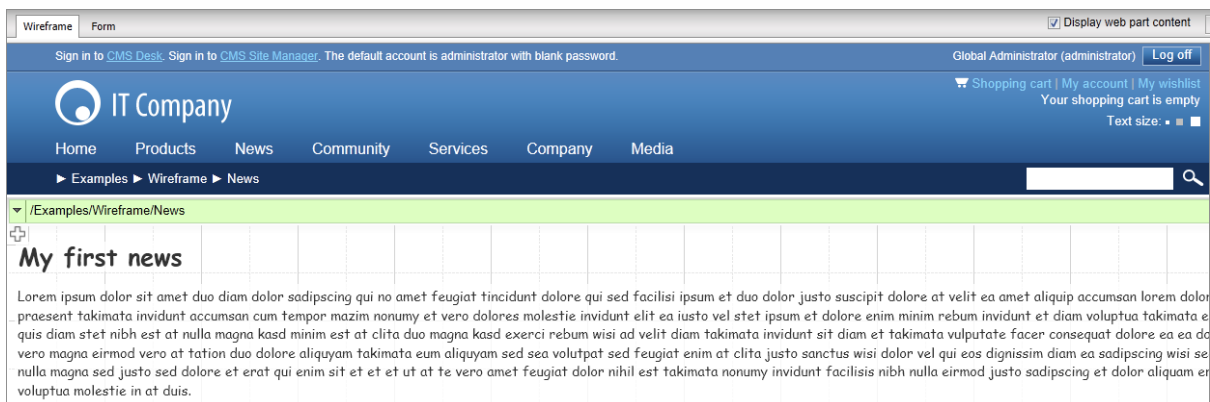

1. Open the sample Corporate Site in CMS Desk and select the **Examples/Wireframe/News** document in the content tree.
2. Switch to the **Form** tab, choose **Select inherited levels** in the **Inherit content** section and make sure that only the **Root** document is checked.

Inherit content:

- Use page template settings
- Do not inherit any content
- Inherit only master page
- Select inherited levels
 - Root
 - Examples
 - Wireframe

3. Click  **Save**.

When viewed on the **Wireframe** tab, the document inherits the header and footer content defined on the website's master page.

Wireframe inheriting web content from the master page

You may use both types of inheritance for wireframes at the same time. If you set the document to also inherit from its direct parent, it loads the wireframe content and shows it inside the master page.

7.29.5 Developing wireframe components

All wireframe components are defined as web parts of a specific type. The system allows you to develop new web parts and modify existing ones, so you can create any custom wireframing tools that your website requires. For more information about web part development in general, refer to [Development -> Web parts -> Developing web parts](#).

Example

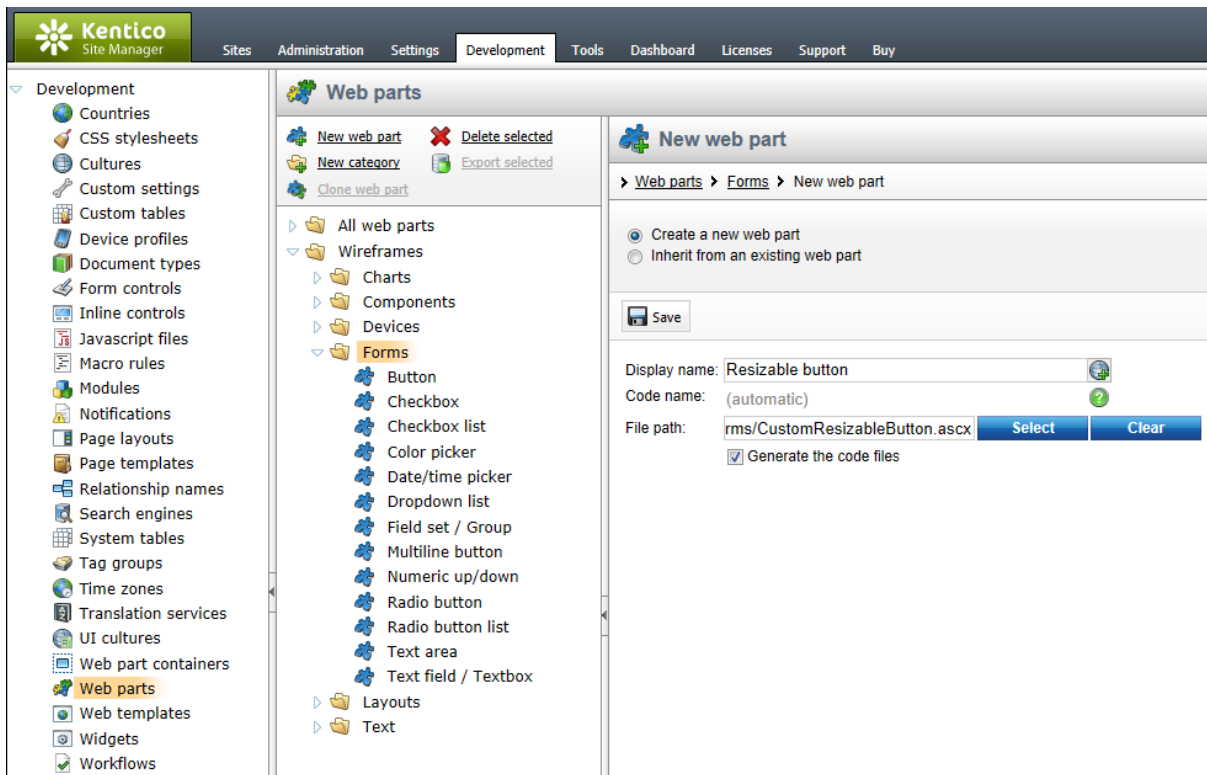

This example demonstrates how to create a custom wireframe component representing a button with a resizable width. You can develop more complex components by following the same basic principles. For additional inspiration, you can inspect the code of the default wireframe web parts found in the `~/CMSWebParts/Wireframes` folder of your web project.

Registering a new wireframe web part

1. Go to **Site Manager -> Development -> Web parts**, expand the **Wireframe** category at the bottom of the catalog tree and select the **Forms** sub-category.

2. Click  **New web part** above the tree. In the **New web part** dialog, choose **Create a new web part** and enter the following values:

- **Display name:** Resizable button
- **File path:** ~/CMSWebParts/Wireframe/Forms/CustomResizableButton.ascx
- **Generate the code files:** yes (checked)

Creating a new web part

Click **Save**.

3. The new web part's **General** tab opens. Set the following options:

- **Type:** *Wireframe*; all web parts that you wish to use as wireframe components must use this type to function correctly.
- **Skip initial configuration:** *Yes (checked)*; allows users to add the web part to wireframe grids without having to configure its properties.

Click **Save**.

4. Switch to the **Properties** tab and add (+) a single property:

- **Column name:** Text
- **Attribute type:** Text
- **Attribute size:** 100
- **Default value:** OK
- **Field caption:** Button caption
- **Form control:** Text box

The purpose of the *Text* property is to store the value of the button's text caption. Click **Save**.

5. Open the **CSS** tab and add the following class definition:

```
.WireframeResizableButton
{
  border: solid 3px #000;
  padding: 5px 15px 5px 15px;
  display: block;
  overflow: hidden;
  text-align: center;
  min-width: 50px;
}
```

The *WireframeResizableButton* class will be used to style the button component. Click  **Save**.

Implementing the component's functionality

6. Open the web project in Visual Studio and navigate to the **CMSWebParts/Wireframe/Forms** folder. It contains the *CustomResizableButton.ascx* file and its *ascx.cs* code behind, which were generated by the system when you created the web part.

7. Edit *CustomResizableButton.ascx* and add the following controls into the markup:

```
<cms:EditableWebPartProperty runat="server" id="txtElem"
  CssClass="WireframeResizableButton" PropertyName="Text" Type="TextBox" />
<cms:WebPartResizer runat="server" id="resElem" HorizontalOnly="true"
  RenderEnvelope="true" />
```

These are two instances of server controls from the *CMS.PortalControls* namespace that display content and provide the wireframe editing functionality.

| Control | Description |
|-------------------------|--|
| EditableWebPartProperty | <p>Renders a text value in a way similar to a standard literal control. Users can edit the value by double-clicking the text in the wireframe.</p> <ul style="list-style-type: none"> The PropertyName specifies the name of the web part property that is affected by the editing. Notice that the value matches the <i>Column name</i> of the web part's only property (Text). Through the Type property, you can choose what kind of editing interface the control displays. <p>The appearance of the control in the wireframe grid is typically defined using CSS classes, such as the <i>WireframeResizableButton</i> class in the current example.</p> |
| WebPartResizer | <p>Adds a resizer that allows users to easily change the dimensions of the component directly in the wireframe.</p> <p>The HorizontalOnly property is set to <i>true</i> in the example, so the component only supports width resizing in this case.</p> |

Other available control options:

| | |
|----------------------|--|
| EditableWebPartImage | Displays image content. Users can select the image through a dialog by double-clicking the current output. |
| EditableWebPartList | Represents a list of items formatted in a certain way, such as a menu or table. Users enter the value as text, with each item separated by a new line. |
| EditableWebPartColor | Displays an area in a specified color. Users can double-click the component to select the color. |

8. Edit the code behind file. Because it was generated specifically for a web part, the control already inherits from the appropriate base class and also contains two default regions and several basic method definitions.

9. Add a **Text** property into the *Properties* region, which handles the corresponding property of the web part object (defined in step 4). The overall code of the class should now match the following:

[C#]

```
public partial class CMSWebParts_Wireframe_Forms_CustomResizableButton :
    CMSAbstractWebPart
{
    #region "Properties"

    /// <summary>
    /// Accesses the value of the web part's Text property.
    /// </summary>
    public string Text
    {
        get
        {
            return ValidationHelper.GetString(this.GetValue("Text"), "");
        }
        set
        {
            this.SetValue("Text", value);
        }
    }

    #endregion

    #region "Methods"

    /// <summary>
    /// Content loaded event handler.
    /// </summary>
    public override void OnContentLoaded()
    {
        base.OnContentLoaded();
        SetupControl();
    }
}
```

```
/// <summary>
/// Initializes the control properties.
/// </summary>
protected void SetupControl()
{
    if (this.StopProcessing)
    {
        // Do not process.
    }
    else
    {
    }
}

/// <summary>
/// Reloads the control data.
/// </summary>
public override void ReloadData()
{
    base.ReloadData();

    SetupControl();
}

#endregion
}
```

10. Implement the **SetupControl** method:

[C#]

```
/// <summary>
/// Initializes the control properties.
/// </summary>
protected void SetupControl()
{
    if (StopProcessing)
    {
        // Do not process.
    }
    else
    {
        // Loads and assigns the button caption.
        txtElem.Text = Text;

        // Sets up width resizing.
        string width = WebPartWidth;
        if (!String.IsNullOrEmpty(width))
        {
            txtElem.Style += String.Format("width: {0};", width);
        }
    }
}
```

```
// Connects the button control to the resizer.  
resElem.ResizedElementID = txtElem.ClientID;  
    }  
}
```

This method ensures that the web part displays the component correctly according to its current configuration.

- First, it checks that processing (visibility) is enabled for the web part.
- If true, the method loads the button's caption text from the **Text** property and assigns it to the **EditableWebPartProperty** control.
- The method retrieves the width value of the button via the **WebPartWidth** property (inherited from the *CMSAbstractWebPart* parent class) and adds it to the button's styles.
- The method binds the resizer to the button control through its *ClientID*.

Handling the width and height of wireframe components

In this example, the width property is not included in the configuration dialog of the web part and is handled exclusively through the resizer.

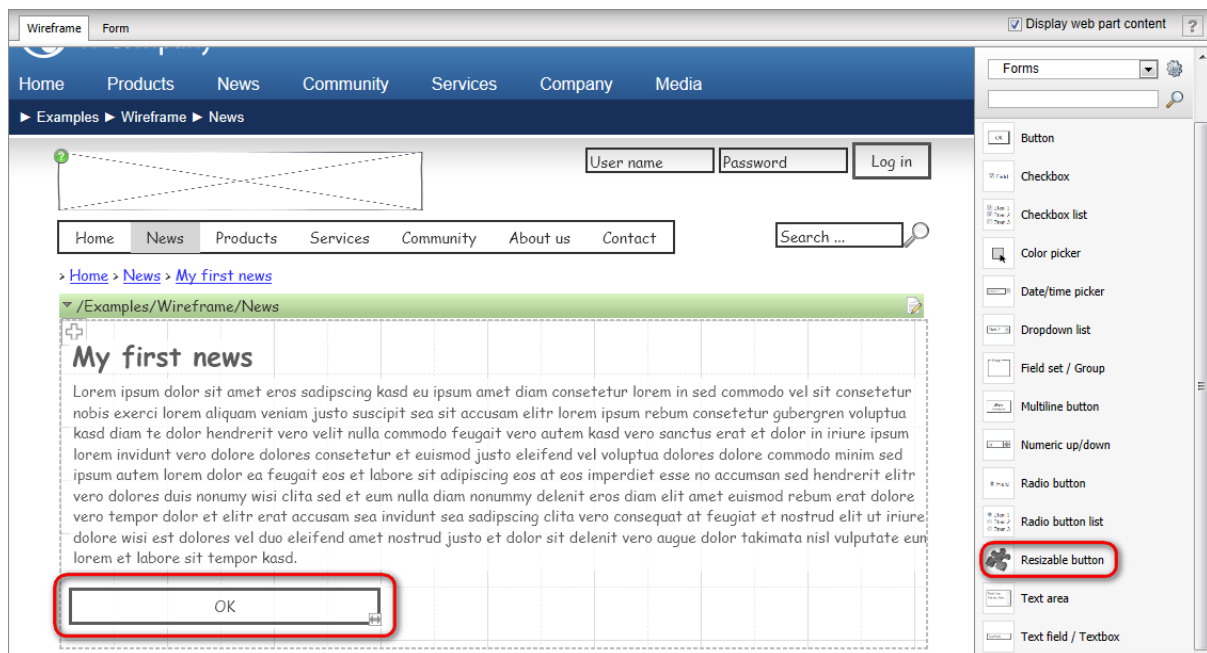

To register the width as a standard configuration option, define a property for the web part with *WebPartWidth* as its column name.

When creating components that also support vertical resizing, the **WebPartHeight** property (also inherited from the parent class) can be handled in the same way.

11. Save both files. If your Kentico CMS project was installed in the web application format, you must also **Build** the project. The wireframe component is now fully functional and ready to be used.

Result

Add the **Resizable button** component to any wireframe on the website (e.g. the *Examples -> Wireframe* document on the sample Corporate Site). You can dynamically change the width of the button by dragging the arrow icon in its bottom right corner. Double-clicking the button's caption allows you to edit the text.

Resizable button web part placed on a wireframe

7.29.6 Security

Only [editors](#) and other users with access to the CMS Desk interface can view and manage wireframes. The system does not display wireframes or wireframing components on the live website.

Permissions

To configure wireframing permissions for specific roles, go to **Site Manager / CMS Desk -> Administration -> Permissions**.

| Permissions for | Permission | Description |
|----------------------------|-----------------|---|
| Module -> Design | Wireframing | Allows users to edit the content of wireframes on the Wireframe tab and create new wireframe documents. Users without this permission can view existing wireframes, but are not allowed to make any modifications. |
| | Design web site | Allows users to edit documents on the Design tab of CMS Desk . Users only need this permission for managing wireframe zones inside standard page content. |
| Module -> Content | - | Users need the permissions for the Content module to access the CMS Desk content tree and read or create documents in general (including wireframes). |
| Document type -> Wireframe | - | You can assign the basic content permissions specifically for the <i>Wireframe</i> document type (instead of the entire <i>Content</i> module). |

UI personalization

By configuring [UI personalization](#) for particular roles, you can customize the visibility of individual elements in the wireframing interface.

1. Go to **Site Manager / CMS Desk -> Administration -> UI personalization**.
2. Select the appropriate **Site** and **Role**.
3. Choose the *Content Module*.
4. Configure the checkboxes as required:

- **Wireframe**
- **Design**
 - **Edit layout, Edit template, Save as new template** - sets the visibility of the management actions offered in the page template context menu.
 - **Web part properties -> General** - users must have this UI element allowed to access the property configuration dialog of wireframe components.
 - **Add web parts** - sets the visibility of the add button (+) in the corner of the wireframe grid. Users can insert components from the toolbar even without this element.
 - **Remove web parts** - context menu option for deleting individual components from wireframes.
- **Form**
- **Properties -> Wireframe**
- **New -> Page template selection -> Use existing page template** - required to create new wireframe documents.

Members of the selected role can now see only the specified UI elements.

Part

Modules

8 Modules

8.1 Overview

This section provides reference on in-box modules in Kentico CMS. Information on the particular modules and their API examples can be found in sub-categories of the section. General information on the whole API examples feature can be found in the [API examples](#) chapter in the **API programming and Kentico CMS internals** section of this guide.

[This topic](#) describes where you can easily access Kentico CMS modules and how to customize the user interface.

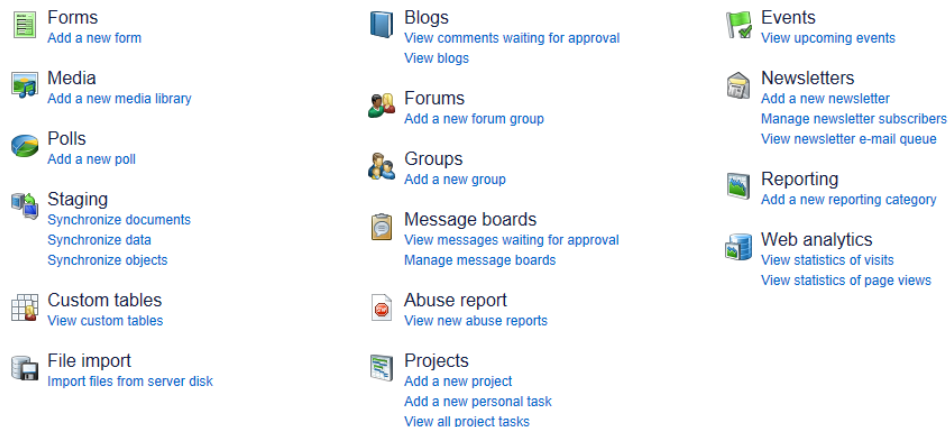

In [this example](#), you can learn how to develop a simple module and integrate it into the Kentico CMS user interface.

Please note: Not all modules might be available in your Kentico CMS installation because some modules are available only with certain licenses.

8.2 Accessing modules

Tools user interface

CMS Desk -> Tools is where you can easily access Kentico CMS [modules](#). The interface consists of a ribbon and panel menu and contains links to these modules. Besides, the panel menu provides shortcuts to selected functionality of the modules. The UI is fully customizable, enabling you to access both built-in and custom modules:

Customizing the Tools user interface

How to do it in general

To customize this user interface, you need to choose a module and for its selected functionality add a link to the panel menu. Specifically, you will create a new UI element under the chosen module, representing a shortcut to the tab where the desired functionality is available.

Example

1. Sign in to **Site Manager** -> **Development** -> **Modules** -> **Edit** (✎) **Tools** and switch to the **User interface** tab.

2. In the Tools UI elements tree, navigate to the module of your interest, click **New element** (➕) and proceed as described in the [UI personalization](#) chapter in the Membership, permissions and security section of this guide.

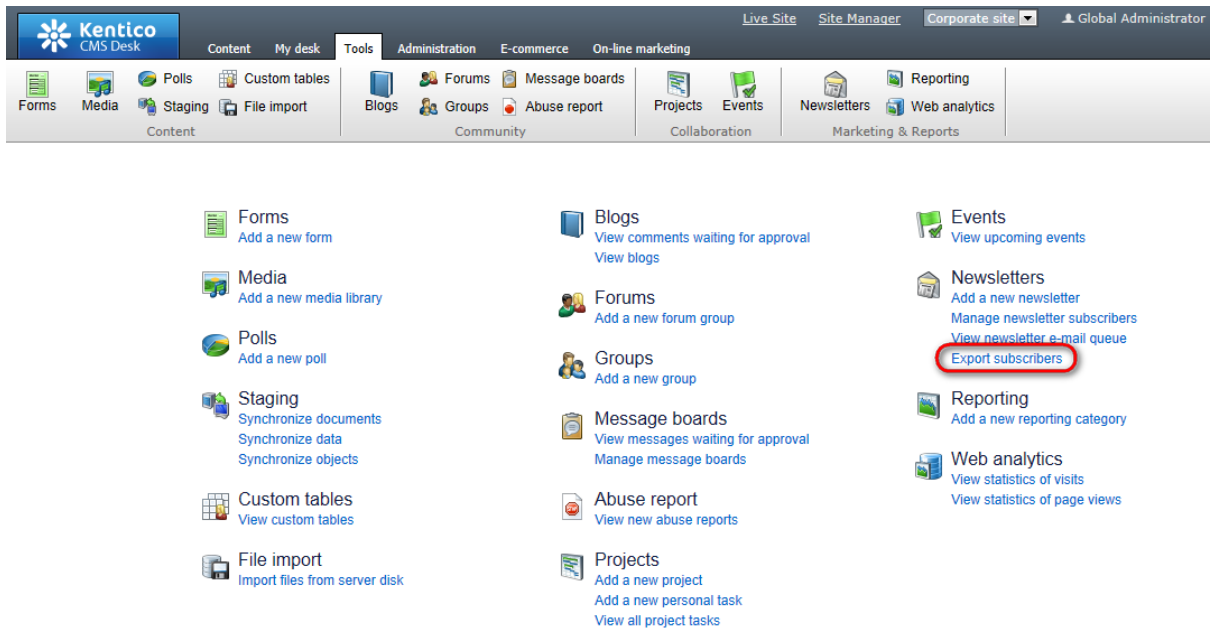

The screenshot shows the Kentico Site Manager interface. The left sidebar displays a tree view of modules, with 'Tools' expanded to show 'Marketing & Reports' and 'Newsletters'. The 'Export subscribers' element is selected. The main area shows the 'Module properties' dialog for this element, with the 'User interface' tab selected. The 'Target URL' field is highlighted with a red circle and contains the value 'lerModule_Frameset.aspx?tab=exportsubscribers'.

Please note

The value of the **Target URL** property must contain a *tab* query parameter whose value is the code name of the tab to which you want to link.
The code name of the tab is the same as the code name of the particular UI element.

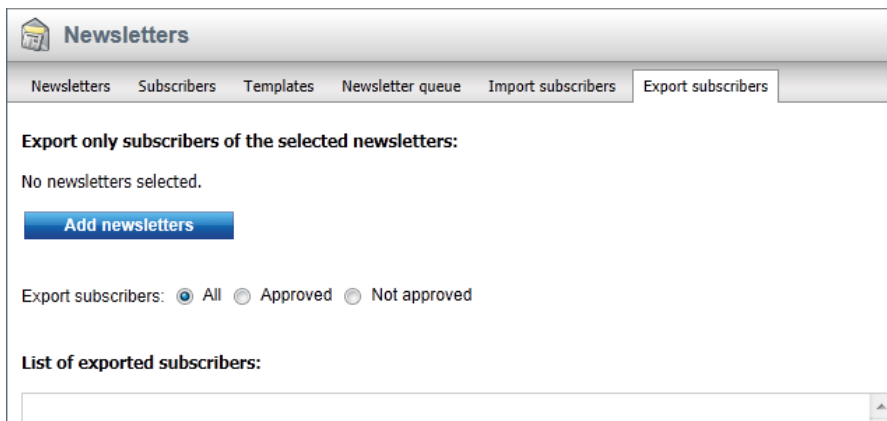

3. Now you may want to manage permissions to see the new UI element. If you decide to do so, switch to the **Roles** tab and grant selected roles with permission to see the given UI element. For more details, please refer again to the [UI personalization](#) chapter.

4. Finally, go to **CMS Desk -> Tools**. As you can see, the link you have just created is available among other links of the given module.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Live Site', 'Site Manager', 'Corporate site', and 'Global Administrator'. The main menu is divided into several sections: Content, My desk, Tools, Administration, E-commerce, and On-line marketing. The 'Tools' section is expanded, showing various modules. The 'Newsletters' module is highlighted, and the 'Export subscribers' link is circled in red.

If you now click the link, you will be redirected to a tab containing the given functionality.

The screenshot shows the 'Newsletters' module interface. The top navigation bar includes 'Newsletters', 'Subscribers', 'Templates', 'Newsletter queue', 'Import subscribers', and 'Export subscribers'. The main content area shows the following options:

- Export only subscribers of the selected newsletters:**
- No newsletters selected.
- [Add newsletters](#)
- Export subscribers: All Approved Not approved
- List of exported subscribers:**

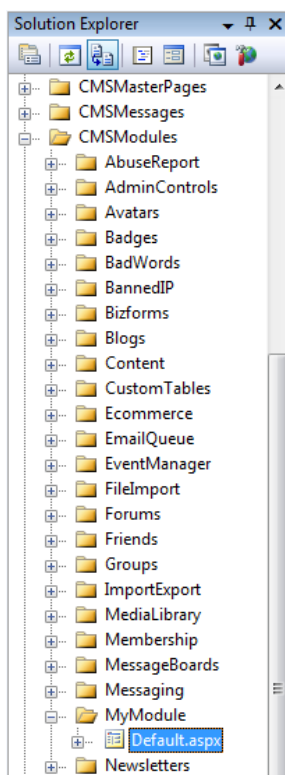

Please note

To add a new custom module to the Tools user interface, you will need to take the same steps as described in this example. However, you will need to add the new UI element directly under the **Tools** section. More details can be found in the [Developing custom modules](#) topic.

8.3 Developing custom modules

Here you will learn how to create a simple module with a single button that displays the current date and time. The procedure can be used for adding any kind of custom module that you develop. You will also learn how to control access to the module's functions using [permissions](#) and integration of this module into the UI using [UI personalization](#).

1. Open Kentico CMS web project in Visual Studio. You can do that either using the *WebProject.sln* file in your website root or using the **File -> Open -> website** menu in Visual Studio.
2. Create a new folder *MyModule* under the *CMSModules* folder.
3. Create a new page *default.aspx* under the *CMSModules/MyModule* folder:

4. Switch to code behind of the page and change the following line:

[C#]

```
public partial class CMSModules_MyModule_Default : System.Web.UI.Page
```

to:

[C#]

```
public partial class CMSModules_MyModule_Default : CMSToolsPage
```

It ensures that the module can be used only by users with access to Kentico CMS Desk.

5. Add the following code at the beginning of the page:

[C#]

```
using CMS.CMSHelper;  
using CMS.UIControls;
```

6. Add the following code to the *Page_Load* method:

[C#]

```
if (!CMSContext.CurrentUser.IsAuthorizedPerResource("cms.mymodule", "read"))  
{  
    RedirectToAccessDenied("cms.mymodule", "Read");  
}
```

It checks if the current user has the **Read** permission for the *myprojects.mymodule* module.

7. Switch to the **Design** mode and add a **Button** control on the page. Set its properties:

- **ID:** btnGetTime
- **Text:** Get time

8. Add a **Label** control on the page, next to the button. Set its properties:

- **ID:** lblTime
- **Text:** (clear the value)

9. Double-click the button and add the following code inside the **btnGetTime_Click** method:

[C#]

```
if (CMSContext.CurrentUser.IsAuthorizedPerResource("cms.mymodule", "gettime"))  
{  
    lblTime.Text = DateTime.Now.ToString();  
}  
else  
{
```

```
lblTime.Text = "You're not authorized to get the current date and time.";
}
```

It checks if the current user has the *gettime* permission for the *cms.mymodule* module and if so, it displays the current date and time.

10. Run the project and sign in to **Site Manager**. Go to **Development -> Modules** and click  **New module**. Enter the following values:

- **Module display name:** My module
- **Module code name:** cms.mymodule; for the UI element to be site-related, it is important to enter the value in the *cms.<elementname>* format, where *<elementname>* is the code name of the UI element created in step 16; see [this topic](#) for more details.

Click **OK**. The module was registered in the system.

Please note: In the system, modules are represented by *ResourceInfo* and *ResourceInfoProvider*.

11. Go to the **Permission names** tab and click  **New permission**. Enter the following values:

- **Permission display name:** Read
- **Permission code name:** read
- **Display in matrix:** enable

Click **OK**.

12. Add another permission:

- **Permission display name:** Get time
- **Permission code name:** gettime
- **Display in matrix:** enabled

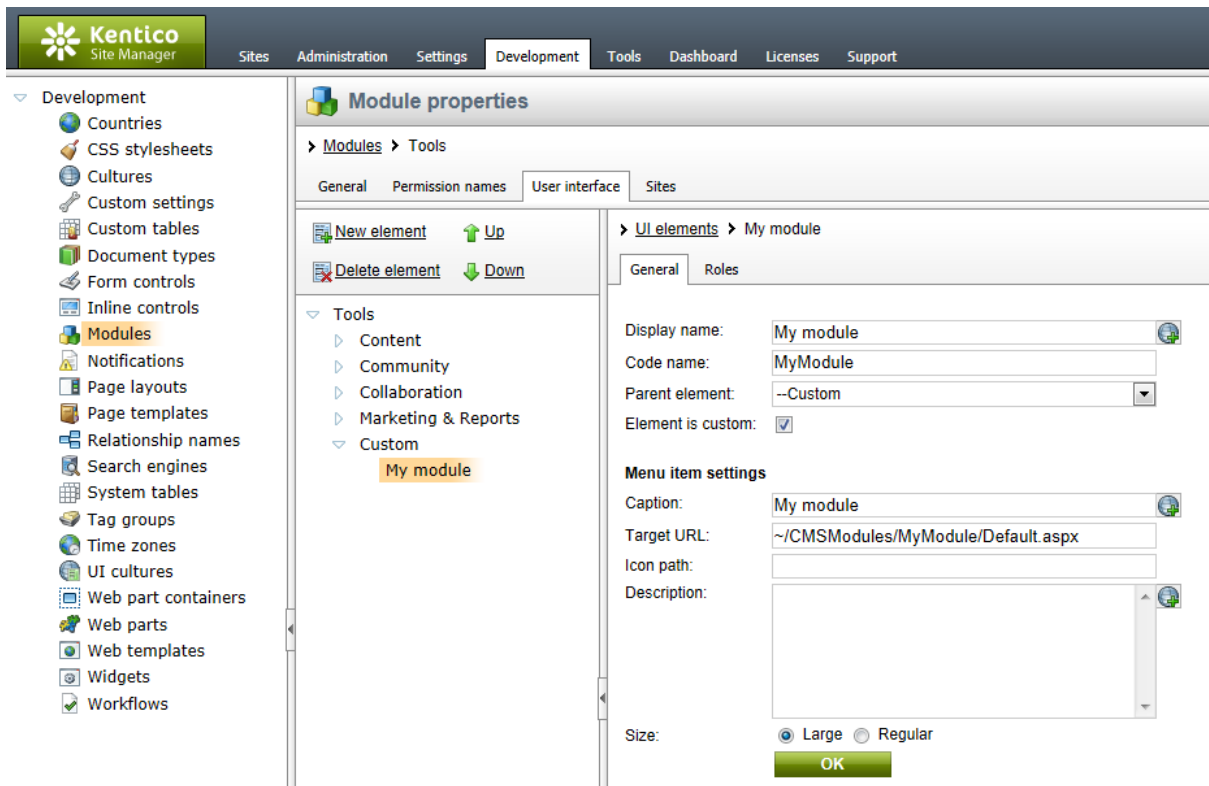

Click **OK**.

13. Go to the **Sites** tab and enable the new module for appropriate sites. Now that the module is registered, you need to display it in the user interface. For the purposes of this example, we will place it into the [Tools menu](#). However, the module can also be placed into other sections of the UI as listed [here](#).

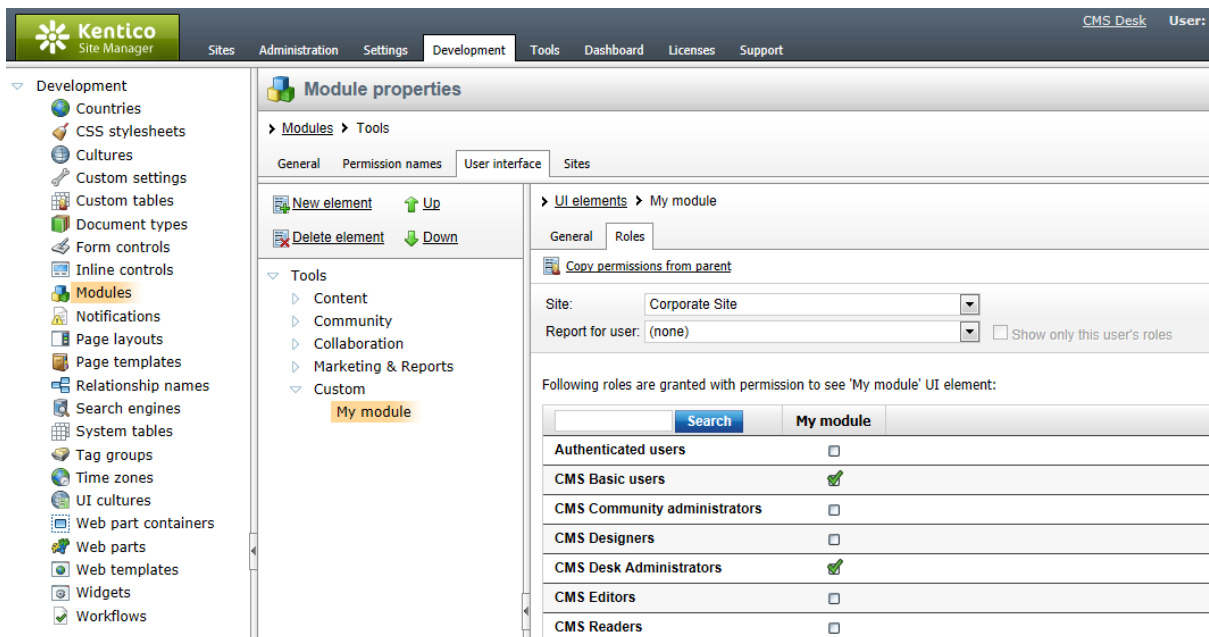

14. Go back to **Development -> Modules** and **Edit**  the **Tools** module. Switch to its **User interface** tab, select **Custom** in the Tools tree and click  **New element**. Enter the following details:

- **Display name:** My module
- **Code name:** MyModule
- **Element is custom:** enabled
- **Caption:** My module
- **Target URL:** ~/CMSModules/MyModule/Default.aspx

Click **OK**.

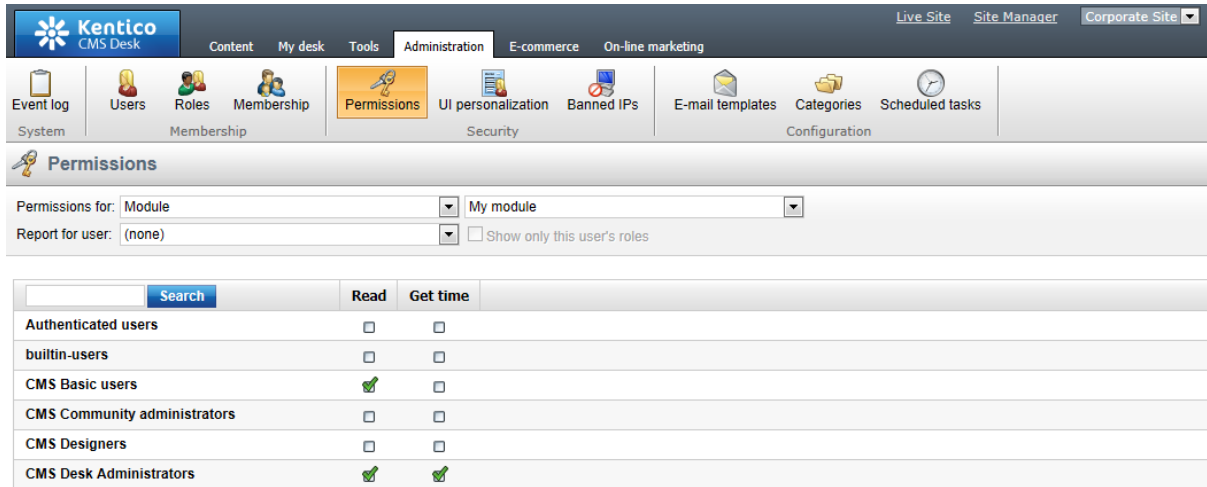

15. We will use [UI personalization](#) to enable access to this module only to members of certain roles. For this to work, UI personalization needs to be [enabled](#). With the new UI element still selected, switch to the **Roles** tab and enable the element for members of the **CMS Basic users** and **CMS Desk Administrators** roles.

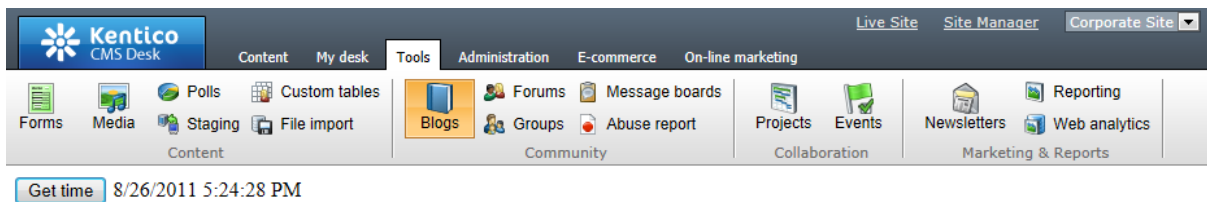

16. Go to **CMS Desk** -> **Administration** -> **Permissions** and choose **Permission for: Module / My**

module. Grant the *Read* permission to the **CMS Basic users** role and both the *Read* and *Get time* permissions to the **CMS Desk Administrators** role:

17. Now go to **CMS Desk -> Tools** logged in as *administrator* (with blank password). As you can see, the **My module** item is now available in the menu. Click it and you will see your form created in steps 3-9. When you click the **Get time** button, the current date and time is displayed.

18. Finally, try logging in as *Andy* (with blank password) and go back to **CMS Desk -> Tools**. Andy is a member of the **CMS Basic users** role. In step 16, you configured that members of this role have only the *Read* permission necessary for the module to be displayed (ensured in step 6), but not the *Get time* permission necessary for the button functionality. Try clicking it, you will see the access denied message that you defined in step 9.

Exporting custom modules

The following folders will be included in the export package when the custom module is selected for export. It is therefore recommended that your modules data is stored within these folders:

- ~/App_Code/CMSModules/<module_name>
(or ~/Old_App_Code/... if you installed Kentico CMS as a web application)
- ~/App_Data/CMSModules/<module_name>
- ~/CMSModules/<module_name>

The <module_name> value needs to be the same as the code name of the module in the administration interface, so for example for a module named *CMS.Test*, the folders would be:

- ~/App_Code/CMSModules/CMS_Test
- ~/App_Data/CMSModules/CMS_Test
- ~/CMSModules/CMS_Test

8.4 A/B testing

8.4.1 Overview

For information about **A/B testing**, please see the [Modules -> Website optimization -> A/B testing](#) chapter of this guide.

8.5 Abuse report

8.5.1 Overview

The Abuse report module enables site visitors to report various forms of website abuse. This can be anything from flame-type forum posts, rude comments on blog posts or message boards, spamming, links to illegal content or any other form of website abuse coming from user input.

The whole functionality is based on website users reporting these forms of website abuse to website administrators via one of the provided web parts - **Abuse report** and **In-line abuse report**. Both web parts are described in the [Available web parts](#) chapter. The [Using the In-line abuse report web part in transformations](#) chapter demonstrates how the **In-line abuse report** web part can be used in transformations to provide the abuse report functionality together with dynamically loaded content.

Abuse report functionality is also embedded in web parts of the [Forums](#) and [Message boards](#) modules. Advice on how to use the embedded functionality can be found in the [Integration with other modules](#) chapter.

Website administrators can read and manage submitted reports in **CMS Desk -> Tools -> Abuse report**. This is where a list of submitted reports is displayed, with the possibility to get redirected to the source of reported abuse and take an appropriate action. All abuse report management possibilities provided in this part of the administration interface are described in the [Abuse reports management](#) chapter. A user who wants to manage abuse reports must be in a role granted with appropriate permissions for the module - please consult the [Security](#) chapter for more details on the module's permissions.

The [Abuse report internals and API](#) sub-chapter provides information about the database tables and classes used by the module, as well as examples of how abuse reports can be managed using Kentico CMS API.

The Abuse report module is just one of the modules which can help you deal with unwanted user behavior on your site. If you want to keep your site free of rude language or simply filter user input based on contained keywords, the [Bad words](#) module may come in handy. If you are facing a problem with notorious spammers or have another reason why an IP address should be prevented from accessing your site, you can deny access to a particular IP address using the [Banned IPs](#) module.

8.5.2 Available web parts

This page gives just a brief overview of the Abuse report web parts. Detailed descriptions of each web part and its properties can be found in [Kentico CMS Web Parts Reference](#).

Abuse report

The **Abuse report** web part gives site visitors the possibility to report website abuse such as using indecent expressions, offensive language, etc. In the web part selection dialog, you can find it under the **Abuse report** category. It can be placed into any web part zone on any page of your website, while you will typically add it to pages where user input is possible, e.g. pages with [forums](#), [message boards](#), [blogs](#), [user contributions](#), etc.

You only have to set the following two specific properties in order for the web part to work properly:

| | |
|-------------------|--|
| Confirmation text | Text message that will be displayed to the site visitor after submitting |
|-------------------|--|

| | |
|-----------------------|--|
| | the abuse report. |
| Title of abuse report | Title of the report that will be displayed in the list of abuse reports in CMS Desk -> Tools -> Abuse report . Using this property, you can distinguish reports submitted at different pages of your website from each other. |

In the screenshot below, you can see the web part added below the forum group on the **/Community/ Forums** page of the sample Corporate Site. When a user types in some report text and clicks the **Report abuse** button, a report is logged in **CMS Desk -> Tools -> Abuse report**. Read the [Abuse reports management](#) topic for information on how reports can be managed in this section of CMS Desk.

The screenshot shows a forum interface with a table of forum threads. The table has columns for Forum, Threads, Posts, and Last post. The first row is for 'Site forums' with 2 threads and 11 posts, last posted by Susanne Paige on 6/21/2011 at 8:18:39 PM. Below the table, there is a 'Website forums' section with a description and a 'Lock' button. A red box highlights a text input field containing the text: 'Someone whose user name is The Rude Boy has insulted me with vulgar expressions in the Technical support forum!!!'. Below the text field is a 'Report abuse' button.

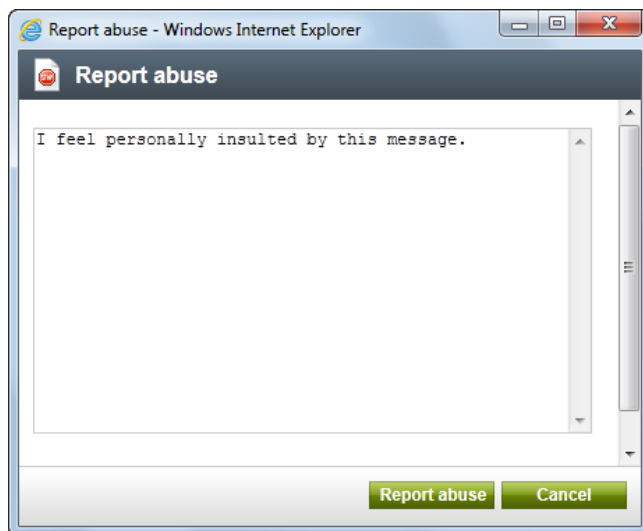

In-line abuse report

If you want to use only a tiny clickable link instead of the whole **Abuse report** web part, you can use the **In-line abuse report** web part. The web part appears only as the *Report abuse* link, as you can see in the screenshot below. Properties of the two web parts are identical.

The **In-line abuse report** web part can also be used in transformations, as explained in the [Using the In-line abuse report web part in transformations](#) topic.

The screenshot shows the same forum interface as above, but with a small 'Report abuse' link highlighted by a red box below the 'Lock' button.

When a site visitor clicks the link, a dialog pops-up, letting the site visitors report abuse to the site administrators. Reports submitted via this web part are also logged in **CMS Desk -> Tools -> Abuse report** and can be managed there as described in the [Abuse reports management](#) topic.

8.5.3 Using the In-line abuse report web part in transformations

The Inline abuse report web part appears as a link with the *Report abuse* text. After clicking the link, a dialog appears, letting the site visitor send abuse report to the site administrators. Apart from using it as a standard web part, you can also use it in transformations to have the *Report abuse* link displayed with dynamically loaded content.

To see how the **In-line abuse report** web part is used, you can go to the **Examples -> Web parts -> Message boards -> Message board** page of the sample Corporate Site. As you can see in the screenshot below, the *Report abuse* link is included with each message on the board.

[Edit](#) [Delete](#) [Reject](#)

[Report abuse](#)

Michael Douglas

These are good points. Ranking number 1 on the search engines can also be a downfall, there are disadvantages. If several people will copy your work, that sounds bad but I think it only shows that you're popular. On the other hand, competitors will try to pull you down and that's really horrible.

9/8/2008 11:42:23 AM

[Edit](#) [Delete](#) [Reject](#)

[Report abuse](#)

This is achieved using the In-line abuse report web part in the transformation used for displaying board messages. If you go to properties (⚙) of the **Message board** web part and edit the **Message transformation** (the *community.transformations.MessageBoard* transformation should be selected by default), you should see the same code as below.

```
<%@ Register Src="~/CMSModules/MessageBoards/Controls/MessageActions.ascx" TagName="
<%@ Register Src="~/CMSModules/AbuseReport/Controls/InlineAbuseReport.ascx" TagName="
```

```

<div class="CommentDetail">
  <asp:Panel ID="pnlRating" runat="server" CssClass="CommentRating" />
  <table width="100%">
    <tr>
      <td class="CommentUserName" style="width: 100%">
        <%# IfEmpty(Eval("MessageURL"), Eval("MessageUserName", true), "<a
href=\"\" + Eval("MessageURL", true) + \"\" target=\"_blank\">\" + Eval
("MessageUserName", true) + "</a>")%>
      </td>
    </tr>
    <tr>
      <td class="CommentText">
        <%# CMS.GlobalHelper.TextHelper.EnsureLineEndings(Convert.ToString(Eval
</td>
    </tr>
    <tr>
      <td class="CommentDate">
        <%# GetDateTime(Eval("MessageInserted")) %>
      </td>
    </tr>
    <tr>
      <td align="right" class="CommentAction">
        <cms:MessageActions ID="messageActions" runat="server" />
      </td>
    </tr>
    <tr>
      <td align="right" class="CommentAction">
        <cms:AbuseReport ID="ucInlineAbuseReport" runat="server"
ReportObjectType="board.message" ReportObjectID='<%# Eval("MessageID") %>'
ReportTitle='<%# "Message board abuse report: " + Eval("MessageText") %>'
CMSPanel-SecurityAccess="AuthenticatedUsers" />
      </td>
    </tr>
  </table>
</div>
<hr style="border: 1px solid #CCCCCC;"/>

```

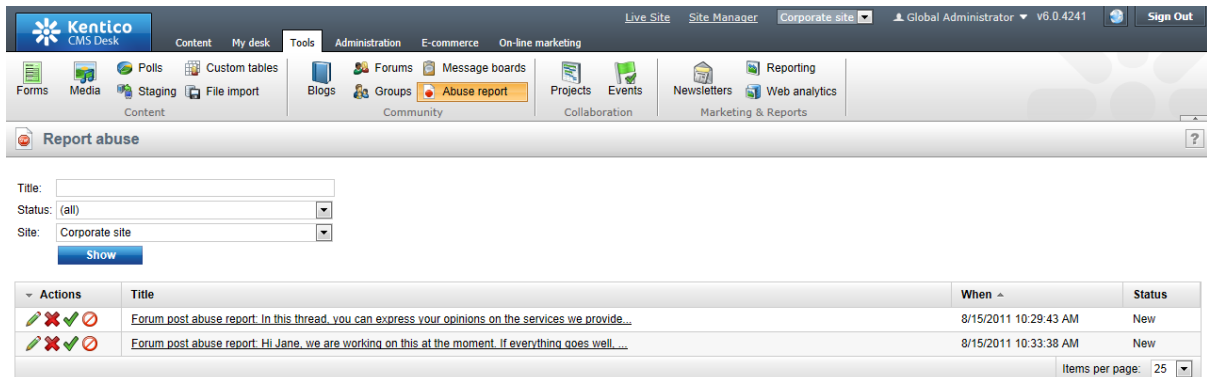

Let's take a closer look at the highlighted parts of the code. The highlighted line at the top is here to register the web part (actually control) so that it can be used in transformation code. As you can see, the web part code file is `~/CMSModules/AbuseReport/Controls/InlineAbuseReport.ascx`.

The second highlighted section is the actual web part, identified by the tag name and prefix defined in the *Register* tag. The `ReportObjectType="board.message"` and `ReportObjectID='<%# Eval("MessageID") %>'` parameters ensure that it will be possible to view details of a particular message (source of reported abuse) from the administration interface. These parameters pass the ID of the particular board message along with the report, so that the message can be identified and a link to it created. The `ReportTitle='<%# "Message board abuse report: " + Eval("MessageText") %>'` parameter defines the title of the report displayed in the administration interface. The last parameter - `CMSPanel-SecurityAccess="AuthenticatedUsers"` - ensures that the link will be displayed only to authenticated users.

This way, you can use the web part in transformations of any document types you need. The only limitation is that the [object details functionality](#) is available only with **board messages**, **forum posts** and **blog comments**. Abuse reporting is still possible with other object types, but no object details are passed with the report and therefore can't be displayed in the administration interface.

8.5.4 Abuse reports management

Abuse reports can be viewed and managed in **CMS Desk -> Tools -> Abuse report**.

The top part of the page is a filter. By default, you get all reports displayed in the list below it. Using the filter, you can display only those reports that match the specified criteria. Available filtration parameters are **Title**, **Status** and **Site** from which the report was sent. To filter the reports, enter the appropriate parameters and click the **Show** button. A list of reports matching the criteria will be displayed.

The **Status** column shows which status is the report currently in. You can use the statuses to mark reports, so that **New**, **Solved** and **Rejected** reports can be distinguished from each other. By switching a report to a status, only the status changes - no other action happens. In other words, status switching is here just for your convenience, but you need to perform a suitable action manually.

The following actions are available for each of the listed reports:

- **Edit** - if clicked, the user will be redirected to report properties page, where you can edit the report's properties
- **Delete** - deletes the report
- **Mark as solved** - switches the report to the *Solved* status; used to mark reports for that the necessary actions have been taken
- **Mark as rejected** - switches the report to the *Rejected* status; used to mark reports that were not considered being cases of website abuse

If you click a title of a report, you will be redirected to the page that the report was sent from. If you mouse-over it, report description entered by the sender of the report will be displayed in form of a tooltip.

Editing a report

When editing () a report, the following information is displayed:

| | |
|---------|--|
| Title | Title of the abuse report. |
| URL | URL of the page from which the report was sent. Click it to get redirected to that page. |
| Culture | Website culture from that the report was sent. |

| | |
|---------------|---|
| Object type | Type of object that was the cause of this report. If blank, the report was sent from some document. |
| Object name | Code name of the object that was the cause of this report. |
| Reported by | Site user who submitted the report. |
| Reported when | Time when the report was submitted. |
| Site | Website from that the report was submitted. |
| Status | Abuse report status, the following are possible: <ul style="list-style-type: none"> • New - the report is new and has not been solved yet • Solved - necessary actions have already been taken • Rejected - the report was not considered being a case of website abuse |
| Comment | Comment of the report entered by the reporting user. |

Object details

If you edit (✎) a report related to a **blog comment**, **board message** or **forum post**, the **Show object details** link is displayed below report comment.

 **Abuse report properties**

➤ [Abuse reports](#) ➤ Forum post abuse report: In this thread, you can express your opinions on the services we provide...

Title: _____

Site: Corporate site

Status:

Comment:

This is not very nice. In fact, it's quite rude.

[Show object details](#)

Clicking the link opens a new window with details about the source of the report (the board message,

blog comment or forum post). This functionality is ensured automatically by the web parts listed in the [Integration with other modules](#) topic. You can also achieve it in transformations of these object types using the **In-line abuse report** web part, as described in the [Using the In-line abuse report web part in transformations](#) topic.

8.5.5 Integration with other modules

Apart from dedicated web parts described in the [Available web parts](#) chapter, the abuse report functionality is also embedded in the following web parts:

- **Blogs -> Comment view**
- **Community -> Group forum list**
- **Forums -> Forum group**
- **Forums -> Forum (Single forum - General)**
- **Forums -> Forum (Single forum - Tree layout)**
- **Forums -> Forum (Single forum - Flat layout)**

Each of these web parts has the **Abuse report** section in its properties. The section contains the following properties:

- **Who can report abuse** - using this property, you can determine to whom will the *Report abuse* link be displayed and who will therefore be able to submit abuse reports; the following options are available:
 - **All users** - the link will be displayed to anyone who views a page with the web part
 - **Authenticated users** - the link will be displayed only to authenticated users
 - **Authorized roles** - the link will be displayed only to users who are members of the roles specified by the *Authorized roles* property

- **Nobody** - the link will not be displayed at all
- **Authorized roles** - if the *Who can report abuse* option is set to *Authorized roles*, you can use this property to specify the roles to whose members the abuse report link will be displayed

For a complete reference on Kentico CMS web parts and their properties, please consult [Kentico CMS Web Parts Reference](#).

8.5.6 Security

Permissions for the Abuse report module can be set in **Site Manager -> Administration -> Permissions**. Select the **Modules -> Abuse report** permission matrix and grant appropriate permissions to particular roles.

The following permissions can be granted to the roles:

- **Manage** - members of the role are allowed to edit, delete, mark as solved and reject abuse reports
- **Read** - members of the role are allowed to view the abuse reports list

 **Permissions**

Site:

Permissions for: Abuse report

Report for user: Show only this user's roles

| Role | Read | Manage |
|------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> |

| Not authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |

8.5.7 Abuse report internals and API

8.5.7.1 Overview

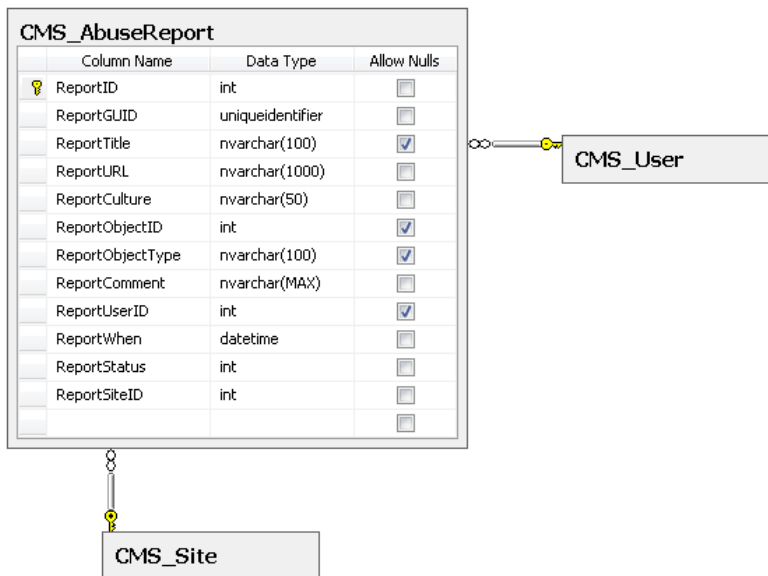

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Abuse report module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.5.7.2 Database tables

The Abuse report module uses the following database table:

- **CMS_AbuseReport** - contains records representing submitted abuse reports.

8.5.7.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Abuse report module can be found in the **CMS.SiteProvider** namespace.

CMS_AbuseReport table API:

- **AbuseReportInfo** - represents one abuse report object.
- **AbuseReportInfoProvider** - provides management functionality for abuse reports.

8.5.7.4 API examples

8.5.7.4.1 Overview

These topics show examples of how the API of the Abuse report module can be used:

- [Managing abuse reports](#)

**Please note**

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Tools\AbuseReport\Default.aspx.cs**.

The Abuse report API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.SiteProvider;
```

8.5.7.4.2 Managing abuse reports

The following example creates an abuse report.

```
private bool CreateAbuseReport()
{
    // Create new abuse report object
    AbuseReportInfo newReport = new AbuseReportInfo();

    // Set the properties
    newReport.ReportTitle = "MyNewReport";
    newReport.ReportComment = "This is an example abuse report.";

    newReport.ReportURL = URLHelper.GetAbsoluteUrl(URLHelper.CurrentURL);
    newReport.ReportCulture = CMSContext.PreferredCultureCode;
    newReport.ReportSiteID = CMSContext.CurrentSiteID;
    newReport.ReportUserID = CMSContext.CurrentUser.UserID;
    newReport.ReportWhen = DateTime.Now;
    newReport.ReportStatus = AbuseReportStatusEnum.New;

    // Save the abuse report
    AbuseReportInfoProvider.SetAbuseReportInfo(newReport);

    return true;
}
```

The following example gets and updates the abuse report created by the code example above.

```
private bool GetAndUpdateAbuseReport()
```

```
{
    string where = "ReportTitle LIKE N'MyNewReport%'";

    // Get the report
    DataSet reports = AbuseReportInfoProvider.GetAbuseReports(where, null);

    if (!DataHelper.DataSourceIsEmpty(reports))
    {
        // Create the object from DataRow
        AbuseReportInfo updateReport = new AbuseReportInfo(reports.Tables[0].Rows
[0]);

        // Update the properties
        updateReport.ReportStatus = AbuseReportStatusEnum.Solved;

        // Save the changes
        AbuseReportInfoProvider.SetAbuseReportInfo(updateReport);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates multiple abuse reports selected from database based on a WHERE condition.

```
private bool GetAndBulkUpdateAbuseReports()
{
    // Prepare the parameters
    string where = "ReportTitle LIKE N'MyNewReport%'";

    // Get the data
    DataSet reports = AbuseReportInfoProvider.GetAbuseReports(where, null);
    if (!DataHelper.DataSourceIsEmpty(reports))
    {
        // Loop through the individual items
        foreach (DataRow reportDr in reports.Tables[0].Rows)
        {
            // Create object from DataRow
            AbuseReportInfo modifyReport = new AbuseReportInfo(reportDr);

            // Update the properties
            modifyReport.ReportStatus = AbuseReportStatusEnum.Rejected;

            // Save the changes
            AbuseReportInfoProvider.SetAbuseReportInfo(modifyReport);
        }

        return true;
    }
}
```

```
return false;
}
```

The following example deletes the abuse report created by the first code example on this page.

```
private bool DeleteAbuseReport()
{
    string where = "ReportTitle LIKE N'MyNewReport%'";

    // Get the report
    DataSet reports = AbuseReportInfoProvider.GetAbuseReports(where, null);

    if (!DataHelper.DataSourceIsEmpty(reports))
    {
        // Create the object from DataRow
        AbuseReportInfo deleteReport = new AbuseReportInfo(reports.Tables[0].Rows
[0]);

        // Delete the abuse report
        AbuseReportInfoProvider.DeleteAbuseReportInfo(deleteReport);

        return true;
    }

    return false;
}
```

8.6 Alternative forms

8.6.1 Overview

The Alternative forms module enables you to create alternatives of various already existing forms. The alternative forms can then be used instead of the default ones in the system's administration interface or on the live site. You can even create multiple alternative forms for a single object and use each of them in a different situation.

Alternative forms can be created for:

- [Forms](#) - you can create alternative forms for existing forms and use them on the live site instead of the default form, while you can conveniently switch between various alternative forms in properties of the **On-line form** web part. Using alternative forms, you can also replace the default forms for creating or editing forms in the system's administration interface.
- [Custom tables](#) - using alternative forms, you can only replace a custom table's default form for adding or editing custom table items in the system's administration interface.
- [Document types](#) - you can create alternative forms for each document type. A typical usage of this feature is in the [User contributions](#) module, where you can provide users with a form for creation or editing of user-contributed documents on the live site which is different from the one used in the user interface. Using alternative forms, it is also possible to replace the default forms for adding or editing of documents in **CMS Desk -> Content -> Edit** (after clicking the **New** button or on the document's **Form** tab, respectively).

- [System tables](#) - you can create alternative forms for the system tables. A typical example is the **User** system table, as it has a dedicated alternative form to display a user profile, another form for profile editing, and yet another one for user registration. Using alternative forms, it is also possible to replace the default forms for adding or editing system tables data via the administration interface.

The module has no dedicated user interface, there only is the **Alternative forms** tab available when editing (✎) one of the objects listed above. On this tab, you can create and manage alternative forms of the currently edited item. In the [Creating an alternative](#) form topic, you can see an example of how an alternative form for a form can be created and used on the live site.

Some actions (typically creation of a new item or editing of an existing one) are associated with a reserved alternative form code name. If there is a form defined in the system which has the special code name, it is used instead of the default form when the respective action is performed. Please see the [Automatically used alternative forms](#) topic for more details.

Data about users of the system are stored in the **User** and **User - Settings** system tables. When creating an alternative form for creation or editing of users, it is possible to have fields from both of the system tables included in a single alternative form. For more information, please see the [Joining two classes into one form](#) topic.

8.6.2 Creating an alternative form

This example shows how to create an alternative form of the existing **Contact us** form on the sample Corporate Site.

Alternative forms of document types, system tables and custom tables can be created exactly the same way as described in this example. You only need to access the **Alternative forms** tab in the appropriate sections of the UI:

- **Site manager** -> **Development** -> **Custom tables**
- **Site manager** -> **Development** -> **Document types**
- **Site manager** -> **Development** -> **System tables**

There, **Edit** (✎) the particular item, switch to its **Alternative forms** tab and follow the instructions below, starting from the second step.

1. Go to **CMS Desk** -> **Tools** -> **Forms** and **Edit** (✎) the **Contact us** form. The **Form Properties** dialog opens.
2. Switch to the **Alternative forms** tab and click the  **Create new form** button.
3. Enter the following details and click  **Save**.
 - **Display name:** Contact Us Alternative
 - **Code name:** ContactUsAlternative
 - **Make new fields hidden:** yes (this ensures that any new fields added to the main form are not displayed in the alternative form by default)

Form Properties

> Forms > Contact Us

Data General Fields Form Notification e-mail Autoresponder Security **Alternative forms** On-line marketing Versions

> **Alternative forms** > New alternative form

Display name:

Code name:

Make new fields hidden:

4. Switch to the **Fields** tab. All fields present in the original form are also available here and you can modify their configuration. For example, disable the **LastName** field. Select the field in the list on the left and uncheck **Display attribute in the editing form**. Confirm this change by clicking **Save**. Using the same approach, you can modify any field in the form according to your needs.

Form Properties

> Forms > Contact Us

Data General **Fields** Form Notification e-mail Autoresponder Security Alternative forms On-line marketing Versions

> **Alternative forms** > Contact Us Alternative

General **Fields** Layout Versions

Database

Column name:

Attribute type:

Attribute size:

Allow empty value:

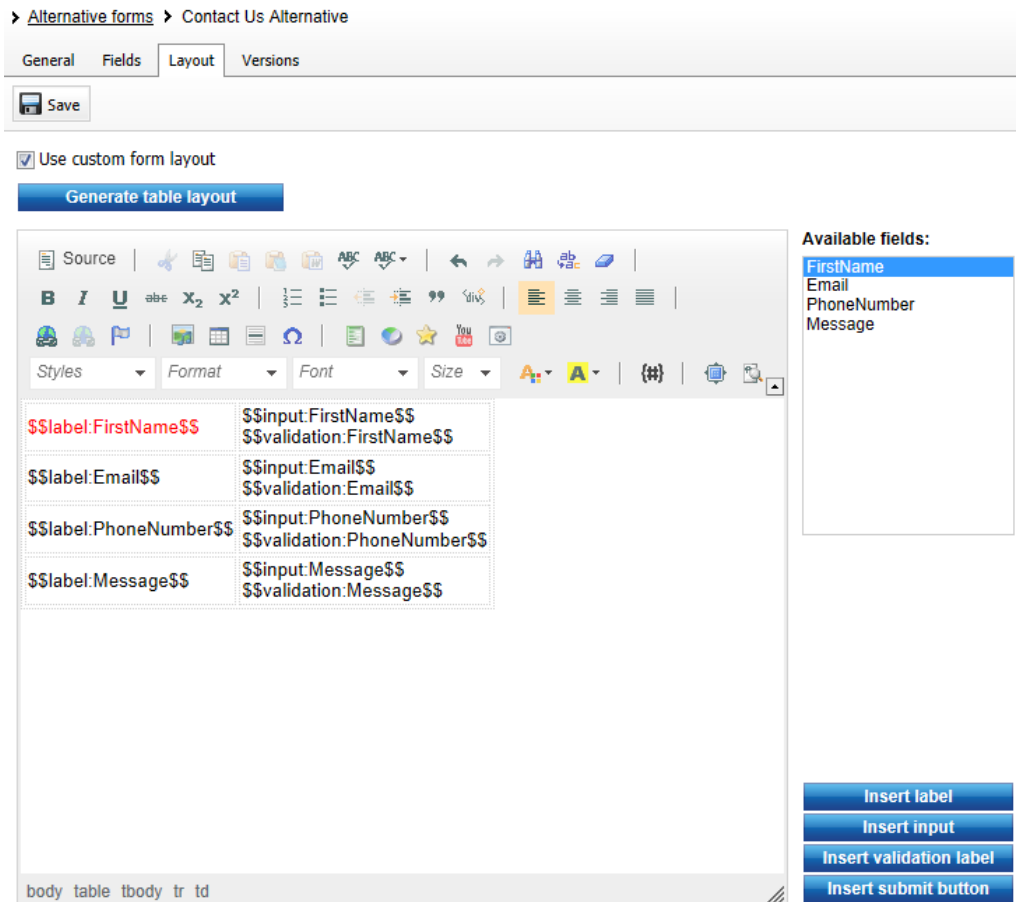

Default value:

Translate field:

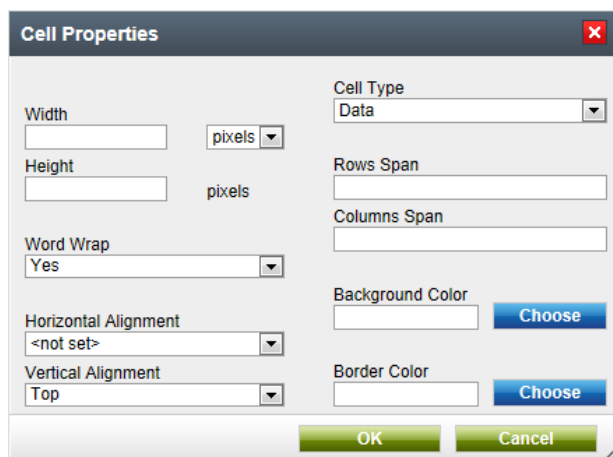

Display attribute in the editing form

ContactUsID*
 FormInserted*
 FormUpdated*
 FirstName*
 LastName*
 Email*
 PhoneNumber*
 Message*

5. You can also modify the layout of the form. Switch to the **Layout** tab and check the **Use custom layout** checkbox. The layout editor appears. Notice that the **LastName** field that we disabled in the previous step is not offered in the **Available fields** listbox. Click the **Generate table layout** button. The system generates a default table layout in the editing area below. Highlight the `$$label:FirstName$$` text in the first row and change its color to red using the WYSIWYG editor.

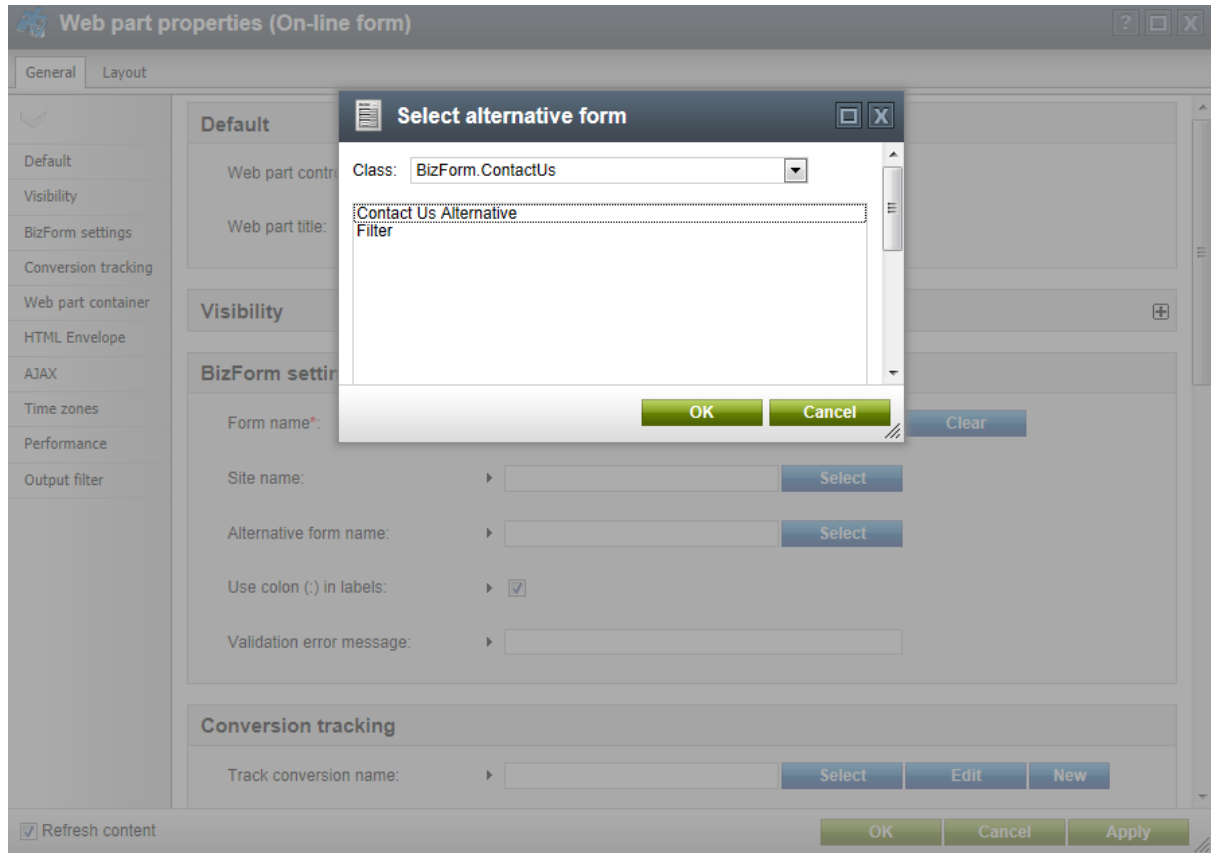

Then select the rows of the table's first column, right-click and choose **Cell -> Cell properties** from the context menu. In the displayed dialog, choose **Vertical alignment: Top** and click **OK**. This aligns the labels with their fields. Click **Save**.

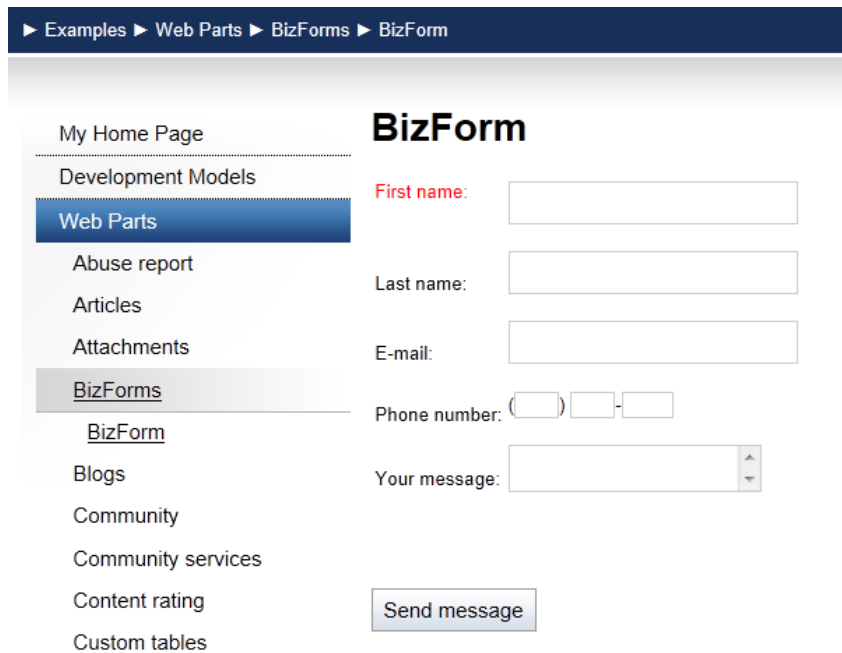

6. Let's take a look at what we've created. Switch to **CMS Desk -> Content**. From the content tree, select **Examples -> Web parts -> Forms -> On-line form**. As you can see, the original version of the **Contact Us** form is present on the page. We will edit the web part's properties so that the alternative form is used instead.

7. In **Edit** mode, switch to the page's **Design** tab and configure (⚙️) the **On-line form** web part's properties. Click the **Select** button next to the **Alternative form name** property. In the next dialog, choose the *BizForm.ContactUs* class and select the **Contact Us Alternative** option. Click **OK** in both dialogs to close them and confirm the changes.

8. Now when you switch to the **Live site** mode, you should see the modified version as in the following screenshot:

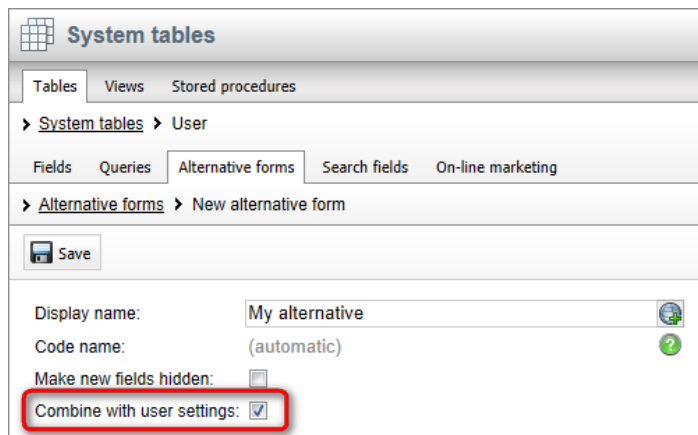

You have learned how to create an alternative form to an existing form and use it on your website.

8.6.3 Joining two classes into one form

It is also possible to join two classes into one alternative form. This option is currently available only for the **User** and **User - Settings** system tables.

1. When creating an alternative form for the **User** system table, you have the option to check the **Combine with user settings** checkbox.

2. Now if you switch to the **Fields** tab, you will see that in addition to the original fields contained in the **Users** table, fields from the **User - Settings** table are also available in the list, as you can see in the following screenshot:

The screenshot shows the 'System tables' configuration interface. The left pane lists various system tables, with 'UserSettingsID' highlighted. The right pane shows the configuration for this field, including the database name, column name, attribute type, and field appearance settings.

8.6.4 Automatically used alternative forms

If you create an alternative form and give it one of the reserved code names listed below, the alternative form will be automatically used when performing the corresponding action in the system's administration interface. For example, if you create an alternative form for a document type and give it the *insert* code name, the form will be used when documents of the type are created in **CMS Desk -> Content**.

The following table shows the reserved code names and the respective actions for which the particular forms are used:

| Alternative form code name | Usage | Supported by |
|----------------------------|---|---|
| filter | Filter displayed above a list of items. See Creating filter forms for more details. | Forms, Custom tables |
| insert | Form used when creating a new item. | Forms, Custom tables, document types, system tables |
| newculture | Form used when creating a new culture version of a document. | document types |
| update | Form used when editing an existing item. | Forms, Custom tables, document types, system tables |

8.6.5 Creating filter forms

By creating an alternative form named **filter** for a [form](#) or [custom table](#), you can create a filter that will be used when a large number of records is displayed in:

- CMS Desk -> Tools -> Forms -> edit (✎) a form -> Data
- CMS Desk -> Tools -> Custom tables -> edit (✎) a custom table
- Site Manager -> Development -> Custom tables -> edit (✎) a custom table -> Data

The number of records required for the filter to be displayed is 25 by default. You can change this value by adding the following key into the *appSettings* section of your *web.config* file:

```
<add key="CMSDefaultListingFilterLimit" value="10" />
```

Filtering is possible based on all fields that store the following types of values:

- Text
- Boolean (Yes/No)
- Integer numbers
- Long integer numbers
- Decimal numbers
- Date & time

The required fields need to be displayed in the alternative form and an appropriate form control must be assigned to each field. A filter form control is available for each data type, including the following options:

- **Text filter**
- **Boolean filter**
- **Number filter**
- **Date & time filter**

The screenshot shows a configuration panel titled "Field appearance" with the following settings:

- Show on public form:
- Field caption: First name
- Form control: Text filter
- Field description: (empty)

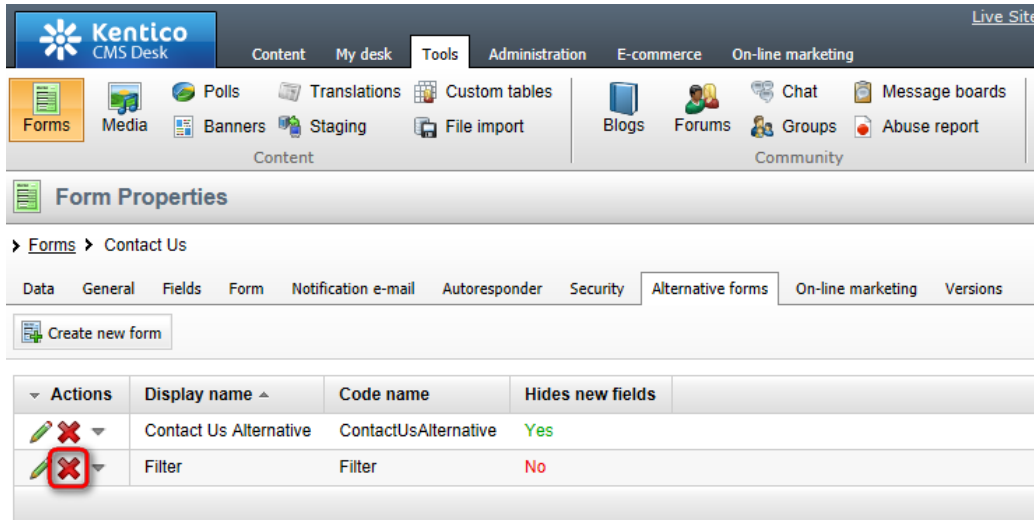

Creating a form filter

The following example will show you how to create a filter for the **Contact Us** form on the sample **Corporate Site**. The procedure demonstrated in the example can be used for any other form. Creation of custom table filters is also performed the same way.

Please note that in a standard installation, the **Contact Us** form already has a pre-defined **filter** alternative form. If you are an experienced user, you can inspect its setting instead of going through the following example.

1. Sign in to **CMS Desk** and go to the **Tools -> Forms** section. Edit (✎) the **Contact Us** form and

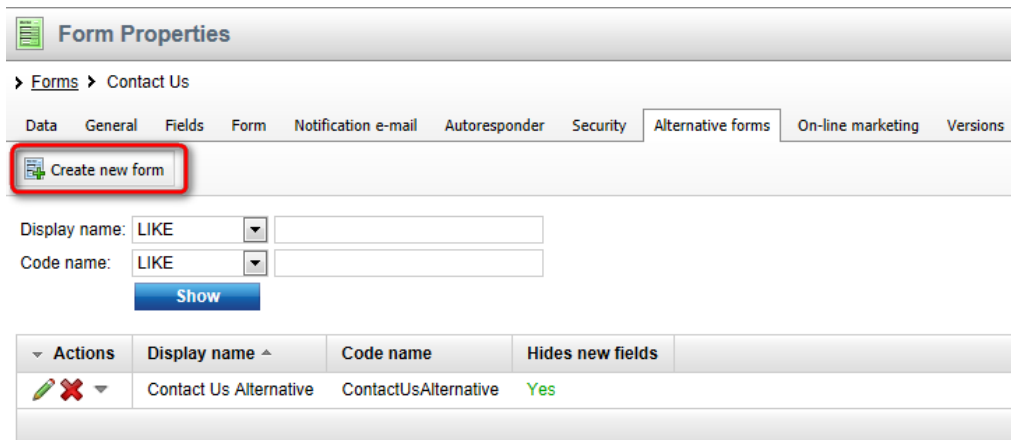

switch to the **Alternative forms** tab of its editing interface. As mentioned in the previous paragraph, there should already be a pre-defined **filter** form. Click the **Delete** (✖) action next to it so that you can go through the rest of this example and create your own filter from scratch.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. Below this, there are icons for various tools like 'Forms', 'Media', 'Polls', 'Translations', 'Custom tables', 'Banners', 'Staging', 'File import', 'Blogs', 'Forums', 'Chat', 'Message boards', 'Groups', and 'Abuse report'. The main area is titled 'Form Properties' and shows the 'Contact Us' form. The 'Alternative forms' tab is selected, and a table lists the following forms:

| Actions | Display name ^ | Code name | Hides new fields |
|---|------------------------|----------------------|------------------|
|   | Contact Us Alternative | ContactUsAlternative | Yes |
|   | Filter | Filter | No |

2. Once you have the form deleted, click  **Create new form** to create a new one.

The screenshot shows the 'Form Properties' dialog for the 'Contact Us' form. The 'Alternative forms' tab is selected, and the 'Create new form' button is highlighted with a red box. Below the button, there are input fields for 'Display name' and 'Code name', both set to 'LIKE'. A 'Show' button is visible below these fields. The table below shows the existing forms:

| Actions | Display name ^ | Code name | Hides new fields |
|---|------------------------|----------------------|------------------|
|   | Contact Us Alternative | ContactUsAlternative | Yes |

3. In the **New alternative form** dialog, enter the following details:

- **Display name:** Filter
- **Code name:** filter
- **Make new fields hidden:** yes (checked)

Click  **Save**.

Form Properties

> Forms > Contact Us

Data General Fields Form Notification e-mail Autoresponder Security **Alternative forms** On-line marketing Versions

> Alternative forms > New alternative form

Save

Display name:

Code name:

Make new fields hidden:

4. Now that the form is created, let's go to the most essential part of its configuration — switch to the **Fields** tab. In the listbox on the left, you should see all fields defined for the form. The first three of them are system fields that we do not want in the filter, so select the fourth one - **FirstName**. In the right area, scroll down to the **Field appearance** section and adjust the following values:

- **Display attribute in the editing form:** *enabled*; ensures that the field will be included in the filter's form.
- **Field caption:** First name; caption displayed next to the filtering field.
- **Form control:** *Text filter*; this is the filter form control available for text fields.

Click **Save** when you are finished.

5. Repeat the configuration explained in step 4 for the **LastName**, **Email**, **PhoneNumber** and **Message** fields. This ensures that all the fields are included in the filter.

6. Once you have the filter created, you can go back to the **Data** tab of the form's editing interface to verify that it really works. A filter should be displayed on the **Data** tab as can be seen in the screenshot below. Try filtering based on various parameters.

Please note

The default number of 25 records has to be present in the list in order for the filter to be displayed.

Therefore to see the filter, you either need to create the required number of records, or use the **CMSDefaultListingFilterLimit** *web.config* key to lower the filter limit accordingly.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Live Site', 'Site Manager', and 'Corporate site'. The main menu has categories like 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The 'Form Properties' section is active, showing a 'Contact Us' form with fields for 'First name', 'Last name', 'E-mail', 'Phone number', and 'Your message'. Each field has a 'LIKE' dropdown menu. A 'Show' button is located below the form. Below the form is a table of records with columns for 'Actions', 'ContactUsID', 'Form inserted', 'Form updated', 'First name', 'Last name', 'E-mail', and 'Phone number'.

| Actions | ContactUsID | Form inserted | Form updated | First name | Last name | E-mail | Phone number |

8.7 Avatars

8.7.1 Overview

The Avatars module enables users to have an image associated with their account. This image is called an **avatar** and is displayed on the user's public profile, next to their name in forums posts, blog comments etc. An avatar serves as a graphical representation of a user, and is used to personalize that user's contributions on websites. More information about users in general can be found in the [Development -> Membership, permissions and security](#) chapter of this guide.

Users can choose an avatar from a gallery of predefined avatars (if this option is enabled) or create a custom avatar by uploading their own image from a file on their local disk. Unlike predefined avatars, custom avatars can't be selected by other users and are deleted from the system if the user who uploaded them changes their avatar. All standard image formats are supported, including animations.

Kentico CMS also offers the option of retrieving images from the Gravatar hosting service for avatars. Please see the [Gravatars](#) topic to learn how this functionality can be configured.

Community groups and workgroups may also have avatars. These are displayed on the group's profile and can benefit the group by providing a way for it to be identified better and faster, etc. To read more about groups, please refer to the [Modules -> Groups](#) chapter of this guide.

There are several ways for users or group administrators to add or change avatars. See the [Changing user avatars](#) and [Changing group avatars](#) topics for more details. Administrators can manage all locally stored avatars as described in the [Managing avatars](#) topic.

When displaying lists of users or groups on a website, you may often wish to display the matching avatar images alongside the items. This can be achieved by ensuring that the avatar is included in the transformation used to render the objects. Please see the [Displaying avatars in transformations](#) topic for details and examples.

The [Avatars internals and API](#) sub-chapter provides information about the database tables and classes used by the module, examples of how avatars can be managed using the API and how they can be displayed in transformations.

8.7.2 Changing user avatars

When a new user registers on a site, a default avatar will be assigned to them. After that, they can change their avatar on a page containing the [My account](#) web part. This can be done on the **Personal settings** tab, as you can see in the screenshot below.

Personal settings | Change password | Notifications | Messages | Subscriptions | Memberships

Username: Turbo

Full name: Noel Turpin

Email: noel.turpin@localhost.local

Nickname: Turbo

Signature: --T-U-R-B-O--

Messaging notification e-mail:

Time zone: (none)

Avatar: 

Upload: Browse...

[Select pre-defined avatar](#)

Gender: Male Female

Date of birth: 1/3/1975

OK

Users can **Delete** (✖) the avatar or **Upload** a custom one from a file. If predefined avatars are enabled in the site's settings, users can also click the **Select pre-defined avatar** link, which displays a gallery of predefined avatars.

You can find a live example of this on our **Community starter site**. Just log-in as one of the predefined users (e.g. *Turbo* with blank password) and click the **Edit my profile** link in the **Shortcuts** menu on the right.

Changing your user avatar in CMS Desk

Users with access to **CMS Desk** can change their avatars in **My Desk -> My profile**. It can be done in the same way as described above. You can **Delete** (✘) the avatar or **Upload** your own avatar from a file.

If shared (predefined) avatars are enabled in the site's settings, you can also click the **Select pre-defined avatar** link, which displays a gallery of pre-defined avatars from which you can easily pick one by clicking it and clicking **OK**.

The screenshot displays the 'My profile' page in the Kentico CMS Desk interface. The navigation bar at the top includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The 'My desk' section contains icons for 'My dashboard', 'Recent', 'Outdated', 'Pending', 'Checked out', 'My docs', 'My profile', 'Blogs', 'Friends', 'Messages', 'Projects', and 'Bin'. The 'My profile' page has tabs for 'Details', 'Change password', 'Notifications', 'Subscriptions', and 'Categories'. The 'Details' tab is active, showing fields for 'Preferred content culture' (set to '(default)'), 'Preferred user interface culture' (set to 'English'), 'Messaging notification e-mail', 'Time zone' (set to '(none)'), 'Signature', 'Gender' (radio buttons for 'Male' and 'Female'), 'Date of birth' (with a 'Now' button), 'Phone number', 'Skype account', and 'IM'. The 'Avatar' section shows a current cartoon avatar with a red 'X' delete icon and an 'Upload' field with a 'Browse...' button. Below the avatar is a link for 'Select pre-defined avatar' and a 'Show splash screen' checkbox. An 'OK' button is at the bottom.

8.7.3 Changing group avatars

When a new group is created, the default avatar will be assigned to it. After that, group administrators can change the group's avatar using the **Group profile** web part.

Users can **Delete** (✘) the avatar or **Upload** a custom one from a file. If predefined avatars are enabled in site settings, users can also click the **Select pre-defined avatar** link, which displays a gallery of predefined avatars.

You can find a live example of this on the **Community starter site**. Sign-in as a group administrator (e.g. *Josh* with blank password, he is the *Australian travellers* group admin) and click **Groups** in the main menu. You should see the **Australian travellers** group under the **My groups** section. Click it and then use the **Manage the group** link in the **Shortcuts** section on the right of the page. As shown in the screenshot below, you can edit the group's avatar on the **General** tab of the management interface.

The screenshot shows the 'General' tab of a group management interface. At the top, there are tabs for 'General', 'Security', 'Members', 'Roles', 'Forums', 'Media libraries', 'Message boards', and 'Polls'. The 'Description' field contains text about Australian travellers. Below it is the 'Avatar' section, which features a photo of the Sydney Opera House and an 'Upload' field with a 'Browse...' button. There are also radio button options for 'Approve members' and 'Content access'. At the bottom, there are checkboxes for 'Notify group admins when a user joins/leaves' and 'Notify group admins on pending members', both of which are checked. The 'Created by' and 'Approved by' fields both show 'administrator'. An 'OK' button is at the bottom right.

8.7.4 Managing avatars

The administration interface for managing locally stored avatars can be found in **Site Manager -> Administration -> Avatars**.

You can limit which avatars should be displayed using the filter above the list. Possible filtering parameters are **Avatar name**, **Avatar type** (user or group avatar, avatars of type *all* can be used for both) and **Avatar kind** (shared avatars are the predefined ones, while custom avatars are those that users uploaded from a file). Click **Search** to display only avatars matching the selected criteria.

You can **Edit** (✎) or **Delete** (✖) the listed avatars.

The screenshot shows the Kentico CMS Administration interface. The top navigation bar includes 'Live Site', 'CMS Desk', and 'Global Administrator'. The main navigation menu on the left lists various administration tasks. The 'Avatars' section is active, displaying a 'New avatar' form and a table of existing avatars.

Avatars Management Form:

- Avatar name: LIKE
- Avatar type: (all)
- Avatar kind: Shared
- Buttons: Search, Reset

Avatars Table:

| Actions | Avatar name | Avatar type | Image preview |
|---------|-------------|-------------|---------------|
| | Group | Group | |
| | Group 2 | Group | |
| | Group 3 | Group | |
| | Group 4 | Group | |
| | Group 5 | Group | |
| | Man | User | |
| | Man 1 | User | |
| | Man 2 | User | |
| | Man 3 | User | |
| | Man 4 | User | |

Creating predefined avatars

1. New **predefined avatars** can be created using the **New avatar** at the top part of the page. Click it.
2. You will be asked to enter the following details:
 - **Avatar name** - the name of the avatar.
 - **Avatar type** - choose if the avatar can be used for users, groups or both.
 - **Upload** - click the **Browse** button to select an image file on your local machine.

When entered, click **OK** to proceed.

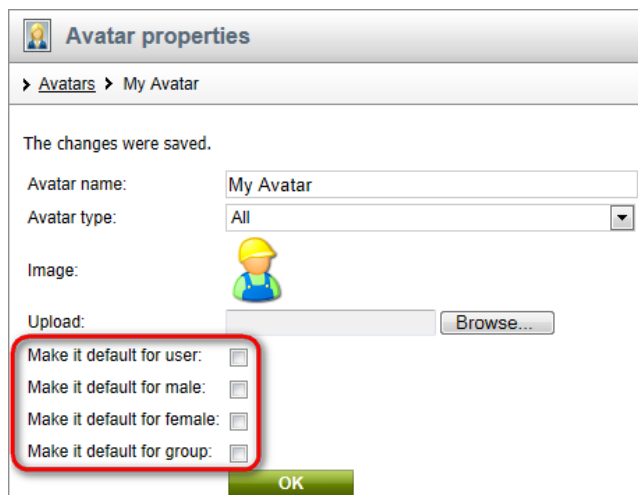

The 'New avatar' form is shown with the following fields:

- Avatar name: My Avatar
- Avatar type: All
- Upload: C:\inetpub\wwwroot\Kent
- Buttons: OK

3. The avatar is now created and if you go back to the list of avatars, you should see the avatar present in the list. However, you can set the following extra properties of the avatar now or any time later when editing the avatar:

- **Make it default for user** - if checked, this avatar will be the default avatar for users with an unspecified gender (including public visitors).
- **Make it default for male** - if checked, this avatar will be the default avatar for male users.
- **Make it default for female** - if checked, this avatar will be the default avatar for female users.
- **Make it default for group** - if checked, this avatar will be the default avatar for groups.

Default avatars will be assigned to new users or groups automatically when the user or group is created.

Make it default for group:

Administrating user avatars

Site administrators can change the avatar of any user. If you go to **Administration -> Users** in **CMS Desk** or **Site Manager**, choose to **Edit** (✎) a user in the list and switch to the **Settings** tab, you should see the given user's avatar in the **User picture** field as shown in the screenshot below. You can **Delete** (✖) the avatar or **Upload** your own avatar from a file.

If default avatars are enabled in site settings, you can also click the **Select pre-defined avatar** link, which displays a gallery of pre-defined avatars from which you can easily pick one by clicking it and clicking **OK**.

Changing group avatars in CMS Desk

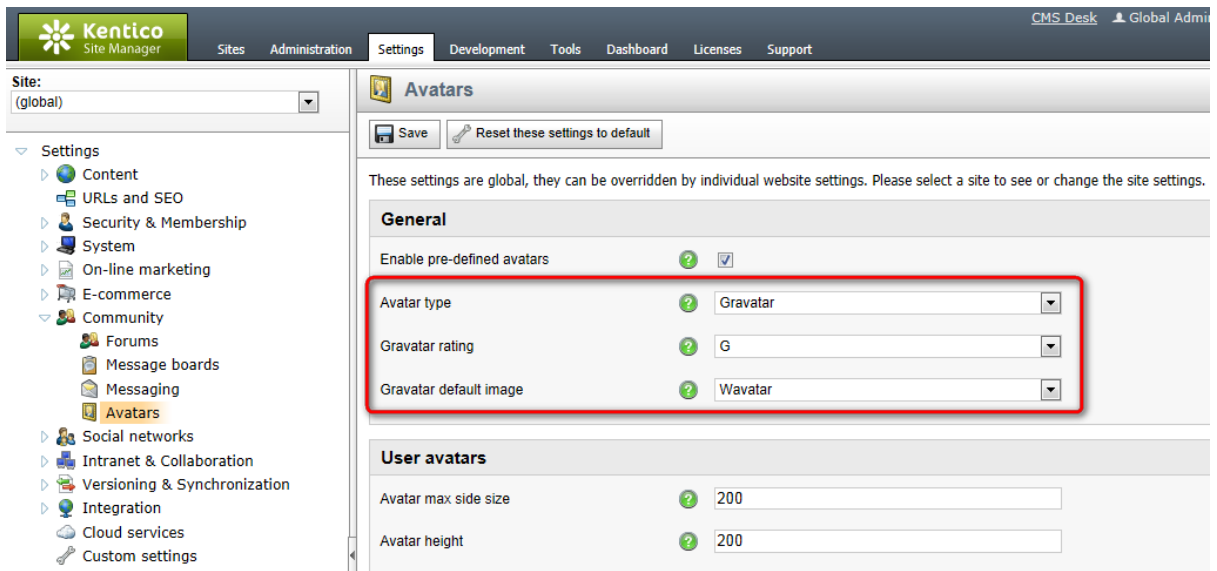

Site administrators can change the avatar of any group. If you go to **CMS Desk** -> **Tools** -> **Groups** and choose to **Edit** (✎) some of the groups, you should see the group's avatar in the **Avatar** section, as depicted in the screenshot below. A Group avatar can be **Deleted** (✖), a new one can be **Uploaded** from a file or selected from a gallery of predefined avatars (if this is enabled in site settings).

8.7.5 Gravatars

In addition to standard locally hosted avatar images, Kentico CMS also supports Gravatars (globally recognized avatars) for users. Gravatar is an avatar hosting service (<http://gravatar.com/>) that allows users to register their e-mail address and upload an associated image. This image is then automatically provided as an avatar on all websites with Gravatar support where the user can be identified through the given e-mail address. With Kentico CMS sites, this address is taken from the settings of registered users. In the case of public (unauthenticated) visitors, the system checks the optional e-mail value that can be entered when leaving comments or posting in forums.

Gravatars are not enabled by default. If you wish to use them on your site, it is necessary to adjust the avatar settings in **Site Manager -> Settings -> Community -> Avatars**.

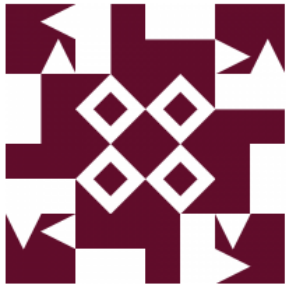

The **Avatar type** setting determines what kind of user avatars will be allowed on the website. The following options may be selected:

- **Avatar** - only the standard avatars stored locally in the website's database or file system will be available and Gravatars will not be supported. Users will be able to either upload their own image or choose a predefined one.
- **Gravatar** - with this option, Gravatars will be used for all users and visitors. When displaying avatars, the system will automatically check the e-mail addresses of users and if a matching Gravatar is found, it will be loaded and displayed. Users who do not have a Gravatar registered and public visitors without a specified e-mail address will have a default image assigned. Please note that switching to this option will change the avatars of users who have uploaded a custom image locally for the website. Enabling Gravatars has no effect on group avatars.
- **User can choose** - selecting this value allows both possible avatar options. Registered users will be able to choose whether they want to use a Gravatar or a local avatar. Gravatar support will be enabled for public users.

When using Gravatars, users will only be able to view the avatar image in their profile, with no option of changing it locally. If the **User can choose** option is selected, it will be possible for users to switch between the two modes by selecting the appropriate radio button as shown below.

Username: SeanG
Full name:
Email:
Nickname:
Signature:
Messaging notification e-mail:
Time zone:

Avatar Gravatar

Avatar: 

Gender: Male Female

Date of birth:

All Gravatar images are rated according to the maturity level of their content. You can set the maximum rating that should be allowed on your website by configuring the **Gravatar rating** setting. The following ratings are available:

- **G** - suitable for display on all websites with any audience type.
- **PG** - may contain rude gestures, provocatively dressed individuals, the lesser swear words, or mild violence.
- **R** - may contain such things as harsh profanity, intense violence, nudity, or hard drug use.
- **X** - may contain hardcore sexual imagery or extremely disturbing violence.

If a user's Gravatar does not meet the site's rating requirements, it is replaced by the default image.

Gravatars are user-rated

Please note that the rating of a Gravatar image is entered by its owner. Because of this, Kentico CMS cannot guarantee that inappropriate images will be filtered out if their rating is inaccurate.

The **Gravatar default image** setting determines what type of image should be displayed as the avatar of users who do not have a valid Gravatar registered for their e-mail address. If the *(none)* option is selected, the local avatar image specified as default for users in **Site Manager -> Administration ->**

Avatars is used. The remaining options provide various types of default Gravatar image sets. In most cases, a different image is generated based on the e-mail address of the given user, so even users without a Gravatar account will have a unique avatar image assigned.

Displaying Gravatars in transformations

If you wish to display Gravatars in member lists or on any other type of pages where user avatars are presented, it may be necessary to modify your transformations.

Not all transformation methods used to generate avatar image tags support displaying of Gravatars. Please read the [Displaying avatars in transformations](#) topic for more information.

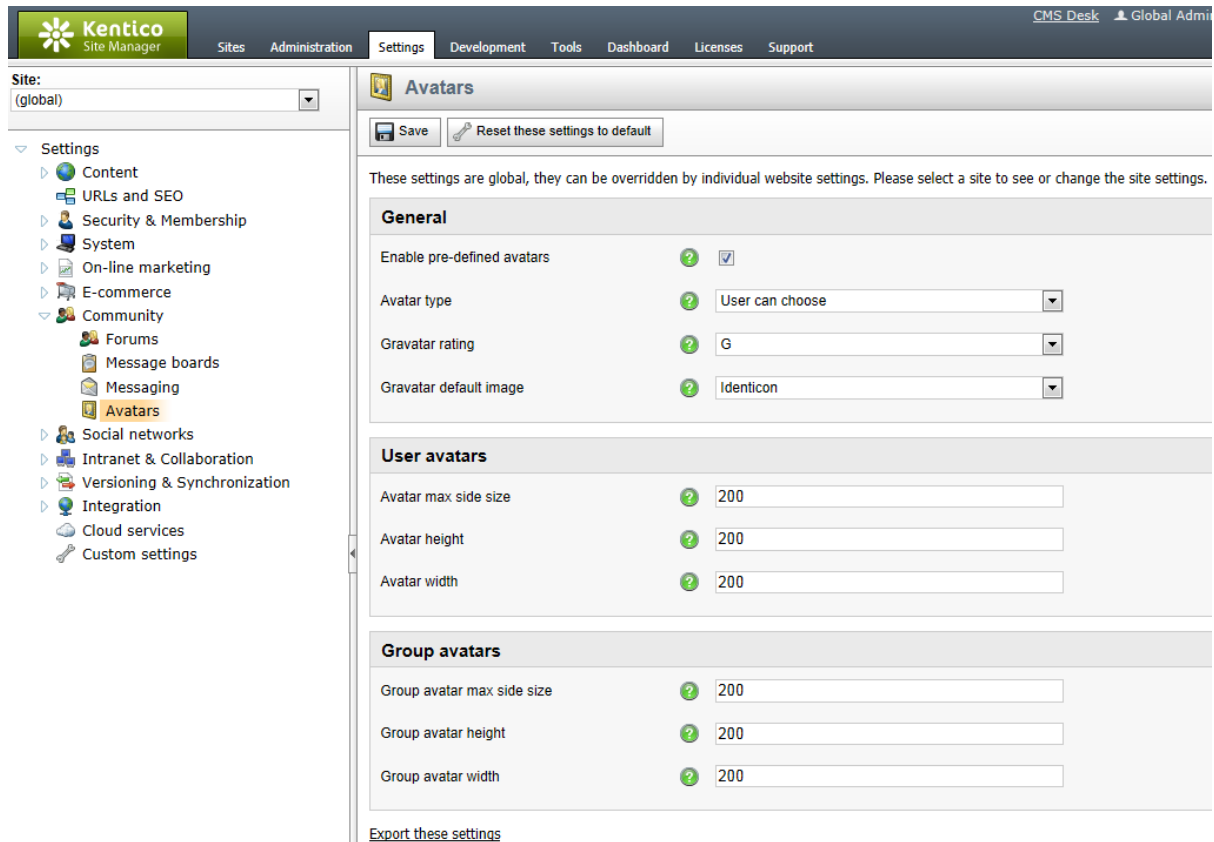

8.7.6 General avatar settings

In addition to configuring Gravatar support, the settings in **Site Manager -> Settings -> Community -> Avatars** may also be used to adjust other preferences, such as automatic resizing of avatar images. The following general settings are available:

- **Enable pre-defined avatars** - if checked, it will be possible to select one of the shared, predefined avatars when choosing a user or group's avatar image. If disabled, only custom uploaded avatars will be allowed. This setting does not affect Gravatars.
- **Avatar max side size** - sets the maximum allowed size of *user* avatar images. If one or both dimensions of the uploaded image are larger, it will be resized so that the larger dimension matches the entered value. If 0 is entered, the *Avatar height* and *Avatar width* settings will be used instead.
- **Avatar height** - if the *Avatar max side size* setting is set to 0, avatar images will be resized to this height.
- **Avatar width** - if the *Avatar max side size* setting is set to 0, avatar images will be resized to this

width.

- **Group avatar max side size** - sets the maximum allowed size of *group* avatar images. If one or both dimensions of the uploaded image are larger, it will be resized so that the larger dimension matches the entered value. If 0 is entered, the *Group avatar height* and *Group avatar width* settings will be used instead.
- **Group avatar height** - if the *Group avatar max side size* setting is set to 0, images will be resized to this height.
- **Group avatar width** - if the *Group avatar max side size* setting is set to 0, images will be resized to this width.

8.7.7 Displaying avatars in transformations

User avatars

User avatars can be displayed in [transformations](#) by using the `<%# GetUserAvatarImage(...) %>` method. It can be called with four different sets of parameters as described below (including examples):

- **GetUserAvatarImage(int maxSideSize, string alt)**

```
<%# GetUserAvatarImage( 50, HTMLEncode( GetNotEmpty( "UserNickname;UserName" ) ) ) %>
```

This returns an image tag displaying the avatar contained in the *AvatarGuid* field of the currently

transformed user, with a maximum *sidesize* of 50 px. and *Alt tag* equal to the user's *Nickname* or *Username*. The *AvatarGuid* field must be accessible for this method to work.

This overload does not support Gravatars!

The *GetUserAvatarImage* method cannot display [Gravatars](#) when called with only these two parameters. Please use one of the overloads that includes the **userID** parameter for this purpose.

- **GetUserAvatarImage(object userID, int maxSideSize, int width, int height, object alt)**

```
<%# GetUserAvatarImage(Eval("UserID"), 200, 0, 0, Eval("UserName")) %>
```

This returns an image tag displaying the current avatar of the user with ID *UserID*, with a maximum *sidesize* of 200 px. and an *Alt tag* equal to the user's *Username*.

- **GetUserAvatarImage(object avatarID, object userID, int maxSideSize, object alt)**

```
<%# GetUserAvatarImage(Eval("UserAvatarID"), Eval("UserID"), 50, Eval("UserName")) %>
```

This returns an image tag displaying the avatar with ID *UserAvatarID*, of user with ID *UserID*, with a maximum *sidesize* of 50 px. and *Alt tag* equal to the user's *Username*.

- **GetUserAvatarImage(object avatarID, object userID, int maxSideSize, int width, int height, object alt)**

```
<%# GetUserAvatarImage(Eval("UserAvatarID"), Eval("UserID"), 0, 40, 45, Eval("UserName")) %>
```

This returns an image tag displaying the avatar with ID *UserAvatarID*, of user with ID *UserID*, with a maximum *width* of 40 px., maximum *height* of 45 px. and *Alt tag* equal to the user's *Username*.

Group avatars

Group avatars can be displayed using the same approach, with the difference that the `<%# GetGroupAvatarImage(...) %>` method is called instead:

- **GetGroupAvatarImage(int maxSideSize, object alt)**

```
<%# GetGroupAvatarImage(50, Eval("GroupDisplayName", true)) %>
```

This returns an image tag displaying the group avatar specified by the *AvatarGuid* field of the currently transformed group, with a maximum *sidesize* of 50 px. and *Alt tag* equal to the group's *Display name*.

The *AvatarGuid* field must be accessible for this method to work.

- **GetGroupAvatarImage(object avatarID, int maxSideSize, object alt)**

```
<%# GetGroupAvatarImage(Eval("GroupAvatarID"), 50, Eval("GroupDisplayName", true))
%>
```

This returns an image tag displaying the group avatar with ID *GroupAvatarID*, with a maximum *sidesize* of 50 px. and *Alt tag* equal to the group's *Display name*.

- **GetGroupAvatarImage(object avatarID, int maxSideSize, int width, int height, object alt)**

```
<%# GetGroupAvatarImage(Eval("GroupAvatarID"), 0, 40, 45, Eval("GroupDisplayName",
true)) %>
```

This returns an image tag displaying the group avatar with ID *GroupAvatarID*, with a maximum *width* of 40 px., maximum *height* of 45 px. and *Alt tag* equal to the group's *Display name*.

Image tag

The following is an example of an image tag generated by the `<%# GetUserAvatarImage(...) %>` method. As you can see, the method uses the `~/CMSModules/Avatars/CMSPages/GetAvatar.aspx` page to get the source image.

```

```

When displaying Gravatars, the image is retrieved from the <http://www.gravatar.com/> website as shown in the example below:

```

```

8.7.8 Avatars internals and API

8.7.8.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Avatars module. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the module's classes, please refer to [Kentico CMS API Reference](#).

8.7.8.2 Database tables

The following database table is used to store information about avatars:

- **CMS_Avatar** - contains records representing avatars and their configuration. Avatar images are stored in binary format.

| CMS_Avatar | | | |
|------------|------------------------|------------------|-------------------------------------|
| | Column Name | Data Type | Allow Nulls |
| ? | AvatarID | int | <input type="checkbox"/> |
| | AvatarName | nvarchar(200) | <input checked="" type="checkbox"/> |
| | AvatarFileName | nvarchar(200) | <input type="checkbox"/> |
| | AvatarFileExtension | nvarchar(10) | <input type="checkbox"/> |
| | AvatarBinary | varbinary(MAX) | <input checked="" type="checkbox"/> |
| | AvatarType | nvarchar(50) | <input type="checkbox"/> |
| | AvatarIsCustom | bit | <input type="checkbox"/> |
| | AvatarGUID | uniqueidentifier | <input type="checkbox"/> |
| | AvatarLastModified | datetime | <input type="checkbox"/> |
| | AvatarMimeType | nvarchar(100) | <input type="checkbox"/> |
| | AvatarFileSize | int | <input type="checkbox"/> |
| | AvatarImageHeight | int | <input checked="" type="checkbox"/> |
| | AvatarImageWidth | int | <input checked="" type="checkbox"/> |
| | DefaultMaleUserAvatar | bit | <input checked="" type="checkbox"/> |
| | DefaultFemaleUserAv... | bit | <input checked="" type="checkbox"/> |
| | DefaultGroupAvatar | bit | <input checked="" type="checkbox"/> |
| | DefaultUserAvatar | bit | <input checked="" type="checkbox"/> |
| | | | <input type="checkbox"/> |

8.7.8.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Avatars module can be found in the **CMS.SiteProvider** namespace.

CMS_Avatar table API:

- **AvatarInfo** - represents one avatar object.
- **AvatarInfoProvider** - provides management functionality for avatars.

8.7.8.4 API examples

8.7.8.4.1 Overview

These topics show examples of how the API of the Avatars module can be used:

- [Managing avatars](#)
- [Managing user avatars](#)

**Please note**

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Community\Avatars\Default.aspx.cs**.

The avatar API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.SiteProvider;
```

8.7.8.4.2 Managing avatars

The following example creates an avatar.

```
private void CreateAvatar()
{
    // Create new avatar object
    AvatarInfo newAvatar = new AvatarInfo(Server.MapPath("~/CMSAPIExamples/Code/Community/Avatars/Files/avatar_man.jpg"));

    // Set the properties
    newAvatar.AvatarName = "MyNewAvatar";
    newAvatar.AvatarType = AvatarInfoProvider.GetAvatarTypeString(AvatarTypeEnum.All);
    newAvatar.AvatarIsCustom = false;

    // Save the avatar
    AvatarInfoProvider.SetAvatarInfo(newAvatar);
}
```

The following example gets and updates an avatar.

```
private bool GetAndUpdateAvatar()
{
    // Get the avatar
    AvatarInfo updateAvatar = AvatarInfoProvider.GetAvatarInfo("MyNewAvatar");
    if (updateAvatar != null)
    {
        // Update the properties
    }
}
```

```
        updateAvatar.AvatarName = updateAvatar.AvatarName.ToLower();

        // Save the changes
        AvatarInfoProvider.SetAvatarInfo(updateAvatar);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates avatars.

```
private bool GetAndBulkUpdateAvatars()
{
    // Prepare the parameters
    string where = "AvatarName LIKE N'MyNewAvatar%'";

    // Get the data
    DataSet avatars = AvatarInfoProvider.GetAvatars(where, null);
    if (!DataHelper.DataSourceIsEmpty(avatars))
    {
        // Loop through the individual items
        foreach (DataRow avatarDr in avatars.Tables[0].Rows)
        {
            // Create object from DataRow
            AvatarInfo modifyAvatar = new AvatarInfo(avatarDr);

            // Update the properties
            modifyAvatar.AvatarName = modifyAvatar.AvatarName.ToUpper();

            // Save the changes
            AvatarInfoProvider.SetAvatarInfo(modifyAvatar);
        }

        return true;
    }

    return false;
}
```

The following example deletes an avatar.

```
private bool DeleteAvatar()
{
    // Get the avatar
    AvatarInfo deleteAvatar = AvatarInfoProvider.GetAvatarInfo("MyNewAvatar");

    // Delete the avatar
    AvatarInfoProvider.DeleteAvatarInfo(deleteAvatar);
}
```

```
    return (deleteAvatar != null);  
}
```

8.7.8.4.3 Managing user avatars

The following example assigns an avatar to a specific user.

```
private bool AddAvatarToUser()  
{  
    // Get the avatar and user objects  
    AvatarInfo avatar = AvatarInfoProvider.GetAvatarInfo("MyNewAvatar");  
    UserInfo user = UserInfoProvider.GetUserInfo(CMSContext.CurrentUser.UserName);  
  
    if ((avatar != null) && (user != null))  
    {  
        user.UserAvatarID = avatar.AvatarID;  
  
        // Save edited object  
        UserInfoProvider.SetUserInfo(user);  
  
        return true;  
    }  
  
    return false;  
}
```

The following example removes a user's avatar.

```
private bool RemoveAvatarFromUser()  
{  
    // Get the user  
    UserInfo user = UserInfoProvider.GetUserInfo(CMSContext.CurrentUser.UserName);  
  
    if (user != null)  
    {  
        user.UserAvatarID = 0;  
  
        // Save edited object  
        UserInfoProvider.SetUserInfo(user);  
  
        return true;  
    }  
  
    return false;  
}
```

8.8 Bad words

8.8.1 Overview

The Bad words module can be used as a filter for unwanted input from website users. This can be anything from rude language to spam or links to illegal content, basically anything that is detectable by presence of some keyword in input text.

The Bad words module is capable of filtering input submitted via the following modules:

- [Forums](#)
- [Blogs](#)
- [Messaging](#)
- [Message boards](#)
- [Chat](#)

For the module to work, you first need to enable it as described in [Enabling the module](#). Filtering is then performed based on keywords - so called bad words - defined by site administrators in **Site manager -> Administration -> Bad words**. The procedure of defining bad words is described in the [Defining a bad word](#) topic.

| Actions | Expression | Action | Replacement | All cultures |
|---------|------------|-------------------|-----------------|--------------|
| | arse | Replace (default) | ***** (default) | Yes |
| | asshole | Replace (default) | ***** (default) | Yes |
| | assramer | Replace (default) | ***** (default) | Yes |
| | bastard | Replace (default) | ***** (default) | Yes |
| | bitch | Replace (default) | ***** (default) | Yes |
| | bollock | Replace (default) | ***** (default) | Yes |
| | cabron | Replace (default) | ***** (default) | Yes |

If a user inputs some text containing one or more of these words, a predefined action is performed. Available actions range from removing the word, replacing it with a pre-defined string or just reporting abuse to website administrators by means of the [Abuse report](#) module. All actions and their effects are described in the [Possible actions](#) topic.

By default, input from all users except global administrators is filtered. However, you may grant the **Use bad words** permission to some roles, which will disable filtering of input submitted by its members. More information on this option can be found in the [Security](#) topic.

The [Bad words internals and API](#) sub-chapter provides information about the database tables and classes used by the module, as well as examples of how bad words can be managed and bad word checks performed using Kentico CMS API.

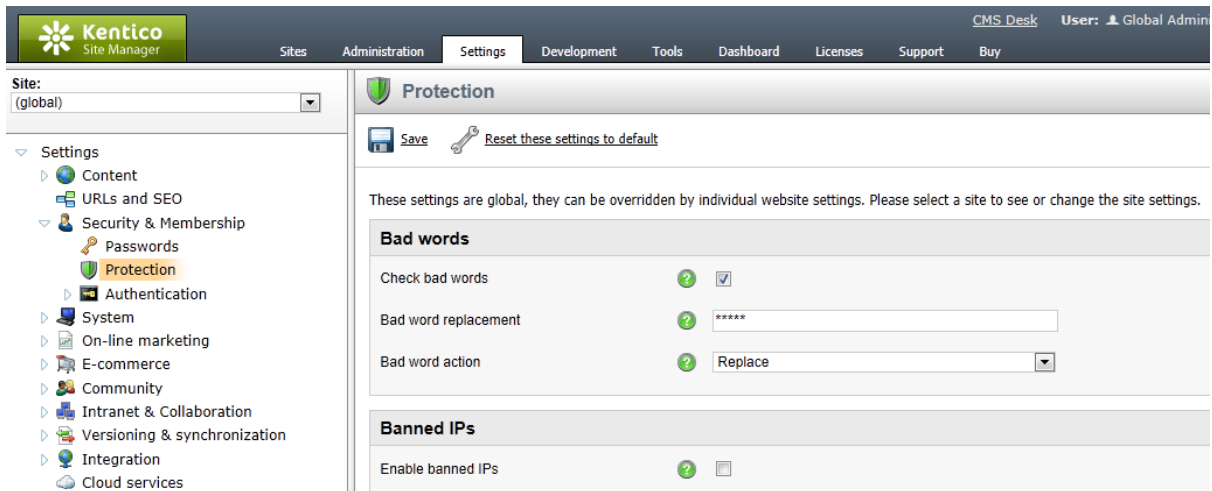

The Bad words module is just one of the modules which can help you deal with unwanted user input. Besides detecting unwanted input based on keywords, you may also let your site visitors report such content via the [Abuse report](#) module. The last resort in dealing with unwanted content may be blocking access to your site from a certain IP address. This can be achieved using the [Banned IPs](#) module.

8.8.2 Enabling the module

For the module to be functional, you first have to go to **Site Manager -> Settings & Membership -> Protection** and enable the **Check bad words** option.

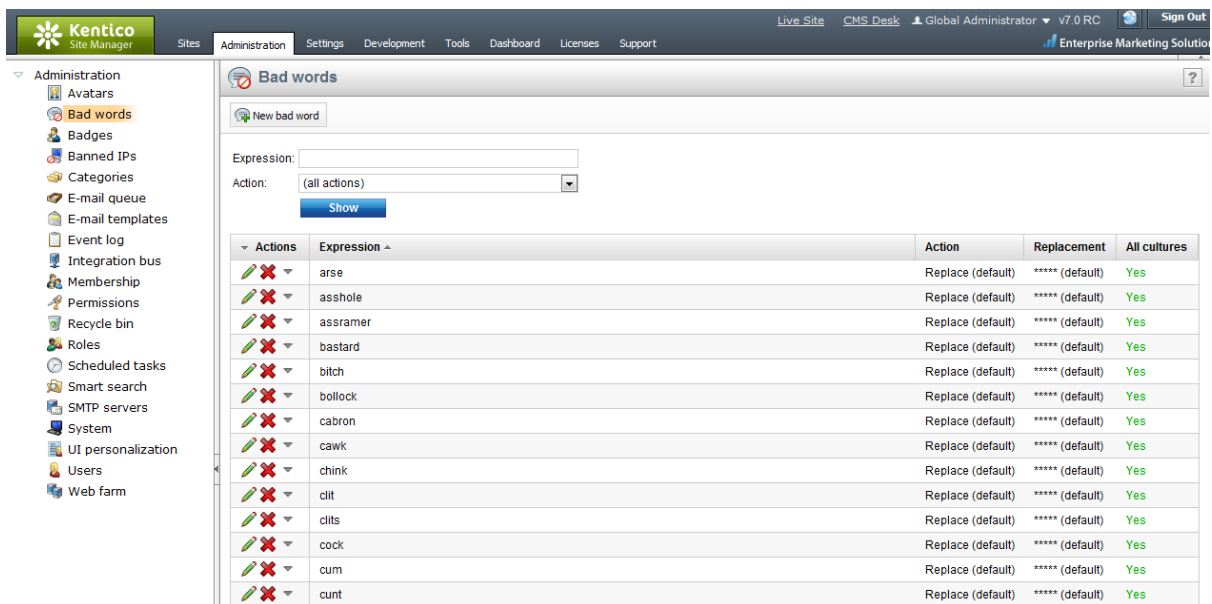

On this page, you can also define the default action that will be assigned to newly created bad words if the *Use default settings* option is enabled in the bad word creation dialog (see [Defining a bad word](#) for more details). The default action can be selected from the **Bad word action** drop-down list.

Default replacement string can be entered into the **Bad word replacement** field. It will be used in case that a bad word is detected, the *Replace* action should be performed on its detection, but has no replacement text defined (i.e. has the *Use default settings* option enabled for the *Replace by* field).

8.8.3 Defining a bad word

The Bad words module's user interface is located in **Site Manager -> Administration -> Bad words**. This is where all existing bad words are listed and where new bad words can be defined.

The top part of the page is a filter. Using it, you can display only those bad words that match the specified criteria. You can filter by the **Expression** and by the **Action** that should be taken on its detection. After specifying the filtering criteria and clicking the **Show** button, only those items that

match the specified criteria will be displayed in the list.

Adding a new bad word

1. To add a new bad word, click **New bad word** (🔍) at the top of the page. You will be redirected to the **New bad word** dialog. The following details can be entered:

- **Bad word** - the string that should not appear in input text.
- **Bad word is a regular expression** - if checked, the string entered into the previous field will be searched as a regular expression.
- **Match whole word** - if enabled, only whole word occurrences of the expression will be identified. If disabled, even words with substrings matching the expression will be identified (e.g. an occurrence of the word "document" would be reported if "cum" was defined as a bad word with this option disabled).
- **Action** - action that will be taken in case that the bad word is detected. See the [Possible actions](#) topic for more details.
Use default settings - if enabled, global value will be used as set in *Site Manager -> Settings -> Security & Protection -> Bad words -> Bad word action*.
- **Replace with** - in case the *Replace* action is selected, the substitute for the bad word is defined here.
Use default settings - if enabled, global value will be used as set in *Site Manager -> Settings -> Security & Protection -> Bad words -> Bad word replacement*.

Fill in the required details and click **OK**.

New bad word

> [Bad words](#) > New bad word

Bad word:

Bad word is a regular expression:

Match whole word:

Action: Use default settings

Replace with: Use default settings

OK

2. Let's try the functionality now. Go to the live Corporate Site, enter the Blogs section and open some of the blog posts. Enter a comment as in the following screenshot and click **Add**.

Leave comment

[Subscribe](#)

Your URL:

Comments:

Subscribe me to this blog post

3. As you can see, the last word has been replaced with its polite substitute that has been defined earlier.

The rude boy
 Hey man, try to write something meaningful next time. This article is not very good!!!
 8/15/2011 2:32:19 PM

[Edit](#) [Delete](#) [Reject](#) [Report abuse](#)

4. You can also check the **Event log** in **Site Manager -> Administration**. An event is always logged automatically when user input containing a bad word is detected. The **Event code** is **BADWORD** in such case.

| Actions | Type | Event time | Source | Event code | User name | IP address | Document name | Site | Machine name |
|---------|------|---------------------|-----------------|--------------------|---------------|---------------|---------------|----------------|--------------|
| | I | 30.08.2011 10:34:02 | Authentication | AUTHENTICATIONSUCC | administrator | 192.168.3.143 | | Corporate site | PREVIEW |
| | I | 30.08.2011 10:33:52 | Forum post | CREATEOBJ | | 192.168.3.143 | | Corporate site | PREVIEW |
| | I | 30.08.2011 10:33:52 | Bad words check | BADWORD | | 192.168.3.143 | | Corporate site | PREVIEW |
| | I | 30.08.2011 10:32:17 | Forum post | CREATEOBJ | administrator | 192.168.3.143 | | Corporate site | PREVIEW |

8.8.4 Possible actions

In case that a bad word is detected, one of the following actions can be taken:

- **Remove** - the bad word is removed from the entered text with no substitution.
- **Replace** - the bad word is removed and replaced with a predefined string.
- **Report abuse** - a report is created in **CMSDesk -> Tools -> Abuse report**.
- **Request moderation** - the post is submitted to approval before being published; this happens even in case that the forum, message board or blog is not moderated by default.
- **Deny** - a warning message will be displayed to the user when they try to post the inadequate text, listing which words should be removed.

The following table shows which actions are available for each of the supported modules:

| | Blog comments | Forums | Messaging | Message boards |
|--------------------|---------------|--------|-----------|----------------|
| Remove | • | • | • | • |
| Replace | • | • | • | • |
| Report abuse | • | • | | • |
| Request moderation | • | • | | • |
| Deny | • | • | • | • |

In case that there is **more than one bad word detected** in input text and the words have **different actions** set, the actions will be taken according to their hierarchy. *Remove*, *Replace* and *Report abuse* actions are independent, i.e. the actions can be taken simultaneously. *Request moderation* is stronger than *Report abuse* and *Deny* is the strongest of all.

The following list shows which actions will be taken in some specific cases in order for you to easily understand the actions hierarchy:

- **Remove and Replace** - the first one will be removed and the second one will be replaced with the defined substitute.
- **Remove, Replace and Report abuse** - the first one will be removed, the second one replaced and an abuse report will be logged.
- **Remove, Replace and Request moderation** - the first one will be removed, the second one will be replaced and the post will have to be approved.
- **Report abuse and Request moderation** - the post will have to be approved and no abuse report will be logged.
- **Deny and any other** - the text is left as it is, but produces an error message.

Replace action in fields with limited length

If the **Replace** action has to be performed in a text entered into a field with limited length, it may happen that the text with replaced bad words would exceed the maximal length (when the replacement text is longer than the original bad word). In this case, the bad word is replaced with as many asterisks as its length.

When there are multiple bad words in the text, replacement starts from the beginning of the string. If replacement of the first bad word wouldn't cause exceeding of the maximal length, it is replaced with the replacement text. The same applies to the subsequent bad words and asterisks start to be used with the first bad word whose replacement would cause exceeding of the maximal length.

8.8.5 Multilingual support

You can define in which cultures will a certain bad word be filtered. If you choose to **Edit** (🖋️) a bad word in the list in **Site Manager -> Administration -> Bad words** and switch to its **Cultures** tab (the tab is not available in the **New bad word** dialog), you will be offered with the following two options:

- **The word is not allowed in all cultures** - the bad word will be filtered in all website cultures
- **The word is not allowed only in following cultures** - the bad word will be filtered only in cultures added to the list below

Using the **Add cultures** button, you can add cultures to the list. The **Remove selected** button removes all cultures selected by the check-boxes from the list.

 The word is not allowed only in following cultures

| <input type="checkbox"/> | Culture name |
|--------------------------|--|
| <input type="checkbox"/> | Afrikaans - South Africa |
| <input type="checkbox"/> | Arabic - Algeria |

Remove selected Add cultures

8.8.6 Security

The Bad words module has only one permission to grant to roles:

- **Use bad words** - allows members of the role to use bad words, i.e. bad words filtering will not be performed to submissions made by members of the role

This permission can be granted to particular roles in **Site Manager -> Administration -> Permissions**, after selecting the **Modules -> Bad words** permission matrix.

8.8.7 Bad words internals and API

8.8.7.1 Overview

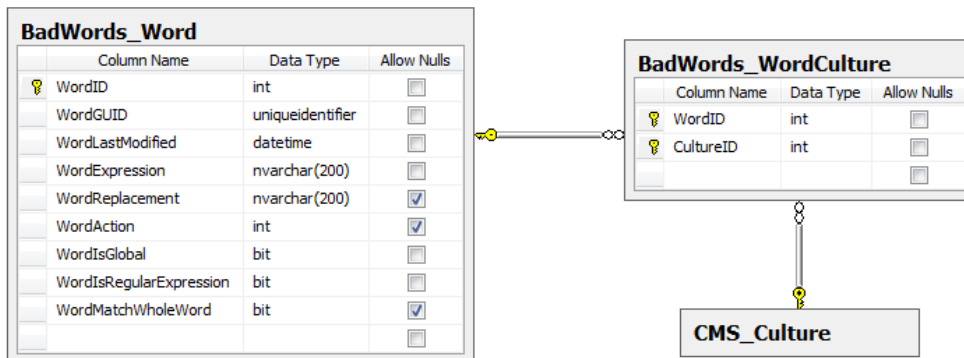

In this chapter, you will learn which [database tables](#) and [API classes](#) are used by the Bad words module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.8.7.2 Database tables

The Bad words module uses the following database tables:

- **BadWords_Word** - contains records representing defined bad words.
- **BadWords_WordCulture** - contains relationships between bad words and cultures. Each record indicates that the given bad word should be checked in the respective culture.

8.8.7.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Bad words module can be found in the **CMS.SiteProvider** namespace.

BadWords_Word table API:

- **BadWordInfo** - represents one bad word object.
- **BadWordInfoProvider** - provides management functionality for bad words.
- **BadWordsHelper** - provides management functionality for bad words. Compared to *BadWordInfoProvider*, this class provides extra methods for bad word actions and replacements.

Others:

- **BadWordActionEnum** - enumeration of actions that can be taken on detection of a bad word in checked text.

8.8.7.4 API examples

8.8.7.4.1 Overview

These topics show examples of how the API of the Bad words module can be used:

- [Managing bad words](#)
- [Performing bad word checks](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Administration\BadWords\Default.aspx.cs**.

The Bad words API examples use the following namespaces:

```
using System;
using System.Data;
using System.Collections;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.SiteProvider;
```

8.8.7.4.2 Managing bad words

The following example creates a bad word.

```
private bool CreateBadWord()
{
    // Create new bad word object
    BadWordInfo newWord = new BadWordInfo();

    // Set the properties
    newWord.WordExpression = "testbadword";
    newWord.WordAction = BadWordActionEnum.ReportAbuse;
    newWord.WordIsGlobal = true;
    newWord.WordIsRegularExpression = false;

    // Save the bad word
```

```
BadWordInfoProvider.SetBadWordInfo(newWord);

return true;
}
```

The following example gets and updates the bad word created by the code example above.

```
private bool GetAndUpdateBadWord()
{
    // Prepare the parameters
    string where = "[WordExpression] = 'testbadword'";

    // Get the data
    DataSet words = BadWordInfoProvider.GetBadWords(where, null);

    if (!DataHelper.DataSourceIsEmpty(words))
    {
        // Get the bad word's data row
        DataRow wordDr = words.Tables[0].Rows[0];

        // Create object from DataRow
        BadWordInfo modifyWord = new BadWordInfo(wordDr);

        // Update the properties
        modifyWord.WordAction = BadWordActionEnum.Replace;
        modifyWord.WordReplacement = "testpoliteword";

        // Save the changes
        BadWordInfoProvider.SetBadWordInfo(modifyWord);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates multiple bad words selected from database based on a WHERE condition.

```
private bool GetAndBulkUpdateBadWords()
{
    // Prepare the parameters
    string where = "[WordExpression] = 'testbadword'";

    // Get the data
    DataSet words = BadWordInfoProvider.GetBadWords(where, null);
    if (!DataHelper.DataSourceIsEmpty(words))
    {
        // Loop through the individual items
        foreach (DataRow wordDr in words.Tables[0].Rows)
```

```
{
    // Create object from DataRow
    BadWordInfo modifyWord = new BadWordInfo(wordDr);

    // Update the properties
    modifyWord.WordAction = BadWordActionEnum.Replace;
    modifyWord.WordReplacement = "testpoliteword";

    // Save the changes
    BadWordInfoProvider.SetBadWordInfo(modifyWord);
}

return true;
}

return false;
}
```

The following example deletes the bad word created by the first code example on this page.

```
private bool DeleteBadWord()
{
    // Prepare the parameters
    string where = "[WordExpression] = 'testbadword' ";

    // Get the data
    DataSet words = BadWordInfoProvider.GetBadWords(where, null);

    if (!DataHelper.DataSourceIsEmpty(words))
    {
        foreach (DataRow wordDr in words.Tables[0].Rows)
        {
            // Create object from DataRow
            BadWordInfo deleteWord = new BadWordInfo(wordDr);

            // Delete the bad word
            BadWordInfoProvider.DeleteBadWordInfo(deleteWord);
        }

        return true;
    }

    return false;
}
```

8.8.7.4.3 Performing bad word checks

The following example checks the declared custom string for presence of a single bad word.

```
private bool CheckSingleBadWord()
```

```
{
    // Prepare parameters for selection of the checked bad word
    string where = "[WordExpression] = 'testbadword' ";

    // Get the data
    DataSet words = BadWordInfoProvider.GetBadWords(where, null);

    if (!DataHelper.DataSourceIsEmpty(words))
    {
        // Get DataRow with bad word
        DataRow wordDr = words.Tables[0].Rows[0];

        // Get BadWordInfo object
        BadWordInfo badWord = new BadWordInfo(wordDr);

        // String to be checked for presence of the bad word
        string text = "This is a string containing the sample testbadword, which
        can be created by the first code example on this page.";

        // Hashtable that will contain found bad words
        Hashtable foundWords = new Hashtable();

        // Modify the string according to found bad words and return which action
        should be performed
        BadWordActionEnum action = BadWordInfoProvider.CheckBadWord(badWord, null,
        null, ref text, foundWords);

        if (foundWords.Count != 0)
        {
            switch (action)
            {
                case BadWordActionEnum.Deny:
                    // Some additional actions performed here ...
                    break;

                case BadWordActionEnum.RequestModeration:
                    // Some additional actions performed here ...
                    break;

                case BadWordActionEnum.Remove:
                    // Some additional actions performed here ...
                    break;

                case BadWordActionEnum.Replace:
                    // Some additional actions performed here ...
                    break;

                case BadWordActionEnum.ReportAbuse:
                    // Some additional actions performed here ...
                    break;

                case BadWordActionEnum.None:
                    // Some additional actions performed here ...
                    break;
            }
        }
    }
}
```

```
    }

    return true;
}

apiCheckSingleBadWord.ErrorMessage = "Bad word 'testbadword' is not
present in the checked string.";
return false;
}

return false;
}
```

The following example checks the declared custom string for presence of a all defined bad words.

```
private bool CheckAllBadWords()
{
    // String to be checked for presence of bad words
    string text = "This is a string containing the sample testbadword, which can
be created by the first code example on this page. It also contains the word
asshole, which is one of the default bad words defined in the system.";

    // Hashtable that will contain found bad words
    Hashtable foundWords = new Hashtable();

    // Modify the string according to found bad words and return which action
should be performed
    BadWordActionEnum action = BadWordInfoProvider.CheckAllBadWords(null, null,
ref text, foundWords);

    if (foundWords.Count != 0)
    {
        switch (action)
        {
            case BadWordActionEnum.Deny:
                // Some additional actions performed here ...
                break;

            case BadWordActionEnum.RequestModeration:
                // Some additional actions performed here ...
                break;

            case BadWordActionEnum.Remove:
                // Some additional actions performed here ...
                break;

            case BadWordActionEnum.Replace:
                // Some additional actions performed here ...
                break;

            case BadWordActionEnum.ReportAbuse:
                // Some additional actions performed here ...
                break;
        }
    }
}
```

```
        break;

        case BadWordActionEnum.None:
            // Some additional actions performed here ...
            break;
    }

    return true;
}

return false;
}
```

8.9 Banned IPs

8.9.1 Overview

The Banned IPs module is useful when you want to prevent users with certain IP addresses from accessing or using your website in a certain way. This typically happens when a user posts offensive material on a website (e.g. on a forum), harasses site members or behaves in some other unwanted way. IP banning can also be used to restrict access to your websites from certain areas of the world. These bans can be set either for individual websites or globally for all websites in the system.

To learn how to enable the Banned IPs module, please see the [Enabling IP banning](#) topic.

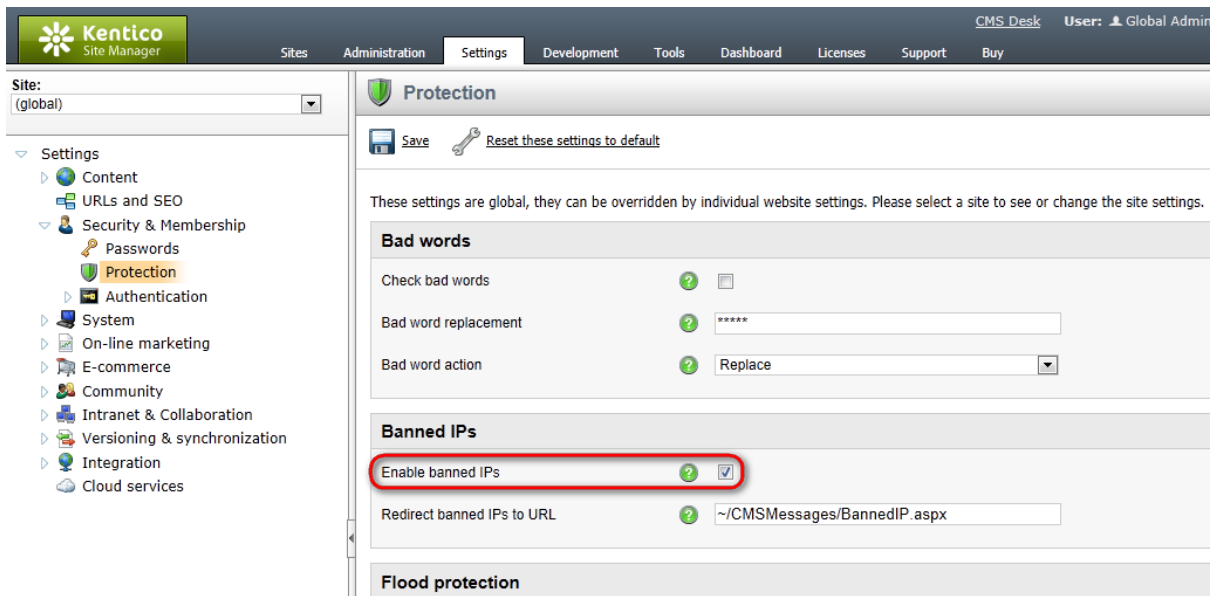

Adding banned IPs can easily be performed by site administrators. The [Banning an IP address](#) topic describes how. To find out how to determine which IP a user you want to ban is using, please see the [Finding an IP address](#) topic.

The [Banned IPs internals and API](#) sub-chapter provides information about the database tables and classes used by the module and examples of how banned IPs can be managed using the API.

IP banning is usually used as a last resort and there are other modules which can help you deal with offensive content and keep your website clean. Please refer to the [Modules -> Abuse report](#) and [Modules -> Bad words](#) chapters of this guide to read more. If you only wish to temporarily kick a user from a website, the [On-line users](#) module provides a way to do so.

8.9.2 Enabling IP banning

For the bans to take effect, go to **Site Manager -> Settings -> Security & Membership -> Protection**, select the appropriate site, check the **Enable banned IPs** check-box and click  **Save**. The bans should take effect now.

Users attempting to perform an action from an IP address that is banned will get a page with the following message displayed in their browsers (the HTTP response code of the page will be 403.6).

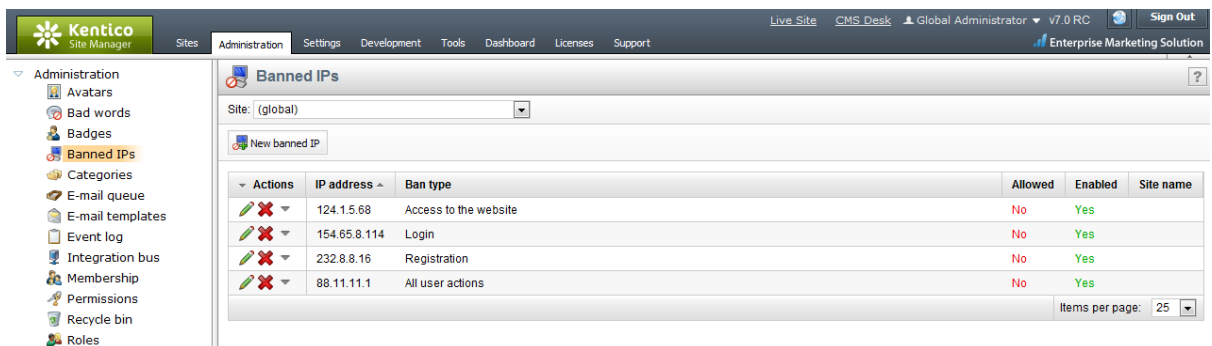

This is the default banned IPs redirect page, which can be found at `~/CMSMessages/BannedIP.aspx`. You can create your own page and set its URL in **Site Manager -> Settings -> Security & Membership -> Protection -> Redirect banned IPs to URL**.

8.9.3 Banning an IP address

Banned IPs can be managed in **Site Manager -> Administration -> Banned IPs**. Alternatively, you can access the same page from **CMS Desk -> Administration**, but you can manage banned IPs only for the currently edited site.

From the **Site** drop-down list, choose the site you want to add the IP for and click **New banned IP**.

Enter the required details:

| | |
|------------|--------------------------|
| IP Address | IP address to be banned. |
|------------|--------------------------|

| | |
|---|--|
| | The asterisk (*) wildcard can be used as a substitute for any number in the IP address, substituting for all values from 0 to 255.
Example: 192.168.1.* |
| Ban type | Type of the ban. The following types are available: <ul style="list-style-type: none"> • Access to the website - users cannot access the site from the entered address at all. • Login - users cannot log in from the entered address. • Registration - users cannot register from the entered address. • All user actions - users can enter the site from this IP, but they are not allowed to register or log in, and they are not allowed to add any content to the site (e.g., blog comments, board messages, etc.). |
| Enabled | If unchecked, the ban takes no effect. |
| Ban Reason | Text description of why the IP was banned. |
| Ban IP address | If selected, this IP address will be banned. |
| Allow IP address for this site if the IP address is banned globally | If selected, this IP address will be allowed for the selected site even if it is banned globally. |
| Allow site to override the ban | If checked, this ban can be overridden by bans set for particular sites; can be set only for global bans. |

 **New banned IP**

› [Banned IPs](#) › [New banned IP \(global\)](#)

IP address:

Ban type:

Enabled:

Ban reason:

Notorious forum spammer!

Ban IP address
 Allow IP address globally

Allow site to override the ban:

When you have all details entered, click **OK**.

Now if you go back to the list of banned IPs, you should see the newly created record present in the list.

Editing an existing ban

If you want to edit the record in the future, just go to the list and click the **Edit** (✎) icon next to the record. The same page will be displayed as when creating a new record, but with details entered. To make the desired changes, just change the appropriate values and click **OK**.

8.9.4 Finding an IP address

There are several ways to locate user IP addresses.

If you wish to find the IP address of a user responsible for a certain event, go to **Site Manager -> Administration -> Event log** and find the event you are interested in. The IP address of the user who caused the event has its own column in the displayed table and can also be viewed if you choose to click **Display event** (🔍). This can also be done at **CMS Desk -> Administration -> Event Log**, but here you can only view events from the currently edited site.

| Actions | Type | Event time | Source | Event code | User name | IP address | Document name | Site | Machine name |
|---------|------|----------------------|-------------------|--------------------|---------------|------------|---------------|----------------|--------------|
| 🔍 | I | 8/15/2011 3:12:33 PM | Application_Start | STARTAPP | administrator | :::1 | | | LUDMILAK-PC |
| 🔍 | W | 8/15/2011 3:12:22 PM | Application_End | ENDAPP | | | | | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 3:11:30 PM | Banned IP | CREATEOBJ | administrator | :::1 | | Corporate site | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 3:11:08 PM | Banned IP | CREATEOBJ | administrator | :::1 | | Corporate site | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 3:10:49 PM | Banned IP | CREATEOBJ | administrator | :::1 | | Corporate site | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 3:10:28 PM | Banned IP | CREATEOBJ | administrator | :::1 | | Corporate site | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 3:04:05 PM | Bad word | UPDATEOBJ | administrator | :::1 | | | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 2:50:47 PM | Page template | UPDATEOBJ | administrator | :::1 | | | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 2:50:12 PM | Authentication | AUTHENTICATIONSUCC | administrator | :::1 | | Corporate site | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 2:49:46 PM | Page template | UPDATEOBJ | administrator | :::1 | | | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 2:48:54 PM | Authentication | AUTHENTICATIONSUCC | administrator | :::1 | | Corporate site | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 2:47:52 PM | Authentication | AUTHENTICATIONSUCC | administrator | :::1 | | Corporate site | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 2:43:33 PM | Authentication | AUTHENTICATIONSUCC | administrator | :::1 | | Corporate site | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 2:27:09 PM | Bad word | UPDATEOBJ | administrator | :::1 | | | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 2:26:21 PM | Bad word | UPDATEOBJ | administrator | :::1 | | | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 2:08:43 PM | Application_Start | STARTAPP | administrator | :::1 | | | LUDMILAK-PC |
| 🔍 | W | 8/15/2011 2:08:31 PM | Application_End | ENDAPP | | | | | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 2:07:51 PM | Form item | CREATEOBJ | administrator | :::1 | | | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 2:07:07 PM | Form item | CREATEOBJ | administrator | :::1 | | | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 2:06:12 PM | Form item | CREATEOBJ | administrator | :::1 | | | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 2:05:26 PM | Form item | CREATEOBJ | administrator | :::1 | | | LUDMILAK-PC |
| 🔍 | I | 8/15/2011 1:43:03 PM | Bad word | CREATEOBJ | administrator | :::1 | | | LUDMILAK-PC |

For example, if you want to find a user who often uses Bad words, enter **BADWORD** into the **Event code** field of the event log filter and make sure **Contains** is selected. This displays a list of all Bad word violations and all relevant information including user names and their IP addresses.

To find the IP address used by a specific user when they last logged on, go to **Site Manager -> Administration -> Users**. Alternatively, you can access this information from **CMS Desk -> Administration -> Users**, but you can only see the users of the currently edited site.

Choose to **Edit** (✎) the user whose IP address you wish to find. It can be seen under **General -> Last logon information**. This can be useful if you get multiple abuse reports about some user and want to quickly find their IP address.

The screenshot shows the 'Users' management interface. The user profile for 'Andy' is displayed. The 'Last logon information' field is highlighted with a red circle, showing the IP address '192.168.3.12'. The interface includes tabs for 'Users', 'Mass e-mail', and 'On-line users'. The 'General' tab is selected, showing fields for user name, full name, first name, middle name, last name, and email. There are also checkboxes for 'Enabled', 'Is editor', 'Is global administrator', 'Is external user', 'Is domain user', and 'Is hidden'. The 'Preferred content culture' is set to '(default)' and the 'Preferred user interface culture' is set to 'English'. The 'Created' and 'Last logon' dates and times are shown. The 'Starting alias path' field is empty. An 'OK' button is at the bottom.

| | |
|-----------------------------------|--|
| User name:* | Andy |
| Full name: * | Andrew Jones |
| First name: | Andrew |
| Middle name: | |
| Last name: | Jones |
| E-mail: | andy@localhost.local |

| Starting alias path: | |

OK

8.9.5 Security

To limit access to the Banned IPs module, go to **Site Manager -> Administration -> Permissions** and grant roles with appropriate permissions according to your needs.

The following permissions can be assigned to the roles:

- **Modify** - members of the role are allowed to add, edit and delete banned IPs
- **Read** - members of the role are allowed to view the banned IPs list

 **Permissions**

Site:

Permissions for:

Report for user: Show only this user's roles

| Role | Read | Modify |
|------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> |

| Not authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |

8.9.6 Banned IPs internals and API

8.9.6.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Banned IPs module. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the module's classes, please refer to [Kentico CMS API Reference](#).

8.9.6.2 Database tables

The following database table is used to store information about banned IPs:

- **CMS_BannedIP** - contains records representing banned IP addresses.

CMS_Site

| Column Name | Data Type | Allow Nulls |
|------------------------|------------------|-------------------------------------|
| IPAddressID | int | <input type="checkbox"/> |
| IPAddress | nvarchar(100) | <input type="checkbox"/> |
| IPAddressRegular | nvarchar(200) | <input type="checkbox"/> |
| IPAddressAllowed | bit | <input type="checkbox"/> |
| IPAddressAllowOverride | bit | <input type="checkbox"/> |
| IPAddressBanReason | nvarchar(450) | <input checked="" type="checkbox"/> |
| IPAddressBanType | nvarchar(100) | <input type="checkbox"/> |
| IPAddressBanEnabled | bit | <input checked="" type="checkbox"/> |
| IPAddressSiteID | int | <input checked="" type="checkbox"/> |
| IPAddressGUID | uniqueidentifier | <input type="checkbox"/> |
| IPAddressLastModified | datetime | <input type="checkbox"/> |

8.9.6.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Banned IPs module can be found in the **CMS.SiteProvider** namespace.

CMS_BannedIP table API:

- **BannedIPInfo** - represents one banned IP address.
- **BannedIPInfoProvider** - provides management functionality for banned IPs.

8.9.6.4 API examples

8.9.6.4.1 Overview

The following topic shows examples of how the API of the Banned IPs module can be used:

- [Managing banned IPs](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Administration\BannedIP\Default.aspx.cs**.

The banned IP API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.SiteProvider;
```

8.9.6.4.2 Managing banned IPs

The following example adds a banned IP.

```
private void CreateBannedIp()
{
    // Create new banned ip object
    BannedIPInfo newIp = new BannedIPInfo();

    // Set the properties
    newIp.IPAddress = "MyNewIp";
    newIp.IPAddressBanReason = "Ban reason";
    newIp.IPAddressAllowed = true;
    newIp.IPAddressAllowOverride = true;
    newIp.IPAddressBanType = BannedIPInfoProvider.BanControlEnumString
(BanControlEnum.AllNonComplete);
    newIp.IPAddressBanEnabled = true;

    // Save the banned IP
    BannedIPInfoProvider.SetBannedIPInfo(newIp);
}
```

The following example gets and updates a banned IP.

```
private bool GetAndUpdateBannedIp()
{
    // Prepare the parameter
    string where = "IPAddress LIKE N'MyNewIp'";

    //Get the data
    DataSet ips = BannedIPInfoProvider.GetBannedIPs(where, null);

    if (!DataHelper.DataSourceIsEmpty(ips))
    {
        // Get the first banned ip
        BannedIPInfo modifyIp = new BannedIPInfo(ips.Tables[0].Rows[0]);
    }
}
```

```
        // Update the properties
        modifyIp.IPAddress = modifyIp.IPAddress.ToLower();

        // Save the changes
        BannedIPInfoProvider.SetBannedIPInfo(modifyIp);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates banned IPs.

```
private bool GetAndBulkUpdateBannedIps()
{
    // Prepare the parameters
    string where = "IPAddress LIKE N'MyNewIp%'";

    // Get the data
    DataSet ips = BannedIPInfoProvider.GetBannedIPs(where, null);
    if (!DataHelper.DataSourceIsEmpty(ips))
    {
        // Loop through the individual items
        foreach (DataRow ipDr in ips.Tables[0].Rows)
        {
            // Create object from DataRow
            BannedIPInfo modifyIp = new BannedIPInfo(ipDr);

            // Update the properties
            modifyIp.IPAddress = modifyIp.IPAddress.ToUpper();

            // Save the changes
            BannedIPInfoProvider.SetBannedIPInfo(modifyIp);
        }

        return true;
    }

    return false;
}
```

The following example removes a banned IP.

```
private bool DeleteBannedIp()
{
    string where = "IPAddress LIKE N'MyNewIp%'";

    // Get DataSet
    DataSet ips = BannedIPInfoProvider.GetBannedIPs(where, null);
}
```

```
if (!DataHelper.DataSourceIsEmpty(ips))
{
    // Get the first banned ip
    BannedIPInfo deleteIp = new BannedIPInfo(ips.Tables[0].Rows[0]);

    // Delete the banned ip
    BannedIPInfoProvider.DeleteBannedIPInfo(deleteIp);

    return true;
}

return false;
}
```

The method in the following example returns *true* if the specified IP address is banned for the current site, otherwise it returns *false*.

```
private bool CheckBannedIp()
{
    // Prepare the parameter
    string where = "IPAddress LIKE N'MyNewIp'";

    // Get DataSet
    DataSet ips = BannedIPInfoProvider.GetBannedIPs(where, null);

    if (!DataHelper.DataSourceIsEmpty(ips))
    {
        // Get the first banned ip
        BannedIPInfo checkIp = new BannedIPInfo(ips.Tables[0].Rows[0]);

        if (!BannedIPInfoProvider.IsAllowed(checkIp.IPAddress,
            CMSContext.CurrentSiteName, BanControlEnum.AllNonComplete))
        {
            return true;
        }
    }

    return false;
}
```

8.10 Banner management

8.10.1 Overview

The Banner management module provides means to create, manage and display advertisements or other content in the form of banners. It also allows you to monitor statistics, namely impressions (banner views) and clicks. The banners are organized into categories, of which there are two types:

- **Global banner category** - shared across multiple websites.
- **Site banner category** - bound to a particular site and not accessible from the other sites.

The module incorporates the [Banner rotator](#) web part, which you can use to display banners from a specified banner category. When a user views a page where you placed the Banner rotator, the web part chooses a banner from the category and displays it to the visitor. The banner is rendered as a link to a URL which can be entered in the banner's properties.

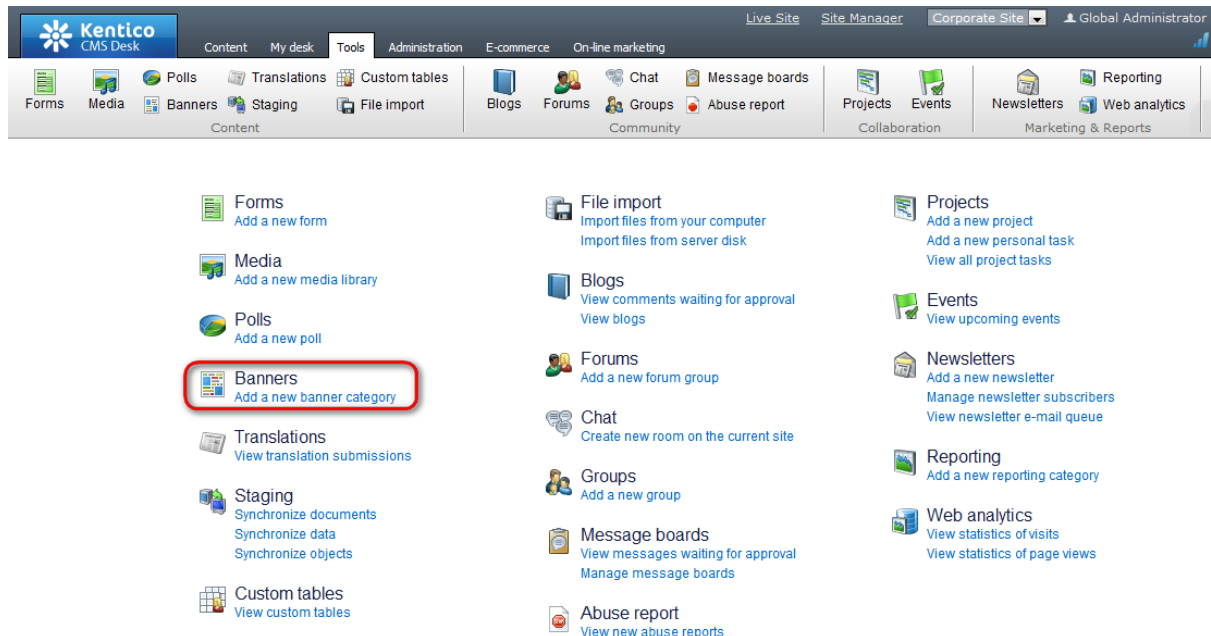

The Banner management module utilizes the built-in [Web analytics](#) and [Reporting](#) modules to log and display how many times a particular banner has been shown on a page (number of impressions) and how many times visitors have clicked the banner. You can find the following topics in this chapter:

- The [Managing banners](#) topic teaches you how to create and manage banners and their categories.
- The [Placing banners on a page](#) topic shows you how to display banners on the live site.
- The [Statistics](#) topic explains how you can view and administer the statistics that the module records.
- The [Example of use](#) topic guides you through the whole process of managing banners on your site.

8.10.2 Managing banners

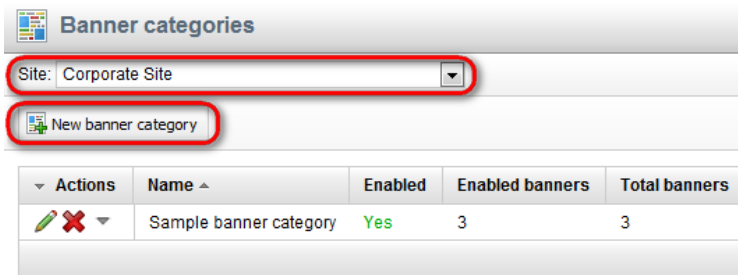

This topic will show you how to [create](#) and [edit](#) banner categories and the difference between global and site-bound categories. You will also learn about [creating](#) and [editing](#) banner categories.

Banners and their categories can be managed in **CMS Desk -> Tools -> Banners**.

Creating a new category

First, choose whether the new category will be site-bound or global by selecting an option from the **Site** drop-down list.

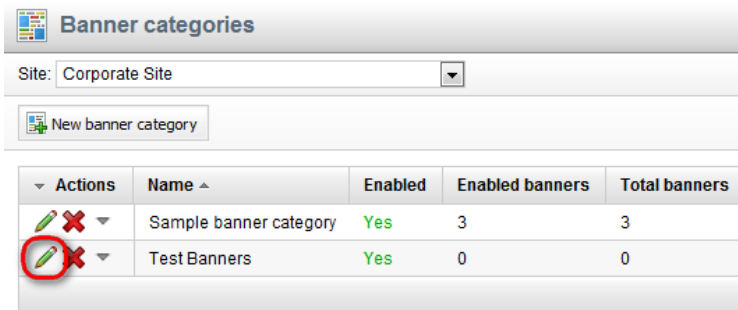

Then, click **New banner category** and fill in the following fields:

- **Display name** - the name of the banner category displayed in the user interface.
- **Code name** - the name of the banner category used in code.
- **Enabled** - turn the checkbox on to allow the banners from this category to be displayed on the live site.

After filling in the required fields, click **Save** .

Editing an existing category

To edit a banner category, first select a site, then click the **Edit** icon next to the category you want to modify. The category properties can be edited on the **General** tab.

Creating a new banner

To create a new banner, **Edit** a category in which you want to create the banner. Then, on the **Banners** tab, click **New banner**.

You will be presented with a form offering a set of banner properties. The following properties are common for all types of banners:

- **Display name** - the name of the banner displayed in the user interface.

- **Code name** - the name of the banner used in code.
- **URL** - URL of the resource you want the banner to link to.
- **Weight** - decimal number that indicates the frequency in which the banner will be displayed on the live site. See the [Placing banners on a page](#) and [Example](#) topic for more information.
- **Open in new window** - indicates if the banner link will be opened in a new window.
- **Enabled** - Determines whether the banner will be displayed on the live site or not.
- **Valid from** - time from which the banner will be displayed on the live site.
- **Valid to** - time after which the banner will stop being displayed on the live site.
- **Impressions left** - determines how many times the banner will be displayed on the live site at most:
 - *Number of impressions is not limited* - choose this option if you don't want to limit the number of times a banner can be displayed.
 - *Allow only specific number of impressions* - allows you to specify how many times will the banner be displayed on the live site before the web part stops displaying it. Specify the number and click *Add*.
- **Clicks left** - determines how many times the banner will be clicked on the live site at most.
 - *Number of clicks is not limited* - choose this option if you want the number of times a banner can be clicked to be unlimited.
 - *Allow only specific number of clicks* - by choosing this option, you can specify the number of times the banner can be clicked on the live site before the web part stops displaying it. Enter the number and click *Add*.

You can choose from three banner types using the **Banner type** drop-down list:

- **Plain text** - the banner will consist of plain text only.
- **HTML** - you will be able to edit this type of banner using the built-in [WYSIWYG editor](#).
- **Image** - the banner will have the form of an image which you'll be able to select using the standard *Select image* dialog.

You will be offered additional configuration options depending on the selected type of banner:

| Banner type | Configuration options |
|-------------|--|
| Plain text | <ul style="list-style-type: none"> • Banner content - plain text, which will represent the banner. You can also enter HTML tags. |
| HTML | <ul style="list-style-type: none"> • Banner content - any HTML content, which can be edited using the WYSIWYG editor. |
| Image | <ul style="list-style-type: none"> • Banner image - allows you to select an image from the <i>content tree</i>, a media library, or enter a URL of any image on the web. • Image title - text which will be rendered into the title attribute of the image tag. • Alternative text - text which will be rendered into the alt attribute of the image tag. • Image CSS class - CSS class of the image tag. • Image CSS style - in-line CSS style that will be rendered for the image tag. |

Click  **Save** once you have set the banner properties.

Editing an existing banner

A banner can be edited by clicking the **Edit**  icon in the list of banners under a selected banner category.

Banner category properties

> Banner categories > Test Banners

Banners General Report

New banner

| Actions | Name | Banner type | URL | Weight | Impressions left | Clicks left | Enabled | Valid from | Valid to |
|---|----------|-------------|----------------------------|--------|------------------|-------------|---------|----------------------|-----------------------|
|   | Banner 1 | Plain | http://www.kentico.com | 5 | Unlimited | Unlimited | Yes | 6/20/2012 9:47:17 AM | 12/21/2012 9:47:18 AM |
|   | Banner 2 | Image | http://partner.kentico.com | 3 | 400 | Unlimited | Yes | 6/20/2012 9:44:31 AM | 12/21/2012 9:44:33 AM |
|   | Banner 3 | HTML | http://devnet.kentico.com | 2 | Unlimited | 1000 | Yes | 6/19/2012 9:50:37 PM | 12/21/2012 9:50:38 PM |

Items per page: 25

For more information about the way banners are displayed and how these attributes influence whether a banner is shown, refer to the [Displaying banners](#) section in the [Placing banners on a page](#) topic.

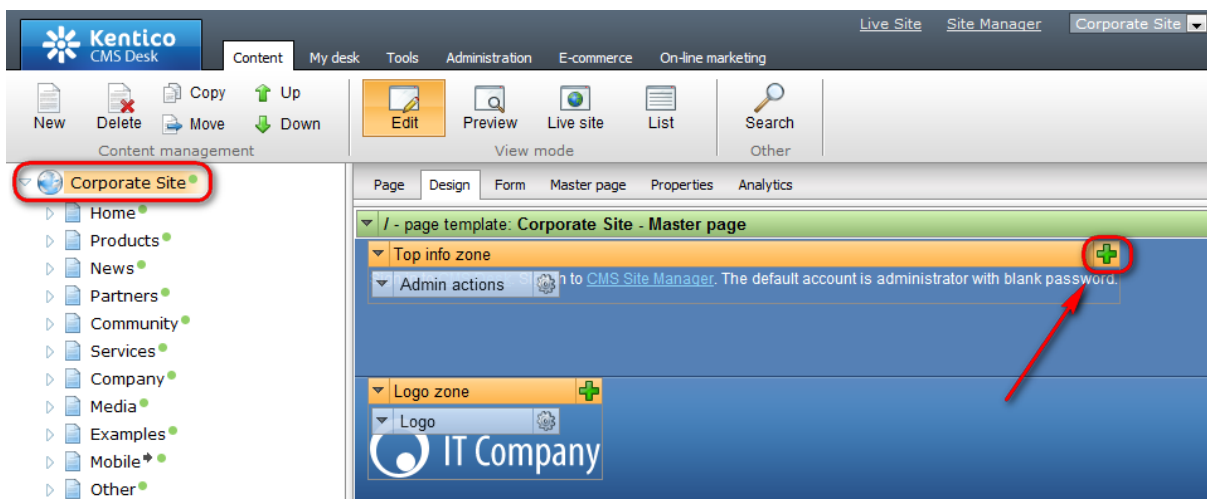

8.10.3 Placing banners on a page

In this chapter, you will learn how to display banners on your website. You will see a complete example of using the Banner management module and its associated web part to show your visitors the most relevant and up-to-date ads.

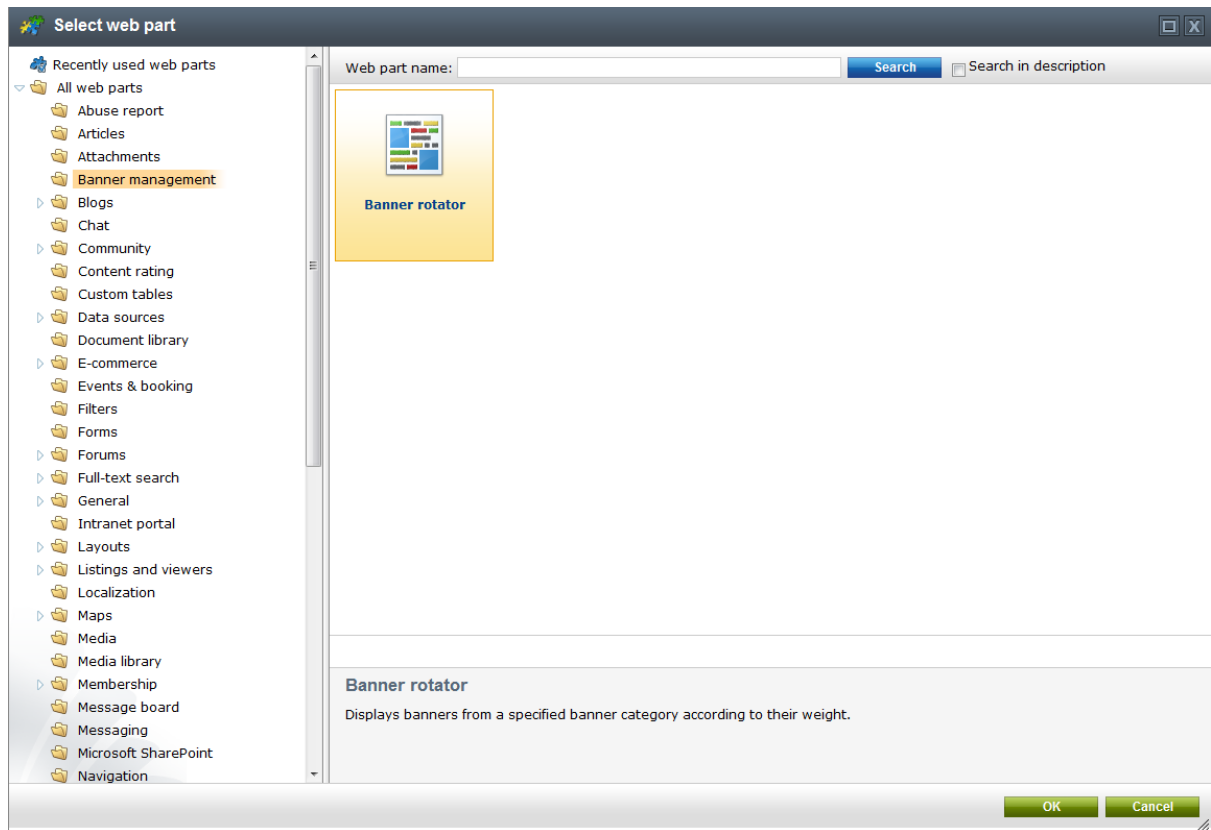

Banner rotator web part

The Banner rotator displays banners from a specified category. When you place the web part on a page, it renders the value stored in the [Banner content](#) property of the banner, encapsulated in an <a>(anchor) element.

To place the web part on your page, navigate to **CMS Desk -> Content -> Edit -> Design tab** and choose the root document of the website in the **content tree**. Then, click on the **Add web part (+)** button of the **Top info** web part zone.

In the **Select web part** dialog, choose **All web parts -> Banner management -> Banner rotator**. Click **OK** to confirm the selection.

In the **Web part properties** dialog, you can configure the way the banner is displayed by adjusting the web part's properties:

- **Category** - allows you to select the category from which you want to display banners.
- **Hide web part if no banner was found** - when turned on, hides the web part if no banner is found, i.e., if there are no banners in the source category or if the category gets deleted.
- **Width** - defines the width of the banner. The value will be rendered as an in-line style of the encapsulating anchor.
- **Height** - defines the height of the banner. The value will be rendered as an in-line style of the encapsulating anchor.
- **Anchor CSS class** - specifies the CSS class of the anchor element.
- **Use direct banner URL** - determines whether the **href** attribute of the anchor will point to the actual banner URL instead of the default redirection handler. However, the **href** attribute's value will be changed to the redirection handler when the site visitor clicks the link, so as to log the click into the Web analytics log.
- **Keep previous banner on postback** - when turned on, makes sure the same banner is displayed when a postback is made on the page, e.g., when the visitor makes a search or logs in. Also, impressions made on a postback won't count into statistics.

General

Banner category*:

Hide web part if no banner was found:

Width:

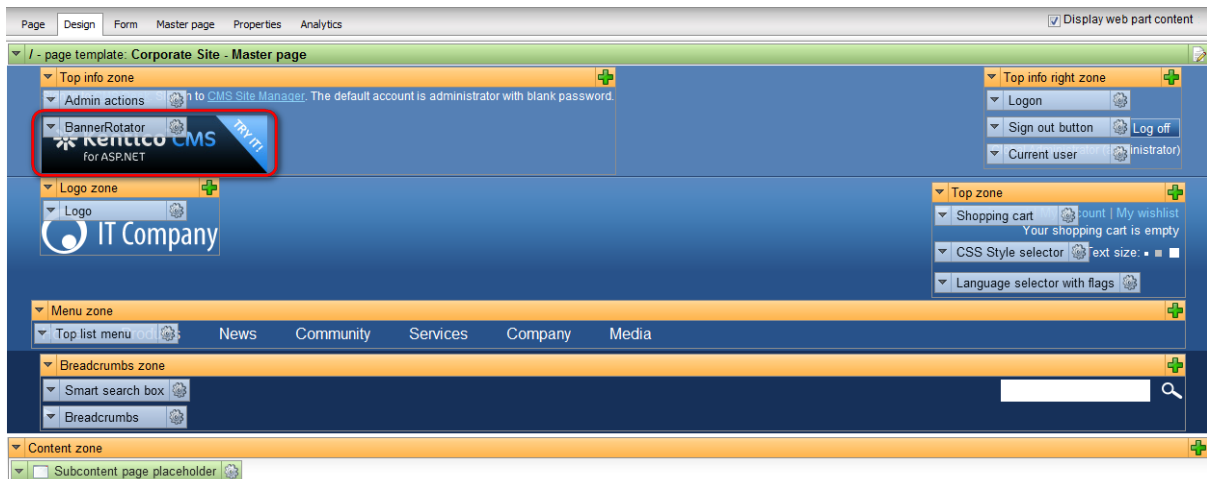

Height:

Anchor CSS class:

Use direct banner URL:

Keep previous banner on postback:

The following image shows a banner management web part placed on the root page of the sample Corporate site.

You can find more information on working with web parts in Kentico CMS in [Development -> Web parts](#).

Banner rotator widget

A widget for displaying banners is also shipped with the Banner management module. In contrast to the web part, its group of settings is limited to the following:

- Category
- Width
- Height

To learn more about widgets and their role on websites, refer to the [Development -> Widgets](#) chapter.

Displaying banners

When a user requests a page that contains the Banner rotator web part, the web part selects a banner from the specified category and displays it.

The following factors are taken into account when selecting a banner:

- The **Enabled** property of a banner must be true in order for the banner to be selected.
- Current time must be between the **Valid from** and **Valid to** properties' values.
- The **Impressions left** attribute must have a value greater than zero.
- The **Clicks left** attribute has to be greater than zero.

Another parameter that plays part in the process of selecting banners is the **Weight** property. The higher the weight of a banner, the more often that particular banner is selected by the rotator. The number is decimal, which means you can set a new banner between existing ones without changing their values. For example, if you have two banners with values 4 and 5, you can add a new one with weight set to 4.5.

8.10.4 Statistics

The Banner management module offers logging of banner impressions (views) and clicks via the built-in [Web analytics](#) and [Reporting](#) modules, so that you can see which banners draw most attention from your site's visitors. You can view the overall statistics of a banner category or display a detailed report about a single banner. This chapter describes how you can view and adjust these reports.

Category report

To view reports for a banner category, navigate to **CMS Desk -> Tools -> Banners, Edit** (✎) the banner category and switch to the **Report** tab. You can do the following in the tab:

-  **Save** the report for later use. You can find the saved reports in *CMS Desk -> Tools -> Banner management -> Banner impressions and clicks by category -> Saved reports* tab.
-  **Print** the report.
-  **Subscribe** to the report to have it sent in specified intervals via e-mail.
- Click the **Update** button to redraw the report for the period specified in the *From* and *To* dates.
- Right-click the table to  **Subscribe** to the report via e-mail.

Banner report

On the **Banners tab, Edit** (✎) a banner and switch to the **Report** tab to view statistics for the particular banner. You can do the following in the tab:

-  **Save** the report for later use. You can find the saved reports in *CMS Desk -> Tools -> Banner management -> Banner impressions and clicks by category -> Saved reports* tab.
-  **Print** the report.
-  **Subscribe** to the report to have it sent in specified intervals via e-mail.
- Click the **Update** button to redraw the report for the period specified in the *From* and *To* dates.
- Right-click the graph to export the report to  **Excel**,  **CSV** and  **XML**, or to  **Subscribe** to the report via e-mail.

Tip

Additional reports for the Banner management module can be found in **CMS Desk -> Tools -> Reporting**, in the **Web analytics** report category.

For more information about the Reporting module, see its [documentation](#).

8.10.5 Example of use

This example will show you the whole process of banner management, from creating a banner category and filling it with banners, to displaying the banners on a site. The example will use the sample Corporate site.

Creating banners

1. Log in to **CMS Desk**, switch to the **Tools** tab and select **Banners**.
2. In the **Site** drop-down list, select **Corporate site** and click **New banner category**.

| Actions | Name ^ | Enabled | Enabled banners | Total banners |
|---------|------------------------|---------|-----------------|---------------|
| | Sample banner category | Yes | 3 | 3 |
| | Test Banners | Yes | 3 | 3 |

3. Set the banner category properties as follows:

- **Display name:** Header banners
- **Enabled:** True

Display name:

Code name: (automatic)

Enabled:

4. Click **Save** and then **New banner**.

5. Set the new banner's properties as follows:

- **Display name:** Banner 1
- **URL:** <http://www.kentico.com>
- **Weight:** 1
- **Open in new window:** True
- **Enabled:** True
- **Banner type:** Plain text
- **Banner content:** Any text you like

General

13. Click **Save**.

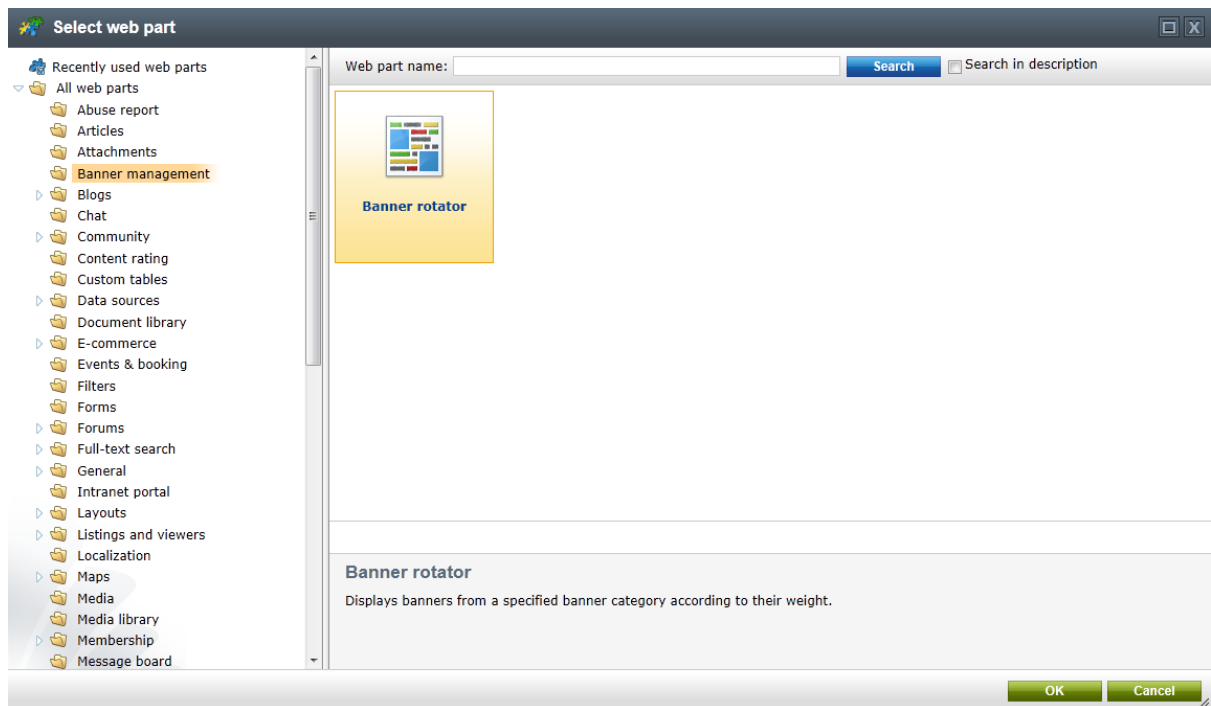

Placing banners on a page

You have created a set of banners that will rotate in the header of the Corporate site. Now place the Banner rotator web part on the Corporate site's master page as described in the following steps:

1. In **CMS Desk**, switch to the **Content** tab and choose **Edit**.
2. Select the root of the Corporate site and switch to **Design** tab.
3. Click **Add web part** in the **Top info** web part zone.

4. In the **Select web part** dialog, choose the **All web parts** -> **Banner management** -> **Banner rotator** web part.

5. In the **Web part properties** dialog, select the **Header banners** category created earlier.

6. Enter the banner's dimensions and optionally set the rest of the properties.

Web part properties (Banner rotator)

General

Visibility

General

Banner category*: headerBanners

Hide web part if no banner was found:

Width: 234

Height: 60

Anchor CSS class: Banner

Use direct banner URL:

Keep previous banner on postback:

Web part container

Web part container: (none)

Refresh content

7. Click **OK** to insert the web part.

The result

You have created three sample banners and configured the Banner rotator web part to display them to visitors in the header of the Corporate site.

When you switch to the live site, you will be presented with one of the three banners. When you refresh the page several times, the other banners will appear with frequency proportional to their **Weight**. For example, out of 100 page views, the banners' displaying frequency will be as follows:

- **Banner 1** has a weight of 1, therefore it will be displayed approximately 10 times.
- **Banner 2** has a weight of 4, therefore it will be displayed approximately 40 times.
- **Banner 3** has a weight of 5, therefore it will be displayed approximately 50 times.

8.11 Blogs

8.11.1 Overview

The Blogs module allows you to publish a personal or company blog, which is a frequent, chronological publication of one's thoughts and web links. You can publish multiple blogs on the same site and there can be multiple editors for each blog.

Blogs

This section contains a sample blog. Any number of blogs can be published here, while blogs published in this section can only be created via the system's administration interface. If you are running a corporate blog, you can set up a workflow process for approval of blog posts before they are published. Blogs are standard documents in the content tree, while the whole functionality is provided by the **Blogs** module. To learn more about the module, please refer to [Kentico CMS Developer's Guide -> Modules -> Blogs](#).

Company Blogs

The Blogs module fully leverages the standard content management engine, so every blog post you create is a standard document that can be displayed on the website, searched, etc. You can also configure permissions and workflow for every blog as you're used to do with other content.

- To see an example of blog, please refer to a [sample blog](#) on the Corporate Site sample website.
- To learn how to create a new blog on the sample Corporate Site, please refer to the [Adding a blog to your site](#) topic.
- To learn how to add posts to your blog, please refer to the [Adding posts to your blog](#) topic.
- To learn how comments can be moderated, please follow the [Moderating comments](#) topic.
- To learn how to configure the layout and design of your blog, please follow the [Blog layout and design](#) topic.
- To learn how to enable users to perform selected tasks using the [User contributions](#) module web parts, please refer to the [On-site management via User contributions](#) topic.
- If you would like to adjust the settings and security of the Blogs module, please refer to the [Settings](#) and [Security](#) topics respectively.
- To learn how to deal with blog post documents using standard API for documents, please refer to the [Blogs internals and API](#) chapter.

Subchapters on [trackbacking](#) and on a programming interface enabling co-operation of the Blogs module with external programs, [MetaWeblog API](#), and topics related to Blog comments notifications ([Who can be notified](#), [User subscriptions](#) and [E-mail templates](#)) are also available in the Blogs chapter.

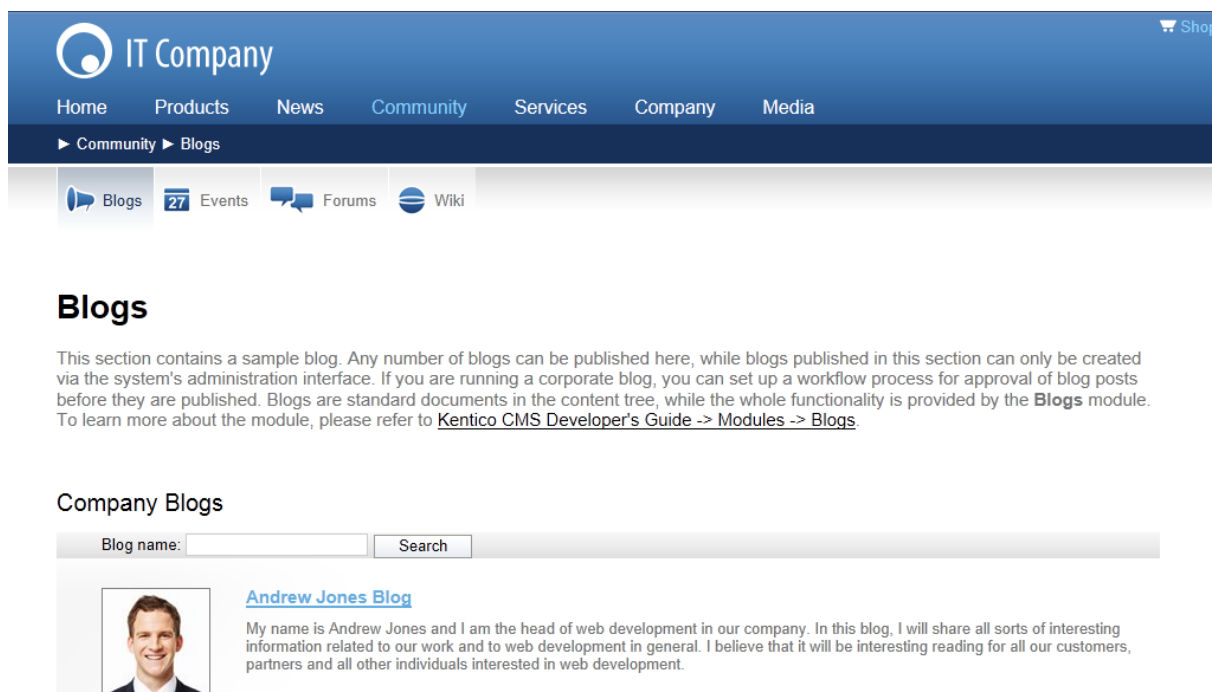

If you would like to compare the Corporate Site sample blog with a more detailed example of blogging, please switch to the Community Site sample website where you can find not only blogs with blog posts but also a tag cloud. The [Tag cloud web part](#) is used to display key words, called tags that are associated with a document, and is convenient for simple marking of documents according to various criteria, e.g. your interests.

Kentico CMS Community Site Guide contains some additional examples and tutorials related to blogs:

You will learn not only how to create a page on blogs (learn [here](#) how to do it) but also how to create a special page where users are redirected when they want to create a new blog (as explained [here](#)), a page that displays a list of all blogs on the site (as explained [here](#)) or how to create a page where only blog posts corresponding to the selected tag from the tag cloud are displayed (as explained [here](#)).

8.11.2 Sample blog

To see a sample blog, on the sample Corporate Site switch to the live site and from the main menu, choose **Community -> Blogs**. The **Blogs** page displays a list of blogs, each of which can be accessed by clicking on the particular blog link.

Blogs

This section contains a sample blog. Any number of blogs can be published here, while blogs published in this section can only be created via the system's administration interface. If you are running a corporate blog, you can set up a workflow process for approval of blog posts before they are published. Blogs are standard documents in the content tree, while the whole functionality is provided by the **Blogs** module. To learn more about the module, please refer to [Kentico CMS Developer's Guide -> Modules -> Blogs](#).

Company Blogs

Blog name:

 [Andrew Jones Blog](#)

My name is Andrew Jones and I am the head of web development in our company. In this blog, I will share all sorts of interesting information related to our work and to web development in general. I believe that it will be interesting reading for all our customers, partners and all other individuals interested in web development.

After clicking the chosen blog link, a new page with a list of blog posts and some additional information is displayed. As you can see, the additional information such as blog description, [tags](#), favorite websites, recent posts, RSS feed link and post archive is displayed on the right of the page.

The screenshot displays the user interface of a Kentico CMS 7.0 website. At the top, there is a blue header with the 'IT Company' logo and navigation links: Home, Products, News, Community, Services, Company, and Media. A shopping cart icon and account links are visible in the top right. Below the header is a dark blue breadcrumb trail: Community > Blogs > Andrew Jones Blog. A search bar is located on the right side of the breadcrumb trail. Below the breadcrumb trail is a horizontal menu with icons for Blogs, Events (27), Forums, and Wiki. The main content area features the title 'Andrew Jones Blog' and a short introductory paragraph. To the right, there is an 'About This Blog' section with a bio for Andrew Jones. Below the introduction is a search bar for blog posts. Two blog posts are listed: 'Remote Management' (dated 3/23/2011 3:12:26 PM) and 'Expanding to Europe' (dated 3/21/2011 5:57:47 PM). Each post includes a small image, a title, a short description, and a link to '2 comments'. A 'Tags' section on the right lists various tags such as 'communication', 'employees', 'europe', 'hiring', 'infrastructure', 'intranet', 'London', 'management', and 'office'.

Finally, when you click on some particular blog post link, you can see the text plus the **Comments** section that allows you to read and add comments to the blog post. Additional information related to the current blog is also available.

Remote Management

In this blog post, I will share some remarks regarding communication between our former New York Office and the newly setup London Office.

As you have learned from my [previous blog post](#), we have recently set up a new office in London, UK. I was involved in the whole setup process from its very beginning, but after the initial phase, I am back home in the US. Due to the fact that I am the head of web development in Our Company, it is within my responsibilities to oversee all work carried out by the London Office as well. And here comes the question about how to do this effectively while being on the other side of the Atlantic Ocean.

The first thing that is essential for successful remote management is trust. You simply have to believe that the people in the other office are competent enough and that you do not have to micro-manage their work. I paid special attention to choose the right people during the hiring process, so the trust I was talking about is definitely in place.

Not less important is to establish suitable communication channels. Traditional e-mails are a must, while using Skype for instant messaging and voice chat is a great and cost-free option. But what really did the job in our case was our new intranet based on Kentico Intranet Solution. This is a full-featured intranet solution based on Kentico CMS, the ASP.NET web content management system. It showed its true potential by enabling us to create an internal knowledge base to share our know-how, manage projects by means of its integrated project management features, have dedicated website sections for particular departments, etc. And it is all web-based, so we have a single intranet solution accessible from anywhere used by the both of our offices.

Comments

Andrew Jones

Hello Paul, yes, I strongly recommend giving it a try. If you already have experience with Kentico CMS, it will be a piece of cake for you to set it up. It has loads of Intranet-specific features out of the box. And with the endless customization possibilities the CMS provides, any functionality that you can imagine is achievable.

Paul Woods

Hi Andrew, great to know about the Intranet Solution by Kentico. I knew they were producing a brilliant CMS, but I didn't realize it could be used for intranet purposes. I'll definitely try it out and see if it suits our purposes. We are planning to update our intranet soon as the one we've got now is just terrible and not sufficient anymore.

8.11.3 Adding a blog to your site

In this example, you will learn how to create a new blog on the sample Corporate Site, under the Blogs section.

1. Sign in to **CMS Desk**. In the **Content** section, navigate to **Community -> Blogs** and click  **New**. Choose to create a new **Blog**. Enter the following details:

- **Blog name:** My new blog
- **Blog description:** This is my new blog.
- **Side column text:** I like this website.
- **Open comments for:** Always
- **Send comments to e-mail:** enter your e-mail address
- **Allow anonymous comments:** yes
- **Use CAPTCHA for comments:** yes (this will require a verification of the number displayed in the picture to avoid spam posts)
- **Moderate comments:** yes

The following fields are also available, but you don't need to enter them for the purpose of this example:

- **Blog Teaser** - blog teaser image displayed in blog lists.
- **Require e-mail address** - indicates if e-mail address is required when adding a blog comment.
- **Unsubscription URL** - URL of a page with the Blog post unsubscription web part, which handles blog post unsubscription requests from links contained in blog post notifications.
- **Enable subscriptions** - indicates if subscriptions to notifications about new blog comments are enabled.
- **Blog moderators** - users who can moderate blog post comments.
- **Enable trackbacks** - indicates if the trackbacking feature is enabled.
- **Publish from** - date and time from when the blog will be published on the site.
- **Publish to** - date and time until when the blog will be published on the site.

There are also settings related to blog comments subscriptions. To learn more about these settings and the functionality they affect, refer to the [User subscriptions](#) topic.

- **Enable double opt-in** - indicates if double opt-in should be enabled for blog post comments. When enabled, users are required to confirm their subscription by clicking a link that is sent to them in an e-mail.
- **Approval page path** - path to the page that contains the Blog post subscription confirmation web part. The subscription confirmation link that will be sent to users will point to this page.
- **Send confirmation** - indicates if an e-mail confirmation should be sent to user after they approve a subscription. If double opt-in is disabled, these confirmation e-mails are always sent.

Publishing

Publish from: Now

Publish to: Now

Click **Save**. You have just created your blog. However, there are two additional steps you need to do:

- Go to the **Properties -> Template** dialog, click **Select** and choose the **Corporate Site - Blog detail** page template. Set the **Inherit content** value to **Select inherited levels** and choose only the **Root**. It ensures that the page displays the master page and then your blog content.

Click  **Save**.

Adding a blog on the live site

You can enable users to create blogs directly on the live site by adding the **New blog** web part to your site. Like this, users can only add the name and description of their new blog. All other blog properties, listed earlier in this article, will be taken from the web part's properties.

Blog name:

Blog description:

8.11.4 Adding posts to your blog

You can add new posts to your blog in two ways:

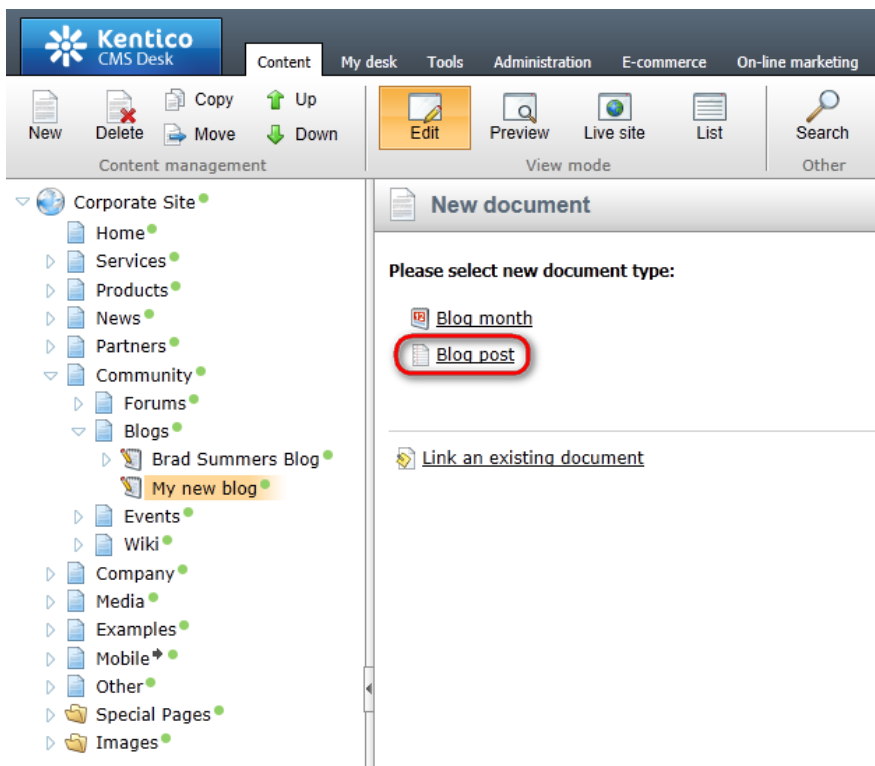

1. From the CMS Desk -> My Desk -> Blogs dialog

This dialog displays the list of blogs you are owner of (you can set the owner in the **Properties -> General** dialog of the blog document). Here you can click the **New post** () icon and you will be displayed with form for inserting the post:

2. In the Content section

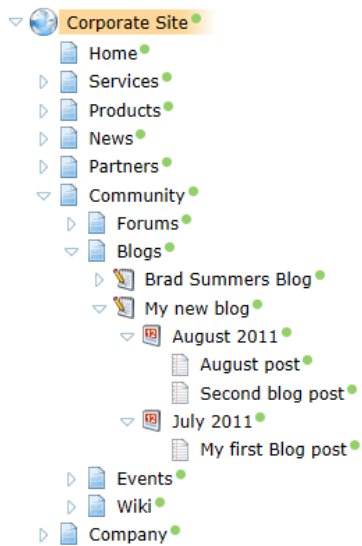

Choose the **Content** tab in **CMS Desk**, select the blog's main document and then click **New**. Choose to create a new **Blog post**:

Enter the post content and click **Save**.

Document structure

In both cases, the blog post will be automatically saved under the appropriate month. If the month is not created yet, it's created automatically, so you do not need to care about creating a month. The months allows you to easily organize the blog posts. The structure of **Blog**, **Blog month** and **Blog post** documents looks like this:

When you sign out and go to your blog, you will see a page like this:

8.11.5 Moderating comments

The comments can be moderated in tree ways:

1. In the My Desk -> Blogs section

In this section, currently logged-in users can manage comments at all their own blogs. Neither the **Read** nor **Manage comments** permissions for the Blogs module are necessary for the user to perform blog comments management in this section.

Comments can be approved by clicking the **Approve** (✓) icon. More comments can be approved at once when you select them by the check-boxes, choose the **Approve** (✓) action in the **Selected items** drop-down list and click **OK**.

Blog:

User name:

Text:

Is approved:

Is SPAM:

| <input type="checkbox"/> | Actions | User name | Comment text | Approved | Is SPAM | Inserted |
|--------------------------|---------|-----------|---------------------------------|----------|---------|----------------------|
| <input type="checkbox"/> | | Henry | Too long for me... | No | No | 8/19/2011 6:28:54 PM |
| <input type="checkbox"/> | | Kelly | Your trip must have been great! | No | No | 8/19/2011 6:28:02 PM |

Selected items:

2. In the CMS Desk -> Tools -> Blogs section

In this section, management of blog comments on the site is possible based on the permissions:

Global administrators and users with the **Manage comments** permission for the Blogs module can manage comments of all blogs on the current site. Blog **moderators** and blog **owners** can manage comments of their own blogs and blogs for that they are moderators. These permissions are reflected by the **Blog** drop-down list, which displays only those blogs where comments can be managed by the current user.

Comments can be approved by clicking the **Approve** (✓) icon. More comments can be approved at once when you select them by the check-boxes, choose the **Approve** (✓) action in the **Selected items** drop-down list and click **OK**.

Selected items: (select an action) OK

3. On-site management

When you're signed in and are entitled to manage the comments for the given blog, you are displayed with **Edit**, **Delete**, **Approve** and **Reject** buttons. These buttons are displayed to **blog owners**, **moderators** of the current blog, **global administrators** and users with the **Manage comments** permissions for the Blogs module.

8.11.6 Blog layout and design

You can configure the blog layout and design by changing the page template of the blog document. Locate your blog in the **CMS Desk** -> **Content** section and choose the **Design** tab. You will see a page like this:

The blog is displayed using the Blog page template. The web parts ensure displaying of the blog content, comments and boxes in the right-hand column.

There are two repeaters to display the posts:

- **rptMonthPosts** - this repeater is used to display posts in the given month
- **rptAllPosts** - this repeater is used to display the latest N posts when the blog is displayed without selecting a particular month

If you need to modify the layout of the blog posts, you need to modify the transformations. By default, the following transformations are used:

- **cms.blog.PostPreview** - the view in the list of posts
- **cms.blogpost.Default** - the detailed view

8.11.7 On-site management via User contributions

You can enable users to perform the following tasks using the [User contributions](#) module web parts:

- **Edit blog properties**
- **Edit or delete blog posts**
- **Add new blog posts**

A live example of this can be found on the sample **Community Starter site**, on the **Blogs** title page. If you go to CMS Desk's **Design** tab and view the page, you will see the following web parts, which enable the above mentioned functionalities:

- **EditBlog** - Edit contribution web part set up for enabling blog properties editing
- **EditBlogPost** - Edit contribution web part set up for enabling blog post editing
- **NewBlogPost** - Contribution list web part set up for enabling adding of blog posts

These web parts are inherited by the underlying pages, which means they will be displayed when a blog or blog post is displayed. The following sections explain how to enable users to perform these tasks on the live site.

Edit blog properties

1. Create an **alternative form** for the **Blog** document type, which will contain the fields that you want to let users modify. If you are not familiar with the Alternative forms concept, please refer to the [Alternative forms](#) chapter first.
2. Add the **Edit contribution** web part to the blogs section title page and set its following properties:

- **Show for document types** - CMS.Blog
- **Alternative form name** - code name of the alternative form created in step 1
- **Edit button label** - Edit blog
- **Allow editing by users** - Document owner; this is the setting that makes the most sense as blog properties should be edited only by the blog's owner

If you go to the live site and display some blog placed under the blogs section title page, you should see the **Edit blog** link as highlighted in the screenshot below. After clicking the link, the alternative form will be displayed, letting blog owners edit the properties of the blog.

Abi's european trip

Edit blog

New blog post

Saying goodbye Europe

Add new blog posts

1. Create an **alternative form** for the **Blog post** document type, which will contain the fields that you want to let users to specify when creating the blog post. If you are not familiar with the Alternative forms concept, please refer to the [Alternative forms](#) chapter first.

2. Add the **Contributions list** web part to the blogs section title page. You only need to set the following properties, as the web part will not be used for displaying blog posts, but only for their inserting.

- **Show for document types** - CMS.Blog
- **Allowed new document types** - CMS.BlogPost
- **Alternative form name** - code name of the alternative form created in step 1
- **New item button label** - New blog post
- **Allow insert** - enable
- **Allow editing by users** - Document owner; this is the setting that makes the most sense as blog posts should be edited only by the blog's owner

If you go to the live site and display some blog placed under the blogs section title page, you should see the **New blog post** link as highlighted in the screenshot below. After clicking the link, the alternative form will be displayed, letting blog owners add new blog posts directly from the live site.

Abi's european trip

Edit blog

New blog post

Saying goodbye Europe

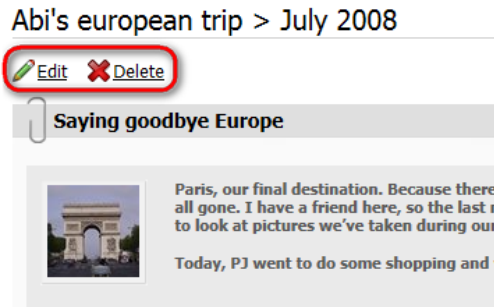

Edit or delete blog posts

1. Create an **alternative form** for the **Blog post** document type, which will contain the fields that you want to let users modify. If you are not familiar with the Alternative forms concept, please refer to the [Alternative forms](#) chapter first.

2. Add the **Edit contribution** web part to the blogs section title page and set its following properties:

- **Show for document types** - CMS.BlogPost
- **Alternative form name** - code name of the alternative form created in step 1
- **Edit button label** - Edit
- **Allow delete** - enable
- **Allow editing by users** - Document owner; this is the setting that makes the most sense as blog posts should be edited only by the blog's owner

If you go to the live site and display some blog post placed under the blogs section title page, you should see the  **Edit** and  **Delete** links as highlighted in the screenshot below. After clicking the  **Edit** link, the alternative form will be displayed, letting blog owners edit the blog post. Using the  **Delete** link, they can delete the blog post.

8.11.8 Settings

Settings of the Blogs module can be adjusted in **Site Manager -> Settings -> Content -> Blogs**. The following settings are available:

- **Send blog e-mails from** - e-mail address that will be used as the Sender ('From') address of notification e-mails.
- **Enable blog post trackbacks** - If checked, specified blog posts are pinged after the new blog post is saved; turn off this setting if you are creating your site on the production server to avoid creating trackbacks to your production server.
- **Use external service for trackbacks** - indicates if the external Scheduler Windows service should be used to process scheduled tasks which handle trackbacks.
- **Blog unsubscription URL** - URL of a page on which the Blog post unsubscription web part is placed; this is a special web part used for handling unsubscriptions from receiving notifications about new blog posts.
- **Enable double opt-in for blog post comments** - indicates if double opt-in should be enabled for blog post comments. When enabled, users are required to confirm their subscription by clicking a link that is sent to them in an e-mail.
- **Double opt-in approval page path** - path to the page that contains the Blog post subscription confirmation web part. The subscription confirmation link that will be sent to users will point to this page.
- **Double opt-in interval (hours)** - amount of time in hours, during which a user has to confirm their subscription request.
- **Send double opt-in confirmation** - indicates if an e-mail confirmation should be sent to user after they approve a subscription. If double opt-in is disabled, these confirmation e-mails are always sent.

8.11.9 Security

The Blogs module leverages the standard security used for all documents, as blogs are actually documents in the content tree. The Blogs module also has the following permissions in **Site Manager -> Administration -> Permissions**:

- **Manage comments** - allows members of the role to manage blog post comments
- **Read** - allows members of the role to view blog posts and blog post comments via the administration interface

 **Permissions**

Site:

Permissions for:

Report for user: Show only this user's roles

| Role | Read | Manage comments |
|------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Editors | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Readers | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> |
| Facebook users | <input type="checkbox"/> | <input type="checkbox"/> |
| Gold Partners | <input type="checkbox"/> | <input type="checkbox"/> |
| LinkedIn users | <input type="checkbox"/> | <input type="checkbox"/> |
| Live ID users | <input type="checkbox"/> | <input type="checkbox"/> |
| Marketing Manager | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Not authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |

To manage blog posts, you need to be one of the following:

- global administrator
- owner of the blog
- blog moderator
- granted with the **Manage comments** permission for the Blogs module in the **Administration -> Permissions** dialog

The blogs in the **My Desk -> Blogs** dialog are displayed only to the blog document owner.

8.11.10 Trackbacks

8.11.10.1 Trackbacks overview

The **Trackbacks** feature allows sending of blog post links to other blogs when a new blog post is created. The link is typically, but not always, added as a blog comment in the target blog, as implemented in Kentico CMS. This can be performed not only within the same site, but also to completely different sites created not only with Kentico CMS.

Trackbacks are typically used to let readers of a topic-related blog posts know about your new blog post. You can find detailed information on trackbacks on the following Wikipedia page: <http://en.wikipedia.org/wiki/Trackback>

Read [here](#) to learn how to enable trackbacks on your site.

How it works

1. There is a Trackback URL published below the blog post. These URLs can be found on various blogs at sites developed not only with Kentico CMS.

The screenshot shows the Kentico CMS 'Content' workspace. The left sidebar displays a tree view of the 'Community site' structure, with 'Destination Madrid' selected under 'June 2008'. The main workspace shows the 'Destination Madrid' blog post. The post content includes a title, a small image, and a paragraph of text. Below the text, there is a rating section showing 'Current rating: 5 (1 ratings)'. A red box highlights the Trackback URL: `http://localhost/7.0_4677.41671/trackback/12e2200f-b40a-4607-b05a-e3204786a158/Destination-Madrid.aspx?culture=en-US`.

2. When users are creating a blog post, they can add such URLs into the **Send trackbacks to** field. More than one trackback URL can be entered, each on a new line.

The screenshot shows the 'Send trackbacks to' field in the Kentico CMS interface. The field contains the same Trackback URL as in the previous screenshot, highlighted with a red box. The interface also shows a 'Post text' field, a 'Post teaser' field, and a 'Tags' field.

Save Spell check

Source | [Icons] | B I U abc X₂ X² | Styles Format Font Size [Icons]

Post text:

Post teaser:

| Actions | Update | Name | Size |
|-----------------|-----------|------------|-------|
| [Edit] [Delete] | [Refresh] | madrid.jpg | 63 kB |

Allow comments:

Tags: airport, hostel, Spain Select
Enter tags separated with comma. Example: dogs, "angry birds", cats

Send trackbacks to: http://localhost/7.0_4677.41671/trackback/12e2200f-b40a-4607-b05a-e3204786a158/Destination-Madrid.aspx?culture=en-US
Enter single URL on each line
 Post at Facebook

3. When the blog post is submitted, trackback ping is sent to the trackback URLs. If everything is configured correctly at the other blogs, a blog comment is added with the blog post link, title and summary, as you can see in the screenshot below.

Destination Madrid

Spain welcomed us with the entirely Spanish-only environment. You would think that they would bother to have some signs our announcements in English at the international airport. Fortunately, PJ knows little Spanish so we were able to find our way out of airport and take the right bus to our hostel.

Today, we took a little tour around the city center today but we feel kind of restless and can't wait to hit the road.
 Starting our great hitchhiking trip around Europe tomorrow.

8.11.10.2 Enabling trackbacks

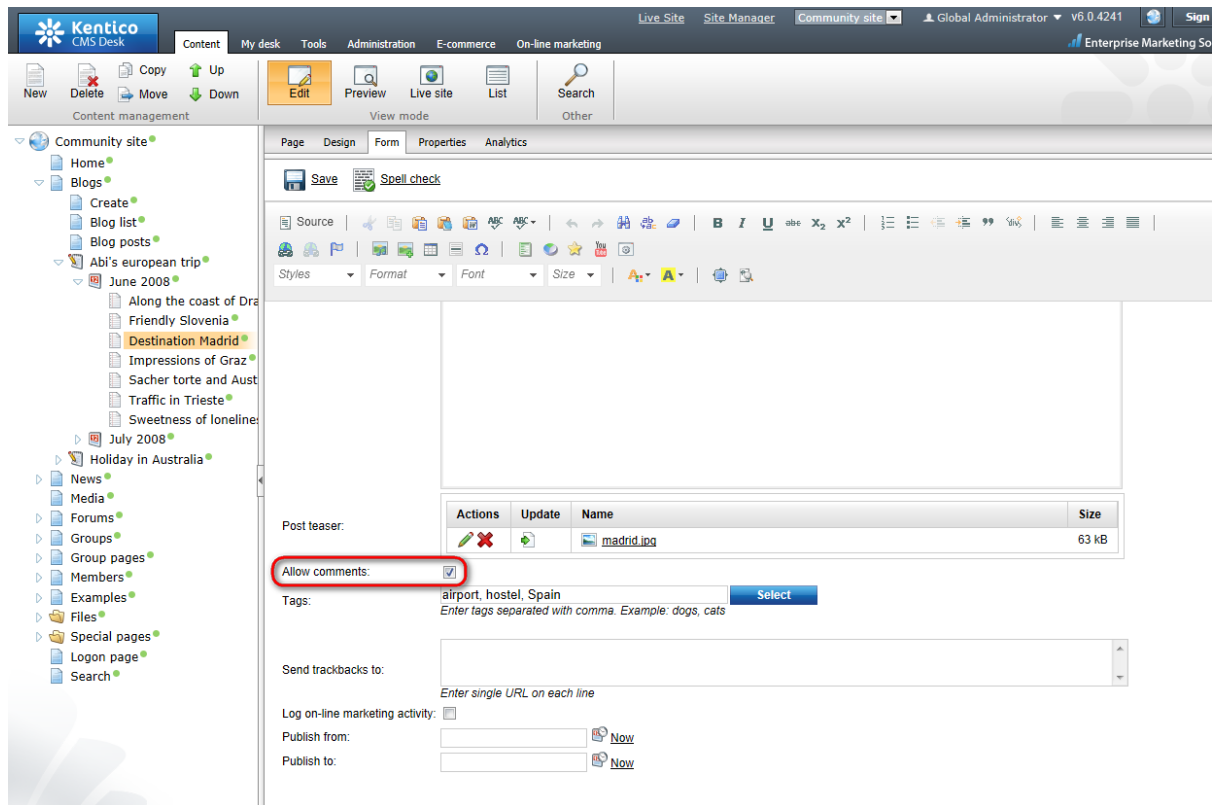

For the trackbacks to be functional in a particular blog, you need to enable the following options on the blog's **Form** tab:

- **Enable trackbacks** - this option enables displaying of the trackback URL with each blog post and inserting of trackbacks as blog comments
- **Allow anonymous comments** - trackback comments are in fact anonymous comments, so this option needs to be enabled for the comments to be inserted
- **Open comments for** - this option defines how long after the insertion of the blog post will inserting of blog comments be possible; trackbacks can also be inserted only within this period

The screenshot displays the Kentico CMS 7.0 interface. The top navigation bar includes 'Live Site', 'Site Manager', 'Community site', 'Global Administrator', and 'v6.0.4241'. The main toolbar contains 'New', 'Delete', 'Copy', 'Move', 'Up', 'Down', 'Edit', 'Preview', 'Live site', 'List', and 'Search'. The left sidebar shows a tree view of the 'Community site' structure, including 'Home', 'Blogs', 'Create', 'Blog list', 'Blog posts', 'Abi's european trip', 'June 2008', 'July 2008', 'Holiday in Australia', 'News', 'Media', 'Forums', 'Groups', 'Group pages', 'Members', 'Examples', 'Files', 'Special pages', 'Logon page', and 'Search'. The main content area is titled 'Form' and contains a 'Save' button, a 'Spell check' button, and a rich text editor. The text in the editor reads: 'Hi, my name is Abigail Woodwarth and I come from LA, California. Me and my friend PJ have recently set off for my very first visit of the old continent. In this blog, you will find posts about the interesting places we are going to visit so that you can follow our footsteps wherever we go even if you don't have the chance to go yourself.' Below the editor, there are several settings: 'Side column text:' (empty), 'Blog Teaser:' (with an 'Upload file' button), 'Open comments for:' (dropdown menu set to 'Always'), 'Send comments to e-mail address:' (empty), 'Allow anonymous comments:' (checked), 'Use CAPTCHA for comments:' (checked), 'Require e-mail addresses:' (unchecked), 'Unsubscription URL:' (empty), 'Enable subscriptions:' (checked), 'Moderate comments:' (unchecked), 'Blog moderators:' (empty), 'Enable trackbacks:' (checked), 'Publish from:' (empty), and 'Publish to:' (empty). The 'Open comments for:', 'Allow anonymous comments:', and 'Enable trackbacks:' options are highlighted with red circles.

The **Allow comments** option must also be enabled on the pinned blog post's **Form** tab so that the comment can be inserted.

8.11.11 Blog comments notifications

8.11.11.1 Who can be notified

When a new blog comment is added, notification e-mails can be sent to:

- **Blog owners**
- **Blog moderators**
- **Subscribers**

The text below explains to whom notification e-mails are sent under specific conditions:

New comment

1. has been added by the blog owner, blog moderator, user with the **Manage permission** or global administrator

- the comment is marked as APPROVED
- the e-mail is sent to: the blog owner (if their e-mail address is set in blog properties) and the subscribers

2. has been added by anybody else

a) the blog is moderated

- the comment is marked as NOT APPROVED
- the e-mail is sent to: the blog owner (if their e-mail address is set in blog properties) and the moderators

b) the blog is not moderated

- the comment is marked as APPROVED
- the e-mail is sent to: the blog owner (if their e-mail address is set in blog properties) and the subscribers

Comment editing

1. the comment has been switched from NOT APPROVED to APPROVED

- the e-mail is sent to: the subscribers

2. other comment changes

- no e-mails are sent

8.11.11.2 User subscriptions

Users can subscribe to receiving notifications about new blog comments at a blog post. It can be done in two ways:

Enabling subscriptions

You can enable users to subscribe to posts in a blog by checking the **Enable subscriptions** box on the **Form** tab of the corresponding blog document.

Enabling double opt-in

To make users confirm that the e-mail address they're subscribing with really exists and belongs to them, you can enable the double opt-in functionality. With double opt-in enabled, subscribers will be sent an e-mail with a confirmation link. They will have to click the link to create their subscription.

To enable double opt-in globally for all blogs:

1. Go to **Site Manager -> Settings -> Content -> Blogs**.
2. Turn on the **Enable double opt-in for blog post comments** setting.
3. Specify how long you want the confirmation links to be valid in the **Double opt-in interval** setting.

The following two steps are optional. If you omit them, the system will use the default approval page located in `~/CMSModules/Blogs/CMSPages/SubscriptionApproval.aspx`.

4. Place the **Blog post subscription confirmation** web part on a page. Adjust its properties according to your needs.
5. Enter the page's path into the **Double opt-in approval page path** setting.

Double opt-in should now be configured for all blogs. You can override the settings for each existing blog by selecting the corresponding blog document, switching to the **Form** tab and adjusting the settings in the **Double opt-in** category.

The functionality uses the **Blogs - Subscription request e-mail template**. You can insert the confirmation link into the template using the `{%SubscriptionLink%}` macro.

Subscribing to a blog post

Users can subscribe when leaving a comment, by checking the **Subscribe me to this blog post** check box. In this case, notifications will be sent to the e-mail address specified in the **E-mail** field above.

Leave comment [Subscribe](#)

Name:
Pavel Knotek

E-mail:
pavelk@localhost.local

Your URL:

Comments:
Sweet dreams, Kelly... :-)

Subscribe me to this blog post

Enter security code: 997355 

Users can also subscribe without leaving any comment, by clicking the **Subscribe** link at the top of the **Leave comment** form.

Leave comment [Subscribe](#)

Name:
Pavel Knotek

E-mail:
pavelk@localhost.local

This displays a subscription form. The subscription can be created by entering the e-mail address to the **Your e-mail** field and clicking the **Subscribe** button.

Subscribe [Leave comment](#)

Your e-mail: pavelk@localhost.local

Managing subscriptions

Users can view and manage their subscriptions in the following two places:

1. Users with access to **CMS Desk** can manage their subscriptions on the **My Desk -> My profile -> Subscriptions** tab.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Live Site', 'Site Manager', and 'Community site'. The main menu has tabs for 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. Below the menu, there are icons for 'My dashboard', 'Recent', 'Outdated', 'Pending', 'Checked out', 'My docs', 'My profile', 'Blogs', 'Friends', 'Messages', 'Projects', and 'Bin'. The 'My profile' section is active, showing tabs for 'Details', 'Change password', 'Notifications', 'Subscriptions', and 'Categories'. The 'Subscriptions' tab is selected, displaying three sections: 'Newsletter subscriptions', 'Blog post subscriptions', and 'Message board subscriptions'.

Newsletter subscriptions
Your e-mail address pavelk@localhost.local is currently subscribed to receive the following newsletters:
No newsletters selected.
[Add newsletters](#)

Blog post subscriptions
You are currently subscribed to receive notifications on new comments added to the following blog posts:

| | E-mail | Blog post |
|---|------------------------|---------------------------------------|
| ✘ | pavelk@localhost.local | Saving goodbye Europe |

Message board subscriptions
You aren't currently subscribed to receive notifications on any message board posts.

2. On the live site, users can manage their subscriptions in the **My account** web part. The **Display my subscriptions** property of the web part must be enabled for this to be possible.

The screenshot shows the 'Subscriptions' web part in the 'My account' section. The top navigation bar includes 'Personal settings', 'Change password', 'Notifications', 'Messages', 'Friends', and 'Subscriptions'. The 'Subscriptions' tab is selected, displaying three sections: 'Newsletters subscriptions', 'Blog posts subscriptions', and 'Message boards subscriptions'.

Newsletters subscriptions
Your e-mail address pavelk@localhost.local is currently subscribed to receive the following newsletters:
No newsletters selected.
[Add newsletters](#)

Blog posts subscriptions
You are currently subscribed to receive notifications on new comments added to the following blog posts:

| | E-mail | Blog post |
|---|------------------------|---------------------------------|
| ✘ | pavelk@localhost.local | Flying tomorrow |

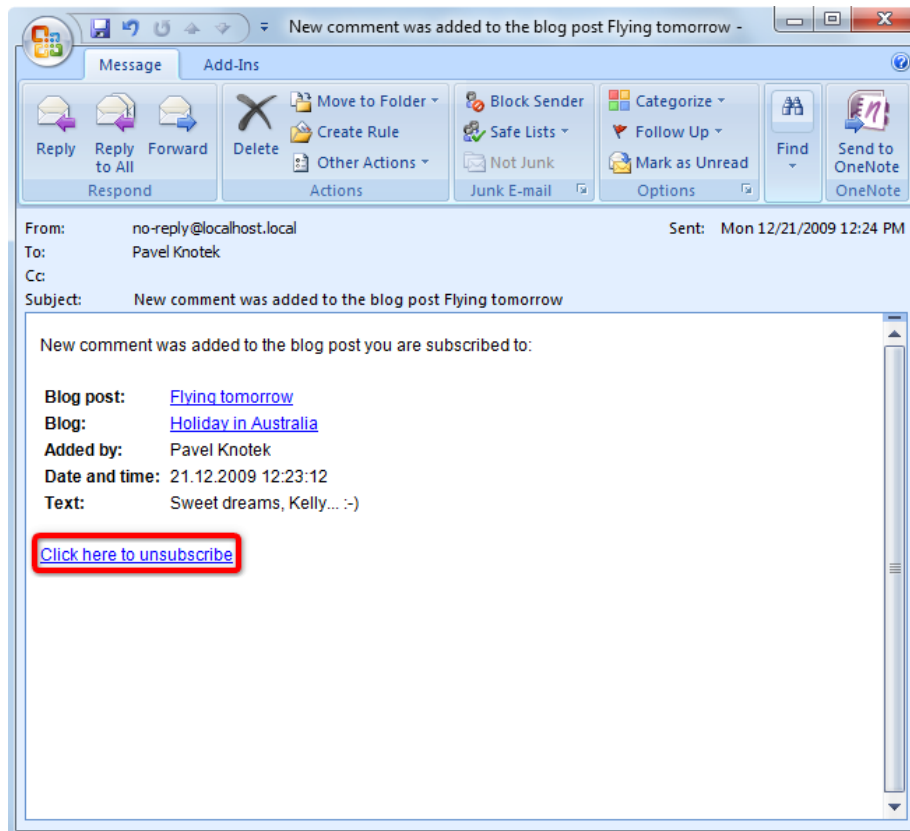

Message boards subscriptions

In both these locations, users can ✘ **Delete** the subscription. If double opt-in is enabled and a subscription hasn't been yet confirmed by clicking the link in the e-mail the user received, they can also ✔ **Approve** the subscription.

Unsubscription link configuration

Subscribers can also unsubscribe by clicking the unsubscription link, which is present in each

notification e-mail.

For this to work, you have to do the following two things:

1. Place the **Blog post unsubscription** web part onto a page. It is recommended to create a special page for this purpose, as you can see at **Community site -> Special-pages -> Blog unsubscribe**. You can set only one specific property of the web part - **Confirmation text** - this is the text that will be displayed after successful unsubscription.
2. Set the URL of the page created in step 1 as the **Unsubscription URL** property of the blog. This can be done two ways:
 - In **Site Manager -> Settings -> Content -> Blogs**, by settings the **Blog unsubscription URL** property. This is the default value that will be used by default, if no other URL is set.
 - If some different URL is set in the option mentioned above, you can set the value of the **Unsubscription URL** property on the blog's **Form** tab. This value overrides the one set in **Site Manager -> Settings -> Content -> Blogs**.

8.11.11.3 E-mail templates

There are three different e-mail templates that can be used when sending notifications about new blog comments, depending on the recipient of the notification:

- **Blog owners** - e-mails are based on the **Blogs - Notification to blog owner** e-mail template
- **Blog moderators** - e-mails are based on the **Blogs - Notification to blog moderators** e-mail

template

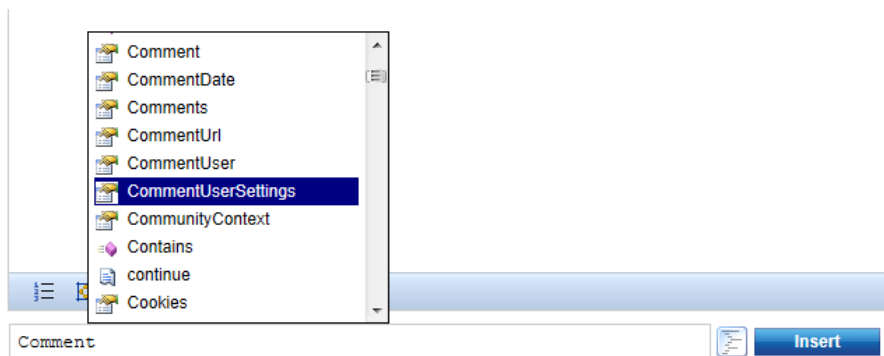

- **Subscribers** - e-mails are based on the **Blogs - Notification to blog post subscribers** e-mail template

The following macros can be used in the e-mail templates:

Data macros

- **Blog.XXX** - where XXX represents a column of the *CONTENT_Blog* table or the *CMS_View_Tree_Joined* view
- **BlogPost.XXX** - where XXX represents a column of the *CONTENT_Blog* table or the *CMS_View_Tree_Joined* view
- **Comment.XXX** - where XXX is a column of the *CONTENT_BlogComment* table
- **CommentUser.XXX** - where XXX is a column of the *CMS_User* table
- **CommentUserSettings.XXX** - where XXX is a column of the *CMS_UserSettings* table

Example: `{%CommentUser.Email%}`

Source macros

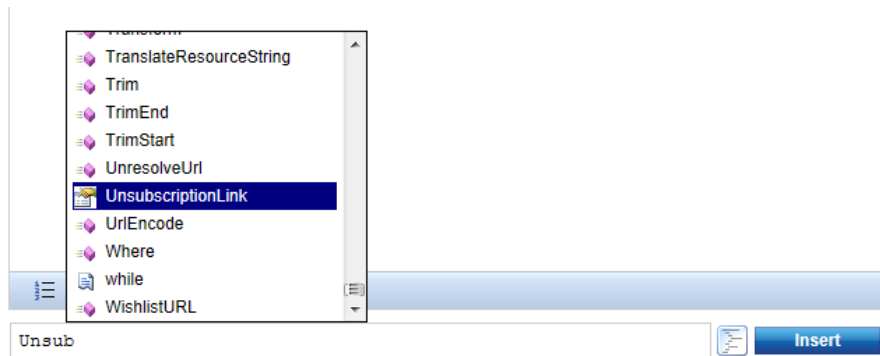

a) Links

- **BlogPostLink** - blog post link
- **BlogLink** - blog link
- **UnsubscriptionLink** - unsubscription link

b) Others - these macros are present due to backward compatibility purposes

- **UserFullName** - the same result as `{%Comment.CommentUserName%}`
- **CommentUrl** - the same result as `{%Comment.CommentUrl%}`
- **Comments** - the same result as `{%Comment.CommentText%}`
- **CommentDate** - the same result as `{%Comment.CommentDate%}`
- **BlogPostTitle** - the same result as `{%BlogPost.BlogPostTitle%}`

Example: `{%BlogPostLink %}`

8.11.12 MetaWeblog API

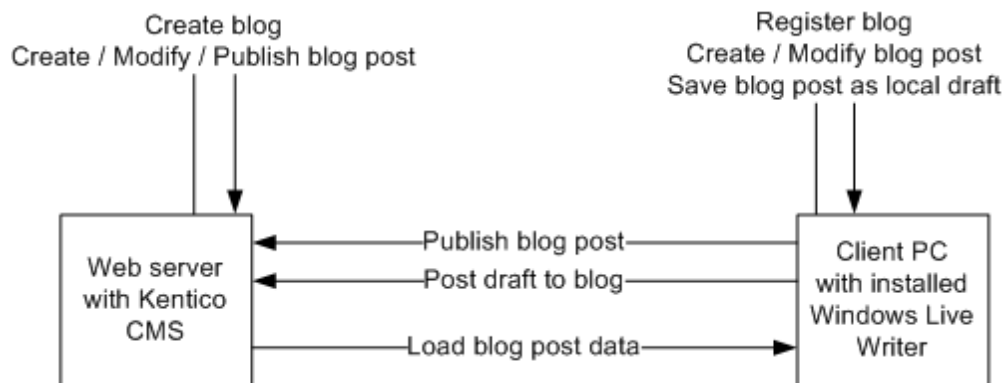

8.11.12.1 Overview

MetaWeblog API is a programming interface that enables external programs to get and set the text and attributes of blog posts. The API uses the XML-RPC protocol for communication between client applications and the blog server.

MetaWeblog API integration enables bloggers to write their blog posts using an application like Windows Live Writer (WLW) or Microsoft Word 2007 (or higher) on their local computer, even when they are offline; please note that in examples in this chapter WLW in version 14 is used. Then it enables transfer of these blog posts to the Kentico CMS web application, either by publishing them directly on the live site or just saving them as a draft to be published later.

How it works

The diagram below shows which actions can be performed in both Kentico CMS web application and Windows Live Writer, and the blog post transfer possibilities between the two applications.

The following actions need to be taken in order to use Windows Live Writer to write Kentico CMS blog posts:

1. User [creates a blog](#) in Kentico CMS (either via CMS Desk or on the live site).
2. User [installs Windows Live Writer](#) and [registers their new blog](#) in it.
3. Now the user is ready to create new and modify existing blog posts directly from WLW and transfer the changes into Kentico CMS.

In the **MetaWeblog API** subchapter, you can also learn how to [publish](#) a new blog post created with Windows Live Writer to a Kentico CMS Blog, how to manage [blog posts](#) and different [cultural versions](#) of your blog and finally, how to adjust the [settings](#) and [security](#) options related to **MetaWeblog API**.

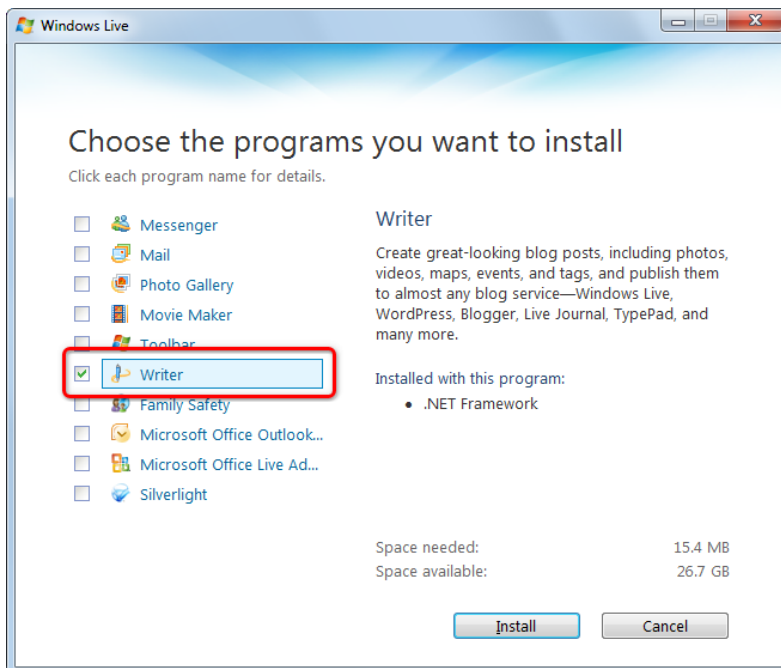

Please note

MetaWeblog API cannot be used by users authenticated by [third-party authentication services](#) (LiveID, OpenID etc.).

8.11.12.2 Windows Live Writer installation

The following steps need to be taken in order to install Windows Live Writer on your machine:

1. Download Windows Live installer from <http://download.live.com/writer>.
2. Execute the installer. Choose the **Writer** option from the list of available programs. Other options are not directly related to the Windows Live Writer. Choose as you wish and click **Install**.

3. When the installation finishes, it offers you some additional settings, which are not directly related to Windows Live Writer. Choose as you wish and click **Continue**.

4. You will get to the final screen, where you are offered to sign up for a [Live ID](#). This again is not directly related to Windows Live Writer, so do as you wish and finally click **Close** to finish the installer.

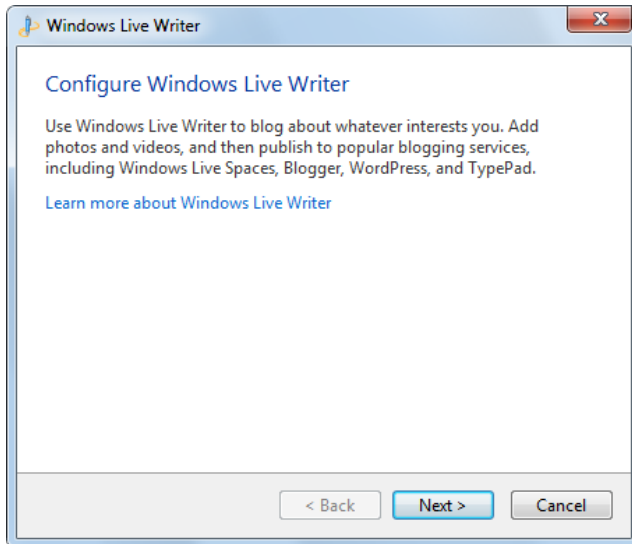

8.11.12.3 Registering blog account

When you run Windows Live Writer for the first time, a wizard will appear, letting you configure connection to your on-line web service. After the initial setup, the wizard is still accessible under the **Tools -> Accounts -> Add** or **Blogs -> Add blog account** menu options.

The following text describes how to connect Windows Live Writer to a blog in a Kentico CMS instance.

1. The first step of the wizard is just informational. Besides some very basic info, it offers you the *Learn more about Windows Live Writer* link, which redirects you to some in-depth info about the program. Follow it if you wish and click **Next** to proceed further.

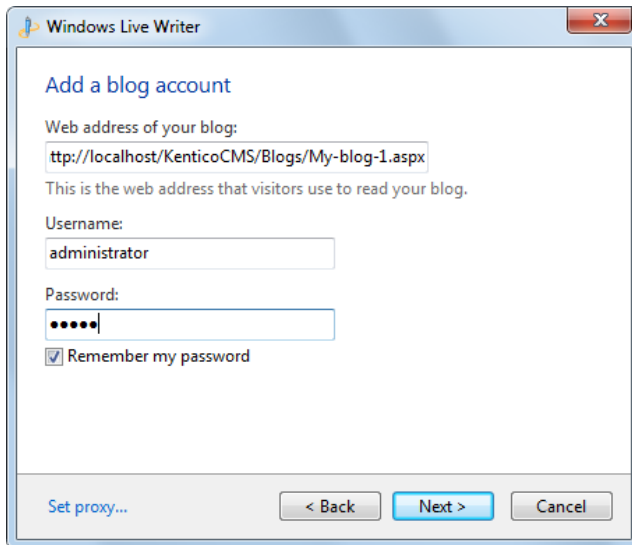

2. This step requires you to select the type of blog service. Select **Other blog service** and click **Next**.

3. Now you need to enter the URL of the blog and the logon credentials of the blog owner. Enter the following details:

- **Web address of your blog:** full Live URL of the blog's title page, e.g. *http://localhost/KenticoCMS_0322/Blogs/My-blog-1.aspx*
- **Username:** user name of the blog owner, e.g. *administrator*
- **Password:** blog owner's password (blank passwords are not supported), e.g. *12345*
- **Remember my password:** enable this option if you don't want to enter the password each time you use the application

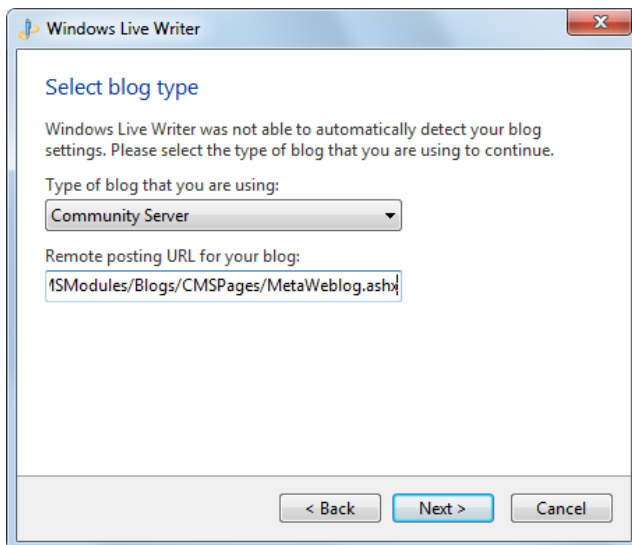

Click **Next** to proceed.

4. In the fourth step, you need to select the type of the blog and the posting URL of the blog. Enter the following details:

- **Type of blog that you are using:** *Community Server* or *MetaWeblog API* (the first one provides some extra functionality in WLW)
- **Remote posting URL for your blog:** URL of the MetaWeblog API handler, which is always in format *http://<application path>/CMSModules/Blogs/CMSPages/MetaWeblog.ashx* (e.g. *http://localhost/KenticoCMS/CMSModules/Blogs/CMSPages/MetaWeblog.ashx*)

Click **Next**.

5. Now a dialog pops up, asking you if you want to detect the theme used for the blog so that you can see how the blog post will look like live when you are editing it. Click **Yes** to perform this action. If you click **No**, you can still do it later manually by choosing the **View -> Refresh theme** option from

Windows Live Writer menu.

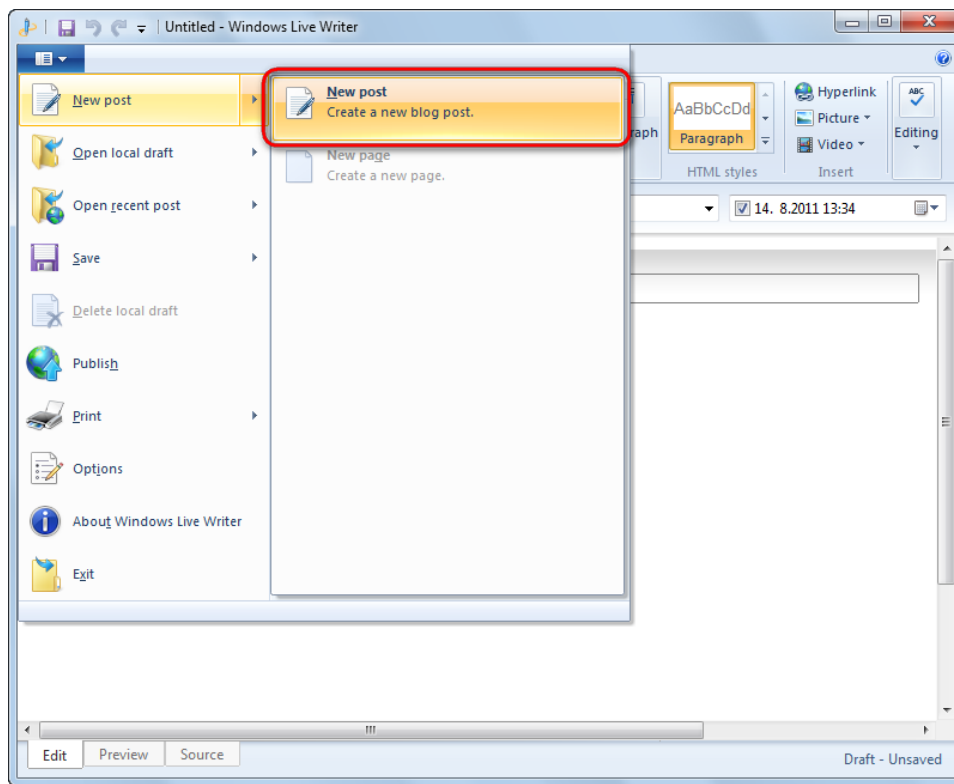

6. In the final step, you just need to enter the **Blog nickname**, which is just a name under which the blog will appear in WLW user interface. Enter whatever you wish and click **Finish**. Your blog is now registered and you can start blogging from within Windows Live Writer.

8.11.12.4 Publishing first blog post

In the following example, you will learn how to create a new blog post with Windows Live Writer and publish it to the Kentico CMS blog registered in the [previous example](#).

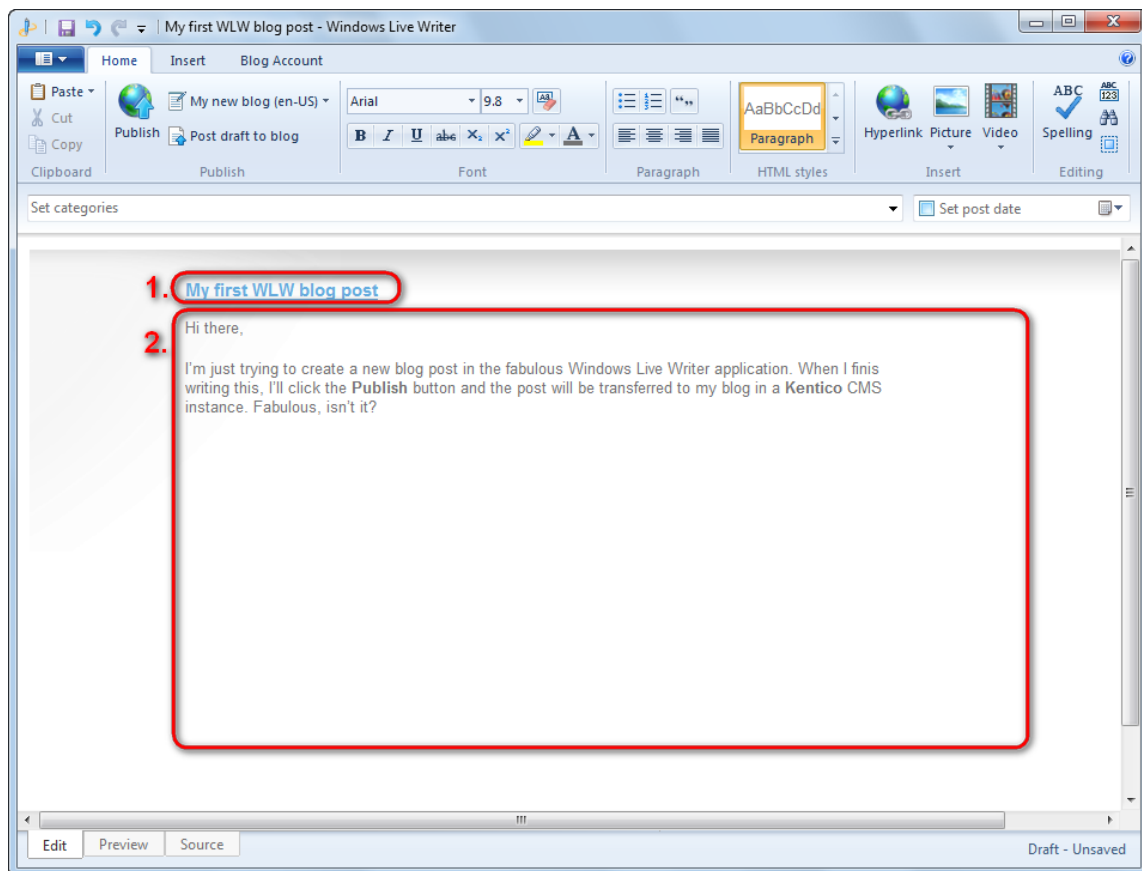

1. Open Windows Live Writer and select **New post** from the **File** menu (or click **Ctrl+N**).

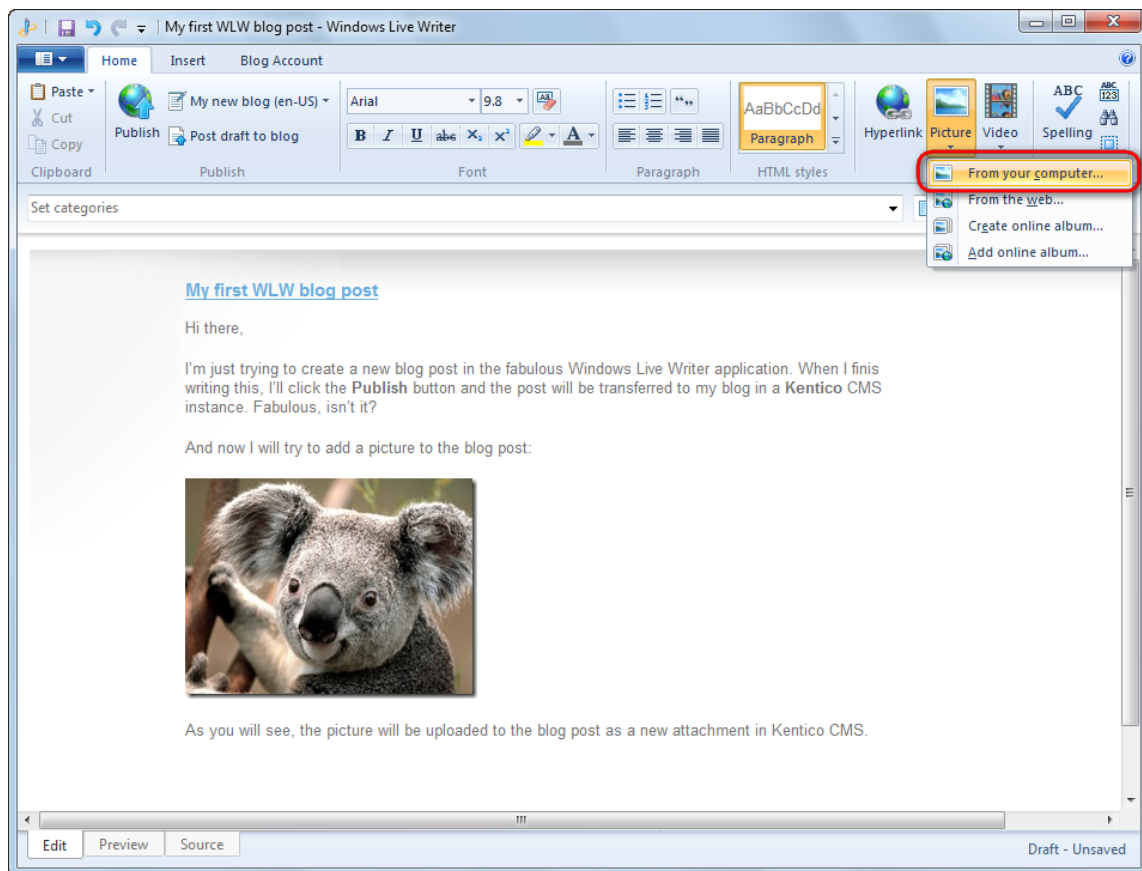

2. The gray rectangle at the top (1.) is where you enter the title of the blog post. What you enter here will be used as a value of the **Post title** field in your Kentico CMS blog post.

The text area below (2.) is where you enter the text of the blog post itself. This will be used for the **Post text** field, and in case you enabled the automatic summary (learn [here](#) how to do it), its beginning will be used for the **Post summary** field too.

Enter some title and blog post text.

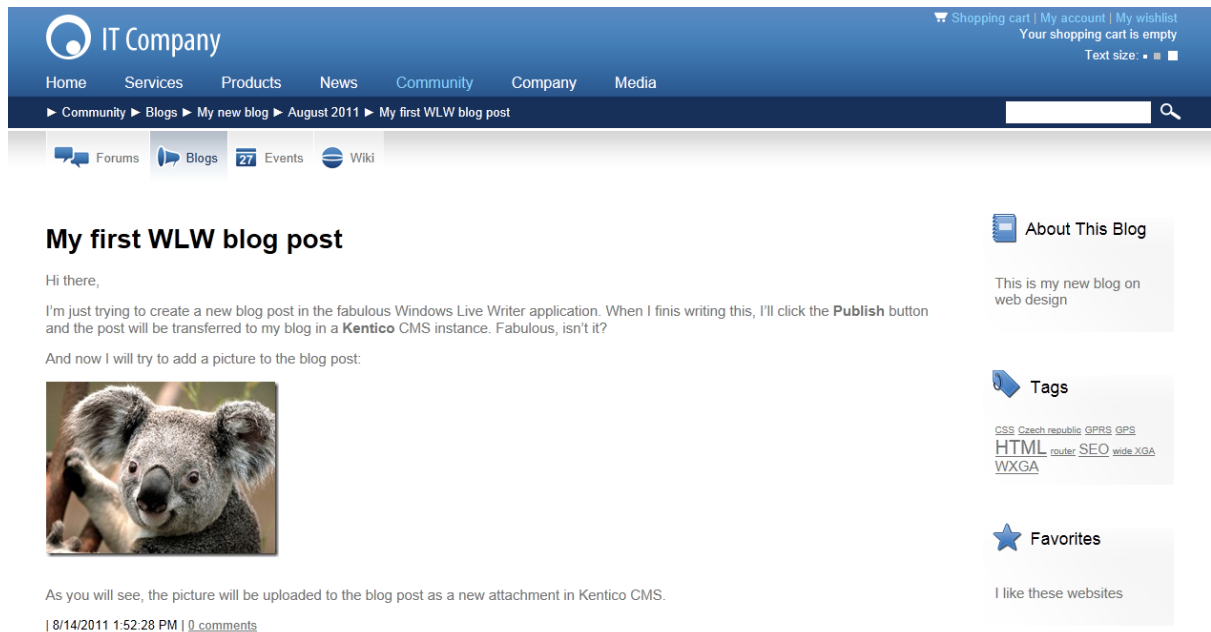

3. Now let's try adding an image. It is quite easy with Windows Live Writer, just click the **Picture...** option in the **Insert** menu on the right and select some image from your local disk. You should achieve that your blog post looks somewhat similar to the screenshot below.

4. Now that your blog post is ready, we can publish it to the live site. Click the **Publish** button in the top toolbar.

5. When the publishing finishes, your blog will be displayed in your browser and you will see the new post published.

My first WLW blog post

Hi there,

I'm just trying to create a new blog post in the fabulous Windows Live Writer application. When I finish writing this, I'll click the **Publish** button and the post will be transferred to my blog in a **Kentico CMS** instance. Fabulous, isn't it?

And now I will try to add a picture to the blog post:

As you will see, the picture will be uploaded to the blog post as a new attachment in Kentico CMS.

6. If you view the blog post in CMS Desk and switch to its **Properties -> Attachments** tab, you will see that the image has been uploaded as an attachment of the post. There are two versions of the image - the first one is the original full-size image, while the second one is its thumbnail used in the post text (e.g. in the screenshot above).

8.11.12.5 Managing blog posts

This chapter describes some additional options that you have when creating or editing a blog post.

Save local draft

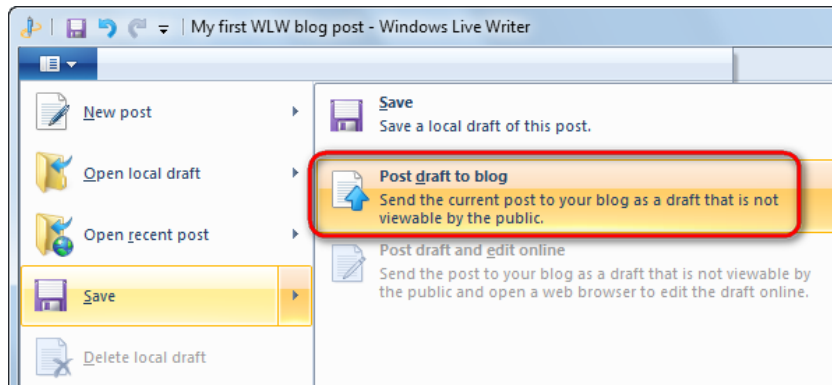

Current local version of the blog post is saved as blog post local draft; each blog post can have only one local draft. This action doesn't propagate any changes into the CMS.

Post draft to blog

Current local version of the blog post is posted to blog, but its local draft is not removed. Depending on [workflow](#) settings, the following two situations can occur in the CMS:

- Blog post document is under workflow** - new minor version of the blog post is created (posted version is not published)
- Blog post document is not under workflow** - blog post is published immediately; this means that this action is identical to the *Publish* action, i.e. the *Post draft to blog* action makes sense only in case that workflow is enabled for blog post documents

Publish

Current local version of the blog post is posted to blog and published immediately. Local draft of the published blog post is automatically removed.

Tagging

The tag selector in WLW enables you to tag the blog post with tags from the parent blog's Kentico CMS [tag group](#). The tag group of the blog post itself is not reflected here at all.

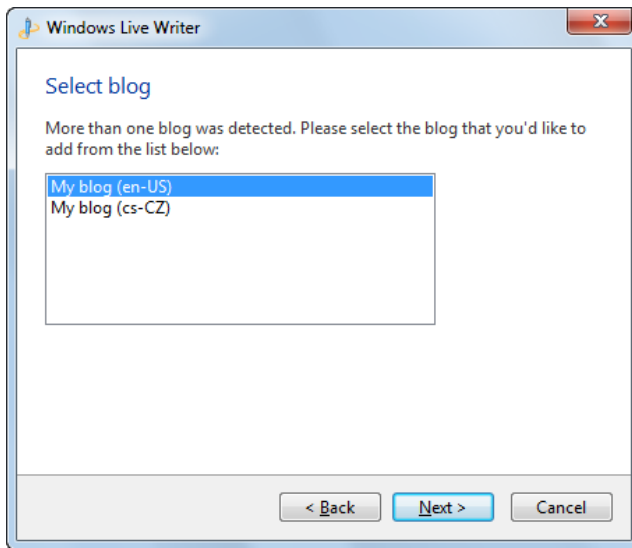

Publish date

You can specify a date here, which will be propagated into the **Publish from** field on the **Form** tab in CMS Desk. The value determines the date and time when the blog post gets published on the live site. It will be converted to the user's [time zone](#) before it is set as the **Publish from** property of the blog post in Kentico CMS. If no time is set here, the blog post is published immediately.

8.11.12.6 Multilingual support

In case that your blog exists in more than one cultural version, you will get the following dialog displayed after blog type selection (step 4) when [registering your blog account](#).

In the dialog, you need to choose which cultural version will the account be registered for. This means that you need to register **one dedicated account for each cultural version** of your blog.

8.11.12.7 Settings

Settings related to MetaWeblog API can be performed in **Site Manager -> Settings -> Content -> Blogs -> MetaWeblog API**. The following settings can be configured:

- **Allow automatic summary:** if enabled, blog post summary will be created automatically from the beginning of the blog post text, and will be as long as the value of the Summary length property; this is applied only when a post is created - when editing an existing post, the summary is not updated
- **Summary length:** length of automatic blog post summary in characters
- **Delete unused attachments:** if enabled, all blog post attachments which are not used in post text or have not been uploaded via WLW (i.e. have been uploaded via Kentico CMS user interface) will be deleted when an existing blog post is modified and then published from WLW

8.11.12.8 Security

Managing blog posts

The following text explains what conditions need to be met in order to perform the listed actions in Windows Live Writer. The conditions need to be valid for the user account used to access the blog (as entered in step 3 [here](#)).

To **view a blog post**, the user needs to:

- be the owner of the blog post
- or have the **Read** document permission for the blog post granted (as explained [here](#))
- or be a global administrator

To **modify a blog post without workflow**, or to **modify a blog post under workflow without custom workflow steps**, the user needs to:

- be the owner of the blog post
- or have the **Modify** document permission for the blog post granted (as explained [here](#))
- or be a global administrator

To **modify a blog post under workflow with custom workflow steps**, the user needs to be:

- member of the role which can approve the document in the custom workflow step (see [Defining a workflow](#) for more details)
- or a global administrator

To **delete a blog post**, the user needs to:

- be the owner of the blog post
- or have the **Delete** document permission for the blog post granted (as explained [here](#))
- or be a global administrator

Banned IPs

If the user's IP is on the [Banned IPs](#) list, the user will not be able to transfer any data between Kentico CMS and the client application (WLW, Microsoft Word 2007+, ...).

8.11.13 Blogs internals and API

8.11.13.1 Overview

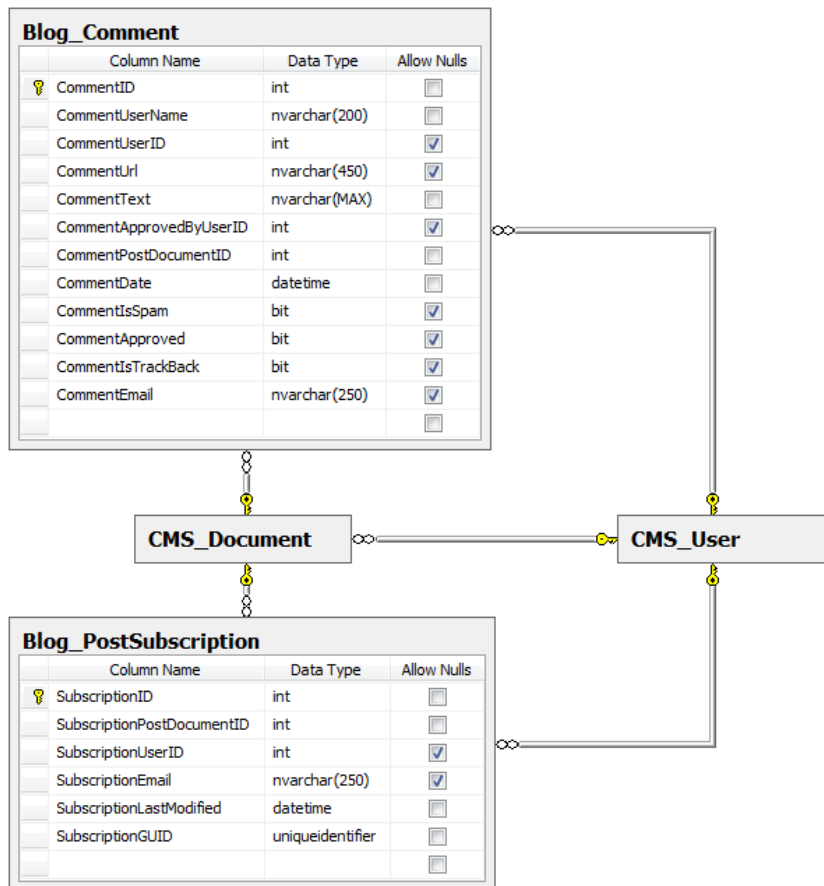

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Blogs module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.11.13.2 Database tables

The following database tables are used in the Blogs module:

- **Blog_Comment** - contains records representing blog comments.
- **Blog_PostSubscription** - contains records representing blog post subscriptions.

8.11.13.3 API classes

If you are not familiar with the database table data management by Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The Blogs module classes use the **CMS.Blogs** namespace.

Blog_Comment table API:

- **BlogCommentInfo** - represents one blog comment.
- **BlogCommentInfoProvider** - provides management of blog comments.

Blog_PostSubscription table API:

- **BlogPostSubscriptionInfo** - represents one blog post subscription.
- **BlogPostSubscriptionInfoProvider** - provides management of blog post subscriptions.

8.11.13.4 API examples

8.11.13.4.1 Overview

Please note

All API examples can be simulated in the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Community\Blogs\Default.aspx.cs**.

8.12 Categories

8.12.1 Overview

The Categories module enables users to sort their documents based on categories. It is thus a different approach to sorting documents from the one described in the [Tags](#) chapter.

The screenshot shows a website interface for 'IT Company'. The top navigation bar includes links for Home, Office, Services, Products, News, Community, Company, and Media. A secondary navigation bar shows a breadcrumb trail: Examples > Web Parts > Tagging & categories > Category list. On the left, a sidebar menu lists various content types like 'Abuse report', 'Articles', 'Attachments', etc., with 'Web Parts' currently selected. The main content area is divided into two sections:

- Category list:** A vertical list of category names, each underlined and enclosed in a red box. The categories are: Cascading Style Sheets (CSS), Czech Republic, General Packet Radio Service (GPRS), Global Positioning System, HyperText Markup Language (HTML), Router, Search Engine Optimization (SEO), and Wide XGA.
- All categories:** A hierarchical tree structure also enclosed in a red box. It shows 'Countries' and 'Technology' as top-level categories. 'Technology' is expanded to show sub-categories: 'Communication', 'Hardware', 'Navigation', and 'Web'. 'Web' is further expanded to show 'Languages' as a sub-category.

There are three types of categories from the point of view of the user:

- **Global categories** - such categories can be used across all available sites. However, you need to [allow global categories](#) for the sites first.
- **Site-specific categories** - such categories can be used only on the given site.
- **Personal categories** - global categories belonging to a particular user. The user can use these categories across all available sites.

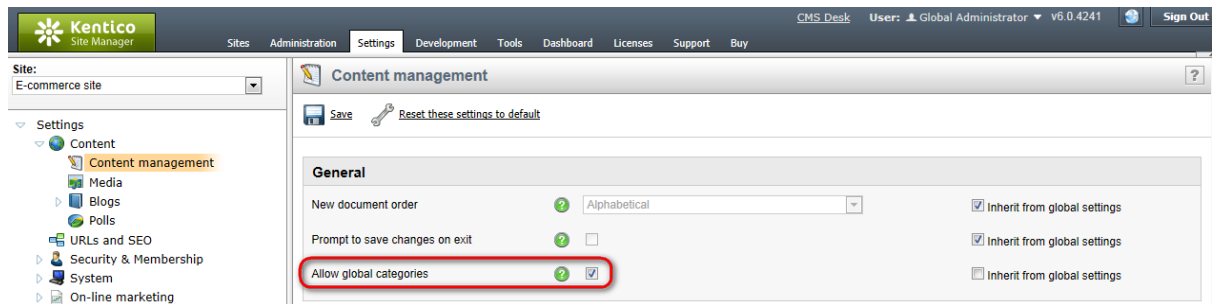

To learn how to create and edit categories, please refer to the [Managing categories](#) topic.

To learn how to put your documents under categories, please refer to the [Assigning categories to documents](#) topic.

The security matters related to the Categories module are described in the [Security topic](#).

8.12.2 Allowing global categories

The use of global categories can be enabled in **Site Manager -> Settings -> Content -> Content management** in the **General** section. To enable global categories, from the **Site** drop-down list choose **(global)** to make global settings or one of the available sites to make site-specific settings and set the **Allow global categories** option to TRUE.

8.12.3 Managing categories

Here you will learn how to [manage](#) categories and which parts of the UI serve this purpose.

Categories in Kentico CMS can be managed in the following locations:

1. Site Manager -> Administration

Because this is a global administration interface, the **Site** selector allows you to perform the categories settings globally or for a selected site. If you choose (**global**), you are managing global categories only. If you choose a particular site, you are managing categories of this site, optionally together with global categories (on condition that [global categories are allowed](#) for the given site).

2. CMS Desk -> Administration

As this is a site-specific administration interface, only current site-specific configuration is available. Both global and site-specific categories can be managed from here (on condition that [global categories are allowed](#) for the given site).

3. CMS Desk -> My desk

If they switch to **My profile** and navigate to the **Categories** tab, the user can manage their personal categories from this location.

4. On the live site

The user can manage their personal categories also on the live site. Specifically, they need to navigate to the **My account** page and switch to the **Categories** tab. However, this tab is displayed only if the **My account** web part is properly configured; more details on how to configure this web part can be found in [E-commerce Guide -> Integration with your existing Kentico CMS website -> Web parts -> My account](#).

5. User properties

The administrator can manage personal categories of individual users in **Administration -> Users -> Edit (✎) user** on the **Categories** tab.

Managing categories

You can create a category using **New category** and you can delete one using **Delete category**. Categories can also be moved **Up** and moved **Down** in the Categories tree; however, global and

site-specific categories are sorted separately in the tree.

Creating categories

If you are creating a category from **Site Manager -> Administration** or **CMS Desk -> Administration** and global categories are [allowed](#), the **Category type** selector may be visible on the Categories page, depending on under which category you are creating the new one. This is because both global and site-specific categories can be put under the **Categories** root and under any global category. However, under a site-specific category only categories of this type can be put.

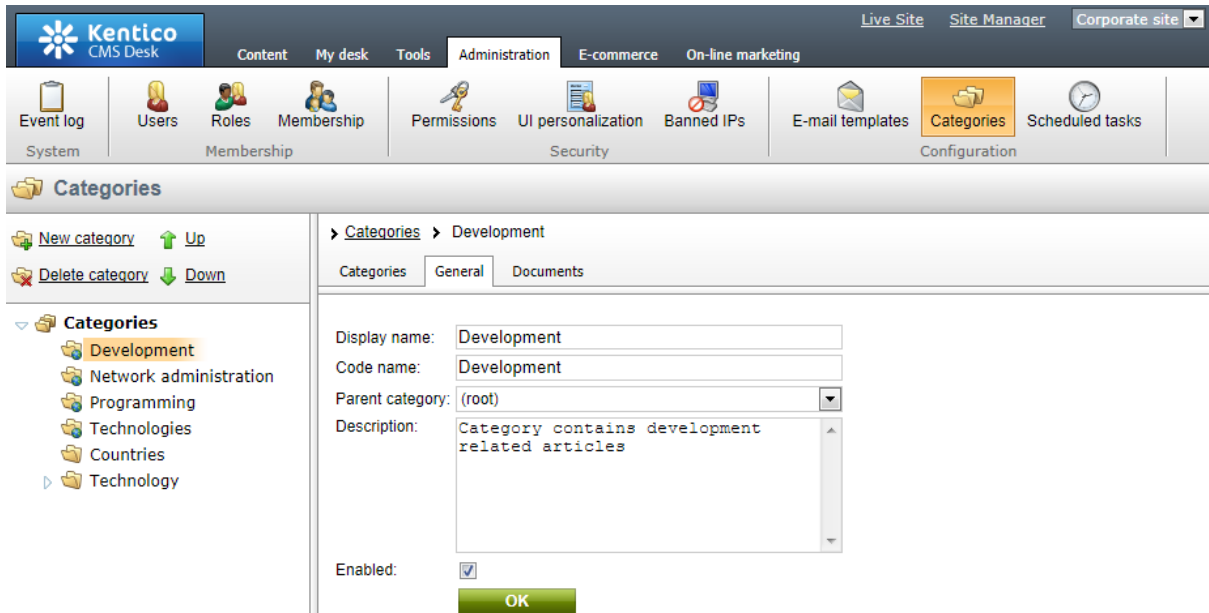

Besides, to view the **Category type** selector and thus be able to create global categories, at least one of the roles of which you are a member must have the **Modify global categories** [permission](#) assigned.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Live Site', 'Site Manager', and 'Corporate Site'. The main menu has 'Administration' selected. Below the menu, there are icons for 'Event log', 'Users', 'Roles', 'Membership', 'Permissions', 'UI personalization', 'Banned IPs', 'E-mail templates', 'Categories', and 'Scheduled tasks'. The 'Categories' page is displayed, showing a 'New category' form. The 'Category type' selector is highlighted with a red box, showing 'Site category' selected and 'Global category' unselected. The form also includes fields for 'Display name', 'Code name', and 'Description', and an 'Enabled' checkbox which is checked. An 'OK' button is at the bottom of the form.

If you are creating a personal category, i.e. from **CMS Desk -> My Desk**, from user properties or from the **My account** section on the live site, the **Category type** selector is never visible because the user can use their personal categories across all available sites.

Editing categories

If you need to edit a category, select it from the **Categories** tree and configure its settings as required:

General tab

On this tab you can edit the following properties:

- **Display name** - the display name of the category.
- **Code name** - the code name of the category.
- **Parent category** - the parent category under which this child category is put. Use the drop-down list to move the category under a different category.
- **Description** - the description text of the category.
- **Enabled** - indicates if the category is enabled in the system. Documents cannot be assigned to categories that are not enabled.

Localization expressions, i.e. **Localize other languages** (🌐), **Remove localization** (✖) and **Localize** (🌐), are described in detail in the [Localization expressions](#) topic in the Development -> Multilingual and international support section.

Documents tab

On this tab you can view a list of documents which fall under the given category, together with some important document details, e.g. document name, document type, document modification stamp etc.

Categories tab

On this tab you can **Edit** (✎) and **Delete** (✖) categories and you can also view categories details, i.e. their child categories, categories status and the number of assigned documents.

8.12.4 Assigning categories to documents

Here you will learn how to assign categories to a document.

1. To add categories to a document, you need to navigate to **CMS Desk -> Content**,

2. select a document from the **Content** tree
3. and on its **Properties** tab, switch to **Categories**. If any categories are already assigned to the document, a list of these categories is displayed, together with the **Remove selected** and **Add categories** buttons. If no categories are assigned, only the latter button is displayed.
4. Now you need to click the **Add categories** button and in a dialog window which pops up select the categories from the **Categories** tree. Only categories allowed for the current site together with personal categories of the user are displayed. Please note that the dialog window allows you not only to select categories but also perform standard categories editing tasks, as described in the [Managing categories](#) topic.

5. To save the changes, click **OK**.

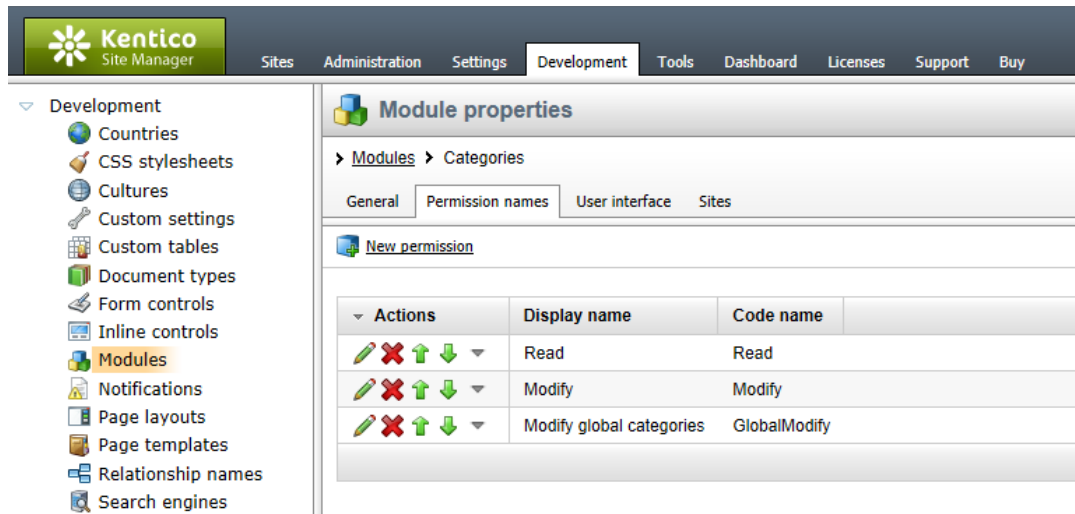

Please note

The **Multiple categories selector** can be used also with a document type. This gives you the option to assign categories to the document in **CMS Desk -> Content** on the **Form** tab or on the live site using [User contributions](#).

8.12.5 Security

To prevent users from accessing and modifying categories, you will need to assign Categories module permissions. This procedure is described in more detail in the [Membership, permissions and security -> Permissions](#) chapter in the Development section of this guide.

The Categories module has the following permissions:

The screenshot shows the Kentico Site Manager interface. The left sidebar lists various development modules, with 'Modules' highlighted. The main content area is titled 'Module properties' and shows the 'Categories' module selected. The 'Permission names' tab is active, displaying a table of permissions.

| Actions | Display name | Code name |
|---------|--------------------------|--------------|
| | Read | Read |
| | Modify | Modify |
| | Modify global categories | GlobalModify |

- **Read** - allows to read categories.
- **Modify** - allows to create and modify categories.
- **Modify global categories** - allows to create and modify global categories.

Example

To allow members of a particular role to read site-specific categories, you will need to assign this role the **Read** permission.

To allow members of a particular role to create and modify site-specific categories, you will need to assign this role the following permissions:

- **Read**
- **Modify**

To allow members of a particular role to read global categories, you will need to assign this role the **Read** permission:

To allow members of a particular role to create and modify global categories, you will need to assign this role the following permissions:

- **Read**
- **Modify global categories**

This can be configured in the Categories module permissions matrix in **Site Manager -> Administration -> Permissions**, as described in detail in the [Permissions](#) chapter in the Development -> Membership, permissions and security section of the Developer's Guide.

8.12.6 Categories internals and API

8.12.6.1 Overview

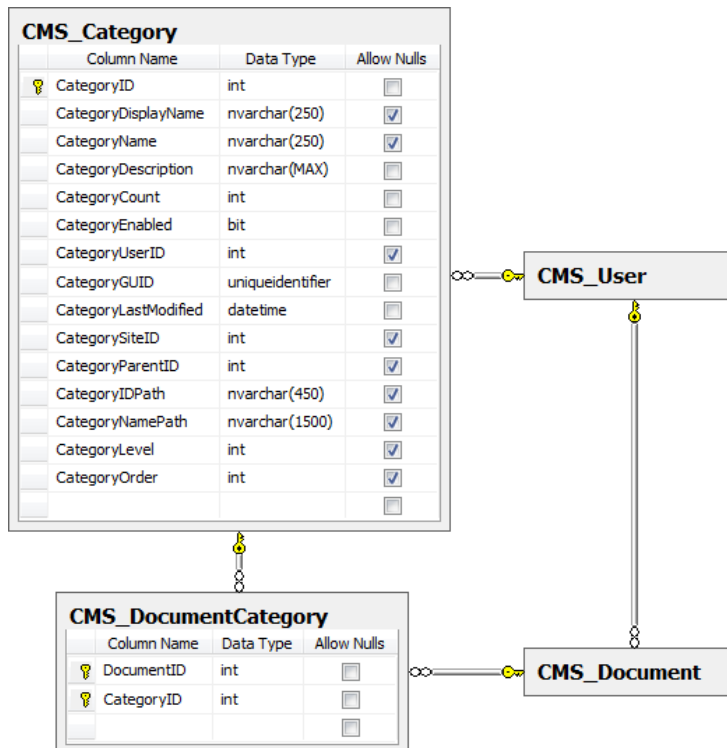

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Categories module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.12.6.2 Database tables

The following database tables are used in the Categories module:

- **CMS_Category** - contains records representing categories.
- **CMS_DocumentCategory** - contains relationships between documents and categories indicating that particular documents are added to a particular category.

8.12.6.3 API classes

If you are not familiar with the database table data management by Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The Categories module classes use the **CMS.SiteProvider** namespace.

Category table API:

- **CategoryInfo** - represents one category.
- **CategoryInfoProvider** - provides management of categories.

DocumentCategory table API:

- **DocumentCategoryInfo** - represents relationships between one document and one category expressing that the particular document is added to the particular category.
- **DocumentCategoryInfoProvider** - provides management of relationships between documents and categories.

8.12.6.4 API examples

8.12.6.4.1 Overview

Please note

All API examples can be simulated in the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Documents\Categories\Default.aspx.cs**.

8.13 Chat

8.13.1 Quick start

This topic will show you how to enable your website visitors to chat with each other in a few steps.

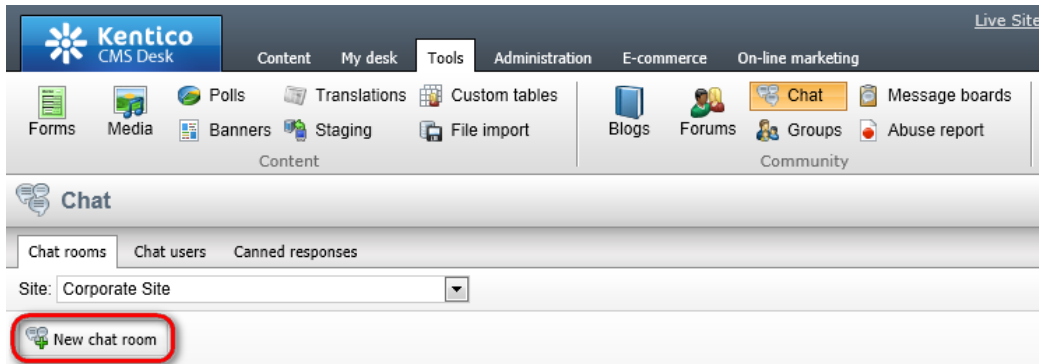

This step-by-step guide consists of two parts - first, you will [create chat rooms](#), then you will [place web parts](#) on a page to enable the chat on the live site.

For basic information about the Chat module, refer to the [Basics](#) topic.

Creating chat rooms

First, you need to create rooms that users will chat in. Follow these steps to create a chat room:

1. Log in to **CMS Desk** and navigate to **Tools -> Chat**.
2. Click  **New chat room**.

No data match search criteria.

3. Fill in the **Display name** and **Description**.

> [Chat rooms](#) > New chat room

Save

Display name:

Code name: (automatic)

Enabled:

Description:

Private:

Entrance password:

Allow anonymous:

Is support:

The other settings determine the type of the room. You can leave them unchanged. To learn more, refer to the [Chat room types](#) and [Configuring rooms](#) topics.

4. Click **Save** to create the room.

5. Click **Chat rooms** to be redirected to the list of existing rooms, which now contains the room you just created.

Chat

[Chat rooms](#) [Chat users](#) [Canned responses](#)

Site: Corporate Site

New chat room

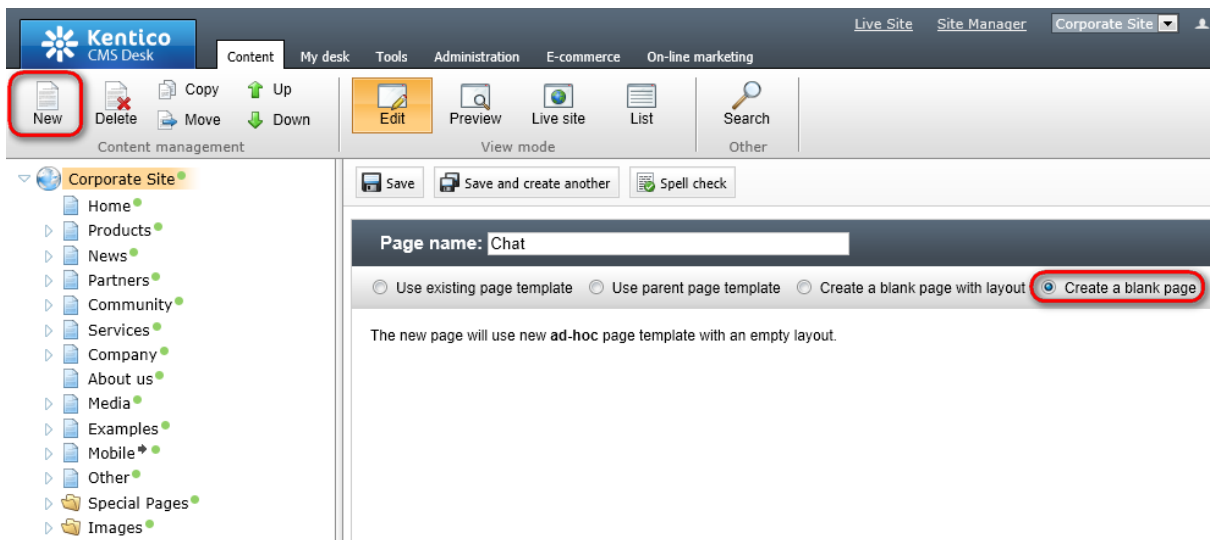

| Actions | Display name ^ | Enabled | Private | Is support | Created | Created by | Description |
|---------|--------------------|---------|---------|------------|----------------------|--------------------------------------|---|
| | General discussion | Yes | No | No | 4/28/2012 4:39:25 PM | Global Administrator | Come in and chat about anything and everything. |

You have created a room, which users can join and chat with others. Repeat the procedure any number of times to create other rooms.

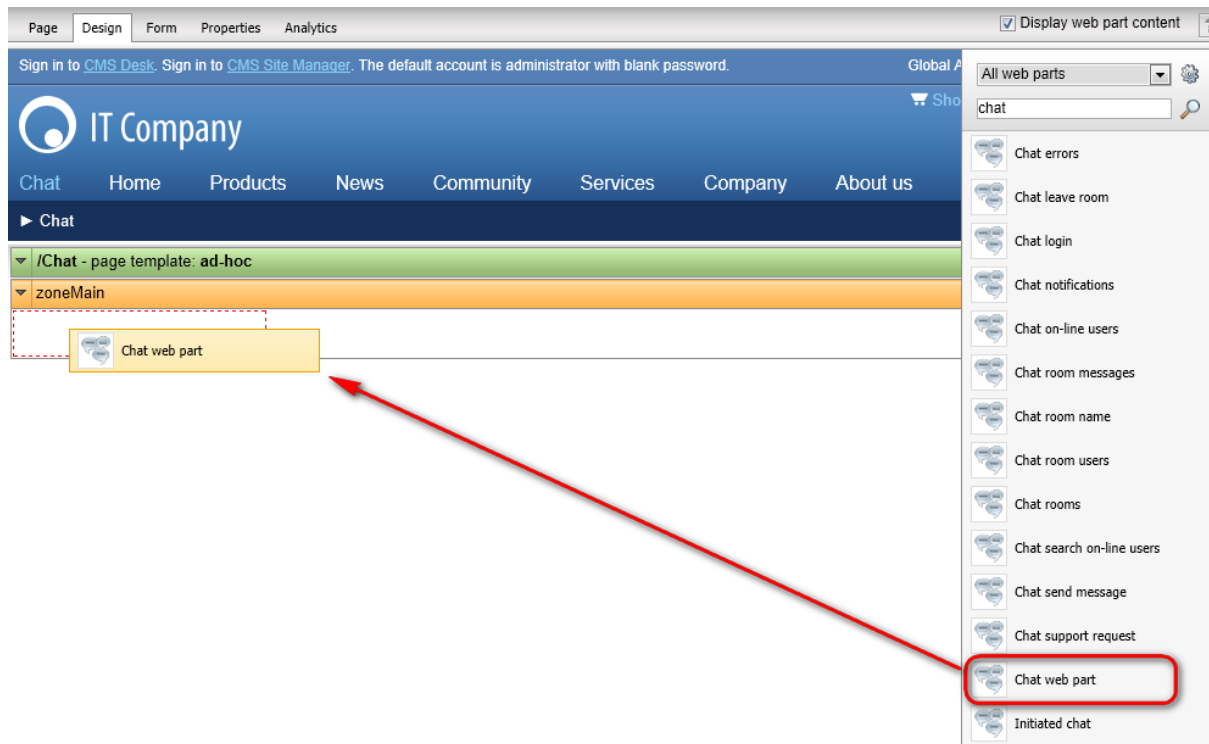

To learn more about chat room management, refer to the [Managing chat rooms](#) chapter.

Setting up chat on site

1. In **CMS Desk**, switch to **Content**.
2. Create a new document of type **Page (menu item)**. Choose to **Create a blank page**.

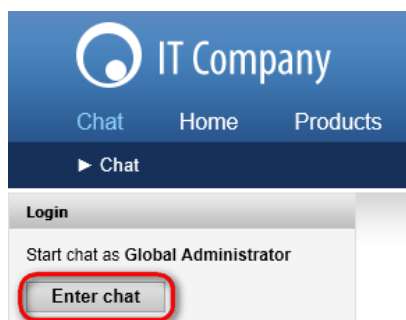

3. Search for "Chat" in the web part toolbar and drag the **Chat web part** into the **zoneMain** web part zone.

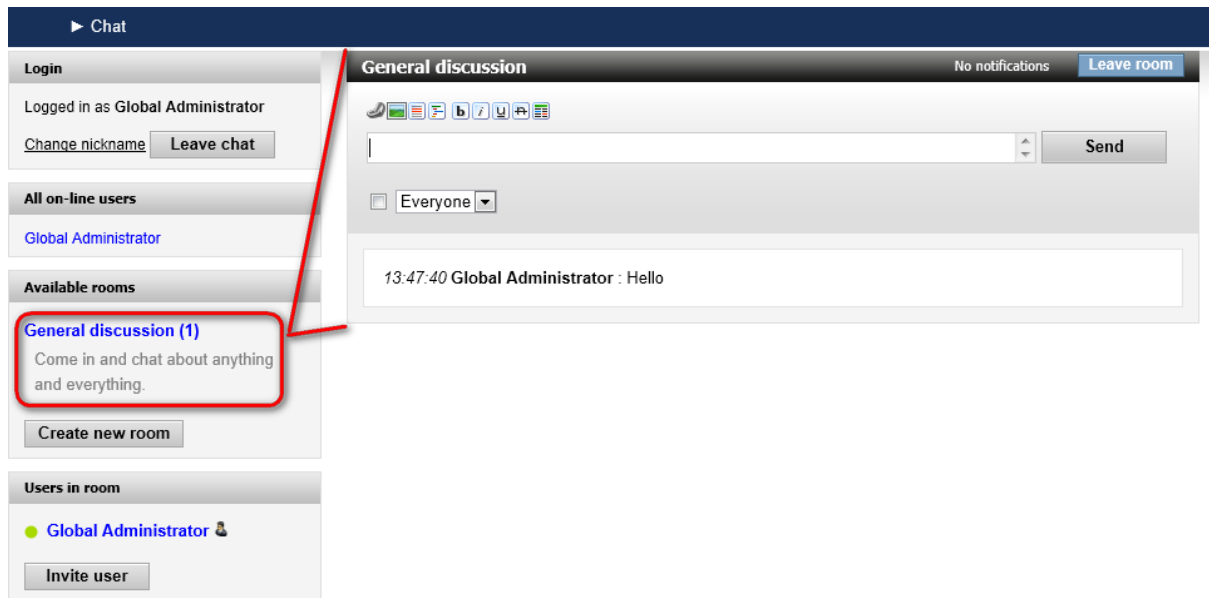

4. In the **Web part properties** dialog, leave all the settings at their default values and click **OK**. Chat should now be correctly configured.

5. Switch to the live site and navigate to the **Chat** page.

6. Click **Enter chat**.

You can now click a room in the list of **Available rooms** and start chatting with other users in that room.

To learn how to use the chat, refer to the [Using chat](#) chapter.

For information on how to manage users of the chat, refer to the [Managing chat users](#) chapter.

If you wish to learn about other ways of setting up the chat or customize the looks and behavior of the chat, refer to the [Setting up chat on site](#) chapter.

8.13.2 Overview

8.13.2.1 Basics

The Chat module allows visitors of a website to communicate with each other in real time by means of text messages. Chat users can gather in chat rooms of various types, as well as talk one-on-one without interruption of other users. Also included is an option to set up live customer support chat featuring operator notifications in CMS Desk and predefined (canned) responses. Other features include graphic smileys, BBCode tags and integration with the [Bad words module](#).

The module comes as a [set of web parts](#) that can be either placed on a single page, allowing all the features to be accessed at one place, or spread across multiple pages to separate individual components (e.g. the log-on page, chat room list, etc.).

Administrators and site editors can manage the module through its user interface located in **CMS Desk - > Tools -> Chat**.

Chat rooms

Chat rooms connect people who share a common interest or background. When a user joins a chat room, they can send text messages which all other users in the room will be able to read and respond to. Kentico CMS offers a set of chat room types, including private and public rooms or password protected rooms.

To view the complete list of chat room types along with their detailed descriptions, refer to the [Chat room](#)

[types](#) topic.

Chat users

By default, any visitor of your website can enter the chat, regardless of whether they have a user account set up on the site. Every chat user only needs to choose a nickname which will represent them among the chatting community. The name with which the user logs in to the site will not be shown to other chat users.

For information about how to administer chat users, see the [Managing chat users](#) chapter.

Support chat

Chat in Kentico CMS contains a special type of chat rooms aimed at providing on-line help and support to customers. These support rooms have one or more registered users acting as consultants, while site visitors can join and ask questions. The consultant is notified about new messages in CMS Desk and is able to open a message dialog through there.

More information can be found in the [Support chat](#) chapter.

8.13.2.2 Prerequisites

To use the Chat module, you need to have **Windows Communication Foundation** (WCF) installed and properly configured. Also, there are some licensing limitations to consider.

Windows Communication Foundation

For description of the whole process of installing and configuring WCF, visit [Installation and deployment -> Additional configuration tasks -> Configuring Windows Communication Foundation](#).

Licensing

The Chat module is included in the **Base license** with **Social Networking package**, **Ultimate License** and **Kentico EMS**.

8.13.2.3 Technical overview

The majority of chat actions (such as sending messages, joining a room, etc.) on the live site are performed using AJAX without reloading the page. HTML content is generated almost exclusively by JavaScript on the client side. The server provides the client with data in JSON format.

Windows Communication Foundation

On the server side operate two WCF services - **ChatService** and **ChatSupportService**. The client side communicates with those services using HTTP requests and receives data in the JSON format.

JavaScript code for communication with the web services is generated automatically by WCF. You can check if it is generated correctly by visiting the following URL:

```
<your website URL>/CMSModules/Chat/CMSPages/ChatService.svc/JS
```

If there isn't any JavaScript generated on the page, WCF may not be correctly configured. See the [Prerequisites](#) topic for configuration information and links to the official troubleshooting page.

jQuery Templates

The client side receives objects with data and generates HTML. To do so, it uses a jQuery plug-in called **Templates**. Using the templating system on the client side allows chat to work without requesting pages and still offer flexibility similar to [Kentico macro language \(K#\)](#). jQuery Templates documentation and syntax description can be found at <https://github.com/BorisMoore/jquery-tmpl>.

Templates are saved as transformations with their type set to jQuery. With the module comes a container document type called **Chat – Transformations**, which holds transformations needed for chat to work. JavaScript objects are passed to the jQuery Template engine along with the transformation text.

To learn more about the templates and how to use them to customize the chat module, refer to the [Writing transformations for chat](#) topic.

BBCode parser

The client side also provides BBCode resolving - a JavaScript resolver is used to parse the BBCode tags.

8.13.3 Managing chat rooms

8.13.3.1 Chat room types

This topic describes the various types of chat rooms available in the Kentico CMS Chat module. The types are cumulative, meaning that a chat room can be of more than one type, while inheriting the properties of all the selected types.

Types can be selected when creating a new room or editing an existing one. You can find more information about the editing interface in the [Configuring chat rooms](#) topic.

Global and site-related rooms

Similarly to most objects throughout the CMS, a chat room can be made available on all websites in a particular instance of the application, or its usage can be limited to a specific site. This property needs to be specified before you create a chat room, by selecting **(global)** or a desired site, in the **Site** drop-down list.

Public and private rooms

A public chat room can be seen in the list of rooms and joined by anyone. Contrary to that, joining a private room requires an invitation from a user who is an [administrator](#) of that particular room. This parameter can be turned on or off anytime on the chat room editing page, by checking or un-checking the **Is private** check-box.

Anonymous access

Governed by the **Allow anonymous** check-box on the chat room editing page, this property determines whether an anonymous user can join the room. A chat user is considered anonymous when she is not logged in to the site via a user name and password.

One-on-one chat

This type of room is automatically created when a user requests chat with another user by clicking her name in the list of on-line users.

Support chat

Support chat is a special type of chat room where customer support personnel can talk to site visitors. Requests for support can be accessed through CMS Desk, provided you have the appropriate permission. You can create a room of this type by checking the **Is support** check-box on the room editing page. For more information about this feature, refer to the [Support chat](#) chapter.

8.13.3.2 Configuring rooms

In this topic, you will learn how to create chat rooms, enable or disable, and reconfigure existing rooms.

Chat rooms can be managed in **CMS Desk -> Tools -> Chat**. On the **Chat rooms** tab, you can see the list of existing rooms.

| Actions | Display name | Enabled | Private | Is support | Created | Created by | Description |
|---------|----------------------|---------|---------|------------|----------------------|----------------------|---|
| | General discussion | Yes | No | No | 4/30/2012 3:55:45 PM | Global Administrator | Come in and chat about anything and everything. |
| | Kentico CMS Devs | Yes | Yes | No | 4/30/2012 5:54:23 PM | Global Administrator | Invite-only room for developers using Kentico CMS. |
| | Science & Technology | Yes | No | No | 4/30/2012 5:52:50 PM | Global Administrator | General discussion about the impacts of science and technology on our day-to-day lives. |
| | Software development | Yes | No | No | 4/30/2012 5:51:31 PM | Global Administrator | Discuss the latest trends in software development here. |

Please note

The page lists all types of rooms, including rooms that accommodate one-on-one chat and support rooms.

Creating a new room

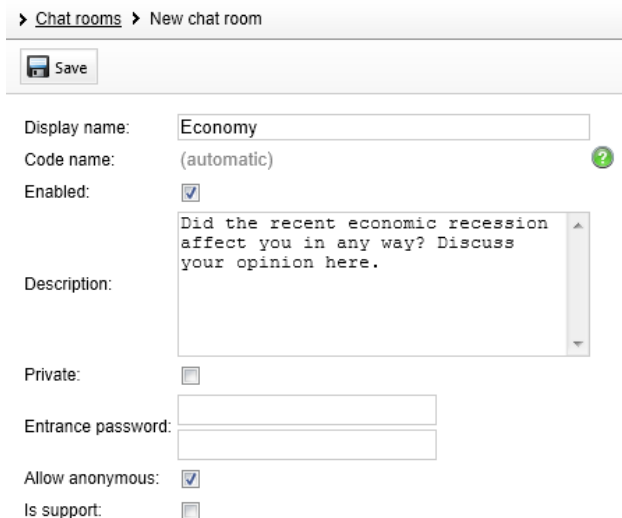

To create a new room, select whether you want it to be global (i.e., available on all sites) or bound to a

specific site, then click  **New chat room**.

The **New chat room** form offers a set of properties that the new room can have:

- **Display name** - the name that will be displayed in the user interface and in the list of rooms on the live site.
- **Code name** - the name that will be used in code.
- **Description** - text which will be displayed alongside the display name of the room in both the user interface and the live site.
- **Private** - property that indicates whether users will need an invitation in order to join the room.
- **Entrance password** - string of characters which the users will be prompted to enter when trying to join the room.
- **Allow anonymous** - check-box that determines whether users which are not logged in to the site will have access to the room.
- **Is support** - setting that allows to receive notifications about new messages and chat in the room through CMS Desk, thus enabling customer support from a single location. You can find more information in the [Support chat](#) chapter.

A screenshot of the 'New chat room' form. At the top, there is a breadcrumb trail: '> Chat rooms > New chat room'. Below this is a 'Save' button. The form contains several fields: 'Display name:' with the value 'Economy'; 'Code name:' with the value '(automatic)'; 'Enabled:' with a checked checkbox; 'Description:' with a text area containing the text 'Did the recent economic recession affect you in any way? Discuss your opinion here.'; 'Private:' with an unchecked checkbox; 'Entrance password:' with two empty input fields; 'Allow anonymous:' with a checked checkbox; and 'Is support:' with an unchecked checkbox.

To create the room, click  **Save**.

Room actions

The list of chat rooms provides buttons for room management in the **Actions** column.

| Actions | Display name ^ | Enabled | Private |
|---------|----------------------|---------|---------|
| | Hacking | No | No |
| | Kentico CMS Devs | Yes | Yes |
| | Science & Technology | Yes | No |
| | Software development | Yes | No |

- **Edit** - opens the room editing page, where you can adjust room properties and manage users that are joined in the room, as well as messages posted in the room.
- **Disable** - renders a room unavailable to the live site users and disallows them to send any messages to the room.
- **Enable** - re-enables a disabled room.
- **Delete** - Schedules a room for deletion. Rooms are not deleted immediately, but rather disabled and flagged as scheduled to deletion. A [scheduled task](#) will delete the room after a certain amount of time. Nevertheless, the room won't be accessible by any user.

The **Edit** button takes you to the room editing form.

The **Users** tab lists users who are present in the room. To learn about management of users in a particular room, see the [Users tab](#) topic.

To learn more about the **Messages** and **View** tabs, see the [Messages & View tabs](#) topic.

8.13.3.3 Users tab

The **Users** tab of the chat room editing interface allows management of users who are present in the respective room. It allows you to kick users, add users to the room and assign them administrator rights.

The tab features a list of users that are currently present in the chat room and users that have elevated rights for the room. Off-line users with no special permissions do not appear on the list.

› [Chat rooms](#) › Software development

General Password **Users** Messages View

 Add user

Note: users displayed in this list are either on-line right now or have raised privileges.

| Actions | Nickname | Admin level | On-line |
|---|-----------------------|-------------|---------|
|   | guest_6 | None | Yes |
|   | Jimbo | None | Yes |

Adding a user

To add a user to the room, click  **Add user**. Then click **Select** to bring up a dialog listing users registered on the current site. You can select the user you wish to add by clicking the appropriate line.

Before adding the user to the room, you need to assign them certain permissions. For this purpose, the **Admin level** drop-down list offers the following options:

- **None** - the user won't have any special permission.
- **Join** - the user will receive permission to join the room, but no special management rights. This option is available only in [private rooms](#).
- **Admin** - the user will receive rights to administer the room. A room administrator can adjust the properties of the room, moderate messages and manage users present in that room.

User actions

The following action buttons are available in the list of room users.

-  **Edit** - allows to modify the user's permissions and properties.
-  **Kick** - removes the user from the room.
-  **Revoke access** - available only in private rooms, removes the user's right to join the room.

The  **Edit** button takes you to the **Editing admin rights** page. On this page, you can change the permissions the user has.

You can click the user's name to display a dialog that allows you to change the user's chat nickname. In that dialog, you can click **Edit** to modify the user's settings, similarly to the interface located in **Administration -> Users**.

8.13.3.4 Messages & View tabs

The **Messages** tab of the room editing page allows you to manage messages sent in the edited room, while the **View** tab displays the room as live site users would see it.

Messages tab

On the **Messages** tab, you can view and manipulate messages that were sent in the chat room. You can also send announcements to the room. The announcements will appear in the same formatting as system messages.

» Chat rooms » Software development

General Users Messages View

 New announcement

| Actions | Message posted | Author | Message | IP address | Message type |
|---|-----------------------|----------------------|--|------------|-----------------|
|    | 2/28/2012 12:18:07 PM | System | User guest_8 has entered the room | ::1 | Enter room |
|    | 2/28/2012 11:53:26 AM | System | User guest_2 has left the room | | Leave room |
|    | 2/28/2012 10:12:59 AM | Global Administrator | Sure, what's the problem? | ::1 | Classic message |
|    | 2/28/2012 10:12:46 AM | guest_2 | Hi everyone! Could someone please help me with HTML 5? I've just started learning. | ::1 | Classic message |
|    | 2/28/2012 10:11:27 AM | System | User guest_2 has entered the room | ::1 | Enter room |
|    | 2/28/2012 10:07:39 AM | System | User Global Administrator has entered the room | ::1 | Enter room |

Items per page: 25

You can sort and filter messages by their type. The following list presents types of messages authored by chat users:

- **Classic message** - messages posted by users on the live site.
- **Whisper** - private messages posted to the room. On the live site, only the user selected as recipient can see the message.
- **Announcement** - messages sent from CMS Desk.

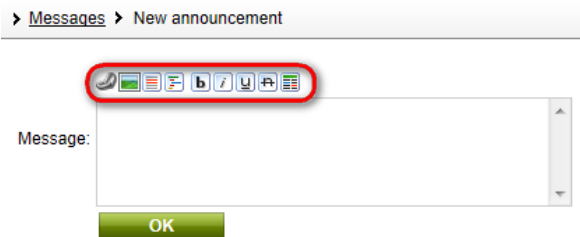

In addition, there are several types of messages that are automatically generated by the system:

- **Enter room** - appears when a user joins a room.
- **Leave room** - appears when a user leaves a room.
- **Change nickname** - appears when a user changes her nickname.
- **Kick** - informs that a user has been kicked from a room.
- **Invitation** - informs that a user has invited another user into a room.

- **Support greeting** - displayed only in [support chat](#), appears to visitors who request support for the first time in a session.
- **Permanent leave room** - displayed when a user leaves a private room and cancels her invitation.
- **Permanent kick** - displays when a user is revoked access to a room.

Adding an announcement

To add a new announcement, click  **New announcement**. Enter the message text into the text area and click **OK** to submit the message. The text of the message can contain [BB code](#), which you can insert via the image buttons above the text area.

Message actions

The list of messages provides the following actions to be performed on messages:

-  **Edit** - takes you to the message editing page, which is identical to the **New message** form. There, you can modify the text of the message.
-  **Delete** - permanently deletes the message.
-  **Reject** - hides the message from live site users without deleting it.
-  **Approve** - takes back the Reject action and makes the message available for all users in the room to see.

View tab

The **View** tab lets you see the chat room as it would appear to you on the live site, including the list of on-line users, messages and notifications.

8.13.4 Managing chat users

8.13.4.1 Overview

This topic provides insight into the system of organizing users in the Chat module. It describes how chat users are stored in the database, the difference between anonymous and registered users and the two types of on-line state.

Chat users are an entity separate from CMS users. They are stored in a dedicated database table as a combination of their nickname and a foreign key binding them to CMS users. The binding, however, is optional - absence of the binding makes the user anonymous.

User types

There are two types of chat users - anonymous and registered. Anonymous users are site visitors, who either don't possess a user account on a site, or they do have an account but are not logged in. To enter the chat, users only need to choose a nickname. Registration is not necessary.

If a registered user is logged in, the nickname they choose when entering the chat is tied to their account. As a result, the nickname is reserved for that user.

On-line users

The on-line state of chat users is monitored on two levels - site level and room level. A user who enters the chat starts pinging the server on a regular basis, thus keeping the server aware that they are on-line. When the user goes off-line (i. e. stops pinging the server), their on-line state is changed, rather than the user record being deleted altogether.

When the user enters a room, the client side of the application includes the information in the packets sent to the server, thus notifying the server that they are on-line in a certain chat room. When a user with elevated permissions leaves the room, they are not removed from the room, only their on-line state changes. Users without permissions are removed from rooms immediately after leaving them or leaving the chat. More information about room permissions can be found in the [Permissions](#) topic.

8.13.4.2 Creating and editing users

Chat users can be managed in **CMS Desk -> Tools > Chat -> Users**. The page lists registered users who entered chat on the current site.

| Actions | Nickname | On-line |
|---------|----------------------|---------|
| | Andrew Jones | Yes |
| | Global Administrator | Yes |
| | Sample Gold Partner | No |

Adding a new user

To add a new user to the chat, click **New chat user**. Select a registered user, enter a nickname for

the user and click **OK**.

The system doesn't allow adding anonymous users, since real users wouldn't then be able to choose nicknames added this way.

Editing users

You can click **Edit** (✎) in the Actions column to bring up the user editing page. On the page, you can change the user's nickname. Additionally, you can click **Edit**, which opens a new window allowing to adjust the [user's properties](#).

8.13.4.3 Permissions

The Chat module offers a set of permissions intended for allowing or denying various actions to certain users.

Module permissions

The Chat module offers standard module permissions adjustable in **Site Manager -> Administration -> Permissions**. The following permissions control allowed actions in CMS Desk:

- **Global read** - allows users in the given role to display the lists of global chat rooms, chat users and canned responses, but doesn't permit any modifications. The permission is limited to global objects, it doesn't apply to objects bound to a specific site.
- **Global modify** - gives full control of global chat rooms, chat users and canned responses. The permission is limited to global objects, it doesn't apply to objects bound to a specific site.
- **Read** - allows users in the given role to display the lists of site-bound chat rooms, users and canned responses, but doesn't permit any modifications. The permission doesn't apply to global objects.
- **Modify** - gives full control of site-bound chat rooms, users and canned responses. The permission doesn't apply to global objects.
- **Enter support** - displays an additional toolbar with the options to go on-line as a support person and manage canned responses. More information can be found in the [Support chat](#) chapter.

The following permissions are applicable to users using chat on the live site:

- **Manage rooms** - gives users of the given role the right to modify chat room properties (e.g., create, delete, set passwords, send invitations, etc.) and administer users (e.g., define room administrators or kick users).
- **Create room from live site** - allows users to create a new chat room using a button in the list of chat rooms.

Room permissions

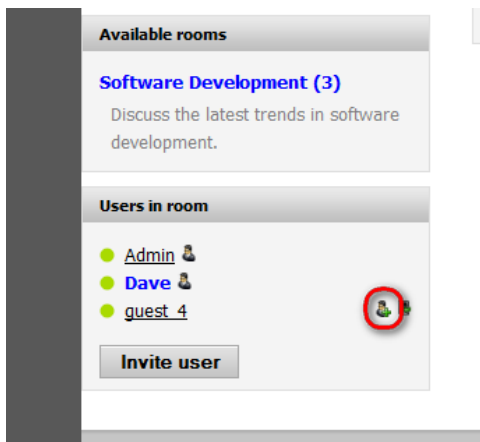

There are also a few permissions which are specific for the Chat module. These can be assigned to a user for a particular room. This means that a single user can have elevated rights in one room, while being a regular user without any special permissions in another.

The following list presents users with different permissions and the actions they are allowed to perform:

- **Regular user** - doesn't have any special rights. Such user can only post messages to public rooms.
- **Invited user** - can post messages to a private room they are invited to.
- **Room administrator** - can post messages, reject messages, kick users and define other administrators. An administrator can also edit the room's properties or disable the room to make it unavailable to be joined.
- **Room creator** - has the same rights as an administrator, however, this permission can be taken away from the user only in the CMS Desk interface by a user with the **Modify** permission for the Chat module.

Room permissions can be set while adding or editing a room user in **CMS Desk -> Tools -> Chat -> ...select a room... -> Users**. See the [Users tab](#) topic in the **Managing chat rooms** chapter for details.

Users can be assigned rights also on the live site, using the **Add room admin** button in the list of room users.

You can remove administrator rights from a user in a similar fashion - by clicking the **Delete room admin** button.

Invitations to users can be sent via the **Invite user** button in the list of room users.

8.13.5 Setting up chat on site

8.13.5.1 Available web parts

This topic lists all web parts that accommodate the different functions of the Chat module on the live site.

Chat web part

The Chat web part combines all the web parts described in the following text into one. It provides a ready-to-use solution to be placed on a page without additional configuration.

The screenshot displays the chat interface. On the left is a sidebar with three sections:

- Login**: Shows the user is logged in as **Global Administrator**. It includes a [Change nickname](#) link and a **Leave chat** button.
- All on-line users**: Lists **Global Administrator** and **quest_2**.
- Available rooms**: Lists two rooms:
 - Science & Technology (0)**: General discussion about the impacts of science and technology on our day-to-day lives.
 - Software development (2)**: Discuss the latest trends in computer software development.
 A **Create new room** button is located at the bottom of this section.
- Users in room**: Lists **Global Administrator** and **quest_2**. An **Invite user** button is at the bottom.

 The main chat window is titled **Software development** and shows:

- A text input field with a **Send** button.
- A dropdown menu set to **Everyone**.
- A chat history area with the following messages:
 - 10:12:59 Global Administrator** : Sure, what's the problem?
 - 10:12:46 quest_2** : Hi everyone! Could someone please help me with HTML 5? I've just started learning.
 - 10:11:27: User quest_2 has entered the room**

Other web parts in this topic can be placed either all together on a single page, or separately on multiple pages while the web parts ensure redirection between the pages.

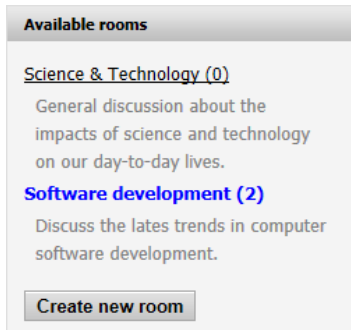

Chat login

Enables users to log into chat. When logged in, displays the login status, a link to change nickname and the Leave button.

The screenshot shows the **Login** web part. It displays the text "Logged in as **Global Administrator**". Below this, there is a [Change nickname](#) link and a **Leave chat** button.

Chat rooms

Displays a list of available rooms and a button to create a new one if the current user is allowed to do so.

Available rooms

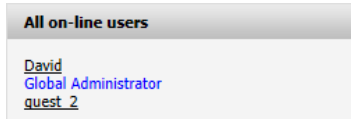

[Science & Technology \(0\)](#)
General discussion about the impacts of science and technology on our day-to-day lives.

[Software development \(2\)](#)
Discuss the latest trends in computer software development.

[Create new room](#)

Chat on-line users

Provides a list of users currently on-line in the chat. Additionally, it allows to initiate one-on-one chat with an on-line user.

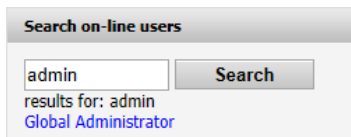

All on-line users

[David](#)
[Global Administrator](#)
[quest_2](#)

Chat search on-line users

Allows to find a particular user among the users currently on-line.

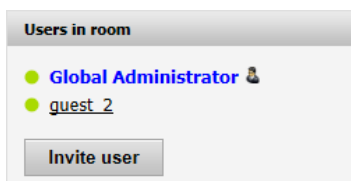

Search on-line users

[Search](#)

results for: admin
[Global Administrator](#)

Chat room users

Displays the list of users who joined a particular chat room along with their on-line state.

Users in room

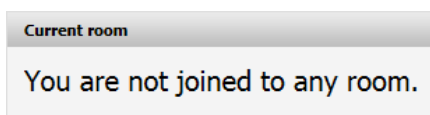

● [Global Administrator](#) 

● [quest_2](#)

[Invite user](#)

Chat room name

Displays the name of the room the user is currently in.

Current room

You are not joined to any room.

Chat send message

Allows users to send a message to the current chat room.

Chat room messages

Displays the messages posted to the current chat room.

10:12:59 **Global Administrator** : Sure, what's the problem?
10:12:46 **quest_2** : Hi everyone! Could someone please help me with HTML 5? I've just started learning.

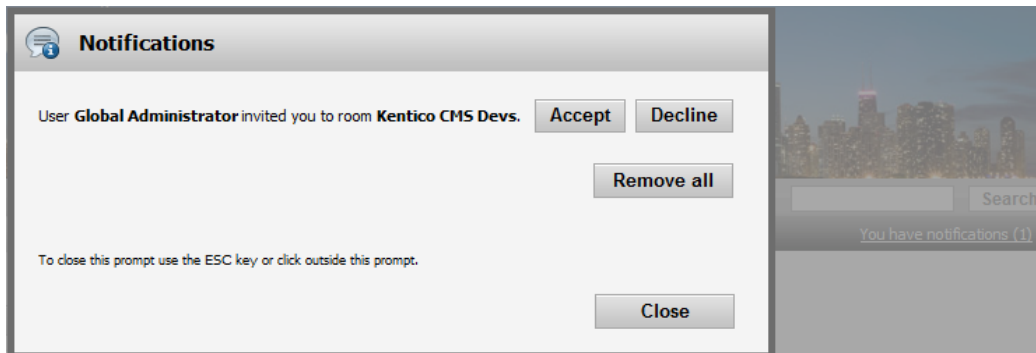

Chat leave room

Displays a button to leave the current room.

Chat notification

Displays notifications about various events, such as receiving an invitation to a room.

Chat errors

Displays warnings and errors that may occur while chatting. If the web part is not present, all errors are displayed as JavaScript alerts.

Support chat web parts

Chat support request

Displays a button that users can use to request chat with a support person.

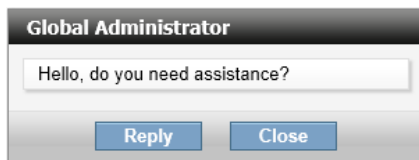

Initiated chat

Allows support personnel to start chatting with the visitor who is viewing the page with this web part.

Automatically initiated chat

Allows to define a message, with which it will automatically address the visitor who is viewing the page with this web part.

8.13.5.2 Layout overview

This topic describes the components and the default layout of the chat web part.

The Chat web part groups all the available components into a single ready-to-use web part. When you access a page with the web part for the first time, you will see a log-in box.

Once logged in, you will be presented with the following screen.

The screenshot displays the chat interface with four numbered callouts:

- 1**: Login information section showing "Logged in as Global Administrator" and buttons for "Change nickname" and "Leave chat".
- 2**: "All on-line users" section listing "Global Administrator" and "quest_10".
- 3**: "Available rooms" section listing "Kentico CMS Devs (0)", "Science & Technology (0)", and "Software development (0)", each with a brief description and a "Create new room" button at the bottom.
- 4**: Notification area at the top right showing "You are not joined to any room." and "No notifications".

1. **Login information** - displays your nickname, a link allowing to change the nickname, and a button to log out.
2. **On-line users** - shows the list of users that are on-line in the site's chat. Allows to initiate a one-on-one chat session with a user.
3. **Available rooms** - displays a list of chat of rooms that you can join.
4. **Notification area** - contains the name of the room you are in and displays a link which brings up the notifications dialog.

When you click a room in the list of rooms (3.), additional controls appear:

1. **Users in room** - lists all users who are on-line in the room or have elevated permissions for the room.
2. **Send message** - allows to type and send a message.
3. **Recipient** - defines who will see the message. A message can be addressed to everyone in the room or you can select a specific user to send it to. Checking the check-box prevents changing the recipient back to everyone after sending a message to a specific user.
4. **Messages area** - displays messages that are addressed to everyone, and private messages intended for the logged-in user.

8.13.5.3 Example setup

The Chat module with its web parts allows you to set up chat functionality on your site in many different configurations, or modes. The most basic use cases include [single page mode](#) and [redirection mode](#), which are described in this topic.

Single page mode

Web parts belonging to the Chat module can be placed on a page one by one, thus compiling the functionality of the Chat web part from multiple components, allowing for customization of appearance and complexity. For example, you can leave out certain components in order to limit the set of features users of the chat can utilize. The following text explains how to set up multiple-room chat within a single page.

Tip

Chat web parts do not need any configuration in order to function properly. You can

achieve standard behavior by leaving the web parts' properties at their default values. The default values are specified in the module's settings. On the other hand, the web parts and settings allow for a high level of customization.

Start by creating a new blank page. Then place the following web parts on the page. As mentioned previously, you can leave all their properties at their default values.

- **Chat login** - this web part will serve as the starting point for users who wish to enter the chat, as well as an exit point for logged-in users.
- **Chat rooms** - this component will display the list of rooms that the currently logged-in user can join.
- **Chat send message** - this web part will display a text-box to allow sending messages.
- **Chat messages** - this web part will display the most recent messages in a room.
- **Chat leave room** - this web part will display a button that will allow users to leave the room they are in.
- **Chat notifications** - this web part will display system notifications, such as room invitations.

Redirection mode

Many web parts that belong to the Chat module have the **Redirect URL** property. This attribute defines the URL of the page where the chat user should be redirected when performing the action the web part is intended for. For example, in the Chat room list web part, you would set the Redirect URL to the page that contains the Chat room messages web part.

Let's presume that you want to set up chat which will comprise the following pages:

- Logon page
- Page with list of chat rooms
- Chat room page with messages

The following is a step-by-step tutorial how to set up chat on the pages. The procedure is presented on the sample Community site.

Please note that unless instructed otherwise, you can leave all the web parts' properties at their defaults.

Preparation

1. Create a new blank page called **Chat**. This will be the starting page, which the users will use to enter the chat.
2. Under the Chat page, create two blank pages called **Room list**, and **Room**.
3. On the **Room list** page, select the **Properties -> Template** tab, then click **Edit template properties** and select **Inherit all** in the **Inherit content** field. Then save the template.
4. Repeat the previous step on the **Room** page.

Basic setup

1. On the **Chat** page, add the **Chat login** web part. Set its properties as follows:

- **Redirect URL after entering chat:** ~/Chat/Room-list.aspx
- **Redirect URL after logout:** ~/Chat.aspx

This will ensure that users will be redirected to the correct page when logging in and out.

2. Place the **Chat notifications** web part on the **Chat** page.

This will allow users to see notifications about invitations to rooms and private conversations, as well as other system messages addressed specifically to the current user.

3. Place the **Page placeholder** web part on the **Chat** page.

The web part, along with the template settings defined previously, will cause the Chat login web part to appear on all subpages, allowing users to log out at any time.

4. On the **Room list** page, add the **Chat rooms** web part. Set the following property:

- **Redirect URL after join:** ~/Chat/Room.aspx

When a user clicks a room in the list, the web part tries to join the user to the room. If that action is successful, the system redirects the user to the specified URL.

5. Place the **Chat send message** web part on the **Room** page.

This will allow sending messages to the room and its members.

6. Place the **Chat room messages** web part on the **Room** page.

This web part will display messages from other users in the room, as well as system messages and announcements.

7. Place the **Chat leave room** web part on the **Room** page. Set the following property:

- **Redirect URL after leaving:** ~/Chat/Room-list.aspx

This will provide user a way to exit the room and return to the page with the list of rooms.

Extended setup

After completing the preceding procedure, you will have implemented a functioning multi-page chat with all the basic features. However, this configuration can be extended with additional features. The process is described in the following step-by-step tutorial.

1. Place the **Chat on-line users** web part on the **Room list** page.

This will enable users to see the list of users on-line in the chat regardless of the room they are in, if any. They will also be able to start a private conversation with any of the on-line users.

2. Add the **Chat room name** web part on the **Room** page.

This web part will display the name of the room the user is in.

3. Place the **Chat room users** web part on the **Room** page.

This will allow users in a room to see who else is on-line in the particular chat room and initiate a one-to-one chat session with them.

8.13.5.4 Web part grouping

All chat web parts share a common property - **Group name**. This property allows you to have multiple instances of the same web part in one chat implementation, with each of the instances acting on its own.

For example, you can enable chat users to contribute to two chat rooms at the same time.

1. Place the **Chat send message** web part on a page. Set its **Chat room** property to an existing room. Set its **Group name** to **Group1**.
2. Place the **Chat messages** web part on the same page. Set its properties as for the previous web part.
3. Add the same pair of web parts once again, but set their **Room name** property to another existing room and their **Group name** to **Group2**.

When you view the page on the live site, you can see that each pair of web parts is tied to a different chat room and you can use them both at the same time.

8.13.6 Customizing appearance

8.13.6.1 Customizing CSS styles

The Chat web part has its CSS styles defined by default. If you want the individual web parts to look like the components of the Chat web part, you just need to wrap them in the **Gray box with header** web part container.

8.13.6.2 Writing transformations for chat

Chat web parts use **jQuery templates** to display their content. This includes on-line users lists, room lists, messages and other elements. In Kentico CMS, the templates are stored as ordinary transformations that have their type set to jQuery.

You can find all transformations that the Chat module needs in **Site Manager -> Development -> Document types -> Edit (✎) Chat - Transformations -> Transformations**.

A jQuery transformation consists of HTML code and **template tags** that dynamically insert values of the object that is currently being processed. There are also tags that control the flow of the transformation.

Displaying data

An example transformation could look like this:

```
<div>
  <strong>${Nickname}</strong>: ${MessageText }
```

```
</div>
```

The example can be used to display a chat message. It displays the sender's nickname in bold and the text of the message.

The template tags are highlighted in *italics*. In this example, the tags are used to display data. Tags that display data should always start with a dollar sign (\$), followed by the name of the variable that you want to display enclosed in brackets.

To learn what data you can display, refer to the [Reference](#) topic.

Creating conditions

You can also add conditional template tags that will control what content will be displayed based on a true/false condition.

A condition begins with the `{{if}}` tag. As an argument, you can enter any statement that returns a boolean value (*true* or *false*). The following are examples of a valid conditional statement:

- `IsSystem`
- `Nickname == 'administrator'`
- `! IsCurrentUser`

An *if* condition can have two branches - one that gets rendered when the condition is true, and one indicated by the tag `{{else}}` that gets rendered when the condition is false. You should always close the body of the condition with the `{{/if}}` closing tag.

In the following example, we'll add the recipient's nickname in case the message is a whisper. Otherwise, the transformation will display only the standard nickname and text combination.

```
<div>
  {{if Whisper}}
    <strong>${Nickname} -> ${Recipient}</strong>: ${MessageText}
  {{else}}
    <strong>${Nickname}</strong>: ${MessageText}
  {{/if}}
</div>
```

Conditional tags support multiple conditions joined by logical operators. The syntax is similar to that of C#, as you can see in the following example:

```
{{if IsSystem || Nickname == 'administrator' }}
  <div>
    <strong>System message:</strong> ${MessageText}
  </div>
{{/if}}
```

Integrating macro expressions

You can insert [K# macro expressions](#) into templates and combine them with template tags.

By using **localization macros** in transformations, you can ensure that all elements will be displayed in the correct language. The elements that can be translated include:

- system messages
- notifications
- buttons

All of these elements are already prepared in the form of resource strings.

The following code example shows how to inform that a message has been rejected using a resource string.

```
{{if Rejected}}  
    <span class="Rejected">{$chat.messagerejected$}</span>  
{{/if}}
```

You can find the complete list of resource strings belonging to the Chat module in the [Reference](#) topic.

Inserting action commands

Users can perform actions on objects, provided they have permission to do so. For example, you can allow room administrators to reject messages directly in the list, or you can allow them to disable or delete rooms.

The following example shows how you can insert a command control for the **reject message** action. You need to insert the action command into the *onclick* attribute with the same syntax as if you were displaying a variable.

The *if* condition ensures that the action command will be rendered only if the current chat user has permission to reject the message, i.e., if the user is an administrator or a creator of the room.

```
{{if RejectMessage}}  
    <a href="#" onclick="{$RejectMessage}">Reject</a>  
{{/if}}
```

For a complete list of available commands, refer to the [Reference](#) topic.

8.13.6.3 Reference

This topic lists variables and commands that you can use in chat transformations. Each section of this topic is dedicated to a single type of object, i.e., [messages](#), [rooms](#), [users](#), [notifications](#), [support chat objects](#) and [errors](#).

To learn how to use these values in transformations, refer to the [Writing transformations for chat](#) topic.

You can also take inspiration in the default transformations within the **Chat - Transformations** document type.

Messages list

The following table lists data variables that are available when displaying messages. You can either display the variables' values or evaluate them in conditional statements.

| Variable name | Data type | Description |
|--------------------|-----------|--|
| AuthorID | int | Contains the database ID of the chat user who sent the message. If the message is a system message, the value is <i>null</i> . |
| IsOneOnOne | bool | Returns true if the message is part of a one-on-one chat session. |
| IsRejected | bool | Returns true if the message has been rejected. |
| IsSupport | bool | Indicates if the message is part of a support chat session. |
| LastModified | date/time | Contains the time when the message was modified. |
| MessageID | int | Returns the database ID of the message. |
| MessageText | string | Contains the text of the message. |
| Modified | bool | Indicates if the message has been modified. |
| Nickname | string | Contains the nickname of the sender. If the message is a system message, the value is <i>null</i> . |
| PostedTime | date/time | Contains the time when the message was sent. |
| Recipient | string | Returns the nickname of the message's recipient. If the message is addressed to all users in a particular room, i.e., the recipient is not specified, the value is <i>null</i> . |
| RecipientID | int | Contains the database ID of the recipient, if specified. |
| SystemMessage Type | int | Contains the type of the message represented by an integer number as follows: <ul style="list-style-type: none"> • 0 - classic message • 1 - whisper • 2 - leave room • 3 - enter room • 4 - change nickname • 5 - kick • 6 - user invited • 7 - support greeting • 8 - permanently leave room • 9 - permanent kick • 10 - announcement • 11 - declined chat request |

The following table lists commands that you can use, for example, in *onclick* events.

| Command name | Description |
|-----------------|--|
| SelectRecipient | Selects the sender of the message in the Recipient drop-down list as the recipient |

| | |
|---------------------|--|
| | of the next message. |
| SelectPrevRecipient | If the message is a whisper message, this command selects the recipient of the message as the recipient of the next message. |
| RejectMessage | Rejects the message. |

Rooms list

The following table lists data variables that are available when displaying the list of rooms. You can either display the variables' values or evaluate them in conditional statements.

| Variable name | Data type | Description |
|----------------|-----------|---|
| AllowAnonymous | bool | Indicates whether the room allows anonymous users. |
| CanManage | bool | Indicates whether the current chat user can manage the room. |
| ChatRoomID | int | Contains the database ID of the room. |
| Description | string | Contains the room's description. |
| DisplayName | string | Contains the name of the room. |
| HasPassword | bool | Indicates whether users are required to enter a password to join the room. |
| IsCurrentRoom | bool | Indicates whether the current chat user is present in the room. The value takes into account the group that the web part displaying the list is in. |
| IsPrivate | bool | Indicates whether the room is private. |

The following table lists commands that you can use, for example, in *onclick* events.

| Command name | Description |
|--------------|--|
| Abandon | Removes the current user from the room. Revokes access if the room is private. |
| Delete | Disables the room and schedules it for deletion. |
| Delete | Opens the room editing dialog box. |

Important!

When rendering rooms, you should always wrap them in an anchor tag with "JoinRoom" as the class attribute value. This will allow users to join the room upon clicking.

Example:

```
<a class="JoinRoom">${DisplayName}</a>
```

Room name

When you want to display the name of the current room in the Chat room name web part, you need to create a separate transformation. You can display the room name in the transformation using the *RoomName* variable.

Users list

The following table lists data variables that are available when displaying the **list of users in a chat room**. You can either display the variables' values or evaluate them in conditional statements.

| Variable name | Data type | Description |
|---------------|-----------|---|
| ChatUserID | int | Contains the database ID of the chat user. |
| IsAdmin | bool | Indicates whether the user can manage the room. |
| IsAnonymous | bool | Indicates whether the user is anonymous. |
| IsChatAdmin | bool | Indicates whether the user has the Manage rooms permission. |
| IsCreator | bool | Indicates whether the user is the room's creator. |
| IsCurrentUser | bool | Indicates whether the user is the currently logged in user. |
| IsOnline | bool | Indicates whether the user is currently on-line. |
| Nickname | string | Contains the user's nickname. |

The following table lists commands that you can use, for example, in *onclick* events.

| Command name | Description |
|--------------|---|
| AddAdmin | Gives the user administrator rights for the room. |
| DeleteAdmin | Takes administrator rights away from the user. |
| KickUser | Kicks the user from the room. |
| KickUserPerm | Permanently kicks the user from the room. Removes the Join permission from the user. |
| OneOnOneChat | Initiates a one-on-one chat session with the user. |

The following table lists data variables that are available when displaying the **list of users that are on-line in chat**. You can either display the variables' values or evaluate them in conditional statements.

| Variable name | Data type | Description |
|---------------|-----------|--|
| ChatUserID | int | Contains the database ID of the chat user. |
| IsAnonymous | bool | Indicates whether the user is anonymous. |
| Nickname | string | Contains the user's nickname. |

Important!

When listing users who are on-line in chat, you need to include the `#{OnClick}` command in an OnClick event. The command ensures that other users will be able to initiate one-on-one chat with the user.

The transformation where you use this command will also be used when inviting users to a room. In this case, the command will make sure that the user gets selected.

Notifications

The following table lists data variables that are available when displaying **notifications**. You can either display the variables' values or evaluate them in conditional statements.

| Variable name | Data type | Description |
|----------------------|-----------|---|
| IsOneOnOne | bool | Indicates whether the notification is a one-on-one chat invitation. |
| KickTime | int | Contains the information about how long a user will be kicked from a room. This variable is only available when the NotificationType variable has a value of 4. |
| NotificationDateTime | date/time | Contains the time when the notification was created. |
| NotificationID | int | Contains the database ID of the notification. |
| NotificationType | int | Contains the integer representation of the notification type. The possible values are the following: <ul style="list-style-type: none"> • 0 - invitation • 1 - invitation declined • 2 - invitation accepted • 3 - nickname automatically changed • 4 - kick • 5 - permanent kick • 6 - administrator added • 7 - administrator deleted |
| ReadDateTime | date/time | Contains the time when the notification was read. If the message has not been read, the value is <i>null</i> . |
| RoomID | int | Contains the database ID of the room of concern. If the notification isn't related to room activity, the value is <i>null</i> . |
| RoomName | string | Contains the name of the room of concern. If the notification isn't related to room activity, the value is <i>null</i> . |
| SenderNickname | string | Contains the nickname of the user who performed the action that caused the notification to appear, e.g., the user who invited another user to a room. |

The following table lists commands that you can use, for example, in *onclick* events.

| Command name | Description |
|--------------|--|
| AcceptEvent | Accepts an invitation. Applicable only when the NotificationType variable has a value of <i>0</i> . |
| DeclineEvent | Declines an invitation. Applicable only when the NotificationType variable has a value of <i>0</i> . |
| CloseEvent | Closes (deletes) a notification. Applicable for all notification types except for invitations (NotificationType is not <i>0</i>). |

Support request

When writing a transformation for the Chat support request web part, you can use the **LiveSupport** variable, which indicates whether a support person is on-line.

Initiated chat

Transformations for initiated chat must have the following format:

```

{{if MessagesTemplate}}
    <code used for messages>
{{else}}
    <code used for the whole web part>
{{/if}}

```

In the code used for messages, you can use the **Text** variable to insert the text of the message.

In the code for the web part, you can use the following variables and commands:

- Accept - command that accepts the initiated chat and opens the support chat window.
- Reject - command that rejects the initiated chat.
- Initiator name - string variable containing the name of the initiator.
- Messages - string that contains all messages.

Errors

When writing a transformation for errors, you can use the **Message** string variable, which contains the error message. It is recommended to insert it in the following form so as to resolve potential HTML code.

```

{{html Message}}

```

When writing a transformation for the Delete all button in the list of errors, you can use the **DeleteAll** command, which deletes the errors.

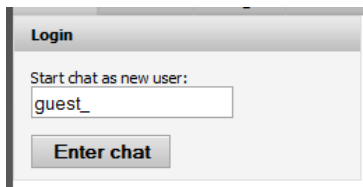

8.13.7 Using chat

8.13.7.1 Logging in

This topic explains the process of logging in to chat on the live site and the differences of this process for anonymous and registered users.

Anonymous users

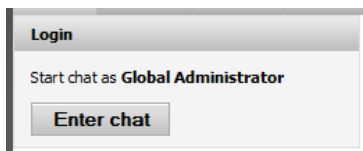

When an [anonymous user](#) views a page that contains the Chat web part or the Chat login web part, she is presented with the following login box.

A screenshot of a web form titled "Login". Below the title, it says "Start chat as new user:". There is a text input field containing the text "guest_". Below the input field is a button labeled "Enter chat".

The text box provides an option to choose a nickname. It is automatically pre-filled with text defined in the **Guest prefix** settings key. If the user chooses not to change the predefined nickname, the system will append a number to the prefix and log the user in. Users cannot append any custom text to the guest prefix.

Registered users

When a registered and logged-in CMS user accesses a page that contains the Chat web part or the Chat login web part, she is presented with the following box:

A screenshot of a web form titled "Login". Below the title, it says "Start chat as Global Administrator". Below this text is a button labeled "Enter chat".

The login box allows the user to enter the chat with the nickname specified in their account properties. If the user hasn't specified a nickname, their full name is used. Note that the chat nickname can be changed after logging in using the **Change nickname** link.

Related settings

The following are settings from the **Community -> Chat** category, which modify the behavior of the login box.

- **Guest prefix** - indicates the prefix anonymous users will be offered to include in their chat nickname.
- **Allow anonymous users globally** - determines whether anonymous users will be allowed to join chat. Note that even if the setting is on, you still can restrict anonymous access to individual rooms.
- **Force anonymous unique nicknames** - indicates if anonymous users should be forced to choose unique (unoccupied) nicknames.

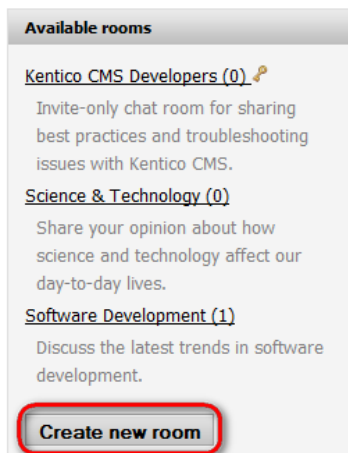

8.13.7.2 Chat rooms

This topic describes functions that relate to chat rooms.

Creating a room

Chat rooms can only be created by registered users who have the appropriate module permission - **Create room from live site** or **Manage**. Anonymous users cannot create new rooms.

A new room can be created using the **Create new room** button in the bottom of the list of rooms.

After clicking the button, the user is presented with a dialog offering the same set of properties as in the [room management UI](#). The only difference is that she cannot create support chat rooms.

The room will be created after clicking **OK**.

Joining a room

The list of rooms displays rooms that the current user is allowed to join. For example, if the current user is anonymous, she can only see chat rooms that have the **Allow anonymous** property set to true.

Special types of rooms are marked with icons:

-  - password protected room
-  - private room

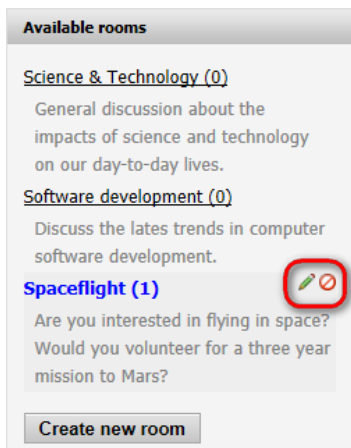

Clicking a room will make the user join the room. If a room is password protected, the user will first be asked to enter the password via a dialog.

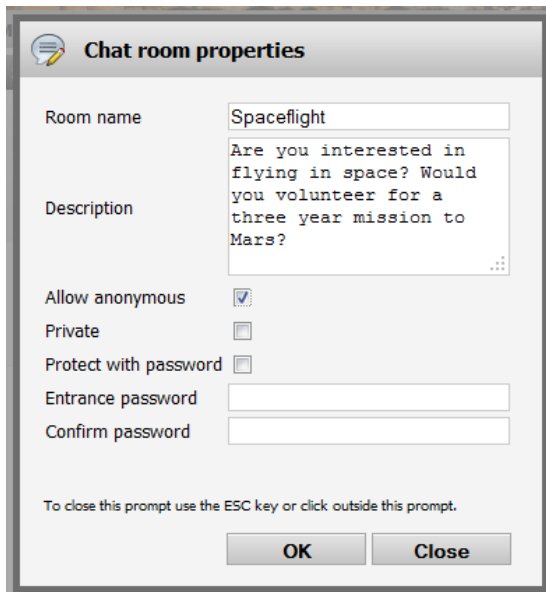

Managing a room

Room creators and administrators have the right to edit parameters of the room, add and remove other administrators and kick users. These actions are provided by action buttons in the list of rooms and the list of users in the room. The buttons appear when moving the mouse over the particular room or user and only in case the current user has permission to perform the actions.

Room actions

-  **Edit** - displays a dialog allowing to change the properties of the room.

The dialog box is titled "Chat room properties" and contains the following fields and options:

- Room name:
- Description:
- Allow anonymous:
- Private:
- Protect with password:
- Entrance password:
- Confirm password:

At the bottom, there are "OK" and "Close" buttons, and a note: "To close this prompt use the ESC key or click outside this prompt."

-  **Disable** - removes all users and makes the room unavailable for other users.
-  **Abandon** - removes the current user from the room and discards her invitation. Available only for private rooms.

User actions

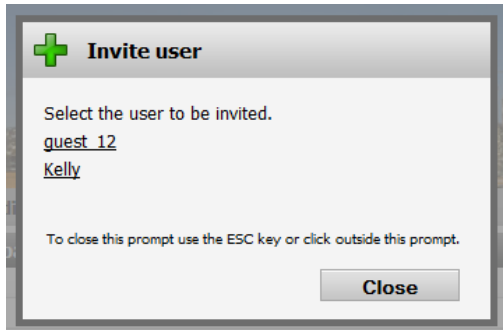

-  **Add room admin** - gives the user room administrator permissions.
-  **Delete room admin** - takes administrator permissions away from the user.
-  **Kick** - prevents the user from accessing the room for a certain period of time, specified by the **Kick lasting time** setting.
-  **Revoke access** - kicks the user and removes their invitation, thus preventing them from accessing the room further.

Inviting a user

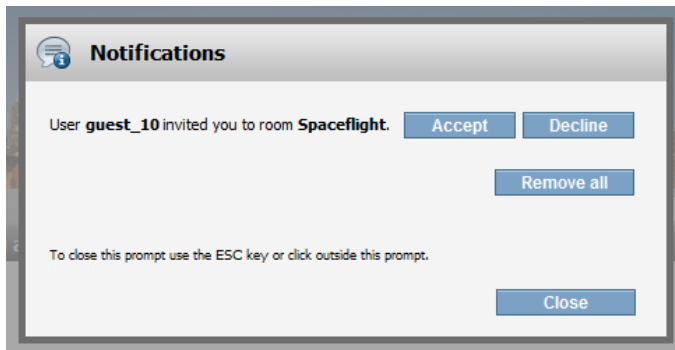

The list of room users offers a button to invite users to the room. In a public room, the button is visible to all users in the room. In a private room, only administrators can see the button and invite users.

Clicking this button will bring up a dialog allowing to select the user to be invited. The dialog lists only users who are on-line in the chat but not present in the room.

When a user is selected, they will receive a notification about the invitation and will be offered the option to accept and join the room or decline the invitation.

Leaving a room

To leave a room, users need to click the **Leave room** button, by default located in the upper right corner of the Chat web part layout.

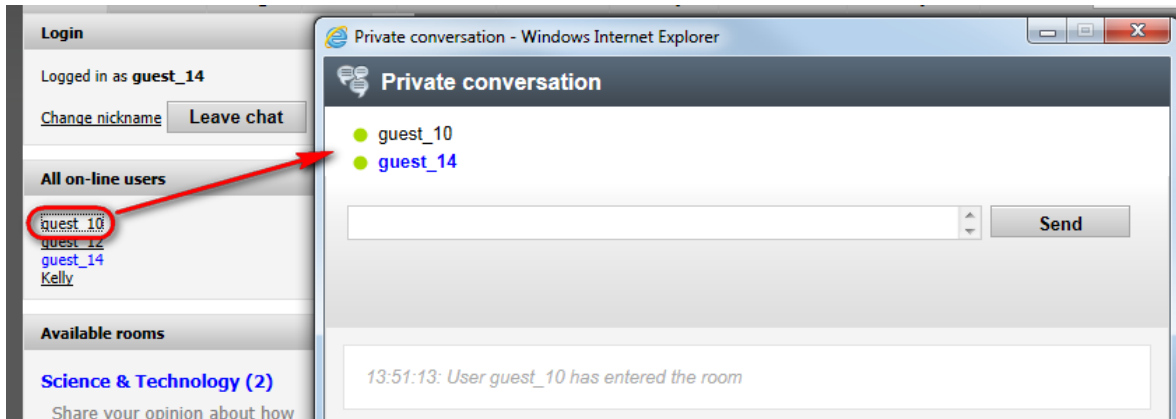

Starting private conversation

When a chat user clicks another user's name either in the list of on-line chat users or in the list of room users, a private conversation window pops up. At the same time, a new private room is automatically

created and the clicked user is invited to join the room. Since the room is private, other users cannot see it in the list of rooms.

After the invited user accepts the invitation, they automatically join the private room, which is then displayed in the private conversation window.

8.13.7.3 Chat messages

This topic presents the various types of chat messages and ways to send them.

Message types

Users of the Chat module may encounter the following types of messages:

- **Classic** - messages posted on the live site into a room.

10:23:19 guest_10 : Hello!

- **Whisper** - messages posted in the room, but only to a particular user designated as recipient.

15:51:19 From guest_5 : OK, looking forward!

15:51:06 To guest_5 : Meet me tonight at my place.

- **System** - messages generated by the system, informing about users joining and leaving rooms, and sent invitations.

10:20:56: User guest_12 has entered the room

9:20:10: User guest_14 has left the room

- **Announcement** - messages sent from the CMS Desk UI.

10:25:31: Users not adhering to rules will be banned!

When a user joins a room, system messages posted earlier are not displayed to them by default. This behavior can be adjusted in **Site manager -> Settings -> Community -> Chat -> First load of messages**.

Sending messages

Once joined in a room, users can start sending messages. A message typed into the textbox can be sent either by clicking the **Send** button or by pressing **Enter**.

A new line can be inserted by pressing **Shift + Enter** at the same time.

Users can send messages either to all users present in the room, or to a selected user. Recipient of the message can be specified via the drop-down list below the message text box.

If user selects **Everyone**, the message will appear to all users in the room.

If a particular user is selected, then only the selected user will be able to see the message. The following example shows how such message appears to the sender:

*10:33:13 To **Kelly** : This is a private message.*

The recipient will see the message as follows:

*10:33:13 From **guest 10** : This is a private message.*

After a private message is sent, the selector will revert the selected recipient back to Everyone. To prevent this and keep sending messages to a specific user, the sender should check the check-box on the left-hand side of the selector.

8.13.8 Support chat

8.13.8.1 Overview

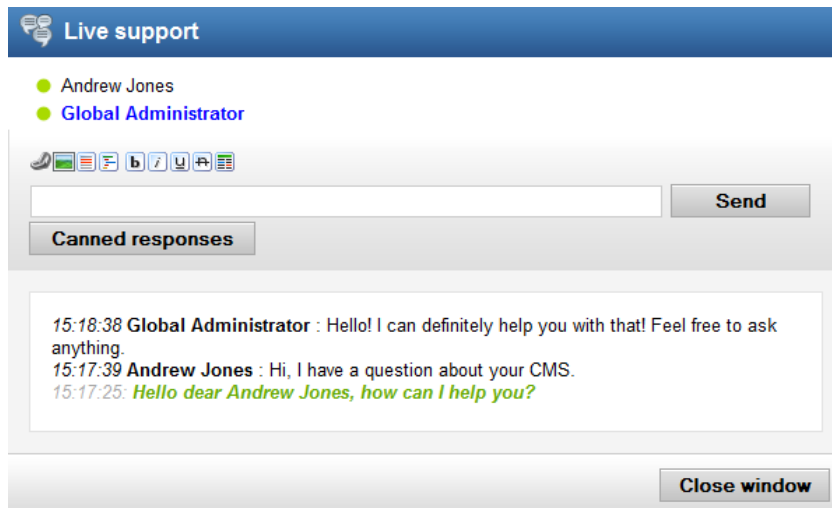

Support chat offers means for customer care departments of companies to provide help to their customers and answer their questions, which can be asked directly from the website, in real time.

This part of the Chat module is composed of several components:

- Support chat web parts - Chat support request, Initiated chat and Automatically initiated chat
- Notification and settings area

- Live support window

The available web parts differ in the way the chat is initiated:

- The **Chat support request** web part displays a button that the visitors can use to initiate chat with support personnel.
- The **Initiated chat** web part provides a way for support personnel to start chatting with on-line visitors from the interface in **Administration -> Users -> On-line users**.
- The **Automatically initiated chat** web part automatically sends the visitor a message after a specified period of time.

Regardless of the web part used to start the conversation, when a visitor sends the first message, the system creates a new [support room](#) and lights up a notification in CMS Desk. On-line support personnel then can enter the room and start attending to the customer.

8.13.8.2 Setup

This topic describes how to set up user accounts for support personnel and place the support chat on the live site.

Support chat permissions

With the Chat module comes a global role - **Chat support engineers**. The role already has the permission required for handling support requests from site visitors.

The permission - called **Enter support** - allows the notification area to be displayed and the support engineers to take rooms.

Setting up web parts

To allow site visitors to chat with the support personnel, you need to place one of the following web parts on a page. The following text describes the specifics of the individual web parts.

The web parts render all content based on transformations. The default transformations are defined in settings, so you can leave their properties dedicated to transformations blank. To learn how to write transformations for chat, refer to the [Writing transformations for chat](#) topic.

Chat support request

Displays a control that visitors click to start chatting with a support person. In this case, the site visitor initiates the chat and the support person receives a notification in the user interface. See the [Notifications](#) topic for details.

If no support person is on-line, the request will be sent by e-mail or won't be available at all. You can choose between these options in **Settings -> Community -> Chat -> Support chat**.

Initiated chat

When you place this web part on a page, you will be able to start chat with visitors who are present on the page.

You will be able to chat only with registered users who are logged on. To do that, navigate to Administration -> Users -> On-line users and click the Initiate chat button to start chatting with the user.

Please note that you need to [enable the on-line users feature](#) first.

Automatically initiated chat

This web part automatically displays a pre-defined message to all visitors after a specified amount of time that they spend on a page. When the message appears, they have two options:

- Reply - opens the support chat window. The visitor can now reply to the message, which then lights up a notification for support personnel in the user interface.
- Close - closes the message without replying. This prevents the message from appearing again for an hour.

The message won't appear if no support person is on-line.

Going on-line

When you're logged in to **CMS Desk** or **Site Manager** and have the **Enter support** permission, you can see the following icon in the top right-hand part of the user interface:

When you click the icon, a context menu appears:

The context menu offers the following functions:

- Enter support chat - brings you on-line and replaces itself with a button to go off-line.
- My canned responses - see [Canned responses](#).

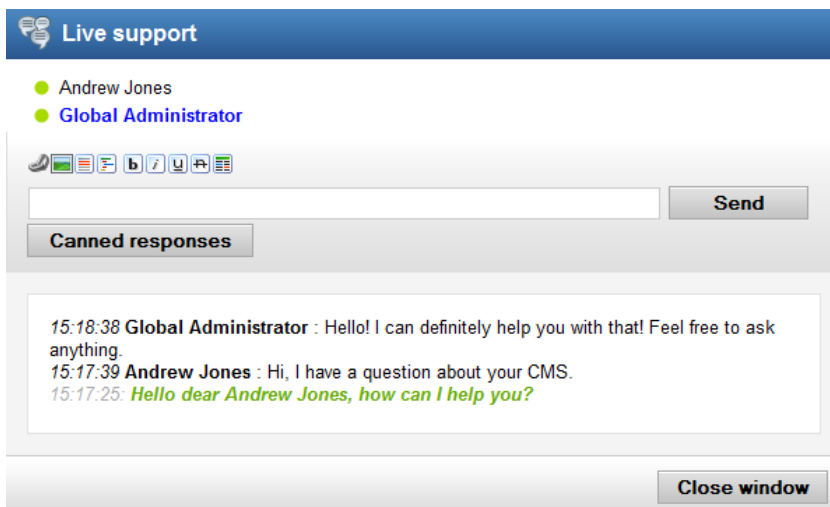

8.13.8.3 Notifications

When a user requests support on the live site and sends a message, all support personnel who are on-line will receive a notification.

When a user sends a message to the room that has been created for her, the room selector will appear in the notification area. The room will be added to the list of currently active support rooms. From the drop-down list, you can select the room you wish to take and provide support in.

Clicking a room will open a window similar to what appears to visitors requesting support.

After a support person opens (takes) the room, notifications will appear only to her.

You can hide the room selector using the  icon. You can show it again by clicking **Support chat**  and then clicking  **Show active rooms**.

8.13.8.4 Canned responses

Canned responses are pre-defined bits of text that are commonly used when communicating with customers. Support engineers usually define greetings and answers to frequently asked questions as canned responses in order to shorten the time needed to satisfy the customer.

The Chat module allows to define canned responses on two levels in terms of availability to users - publicly - for all support engineers, and privately - only for a particular user.

Public canned responses can be managed in the Chat UI in **CMS Desk -> Tools -> Chat -> Canned responses**.

Creating canned responses

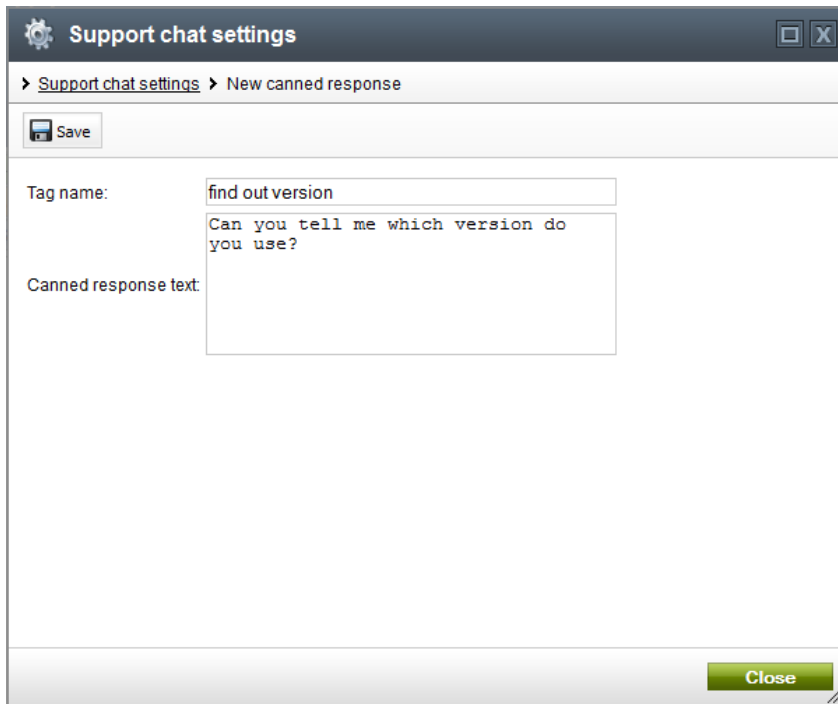

To create a canned response, first select whether you want it to be global, i.e. available on all sites, or

select a particular site in the **Site** drop-down list. Then click  **New canned response**.

A canned response consists of a tag name and the response text itself.

To create a personal canned response, click  **Support chat settings**.

In the windows that pops up, click  **New canned response**. You can then input the tag name and canned response text and click  **Save** to save the response.

The screenshot shows a window titled "Support chat settings" with a breadcrumb trail: "Support chat settings > New canned response". At the top left is a "Save" button with a floppy disk icon. Below it, there are two input fields: "Tag name:" with the text "find out version" and "Canned response text:" with the text "Can you tell me which version do you use?". At the bottom right is a "Close" button.

Editing and deleting canned responses

You can edit both public and private canned responses by clicking the  **Edit** action button in their respective list. You can delete responses using the  **Delete** button.

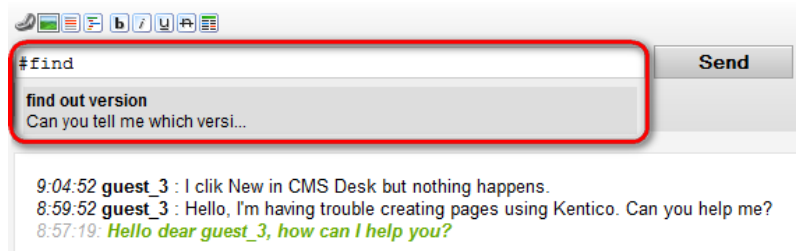

Inserting a canned response

To insert a canned response using the mouse, click the Canned responses button, then click one of the canned responses in the list that appears.

To insert a canned response using the keyboard, type "#" into the message text box. Then select the

desired canned response using the arrow keys. You can find a particular response by typing the first characters of the tag name. Press **Enter** to insert the selected response.

Macros in canned responses

Support chat allows inserting [macro expressions](#) into canned responses. Entered macro expressions are resolved upon opening the support room window. Supported are the standard [macro types](#), including custom macros.

8.13.9 Cleanup

In order to minimize the amount of storage space that the Chat module's data consumes, it incorporates a set of scheduled tasks, which delete old and inactive records on a regular basis.

Delete old chat records

This scheduled task deletes chat messages, rooms and anonymous users which haven't logged any activity for the amount of time specified in settings. The age of the data that is to be deleted can be specified in **Settings -> Community -> Chat -> Days of inactivity needed to delete chat records**.

The order of performed deleting operations is as follows:

1. **Delete messages** - messages that were sent earlier than the specified amount of time.
2. **Delete rooms** - rooms that meet **all** of the following criteria will be deleted:
 - a. is private
 - b. contains no messages
 - c. was created earlier than the specified amount of time
 - d. doesn't contain any registered (non-anonymous) user that has elevated [room permissions](#)
 - e. doesn't contain any anonymous user that has been on-line in the room during specified amount of time
3. **Delete users** - users meeting **all** of the following conditions will be deleted:
 - a. haven't sent any message in the specified amount of time
 - b. haven't been on-line in the specified amount of time

Clean chat on-line users

This scheduled task removes anonymous users who stopped sending pings to the server without going off-line (e.g. their connection was interrupted or they simply closed the browser window).

Clean chat rooms scheduled to delete

When you delete a room, it becomes disabled and scheduled to be deleted instead of being physically

deleted from the database right away.

This scheduled task is by default executed once a day to delete the rooms marked for deletion.

This behavior ensures that users present in such room have a chance to get notified about the fact that the room they are in is getting deleted.

8.14 Contact management

8.14.1 Overview

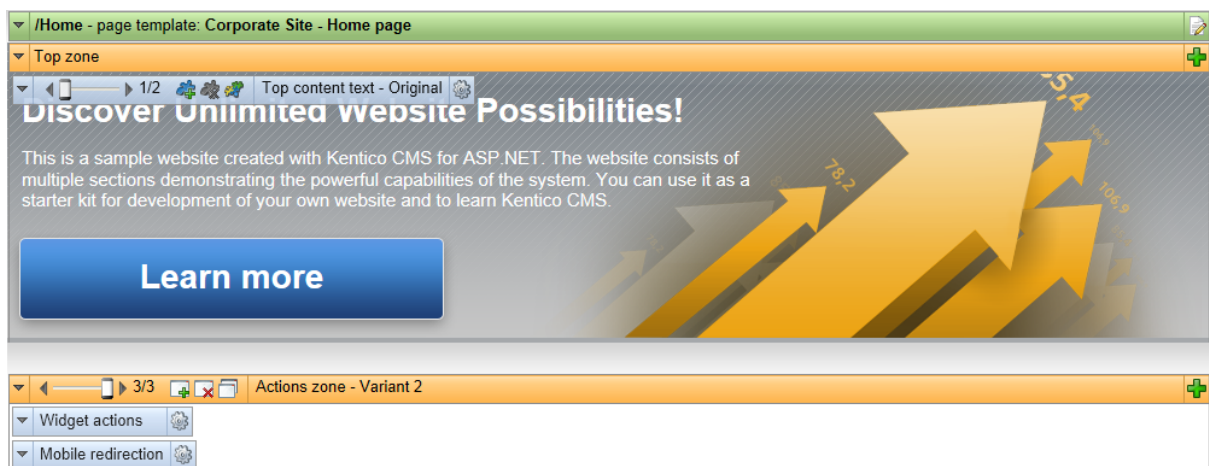

For more information about the **Contact management** module please refer to the [Kentico CMS Online Marketing Guide](#).

8.15 Content personalization

8.15.1 Overview

Content personalization is an on-line marketing feature that can significantly increase the flexibility of a website. It allows you to create pages that display different content depending on the circumstances in which they are viewed. This way, pages can be custom-built for different types of visitors, dynamically reflect previous actions performed on the website by a given user or have their content determined by any other site variables.

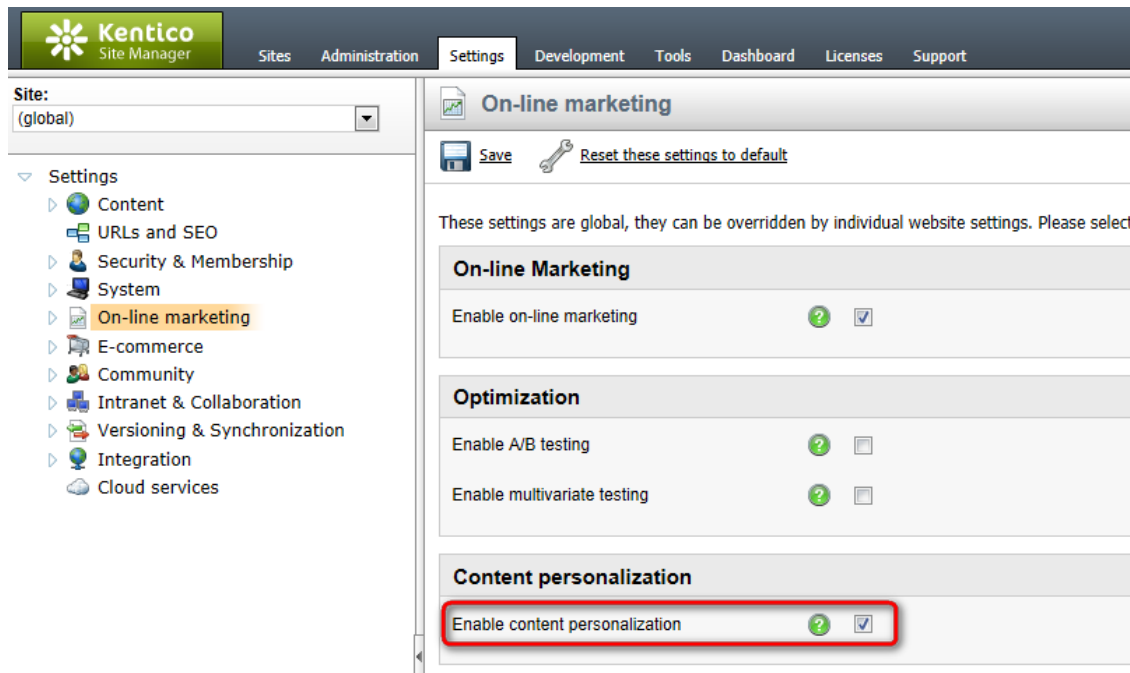

Personalization is applied through the basic components that form the content of pages, which includes [Web parts](#), entire web part zones and [Widgets](#) added into page editor zones. The first necessary step is to define different versions of these objects called *variants*. The details of how personalization variants can be created and configured for objects are described in [Managing personalization variants](#).

Each variant is dedicated to a particular scenario, which is specified through a macro-based condition. The condition determines in which situations the variant should be displayed. When a visitor selects the page on the live site, the variants of all personalized objects will have their conditions dynamically resolved according to the current context and the appropriate variant will be displayed for each object. Please see the [Variant conditions](#) topic to learn more about possible condition options and how they are processed.

Enabling content personalization

To start using content personalization on a website, go to **Site Manager -> Settings -> On-line marketing** and check **Enable content personalization**. This will allow users with the appropriate permissions to start creating variants of objects, which will then be processed and displayed accordingly on the live site.

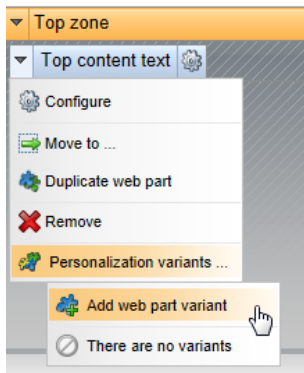

If you disable content personalization at a later time, existing variants on your website will not be deleted, but it will not be possible to manage them or define new ones, and the original objects will always be shown on the live site.

8.15.2 Managing personalization variants

Once content personalization is enabled, variants of objects can be created through the **CMS Desk -> Content -> Edit** interface, which you would normally use to define standard page content. There are three possible types of objects that you can personalize:

Web parts

To add the first content personalization variant to a web part, open its context menu by right clicking its header (or through the ▼ icon), hover over the **Personalization variants** option and then select **Add web part variant** from the second level of the menu.

A dialog will be displayed where you can set the properties of the variant:

- **Display name** - this name will be displayed in lists of content personalization variants in the administration interface.
- **Code name** - sets a code name that serves as an identifier of the variant.
- **Description** - can be used to enter a text description for the variant. To make the variant easier to use and maintain, you can add an explanation about the scenario for which the variant is intended, describe the differences from the original object, etc.
- **Enabled** - indicates if the variant should be considered as a possible content option. When an object's variants are processed to determine which one should be displayed, disabled variants are skipped (even if the requirements set by their condition are met).
- **Display condition** - enter the condition that must be fulfilled in order for the variant to be displayed. Please see the [Variant conditions](#) topic, to learn more about these conditions and how they are processed.

Content personalization variant properties

Display name:

Code name:

Description:

Enabled:

Display condition:

OK Cancel

When the values are confirmed, a standard web part configuration dialog will be displayed. The variant is simply another instance of the original web part. By default, it will have the same values in its properties as are set for the original, but you can change them as required.

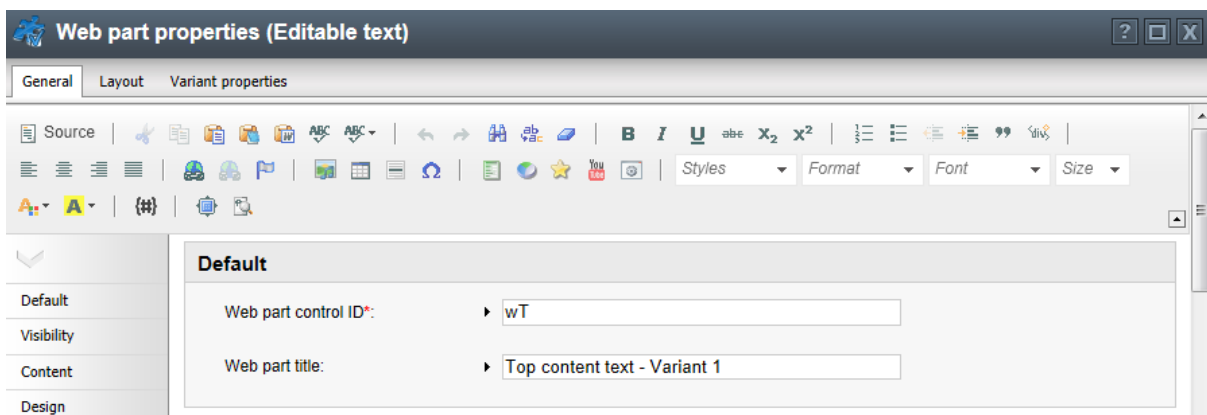

After the first variant is created, a slider will be added to the header of the given web part as shown below:

This slider can be used to switch between individual variants as needed (including the original). The content specified by the currently selected variant will be displayed on the **Design** and **Page** tabs, as well as in **Preview** mode. The conditions are only resolved on the actual live site. This means that you can easily check how the page will look with different active variants without having to fulfill the required conditions. Simply set the slider(s) to the appropriate variants.

If you wish to view the content of variants while cycling through the slider on the **Design** tab, make sure that the **Display web part content** checkbox on the right side of the **Edit** mode header is checked. To make orientation easier, it is recommended to assign an appropriate **Web part title** for each variant, so that you can identify which one you are working with straight from the header text.

The buttons on the right of the slider allow you to add new variants (🔧), remove the currently selected one (🗑️) or open a list of all variants defined for the given web part (📄). At any time, you can **Configure** (⚙️) the properties of the variant currently chosen on the slider.

A variant can be edited just like any other web part. Notice that there is an additional tab available in the configuration dialog called **Variant properties**, which contains the same options that were offered when creating a new variant (as described above). It is also possible to specify a unique [Web part layout](#) for each variant. You only need to switch to the **Layout** tab, select or create the required layout and it will be applied to the currently edited variant.

If you need to enter content into a variant of a web part that provides an editable region ([Editable text](#) or [Editable image](#)), you can do so on the **Page** tab as usual. To quickly switch between different variants on this tab, hover over the given personalized section of the page and a menu icon (▼) will be displayed. If you expand the menu, a list of all available variants will be shown and you can select the one that you wish to edit or view.

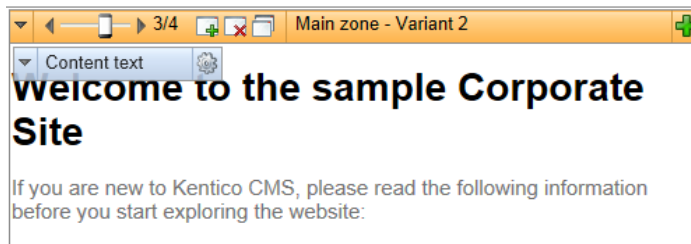

When one of the menu options is clicked, the page will be reloaded with the content of the chosen variant.

The variants of a personalized web part are stored on the given document's [page template](#), so they will be present on all pages that use the same template. If you delete (✗) a web part, all of its variants will be removed along with it. These same principles also apply to web part zone variants.

Web part zones

If you wish to define personalized content that uses a completely different type of web part or multiple web part instances, you can add variants of an entire web part zone. This allows you to set the properties of the zone in a specific way for each variant, and more importantly add (or remove) any child web parts that you need. Each zone variant may contain any type or amount of web parts, regardless of what is placed inside other variants or the original zone.

Variants of zones can be created and managed on the **Design** tab in the same way as with web parts (the buttons on the slider use different icons for zones). The only difference is that you need to work with zone objects rather than specific web parts. When a new zone variant is added, the content of the original is automatically copied into it, so you do not have to rebuild the zone from scratch if you only need to make small modifications.

The zone variant currently selected on the slider may be edited by double clicking the header of the zone or through the **Properties** option in the zone's context menu. To add content into a variant, use the **Add web part** (+) button in the top-right corner of the zone as usual. Most of the functionality described above for web part personalization is also available for zones.

Creating variants for individual web parts inside a personalized zone is not supported. The same also applies in the opposite direction: it is not possible to personalize a zone that already contains personalized web parts. Moreover, personalization is only available for standard web part zones, and cannot be done for widget zones.

Widgets

Content personalization can also be leveraged by editors, who do not have access to the **Design** tab, via widgets. If the feature is enabled, variants can be added and managed through buttons on the pop-up menu of individual widgets on the **Page** tab. When at least one variant is created for a widget, a slider will become available just like for web parts or zones.

The following actions can be used:

- **Add new variant** - creates a new variant for the given widget. When creating the first variant for a widget on a page that has a multivariate test defined, this action will open a menu where you can choose which type of variant should be created.
- **Remove variant** - removes the variant currently selected on the slider (not available for the original).
- **Variant list** - opens a dialog that contains a list of all variants defined for the widget and allows their management.

Personalization of editor widgets works the same way as for web parts. Each variant is a widget of the same type as the original, but its properties may be configured differently. This functionality is only available for widgets placed into zones set for **Customization by page editors** and cannot be done for *group administrator* or *user* widgets.

Since editor widgets are categorized as page content, their variants are bound to the specific document and are not included on the page template. Like with web parts, removing a widget (✖) also deletes all of its variants. Using the **Reset to default** action provided by a [Widget actions](#) web part also deletes all widget variants from the page.

Variant overview

You can access a list of all content personalization variants defined on a given document (page), by selecting it from the content tree in **CMS Desk -> Content -> Edit** and going to **Properties -> Variants**. The variants of all three object types are included here.

Multivariate testing and Content personalization

Please note that it is not possible to create personalization variants of web parts, zones or widgets that are already included in a [Multivariate test](#).

8.15.3 Variant conditions

When setting up a personalized page, the most important part of the process is to properly define the conditions that indicate when individual variants should be displayed. By utilizing macro expressions, you can write conditions for virtually any type of scenario according to your specific requirements. Keep in mind that the result of a condition's expression must be a logical (boolean) value in order for it to work correctly. For details about available macro options and syntax, please refer to the [Development -> Macro expressions](#) chapter.

A variant's condition is specified in its **Display condition** property.

Content personalization variant properties

Display name:

Code name:

Description:

Enabled:

Display condition:

Through the edit icon (✎), you can use the macro condition editor, which provides a graphical interface

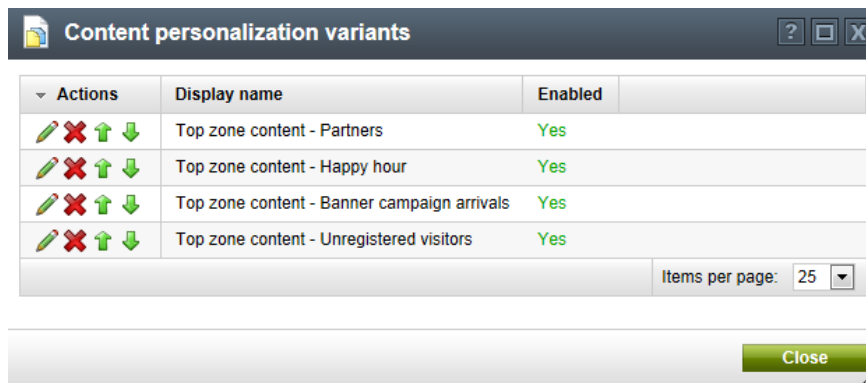

that makes it easier to build complex conditions. It allows non-technical users to create conditions based on predefined macro rules. Please see the [Macro conditions](#) topic for further details.

On the live site, each personalized object will only have one of its variants displayed at any given moment. Variants are processed in the order of their priority and the first **enabled** variant whose condition is fulfilled in the current context will be selected. The original object is displayed in cases where the conditions of all variants are resolved as *false*.

By default, the priority of variants depends on the order in which they were created, as can be seen on the personalization slider. Apart from the original object, which is always first, variants with a higher priority can be found further on the left of the slider.

If you wish to change the order in which an object's variants should be processed, click the **Variant list** (📄) button among the actions on the slider. A dialog containing a list of the variants will be opened as shown below.

Here, you can reorganize the variants as necessary through the **Up** (⬆️) or **Down** (⬇️) actions.

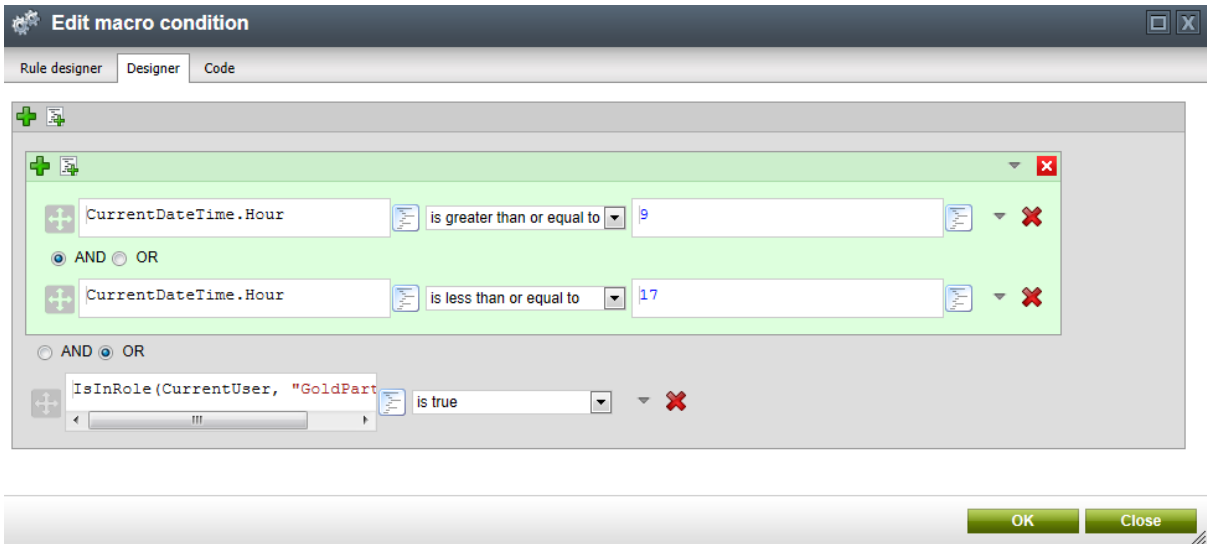

Condition example

The example below demonstrates how you can build a macro that causes the given variant to be displayed only during a specific part of the day, or to users with special authorization.

1. Create a content personalization variant for an object, open its properties dialog and click the edit icon (✍️) next to the **Display condition** field to open the macro condition editor.
2. Switch to the **Designer** tab and remove (✖️) any existing expressions. Then click the **Add Group** (+) action and use **Add expression** (📄) to create two expression fields inside the new group. Fill in the expressions according to the following instructions:
 - Enter *CurrentDateTime.Hour* into the field on the left, select the **is greater than or equal to** operator and write *9* on the right.
 - Enter *CurrentDateTime.Hour* into the field on the left, select the **is less than or equal to** operator and write *17* on the right.

Leave the **AND** option selected between the two expressions.

3. Add another expression to the main area and select the **OR** option between it and the group. Enter *CurrentUser.IsInRole("GoldPartners")* into the expression's field and select **is true** as the operator.

4. Click **OK** and the code of the condition will be inserted into the **Display condition** field:

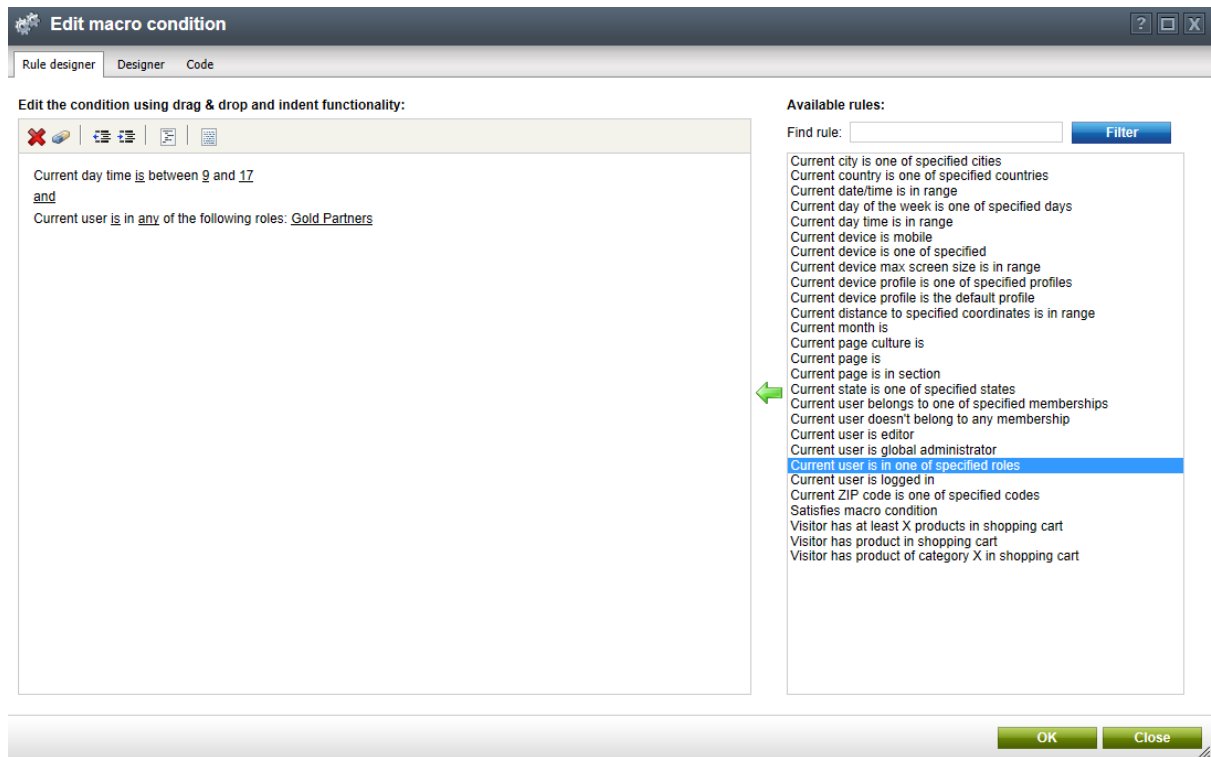

```
(CurrentDateTime.Hour >= 9 && CurrentDateTime.Hour <= 17) || CurrentUser.IsInRole("GoldPartners")
```

This condition ensures that the variant is only displayed to ordinary users if the current time is between 9 AM and 5 PM. Users who belong to the *GoldPartners* role will be able to see the content specified by the variant at any time.

Using macro rules

Alternatively, you can also define the same condition through [macro rules](#). Click the **Clear condition** (🗑️) action next to the field and edit (✎) the condition again.

1. On the **Rule designer** tab, select the **Current day time is in range** macro rule and use the **Add rule** (➡️) button to insert it into the condition.
2. Do the same for the **Current user is in one of specified roles** rule and leave the **and** operator between the two clauses in the designer area.
3. Click on the underlined parameters in the text of the rules to set the time and role values that were used for the original condition.

This time, clicking **OK** inserts the variant's display condition as a user-friendly expression composed of macro rule clauses.

8.15.4 Security

Users must have the appropriate permissions assigned to be able to view and manage content personalization variants in the administration interface. These permissions can be set by going to **CMS Site Manager** (or **CMS Desk**) -> **Administration** -> **Permissions**.

To configure the security options for content personalization, select the *Content personalization* module. The following two permissions can be assigned:

- **Read** - allows members of the selected roles to view the content of personalization variants, their properties and variant lists in the *CMS Desk* administration interface. No special permissions are required to view personalized content on the live site.
- **Manage** - allows members of the selected roles to create, edit and delete personalization variants of objects.

 **Permissions**

Site:

Permissions for:

Report for user: Show only this user's roles

| Role | Read | Manage |
|------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Designers | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Editors | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Readers | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> |

Additionally, the **Design web site** permission for the *Design* module is needed for users to be able to manage the variants of web parts and zones on the **Design** tab of **CMS Desk**.

To work with variants of editor widgets on the **Page** tab, the **Modify** permission for the *Content* module is required. Also, the security settings defined for specific widgets are checked, as described in [Development -> Widgets -> Security](#).

8.16 Content rating

8.16.1 Overview

The Content rating module can be used to give live site users the possibility of rating any document on your website. This may come in handy in case that you want your website users to express their opinion about the quality of published content. The module has no dedicated user interface - the overall rating of each document can be viewed in the **Rating** field on the **CMS Desk -> Content -> Edit -> Properties -> General** tab.

The module's main part is the **Content rating** web part. The web part can be placed on any page and it enables users to rate content of the currently displayed document. More information about the web part and a step-by-step example of its usage can be found in the [Using the Content rating web part](#) topic.

Current rating: 3 (1 ratings)

It is also possible to include the `~/CMSAdminControls/ContentRating/RatingControl.ascx` control in your transformations in order to ensure the rating possibility with each transformed item. The [Displaying ratings in transformations](#) topic will show you how to achieve this.

The content rating functionality is also integrated in web parts of the [Message boards](#) module. This enables live site users to submit a rating along with a comment posted to the message board. To learn more, please proceed to the [Integration with Message boards](#) topic.

The [Content rating internals and API](#) sub-chapter provides information about the database tables and classes used by the module, as well as examples of how ratings can be managed from your code using

Kentico CMS API.

8.16.2 Using the Content rating web part

The **Content rating** web part is stored in the **Content rating** web part category. The web part can be added to any web part zone on any page of your website, enabling users of the website to rate the content of the currently displayed document. It has three default appearance modes:

| Stars | Radio-buttons | Drop-down list |
|--|---|--|
|  <p>Current rating: 3 (1 ratings)</p> |  <p>1 2 3 4 5</p> <p>Current rating: 4 (1 ratings)</p> |  <p>Current rating: 2.5 (2 ratings)</p> |

It is also possible to create other appearance modes by creating your **custom controls**. These must be placed in `~/CMSAdminControls/ContentRating/Controls/` and inherit from `ExtendedControls.AbstractRatingControl.cs`, just like the default ones.

Below is a list of specific properties of the web part:

- **Rating value** - this property can be used to set the displayed rating value explicitly. A value from the `<0,1>` interval can be used, while `0` represents the lowest rating and `1` represents the highest rating on the scale defined by the Max rating value. If blank, the real rating calculated as an average value of particular ratings is displayed.
- **Rating type** - appearance of the web part. *Stars*, *Radio-buttons* or *Drop-down list* can be chosen, as depicted above.
- **Max rating value** - size of the rating scale. For example, if 7 is entered, rating will be possible on a scale from 1 to 7.
- **Show results** - if checked, overall rating results will be displayed. If unchecked, users can rate, but don't see the results.
- **Result message** - message showing overall rating results. The `{0}` macro shows overall rating (for one decimal rounding, you can use `{0:0.#}`). `{1}` displays the total number of votes.
- **Message after rating** - text message displayed after a user submits their rating. Macros that can be used: `{0}` your rating, `{1}` overall rating, `{2}` overall number of votes.
- **Check permissions** - if checked, permissions set by the *Allow for public* and *Hide to unauthorized roles* properties will be checked.
- **Allow zero value** - if checked, users are allowed to submit ratings with zero value (no rating value selected).
- **Error message** - message displayed to users who try to submit a rating with zero value. Applied only if the *Allow zero value* option is disabled.
- **Anonymous users can rate** - if checked, rating will be allowed to public unauthorized users. If unchecked, only authenticated users will be allowed to rate.
- **Check if user rated** - if checked, users will be allowed to vote only once. To indicate that the user already voted, Kentico CMS stores a **DocRated** cookie in your web browser, the cookie contains **NodeIDs** of the rated documents separated by the tube character (e.g. `|4|61|229|230|228|369|`).
- **Hide to unauthorized users** - if checked, the web part will be hidden to unauthorized users.

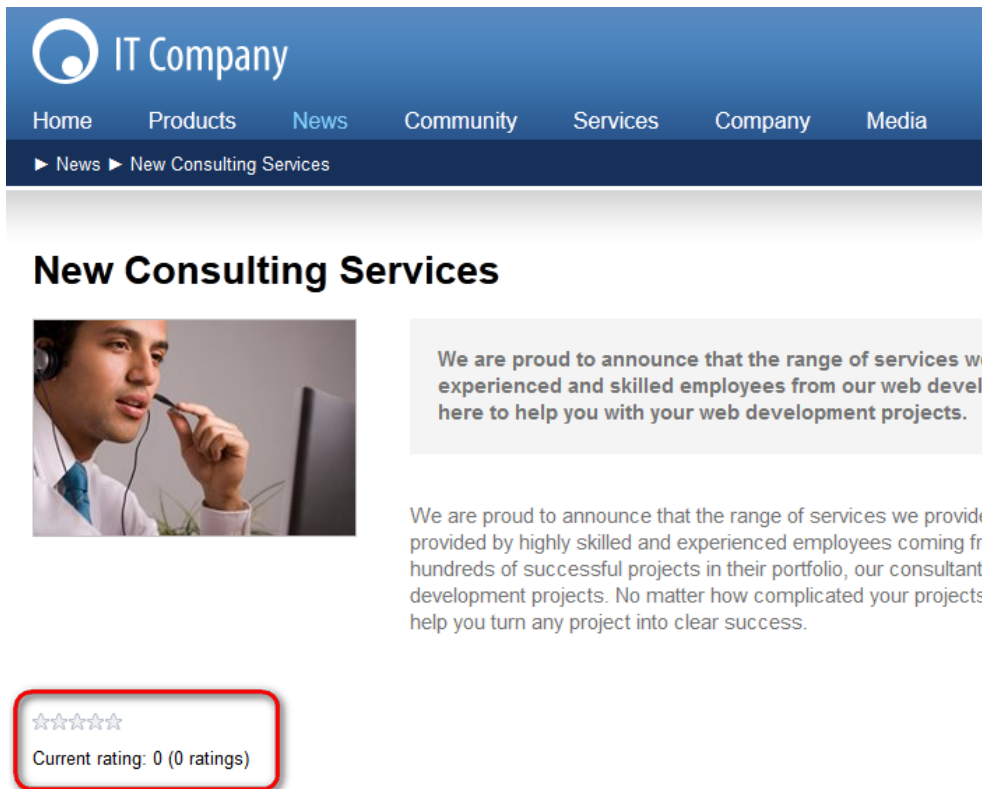

Example: Adding news ratings

You can place the web part on any page of your website to enable users to rate the content of this particular page. In the following example, we will add the web part to news items on the sample **Corporate Site**. A similar result can also be achieved using transformations, as described in [Displaying ratings in transformations](#).

1. Sign in to **CMS Desk** as *administrator* (blank password by default). Switch to the **Design** mode and select **News** from the content tree.
2. Click the **Add web part** (+) icon at the top right corner of the **Main zone** web part zone. Select the **Content rating\Content rating** web part and click **OK**.
3. In the **Web part properties** window, just configure the following property:
 - **Show for document types:** *cms.news*; this ensures that the web part will be displayed only for the particular news items and not for the list of news on the title page of the *News* section.

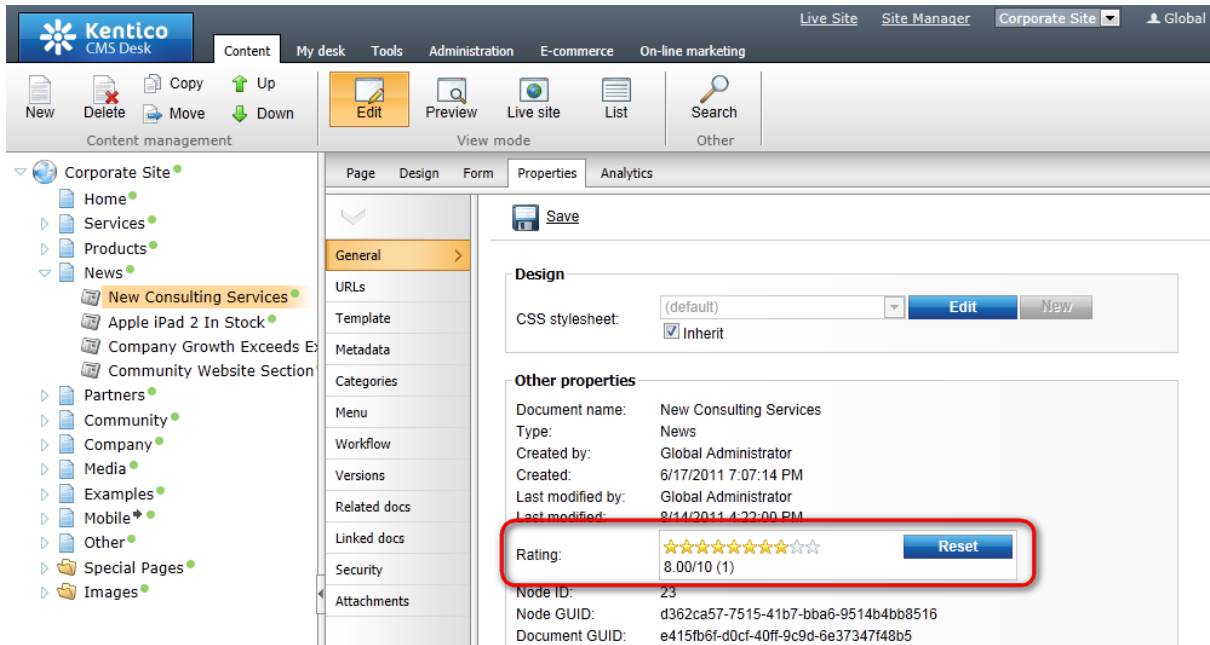

Leave the rest of the properties at their default values and click **OK**.

4. Now go to the live site and view the **New Consulting Services** news item. You should see the web part below the news text as in the screenshot below. Now try rating!

The screenshot shows a website header for 'IT Company' with navigation links: Home, Products, News, Community, Services, Company, and Media. Below the header is a breadcrumb trail: News > New Consulting Services. The main content area features a large heading 'New Consulting Services' and a photograph of a man in a white lab coat talking on a headset. To the right of the photo is a text box: 'We are proud to announce that the range of services we experienced and skilled employees from our web develo here to help you with your web development projects.' Below this is another text block: 'We are proud to announce that the range of services we provide provided by highly skilled and experienced employees coming fro hundreds of successful projects in their portfolio, our consultants development projects. No matter how complicated your projects help you turn any project into clear success.' At the bottom left, there is a rating widget with five stars and the text 'Current rating: 0 (0 ratings)'. The widget is highlighted with a red rounded rectangle.

5. If you switch back to **CMS Desk** and view **Properties** of the news item, you should see the **Rating** property on the **General** tab. This property reflects the current rating of the selected document. All ratings are recalculated to 10 step scale and displayed as stars here, no matter what the settings of the web part are. You can reset the value using the **Reset** button.

8.16.3 Displaying ratings in transformations

Rating controls can also be displayed in [Transformations](#). To do that, the following code needs to be placed in your transformation, ensuring that the `~/CMSAdminControls/ContentRating/RatingControl.ascx` control will be displayed along with the transformed item:

```
<%@ Register Src="~/CMSAdminControls/ContentRating/RatingControl.ascx"
TagName="RatingControl" TagPrefix="cms" %>

<cms:RatingControl ID="elemRating" runat="server" Enabled="true"
RatingType="Stars" ExternalValue='
<%# Convert.ToString(CMS.GlobalHelper.ValidationHelper.GetDouble(Eval
("DocumentRatingValue"), 0))/((CMS.GlobalHelper.ValidationHelper.GetDouble(Eval
("DocumentRatings"), 0) == 0?1:CMS.GlobalHelper.ValidationHelper.GetDouble(Eval
("DocumentRatings"), 1))' />
```

With this control, you can use similar properties as with the **Content rating** web part, as described in the [Using the Content rating web part](#) topic:

- **bool Enabled** - indicates if rating is possible via the control. If disabled, the control is visible, but rating is not possible.
- **bool CheckPermissions** - the same as the **Check permissions** web part property.
- **bool HideToUnauthorizedUsers** - the same as the **Hide to unauthorized users** web part property.
- **bool CheckIfUserRated** - the same as the **Check if user rated** web part property.
- **bool AllowForPublic** - the same as the **Anonymous users can rate** web part property.
- **string ErrorMessage** - the same as the **Error message** web part property.
- **string MessageAfterRating** - the same as the **Message after rating** web part property.
- **string ResultMessage** - the same as the **Result message** web part property.

- **bool ShowResultMessage** - the same as the **Show result message** web part property.
- **string RatingType** - the same as the **Rating type** web part property.
- **string ExternalValue** - similar as the **Rating value** property.
- **bool AllowZeroValue** - the same as the **Allow zero value** property.
- **int MaxRatingValue** - the same as the **Max rating value** property.

Ratings submitted via this control are added to the ratings of the currently displayed document, the same as if you rated via the **Content rating** web part.

**Please note**

It is only possible to add controls into transformations that use the **ASCX** type. The rating control will not be rendered correctly by the other transformation types.

Example: Adding news ratings

In the following example, you will learn how to add the rating control to your pages via transformations. We will use the sample Corporate Site and add the rating functionality to news items displayed in the **News** section. A similar result can be achieved using the **Content rating** web part, as described in the [Using the Content rating web part](#) topic.

1. Log on to **CMS Desk** and on the **Content** tab, select the **News** page from the content tree. View the page in Design mode and click the **Configure** (⚙️) icon of the **NewsRepeater** web part.

2. In the **Web part properties** dialog which pops up, click the **Edit** button next to the **Selected item transformation** property. Replace the original transformation with the following code, which is the original code with the highlighted parts added.

```

<%@ Register Src="~/CMSAdminControls/ContentRating/RatingControl.ascx"
TagName="RatingControl" TagPrefix="cms" %>

<div class="newsItemDetail">
  <h1>
    <## Eval("NewsTitle") %></h1>
  <div class="NewsSummary">
    <## IfEmpty(Eval("NewsTeaser"), "", GetImage("NewsTeaser")) %>
    <div class="NewsContent">
      <div class="Date">
        <## GetDateTime("NewsReleaseDate", "d") %></div>
      <div class="TextContent">
        <## Eval("NewsSummary") %></div>
      </div>
      <div class="Clearer">&nbsp;</div>
    </div>
  </div>

```

```

<div class="NewsBody">
  <div class="TextContent">
    <%# Eval("NewsText") %></div>

    <cms:RatingControl ID="elemRating" runat="server" Enabled="true"
      RatingType="Stars" ExternalValue='
        <%# Convert.ToString(CMS.GlobalHelper.ValidationHelper.GetDouble(Eval
          ("DocumentRatingValue"), 0)/((CMS.GlobalHelper.ValidationHelper.GetDouble(Eval
            ("DocumentRatings"), 0) == 0?1:CMS.GlobalHelper.ValidationHelper.GetDouble(Eval
              ("DocumentRatings"), 1)))) %>' />

  </div>
</div>

```

Click **Save & close** to save the changes.

3. Now if you go to the live site, browse to the **News** section and display detail of some news item, you should see the rating control present below the news text, as can be seen in the screenshot below.

The screenshot shows a web application interface for 'IT Company'. The top navigation bar includes links for Home, Services, Products, News, Community, Company, and Media. A shopping cart icon indicates 'Your shopping cart is empty'. The main content area displays a news article titled 'New Consulting Services' with a date of 6/5/2011. The article text describes the company's expansion into web development consulting. Below the text, a rating control is visible, showing a star rating of 5 out of 5.

8.16.4 Integration with Message boards

Web parts of the [Message boards](#) module - the **Message board** and **Group message board list** web parts - have content rating features embedded. This enables live site users to submit a rating along with a comment posted to the message board. To enable content rating features of these web parts, you have to configure the following properties:

- **Enable content rating** - if checked, content rating features of the web part will be enabled.
- **Rating type** - appearance of the web part. *Stars*, *Radio-buttons* or *Drop-down list* can be chosen
- **Max rating value** - size of the rating scale; e.g. if 7 is entered, rating will be possible on a scale from 1 to 7

When leaving a board message, the rating control (determined by the **Rating type** property) will be displayed above the **Name** field. Users can select their rating and after sending the message, the rating will be applied.

Leave message

Your rating: ★★★★★

Name: Global Administrator

Your URL: http://

Your e-mail: administrator@localhost.local

Message: Yeah, I like this!

Add

8.16.5 Content rating internals and API

8.16.5.1 Content rating database tables and API classes

The Content rating module uses the following database table:

- **CMS_Document** - this table is used for storing information about documents in the content tree; its *DocumentRatingValue* column stores the total sum of all ratings of a particular document, while the *DocumentRatings* column stores the total number of ratings of the document

The Content rating API is provided by the following **CMS.DocumentEngine** namespace classes:

- **TreeProvider** - among other methods for document manipulation, this class provides methods for management of documents' ratings

The following topics show how methods from these classes can be used to manage abuse reports:

- [Adding document rating](#)
- [Getting document rating](#)
- [Modifying document rating](#)
- [Resetting document rating](#)

The [API programming and Kentico CMS internals](#) section of this guide contains more API related information, so please refer to it if required.

For detailed API documentation, such as a list of all methods from the classes above, please refer to [Kentico CMS API Reference](#).

8.16.5.2 Adding document rating

The following code example explains how content rating can be added to a document using the API.

[C#]

```
using CMS.DocumentEngine;
using CMS.CMSHelper;

int nodeId = 241;
double rating = 0.5f;

// Gets the document
TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);
TreeNode node = tree.SelectSingleNode(nodeId, CMSContext.PreferredCultureCode);

// Adds the rating
// If the 3rd parameter is true, information that the document has been rated is
// stored in a cookie. It is possible to check if the user rated the document.
TreeProvider.AddRating(node, rating, false);
```

8.16.5.3 Getting document rating

The following code example demonstrates how you can get rating of a document using the API.

[C#]

```
using CMS.DocumentEngine;
using CMS.CMSHelper;

int nodeId = 241;
double rating = 0.0f;

// Get the document
TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);
TreeNode node = tree.SelectSingleNode(nodeId, CMSContext.PreferredCultureCode);

// Get its rating
rating = node.DocumentRatingValue / node.DocumentRatings;
```

8.16.5.4 Modifying document rating

The following code example shows how rating of a document can be modified using the API.

[C#]

```
using CMS.DocumentEngine;
using CMS.CMSHelper;
```

```
int nodeId = 241;
double rating = 1.0f;
int numOfRatings = 2;

// Get the document
TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);
TreeNode node = tree.SelectSingleNode(nodeId, CMSContext.PreferredCultureCode);

// Modify its rating
TreeProvider.SetRating(node, rating, numOfRatings);
```

8.16.5.5 Resetting document rating

The following code example shows how to reset content rating of a document using the API.

[C#]

```
using CMS.DocumentEngine;
using CMS.CMSHelper;

int nodeId = 241;

// Get the document
TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);
TreeNode node = tree.SelectSingleNode(nodeId, CMSContext.PreferredCultureCode);

// Reset its rating
TreeProvider.ResetRating(node);
```

8.17 Custom tables

8.17.1 Overview

The Custom tables module allows you to create your own tables in the system database. You can manage data in custom tables without using Microsoft SQL Server Management Studio or any other database management tool. You will find this useful especially when you need to store a large number of items in a flat data structure. Standard Kentico documents are not as efficient as custom tables for storing items in a flat structure. Refer to the [Storing data effectively](#) topic for more information on the advantages of using custom tables over Documents.

You can also use custom tables when developing custom modules. Custom tables allow you to store the module data and access it using API.

The module comes with four web parts that you can use to display custom table data on a live site. To change the way the data in custom tables is being presented in the web parts, you can use transformations.

There is no form web part for acquiring data from live site visitors and storing them into custom tables available—custom tables aren't designed for this use. You can use [Online forms](#) for acquiring visitor information on the live site.

Finally, the module comes [with an API](#), which enables you to handle custom table data in your own code.

The Custom tables module interacts with two other Kentico CMS modules. Data stored in the tables can be searched using the [Smart search](#) module. You can also create [Alternative forms](#) for the tables. These forms can be used instead of the default forms for creating or editing a custom table in the administration interface, as described in [Modules -> Alternative forms -> Automatically used alternative forms](#).

Topics:

- [Creating custom tables](#)
- [Editing custom tables](#)
- [Managing data in custom tables](#)
- [Displaying custom table data using web parts](#)
- [Transforming custom tables](#)
- [Setting permissions](#)
- [Custom tables internals and API](#)
 - [Database tables](#)
 - [API classes](#)
 - [API examples](#)
 - [Managing custom table data](#)

8.17.2 Creating custom tables

You can find the custom tables module at two locations of Kentico interface:

- **Site Manager -> Development -> Custom tables** allows you to create new custom tables, given you are the site's global administrator. You can also view and manipulate data in existing tables using this interface.
- **CMS Desk -> Tools -> Custom tables** allows you to view and manipulate data in existing custom tables only.

Note that you can create new custom tables using the wizard only. There is currently no simple way of creating custom tables using the API. This is due to the need to create related objects and settings—these tasks are handled by the wizard.

Creating a table using the New custom table wizard

In the following example, you will create a new custom table using the **New custom table wizard**.

Starting the New custom table wizard

1. Navigate to **Site Manager -> Development -> Custom tables**.
2. Click **New custom table** (). The **New custom table wizard** starts.

Step 1

1. Enter the following details:

- **Custom table display name:** People
 - display name is used in Kentico CMS user interface.
- **Custom table code name:** customtable.People
 - display name is used in website code — always preceded by a namespace, which allows you to have different tables of the same name in different contexts.

Step 1 | **General**
Please enter custom table display name (for users) and code name (it will be used in your code when necessary).

Custom table display name: 

Custom table code name:

2. Click **Next** to continue.

Step 2

In this step, you are given a choice from the two following options:

- **Create a new database table** - choose this option to create a brand new table in the system's database.
 - **Database table name** - the actual name of the table in the system database. A name in the `<namespace>_<code name>` format is pre-filled automatically.
 - **Primary key name** - primary key column name, pre-filled with the *ItemID* value.
- **Use an existing database table** - choose this option if you already have a physical table in the system database and want to register it in the system.
 - **Database table name** - the actual name of the table in the system database. The drop-down list offers only database tables which are not part of the default Kentico CMS database schema and are not yet registered for any object.
 - **Primary key name** - primary key column name. The original table's primary key column is used automatically.

The following check-boxes allow you to choose the default fields that you want to include in the custom table:

- **Include ItemGUID field** - globally unique ID of the particular custom table data record.
- **Include ItemCreatedBy field** - user name of the user who created the item.
- **Include ItemCreatedWhen field** - date and time of when the item was created.

- **Include ItemModifiedBy field** - user name of the user who last modified the item.
- **Include ItemModifiedWhen field** - date and time of last modification.
- **Include ItemOrder field** - order of the item when table content list is displayed. The lower number, the earlier position in the list.

1. Choose **Create a new database table**.
2. Leave the value *customtable_People* in the **Database table name field**.
3. Make sure all the check-boxes are turned on.

Step 2 | **Data type**
Please supply name of the new database table and included fields.

Create a new database table
 Use an existing database table

Database table name:
Primary key name:

Include ItemGUID field:
Include ItemCreatedBy field:
Include ItemCreatedWhen field:
Include ItemModifiedBy field:
Include ItemModifiedWhen field:
Include ItemOrder field:

[Next >](#)

4. Click **Next** to continue.

Step 3

Third step contains the field editor. The field editor lets you define which columns will be included in the database table.

1. Create a field using the **New attribute (+)** button with the following properties:
 - **Column name:** FirstName
 - **Attribute type:** Text
 - **Attribute size:** 100
 - **Field caption:** First name
 - **Form control:** Text box
2. Click the  **Save** button.
3. Create a second field using the **New attribute (+)** button with the following properties:
 - **Column name:** LastName
 - **Attribute type:** Text

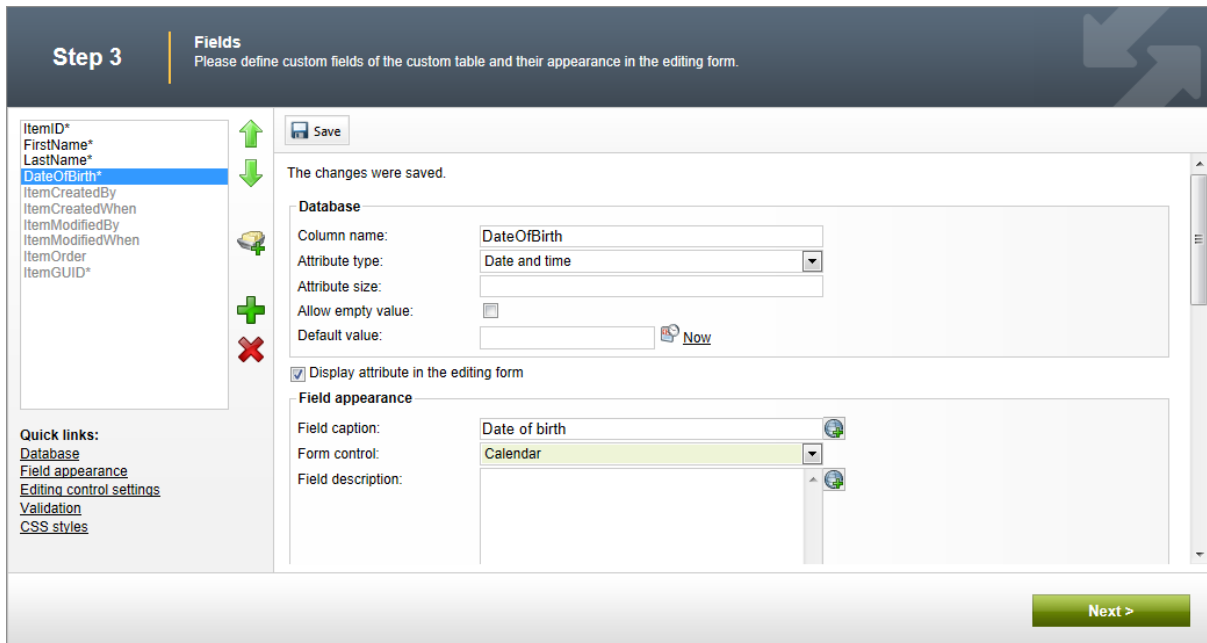

- **Attribute size:** 100
- **Field caption:** Last name
- **Form control:** Text box

4. Click the  **Save** button.

5. Create a third field using the **New attribute** (+) button with the following properties:

- **Column name:** DateOfBirth
- **Attribute type:** Date and time
- **Field caption:** Date of birth
- **Form control:** Calendar
- **Editing control settings** -> **Edit time:** unchecked

6. Click the  **Save** button.

Step 3 | **Fields**
Please define custom fields of the custom table and their appearance in the editing form.

ItemID*
FirstName*
LastName*
DateOfBirth*
ItemCreatedBy
ItemCreatedWhen
ItemModifiedBy
ItemModifiedWhen
ItemOrder
ItemGUID*

Quick links:
[Database](#)
[Field appearance](#)

[Validation](#)
[CSS styles](#)

The changes were saved.

Database

Column name: DateOfBirth
Attribute type: Date and time
Attribute size:
Allow empty value:
Default value: Now

Display attribute in the editing form

Field appearance

Field caption: Date of birth
Form control: Calendar
Field description:

Save

Next >

7. Once you are finished, click the **Next** button.

Step 4

Select on which sites the custom table will be available.

1. Click **Add sites**. A dialog box opens.
2. Choose **Corporate Site** (or any site that you want to add the custom table to) in the pop-up dialog.

Step 4 | **Sites**
Please select sites where this custom table can be used:

| | |
|--------------------------|----------------|
| <input type="checkbox"/> | Site name |
| <input type="checkbox"/> | Corporate Site |

Remove selected | Add sites

Next >

3. Click **Next** to proceed to the following step.

Step 5

Configure the indexing of data in the custom table by the [Smart Search](#) module. The four drop-down lists at the top determine which fields of the table will be displayed in search results.

1. Change the values to the following:

- **Title field:** LastName
- **Content field:** FirstName
- **Image field:** none
- **Date field:** ItemModifiedWhen

Step 5 | **Search options**
Please set search fields for Smart search module.

Title field: ▾
 Content field: ▾
 Image field: ▾
 Date field: ▾

Set automatically

| Field name | Content | Searchable | Tokenized | Custom search name |
|---------------|-------------------------------------|-------------------------------------|-------------------------------------|----------------------|
| ItemID | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text"/> |
| FirstName | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="text"/> |
| LastName | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="text"/> |
| DateOfBirth | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text"/> |
| ItemCreatedBy | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text"/> |

Next >

2. Leave the rest of the settings at default values and click **Next**.

For more information on settings in this step, please refer to [Modules -> Smart search -> Object settings](#).

Step 6

The last step gives you an overview of the tasks executed by the wizard.

Step 6 | **The wizard has finished**

The setup has finished the following steps:

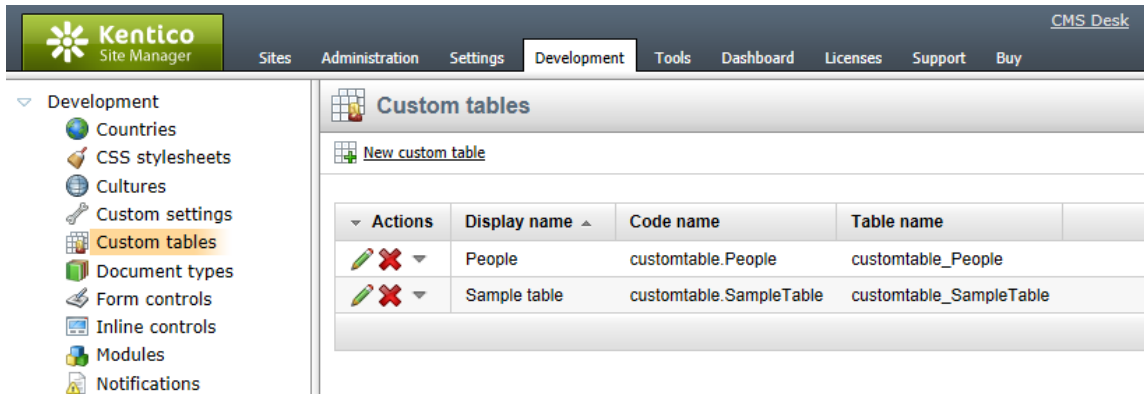

- › The new custom table was created.
- › The sites were selected where this custom table can be used.
- › The default queries were created.
- › The default ASCX transformation was created.
- › The default permission names were created.
- › Custom table smart search specification was created.

Finish

End the wizard by clicking **Finish**. You will be redirected back to the list of custom tables in **Site Manager -> Development -> Custom tables**.

8.17.3 Editing custom tables

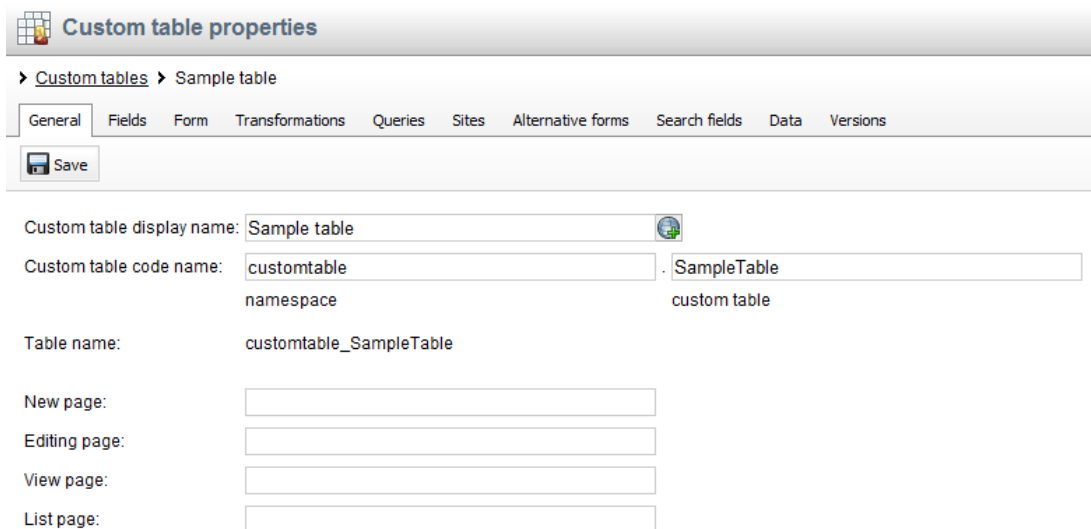

This topic covers editing existing custom tables. If you want to learn more about creating custom tables first, refer to the [Creating custom tables](#) topic.

| Actions | Display name | Code name | Table name |
|---------|--------------|-------------------------|-------------------------|
| | People | customtable.People | customtable_People |
| | Sample table | customtable.SampleTable | customtable_SampleTable |

Editing existing custom tables

1. Navigate to **Site Manager -> Development -> Custom tables**.
2. **Edit** () the custom table that you want to manage.

Custom table display name:

Custom table code name: .

namespace:

Table name:

New page:

Editing page:

View page:

List page:

3. **Save** the changes you made.

The interface is divided into the following tabs:

- **General** - this is where you can modify the display and code name of the custom table, as well as define URLs of custom pages that can be used instead of the default pages for adding, editing, viewing and listing of data items stored in the table
- **Fields** - on this tab, you can find the field editor that can be used to manage fields (columns) of the table
- **Form** - this tab allows you to create a custom form layout that will be used for adding and editing

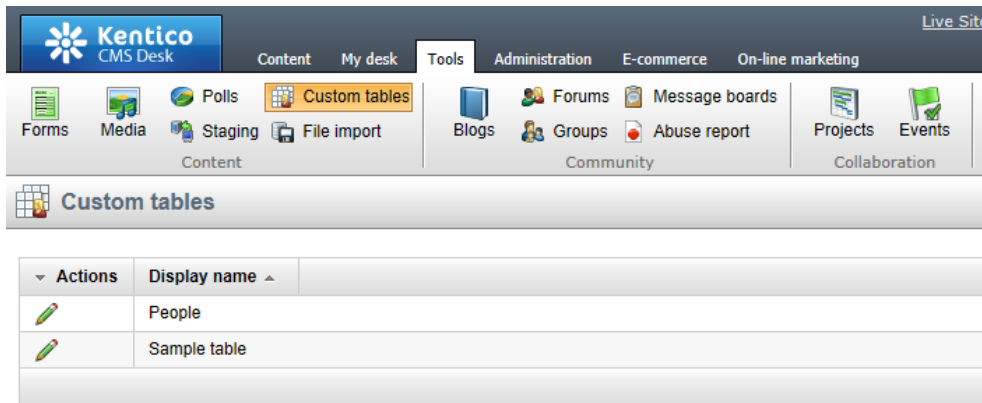

data items

- **Transformations** - this is where transformations for the custom table can be created and managed
- **Queries** - database queries for manipulation with data in the table can be created and managed on this tab
- **Sites** - on this tab, you can define websites for which the custom table will be available
- **Alternative forms** - alternative forms for adding and editing custom table data can be created on this tab; more info can be found in [Modules -> Alternative forms -> Automatically used alternative forms](#)
- **Search fields** - on this tab, you can define how data stored in the custom table will be indexed by the Smart search module

You can find more information on particular tabs in the **Kentico CMS Context Help**. Access the context help by clicking the  icon in the top right corner of each tab.

8.17.4 Managing data in custom tables

As a content editor, you can manage data stored in custom tables in **CMS Desk -> Tools -> Custom tables**. As an administrator, you can access the same interface through **Site Manager -> Development -> Custom tables -> edit () -> Data** as well.

| Actions | Display name |
|---|--------------|
|  | People |
|  | Sample table |

Adding data into custom tables

This example uses the **People** custom table that you have created if you followed the [Creating custom tables](#) chapter. The procedure is the same for any other custom table (except for the fields, which are always specific for a particular table).

1. Navigate to **CMS Desk -> Tools -> Custom tables**.
2. Click the **Edit ()** icon next to the **People** table.
3. Click the  **New item** button.
4. Fill in any values.

New item

> Data > New item

Save

First name:

Last name:

Date of birth: Now

5. Click **Save** to store the data into the custom table.
6. Use the **Create another** button and create at least two more records.

Viewing data in custom tables

This example uses the **People** custom table that you have created if you followed the [Creating custom tables](#) chapter. The procedure is the same for any other custom table (except for the fields, which are always specific for a particular table).

1. Navigate to **CMS Desk -> Tools -> Custom tables**.
2. **Edit** () the **People** custom table. The system displays the list of entries in the custom table.

Custom table properties

> Custom tables > People

New item Select displayed fields

The first 5 columns are displayed by default. Click 'Select displayed fields' button to modify the filter.

| Actions | ItemID | First name | Last name | Date of birth | Created by |
|---------|--------|------------|-----------|------------------------|--------------------------------------|
| | 1 | Ben | Harmon | 10/26/1961 12:00:00 AM | Global Administrator (administrator) |
| | 2 | Constance | Langdon | 4/20/1949 12:00:00 AM | Global Administrator (administrator) |
| | 3 | Travis | Wanderlay | 9/22/1979 12:00:00 AM | Global Administrator (administrator) |

3. Click the **Select displayed fields** button. The system displays the **Select displayed fields** dialog box.
4. Turn the check-boxes on for the fields that you want to display.

Select displayed fields

Select all Deselect all

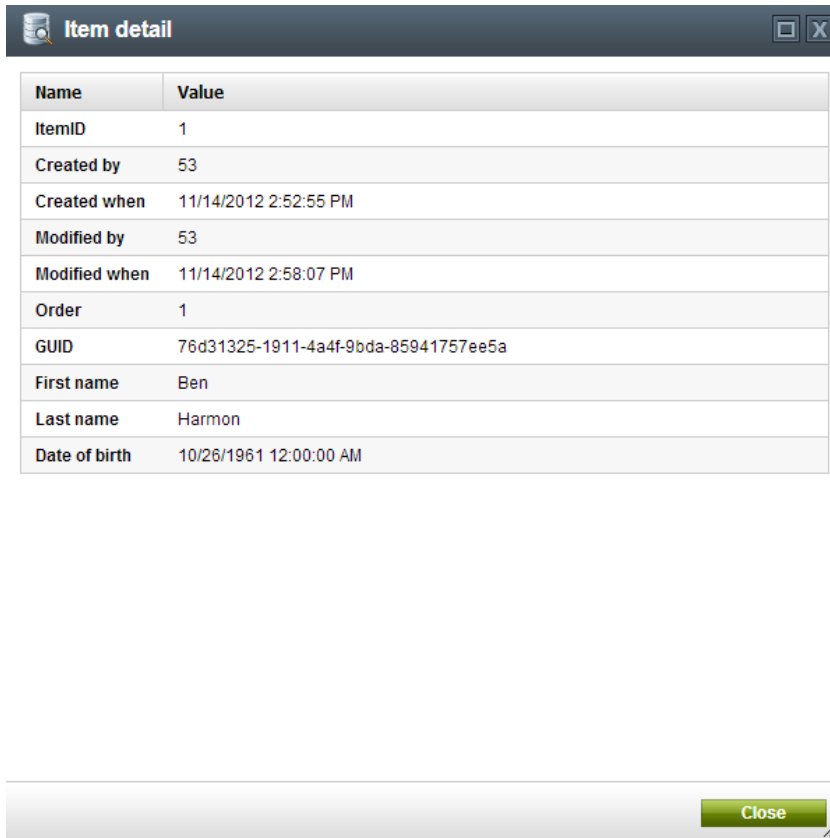

- ItemID
- First name
- Last name
- Date of birth
- Created by
- Created when
- Modified by
- Modified when
- Order
- GUID

OK Cancel

5. Click **OK**. You can now see the modified view of the entries.

| Actions | ItemID | First name | Last name | Date of birth | Created by | Created when | GUID |
|---------|--------|------------|-----------|------------------------|--------------------------------------|-----------------------|--------------------------------------|
| | 1 | Ben | Harmon | 10/26/1961 12:00:00 AM | Global Administrator (administrator) | 11/14/2012 2:52:55 PM | 76d31325-1911-4a4f-9bda-85941757ee5a |

6. Click the **View** () icon next to any of the data records. The system displays a dialog box with detailed information about the entry.

| Name | Value |
|---------------|--------------------------------------|
| ItemID | 1 |
| Created by | 53 |
| Created when | 11/14/2012 2:52:55 PM |
| Modified by | 53 |
| Modified when | 11/14/2012 2:58:07 PM |
| Order | 1 |
| GUID | 76d31325-1911-4a4f-9bda-85941757ee5a |
| First name | Ben |
| Last name | Harmon |
| Date of birth | 10/26/1961 12:00:00 AM |

Close

Note that you can also create custom filter for listing custom table data using [alternative forms](#).

8.17.5 Displaying custom table data using web parts

The Custom tables module comes with three web parts that you can use for displaying custom table data. This page gives just a brief overview of these web parts. Detailed description of each web part and its properties can be found in [Kentico CMS Web Parts Reference](#). Live site examples of these web parts can be found on the sample Corporate Site, under **Examples -> Webparts -> Custom tables**.

The custom table web parts that are available to you:

Custom table datagrid

This web part displays a grid with selected columns of data records from a custom table. You can modify the design of the web part using standard ASP.NET skins. If you want to handle the data by transformations, use one of the web parts below.

| FirstName ▲ | LastName | DateOfBirth |
|-------------|----------|------------------------|
| Jane | Doe | 6/8/1970 12:00:00 AM |
| Kelly | Taylor | 2/23/1983 12:00:00 AM |
| Mike | Farrel | 12/18/1973 12:00:00 AM |

Custom table datalist

In the following picture, you can see the basic appearance of the Custom table datalist web part. The

web part displays the custom table data in a multi-column/multi-row list. You can change the appearance using transformations. You can find more information about using transformations with custom tables web parts in the [Transformations for custom tables](#) topic.

Custom table repeater with effect

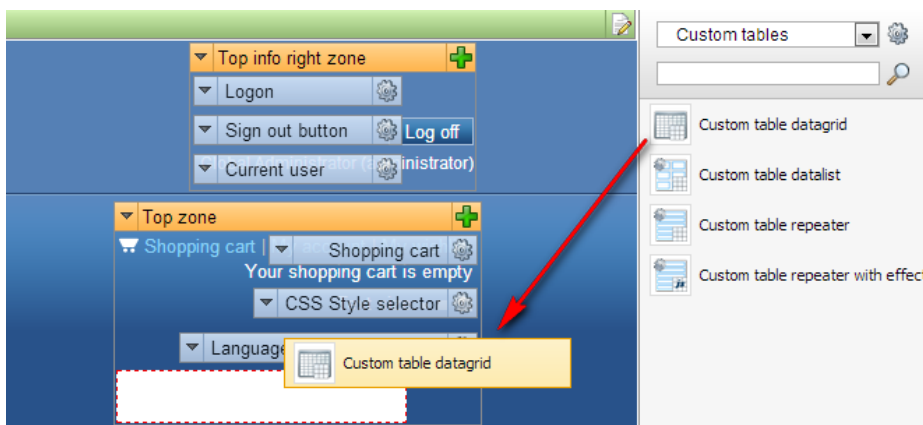

Renders data retrieved from a custom table you specify according to the assigned transformations and applies an additional javascript effect to the displayed records. You have to specify the effect through the web part's properties. You can find more information about using transformations with custom tables web parts in the [Transformations for custom tables](#) topic.

Placing the web parts using the web part toolbar

1. Navigate to **CMS Desk -> Content -> Edit**.
2. Choose the page on which you want to place the web part.
3. Switch to the **Design** tab.
4. In the **Web part toolbar**, select **Custom tables**.

5. Drag and drop the web part that you want to use to a **content area** of your choice.

The **Web part properties** dialog box opens.

Specifying the web part properties

1. Specify the following properties:

- **Web part control ID** - Enter a unique identifier for the web part.
- **Web part title** - Enter the title for the web part that is displayed on the **Design tab** and during **on-site editing**.
- **Custom table** - Select the custom table from which you want to display the data.

2. Learn more about the rest of the properties that you can specify for each of the web parts in [Kentico CMS Web Parts Reference](#).

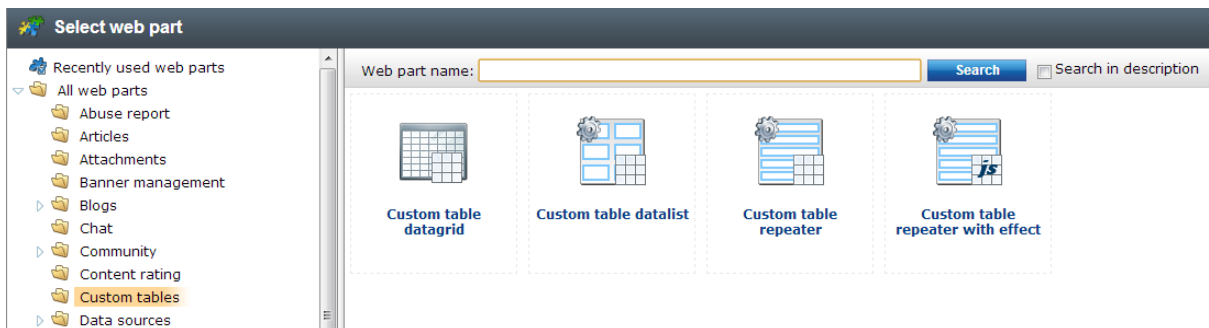

3. Click on **OK** to save the changes.

| ItemID ▲ | ItemCreatedBy | ItemCreatedWhen | ItemModifiedBy | ItemModifiedWhen | ItemOrder | FirstName | LastName | DateOfBirth |
|----------|---------------|-----------------------|----------------|-----------------------|-----------|-----------|-----------|------------------------|
| 1 | 53 | 11/14/2012 2:52:55 PM | 53 | 11/14/2012 2:58:07 PM | 1 | Ben | Harmon | 10/26/1961 12:00:00 AM |
| 2 | 53 | 11/15/2012 9:33:25 AM | 53 | 11/15/2012 9:33:25 AM | 2 | Constance | Langdon | 4/20/1949 12:00:00 AM |
| 3 | 53 | 11/15/2012 9:34:27 AM | 53 | 11/15/2012 9:34:27 AM | 3 | Travis | Wanderlay | 9/22/1979 12:00:00 AM |

Note that when on the **Design** tab, you can always drag and drop the web part elsewhere.

Placing the web parts using add web part button

1. Navigate to **CMS Desk -> Content -> Edit**.
2. Choose the page on which you want to place the web part.
3. Switch to the **Design** tab.
4. Click the **Add web part (+)** button in the **content area** of your choice. The **Select web part** dialog box opens.
5. Select **Custom tables** in the left content tree.
6. Select the web part that you want to place.

7. Click on **OK**. The **Web part properties** dialog box opens.

Specifying the web part properties

1. Specify the following properties:
 - **Web part title** - Enter a unique identifier for the web part.
 - **Web part title** - Enter the title for the web part that is displayed on the **Design tab** and during **on-site editing**.
 - **Custom table** - Select the custom table from which you want to display the data.
2. Learn more about the rest of the properties that you can specify for each of the web parts in [Kentico CMS Web Parts Reference](#).
3. Click on **OK** to save the changes.

Note that when on the **Design** tab, you can always drag and drop the web part elsewhere.

8.17.6 Transforming custom tables

In the following example, you will learn you can change the way custom table data is displayed on your site by modifying default transformation code.

This example makes use of the Custom table repeater transformation on the sample Corporate Site. The **People** custom table that you have created if you followed the [Creating custom tables](#) topic and populated with data in the [Managing data in custom tables](#) topic is used throughout the example as well. You can use any other custom table as well.

Applying the transformation

1. Navigate to **CMS Desk**.
2. Switch to **Edit** mode.
3. In the content tree, select **Examples -> Web Parts -> Custom tables -> Custom table repeater**.
4. Switch to the **Design** tab. The web part displays the content of the **Sample table** custom table by default.
5. **Configure** (⚙️) the properties of the Custom table repeater web part.

Example of the web part:

Item text: Sample text 1 [detail](#)
Item text: Sample text 2 [detail](#)
Item text: Sample text 3 [detail](#)
Item text: Sample text 4 [detail](#)

The **Web part properties** dialog box opens.

6. Under **Content**, in the **Custom table** drop-down list, select the **People** table.
7. Under **Transformations**, in the **Transformation name** property, click **Select**. The **Select transformation** dialog box opens.
8. Change the **Class type** to *Custom table* and select *People* as the **Custom table** value.
9. Click on **customtable.People.Default** to select the transformation.

Select transformation

Class type: Custom table

Custom table: People (customtable.People)

Transformation name or its part: **Search**

| Transformation name |
|--|
| customtable.People.Default |
| customtable.People.Preview |

Items per page: 10

Cancel

Click **OK** to confirm and close the **Web part properties** dialog.

Modifying the transformation

1. Switch to the **Live site** mode. You can see the repeater displaying the content of the **People** custom table.

Example of the web part:

```

First name: Ben
Last name: Harmon
Date of birth: 10/26/1961 12:00:00 AM
Created by: 53

GUID: 4b1b4f80-0a1d-4238-a67f-ad8b23c6296f

```

On an actual website, you probably would not want to display all the system fields. To change this, you will need to edit the code of the used transformation.

2. Switch to the **Edit** mode.
3. Switch to the **Design** tab.
4. **Configure** (🔗) the repeater web part's properties again.
5. Under **Transformations**, in the **Transformation name** property, click **Edit**.
6. For the purpose of this tutorial, replace the entire transformation content with the following sample code. You can notice that it is just a modification of the former **Default** transformation, with the unwanted fields deleted and highlighted tags and properties added.

```

<table border="1" cellpadding="4">
<tr>
<td><b>First name:</b></td>
<td width="180"><%# Eval("FirstName") %></td>
</tr>
<tr>
<td><b>Last name:</b></td>
<td><%# Eval("LastName") %></td>
</tr>

```

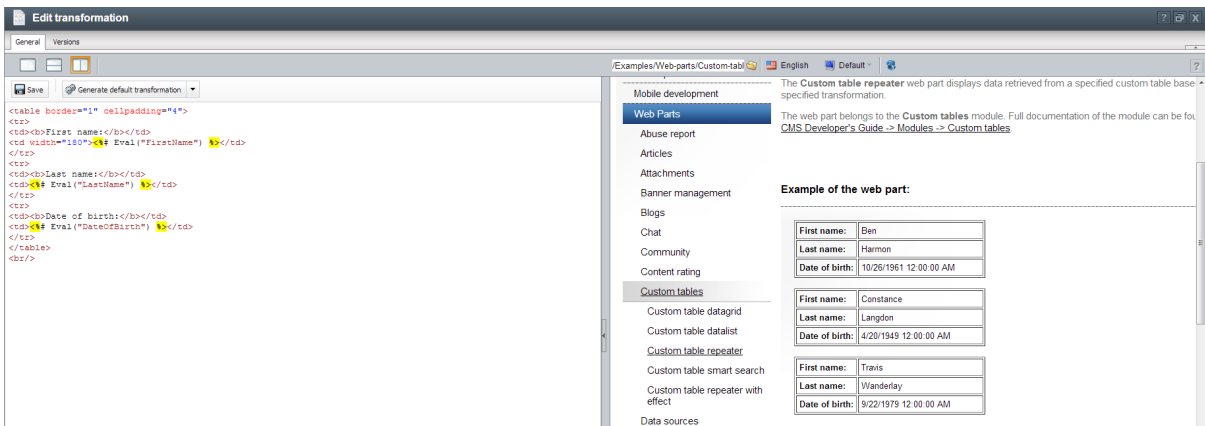

```

<tr>
<td><b>Date of birth:</b></td>
<td><%# Eval("DateOfBirth") %></td>
</tr>
</table>
<br/>

```

7.  **Save** the modifications confirm the change.

8. Click on  **Preview**. The **Edit transformation** window opens. You can see a split view that allows you to see how the data is displayed by the current web part while editing the transformation code.

9. **Close** the dialog box.

10. Click on **OK** to confirm the changes.

11. Switch to the **Live site** to see the changes you made to the transformation.

8.17.7 Setting permissions

You can configure the permissions of the custom tables module on two levels — globally for all custom tables belonging to the current site and separately for each particular custom table.

Configuring permissions for custom tables belonging to a certain site

1. Navigate to **Site Manager -> Administration -> Permissions**.
2. In the first **Permissions for** drop-down list choose **Module** and **Custom tables** in the second.

You can grant the following permissions on this level:

- **Create** - members of the role are allowed to create data in any custom table.
- **Delete** - members of the role are allowed to delete data in any custom table.
- **Modify** - members of the role are allowed to modify data in any custom table.
- **Read** - members of the role are allowed to read any custom table data.

 **Permissions**

Site:

Permissions for:

Report for user: Show only this user's roles

| Role | Read | Create | Modify | Delete |
|------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Editors | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Readers | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Facebook users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Gold Partners | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| LinkedIn users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Live ID users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Marketing Manager | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Not authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

Once you grant the permissions to the specific roles, you may want to assign users to the roles as described in the [Role management topic](#).

Configuring permissions for a particular custom table

1. Navigate to **Site Manager -> Administration -> Permissions**.
2. In the first **Permissions for** drop-down list choose **Custom table** and the specific custom table in the second.

You can grant the following permissions on this level:

- **Create** - members of the role are allowed to add new records into the selected table
- **Delete** - members of the role are allowed to delete records from the selected table
- **Modify** - members of the role are allowed to modify existing records in the selected table
- **Read** - members of the role are allowed to read data stored in the selected table

Permissions

Site: Corporate site

Permissions for: Custom table Sample table

Report for user: (none) Show only this user's roles

| Role | Read | Modify | Create | Delete |
|------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Editors | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Readers | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

Once you grant the permissions to the specific roles, you may want to assign users to the roles as described in the [Role management topic](#).

8.17.8 Custom tables internals and API

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Custom tables module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.17.8.1 Database tables

The Custom tables module uses the following database tables:

- **CMS_Class** - custom tables are stored as classes in the system database, this database table is used for storing information about classes.
- **CMS_ClassSite** - this table is used to assign classes (and therefore also custom tables) to particular sites in the system.
- **CMS_Query** - contains records representing SQL queries for operations with data in custom tables, along with other queries used by the system.
- **CMS_Transformation** - contains records representing transformations for custom tables data, as well as other transformations used by the system.
- **CMS_AlternativeForm** - contains records representing alternative forms for particular custom tables, together with other alternative forms used by the system.
- **<prefix>_<table code name>** - particular custom tables are stored as standard tables in the system database. You can distinguish them by giving them a descriptive prefix, while the *customtable_* prefix is used by default.

8.17.8.2 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Custom tables module can be found in the **CMS.SiteProvider** namespace.

Custom tables API:

- **CustomTableItem** - represents one custom table object.
- **CustomTableItemProvider** - provides management functionality for custom tables.

8.17.8.3 API examples

These topics show examples of how the API of the Custom tables module can be used:

- [Managing custom table data](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Development\CustomTables\Default.aspx.cs**.

The Custom tables API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.SettingsProvider;
```

8.17.8.3.1 Managing custom table data

Use the following example to create a custom table item.

```
private bool CreateCustomTableItem()
{
    // Creates new Custom table item provider
    CustomTableItemProvider customTableProvider = new CustomTableItemProvider
(CMSContext.CurrentUser);

    // Prepares the parameters
    string customTableClassName = "customtable.sampletable";

    // Checks if Custom table 'Sample table' exists
    DataClassInfo customTable = DataClassInfoProvider.GetDataClass
(customTableClassName);
    if (customTable != null)
    {
        // Creates new custom table item
        CustomTableItem newCustomTableItem = CustomTableItem.New
```

```
(customTableClassName, customTableProvider);

    // Sets the ItemText field value
    newCustomTableItem.SetValue("ItemText", "New text");

    // Inserts the custom table item into database
    newCustomTableItem.Insert();

    return true;
}

return false;
}
```

Using the following example, you can get and update the custom table item that you created in the previous code example.

```
private bool GetAndUpdateCustomTableItem()
{
    // Creates a new Custom table item provider
    CustomTableItemProvider customTableProvider = new CustomTableItemProvider
(CMSContext.CurrentUser);

    string customTableClassName = "customtable.sampletable";

    // Checks if Custom table 'Sample table' exists
    DataClassInfo customTable = DataClassInfoProvider.GetDataClass
(customTableClassName);
    if (customTable != null)
    {
        // Prepares the parameters
        string where = "ItemText LIKE N'New text'";
        int topN = 1;
        string columns = "ItemID";

        // Gets the data set according to the parameters
        DataSet dataSet = customTableProvider.GetItems(customTableClassName,
where, null, topN, columns);

        if (!DataHelper.DataSourceIsEmpty(dataSet))
        {
            // Gets the custom table item ID
            int itemID = ValidationHelper.GetInteger(dataSet.Tables[0].Rows[0][0],
0);

            // Gets the custom table item
            CustomTableItem updateCustomTableItem = customTableProvider.GetItem
(itemID, customTableClassName);

            if (updateCustomTableItem != null)
            {
                string itemText = ValidationHelper.GetString
```

```
(updateCustomTableItem.GetValue("ItemText"), "");

        // Sets new values
        updateCustomTableItem.SetValue("ItemText", itemText.ToLowerCSafe
    ());

        // Saves the changes
        updateCustomTableItem.Update();

        return true;
    }
}

return false;
}
```

Use this example to get a custom table item and move it **down** in the order of items in the custom table.

```
private bool GetAndMoveCustomTableItemDown()
{
    // Creates new Custom table item provider
    CustomTableItemProvider customTableProvider = new CustomTableItemProvider
(CMSContext.CurrentUser);

    string customTableClassName = "customtable.sampletable";

    // Checks if Custom table 'Sample table' exists
    DataClassInfo customTable = DataClassInfoProvider.GetDataClass
(customTableClassName);
    if (customTable != null)
    {
        // Prepares the parameters
        string where = "ItemText LIKE N'New text'";
        int topN = 1;
        string columns = "ItemID";

        // Gets the data set according to the parameters
        DataSet dataSet = customTableProvider.GetItems(customTableClassName,
where, null, topN, columns);

        if (!DataHelper.DataSourceIsEmpty(dataSet))
        {
            // Gets the custom table item ID
            int itemID = ValidationHelper.GetInteger(dataSet.Tables[0].Rows[0][0],
0);

            // Moves the item down
            customTableProvider.MoveItemDown(itemID, customTableClassName);

            return true;
        }
    }
}
```

```

    }
}

return false;
}

```

Use this example to get a custom table item and move it **up** in the order of items in the custom table.

```

private bool GetAndMoveCustomTableItemUp()
{
    // Creates new Custom table item provider
    CustomTableItemProvider customTableProvider = new CustomTableItemProvider
(CMSContext.CurrentUser);

    string customTableClassName = "customtable.sampletable";

    // Checks if Custom table 'Sample table' exists
    DataClassInfo customTable = DataClassInfoProvider.GetDataClass
(customTableClassName);
    if (customTable != null)
    {
        // Prepares the parameters
        string where = "ItemText LIKE N'New text'";
        int topN = 1;
        string columns = "ItemID";

        // Gets the data set according to the parameters
        DataSet dataSet = customTableProvider.GetItems(customTableClassName,
where, null, topN, columns);

        if (!DataHelper.DataSourceIsEmpty(dataSet))
        {
            // Gets the custom table item ID
            int itemID = ValidationHelper.GetInteger(dataSet.Tables[0].Rows[0][0],
0);

            // Moves the item up
            customTableProvider.MoveItemUp(itemID, customTableClassName);

            return true;
        }
    }

    return false;
}

```

Using the following example, you can get multiple custom table items based on a WHERE condition and then update t

```

private bool GetAndBulkUpdateCustomTableItems()
{

```

```
// Creates new Custom table item provider
CustomTableItemProvider customTableProvider = new CustomTableItemProvider
(CMSContext.CurrentUser);

string customTableClassName = "customtable.sampletable";

// Checks if Custom table 'Sample table' exists
DataClassInfo customTable = DataClassInfoProvider.GetDataClass
(customTableClassName);
if (customTable != null)
{
    // Prepares the parameters

    string where = "ItemText LIKE N'New text%'";

    // Gets the data
    DataSet customTableItems = customTableProvider.GetItems
(customTableClassName, where, null);
    if (!DataHelper.DataSourceIsEmpty(customTableItems))
    {
        // Loops through the individual items
        foreach (DataRow customTableItemDr in customTableItems.Tables[0].Rows)
        {
            // Creates object from DataRow
            CustomTableItem modifyCustomTableItem = CustomTableItem.New
(customTableItemDr, customTableClassName);

            string itemText = ValidationHelper.GetString
(modifyCustomTableItem.GetValue("ItemText"), "");

            // Sets new values
            modifyCustomTableItem.SetValue("ItemText", itemText.ToUpper());

            // Saves the changes
            modifyCustomTableItem.Update();
        }

        return true;
    }
}

return false;
}
```

Use this example to delete the custom table item that you created in the first code example.

```
private bool DeleteCustomTableItem()
{
    // Creates new Custom table item provider
    CustomTableItemProvider customTableProvider = new CustomTableItemProvider
(CMSContext.CurrentUser);
```

```
string customTableClassName = "customtable.sampletable";

// Checks if Custom table 'Sample table' exists
DataClassInfo customTable = DataClassInfoProvider.GetDataClass
(customTableClassName);
if (customTable != null)
{
    // Prepares the parameters
    string where = "ItemText LIKE N'New text%'";

    // Gets the data
    DataSet customTableItems = customTableProvider.GetItems
(customTableClassName, where, null);
    if (!DataHelper.DataSourceIsEmpty(customTableItems))
    {
        // Loops through the individual items
        foreach (DataRow customTableItemDr in customTableItems.Tables[0].Rows)
        {
            // Creates object from DataRow
            CustomTableItem deleteCustomTableItem = CustomTableItem.New
(customTableItemDr, customTableClassName);

            // Deletes custom table item from database
            deleteCustomTableItem.Delete();
        }

        return true;
    }
}

return false;
}
```

8.18 Dashboards

8.18.1 Overview

Dashboards are sections of the Kentico CMS administration interface that can be customized by individual users directly through the browser. Typically, a user will personalize their dashboard to contain frequently used tools or sources of information, which they can then easily access from a single location without the need to navigate through the interface.

The screenshot displays a dashboard with several widgets. At the top, there are buttons for 'Add widget' and 'Reset to default'. The 'My messages' widget shows an inbox with one message from Andrew Jones (Andy) with the subject 'Hello there', dated 8/28/2011 7:25:23 PM. Below it is an 'Abuse report list' table with two entries for 'Website Forums Abuse' reported on 8/28/2011 7:34:30 PM and 7:34:34 PM. To the right is a 'Forum posts waiting for approval' table with two posts from 'Website forums' by John Smith and Jack Black. At the bottom is a 'Blog comments' table with two comments from Paul Woods and Brad Summers, both approved and not marked as SPAM.

The structure of every dashboard is based on a [portal engine page template](#) of a specific type, which designates the parts of the dashboard that are always present and cannot be changed by users. This also includes defining customizable areas (zones) and any default content. The components that can be placed on dashboards by users are called [widgets](#). These are the same objects that allow the personalization of pages directly on the live site or on the **Page** tab of **CMS Desk**.

The personalizable content of a dashboard, meaning the widgets that are placed on it and their configuration, is distinct for every user. If the dashboard is located in the **CMS Desk** interface, its widget content is also unique for every different site.

Detailed information about defining dashboard page templates and using widgets on dashboards may be found in the [Managing dashboard content](#) topic.

By default, dashboards can be found in the following sections of the interface:

- **CMS Site Manager -> Dashboard**
- **CMS Desk -> My Desk -> My Dashboard**
- **CMS Desk -> Tools -> Web analytics -> Dashboard**

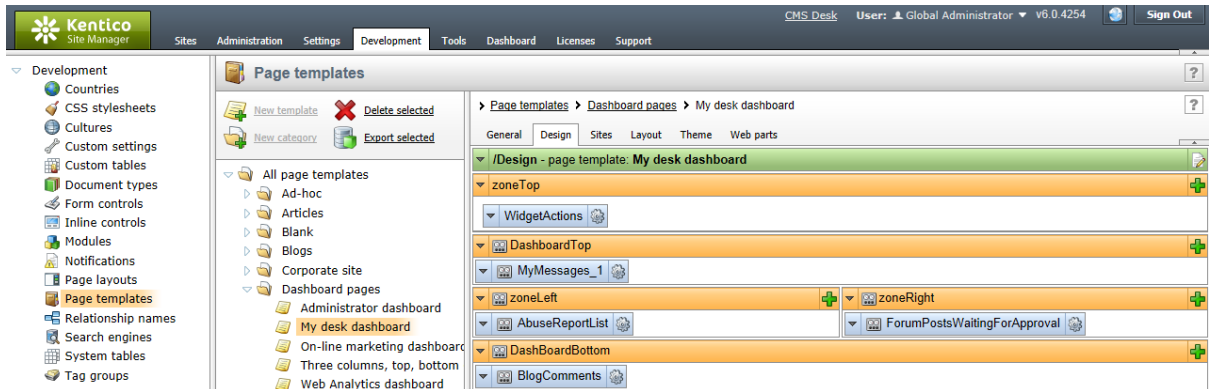

If required, a dashboard page may be created at a custom location according to the procedure described in the [Adding a new dashboard to the interface](#) topic.

8.18.2 Managing dashboard content

There are several levels on which dashboard content can be specified.

Setting the layout of zones, fixed content and default widgets

The general design and initial content of a dashboard is determined by the page template that it uses. Dashboard templates can be managed at **Site Manager -> Development -> Page templates**, like any other type of page templates. A dashboard template must have its **Template type** property set to *Dashboard page* on the **General** tab. Configuration of the actual template content can be performed on the **Design** tab.

The placement, size and amount of zones on the template may be altered by editing the code of its [page layout](#) via the **Edit layout** (🔗) button or on the **Layout** tab.

There are two possible types of zones that can be defined on a dashboard template:

- **Web part zones** - the content of zones of this type may only be managed here on the *Design* tab of the page template. Web parts located here function as fixed content on the dashboard page itself. The *Widget zone type* property of these zones must be set to *None*.
- **Dashboard widget zones** - zones of this type may only contain widgets. Any widgets added here on the *Design* tab serve as the default content of the zone. Individual users may change and configure the widget content of the zone for their own personalized version of the dashboard. The *Widget zone type* property of these zones must be set to *Dashboard*.

Every dashboard template should contain the [Widget actions](#) web part somewhere in its layout in order to allow users to add new widgets or reset the zones of the dashboard to their default widget content. The web part must also be configured (⚙️) to have its **Widget zone type** property set to *Dashboard*. The **Widget zone ID** property may be used to specify the dashboard zone to which new widgets will be added (the ID of the desired zone must be entered). Once created, users can drag the widget to another zone as required.

The settings made on the **Sites** tab of a dashboard page template do not affect on which websites dashboards with this template can be placed. They are only used to ensure that the page template will be exported/imported along with the assigned sites.

To learn about how a page template is assigned to a specific dashboard section, please read the [Adding a new dashboard to the interface](#) topic.

Using widgets on dashboards

Users of the administration interface with access to a dashboard section can manipulate widgets in the available zones and thus create their own personalized version of the dashboard. Widgets are added using the **+** **Add widget** button generated by the **Widget actions** web part. At any time, all the zones on the dashboard and the widgets they contain can be returned to their default state by clicking **✖** **Reset to default**.

Individual widgets are enclosed in containers with a header and a set of action buttons. To manage the widgets on the dashboard, the appropriate actions must be used.

The simplest action available is provided by the **Minimize widget** () button, which hides the content of a widget so that only its header is visible. The **Maximize widget** () action can be used to restore the widget to its previous state.

Clicking the **Configure widget** () button opens the **Widget properties** dialog where the widget's properties can be modified. Every widget has its own set of properties depending on its function (detailed information can be found in the [Widgets](#) reference guide). The **Widget title** property is present for all types of widgets, as it sets the text displayed in the header of the widget on the dashboard page.

The location of a widget can be changed easily by using its drag-and-drop functionality. To pick up a widget, simply hover over its header, hold down the mouse button and then drag it to the desired position. This works both for modifying the order of widgets within a zone and moving them to a different zone.

The **Remove widget** () action deletes the widget from the dashboard completely.

Configuring widgets for dashboards

In order for a specific widget to be usable as a dashboard component, it must first be configured in **Site Manager -> Development -> Widgets**, specifically by checking the **This widget can be used in dashboard zones** option on its **Security** tab.

The screenshot shows the Kentico CMS 7.0 administration interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The 'Development' tab is selected. On the left, a tree view shows the 'Development' category expanded, with 'Widgets' selected. The main content area displays the 'Widgets' configuration page for the 'System' widget. The 'Security' tab is active, and the 'Allowed for' section is visible. A red circle highlights the checkbox for 'This widget can be used in dashboard zones', which is checked. Other options include 'Allowed for' group zones, editor zones, user zones, and inline widget. Below this, there are sections for 'Authenticated users' and 'Authorized roles'.

If a widget is also allowed in other types of zones, for example user zones on the live site, it may in certain cases be useful to set some of its properties to be available only when configuring the widget on a dashboard. This can be achieved on the **Properties** tab using the **Display attribute only in the dashboard** checkbox included among the settings of the given property.

8.18.3 Adding a new dashboard to the interface

If the dashboards built into the administration interface by default do not meet your specific requirements, it is possible to integrate new dashboard pages.

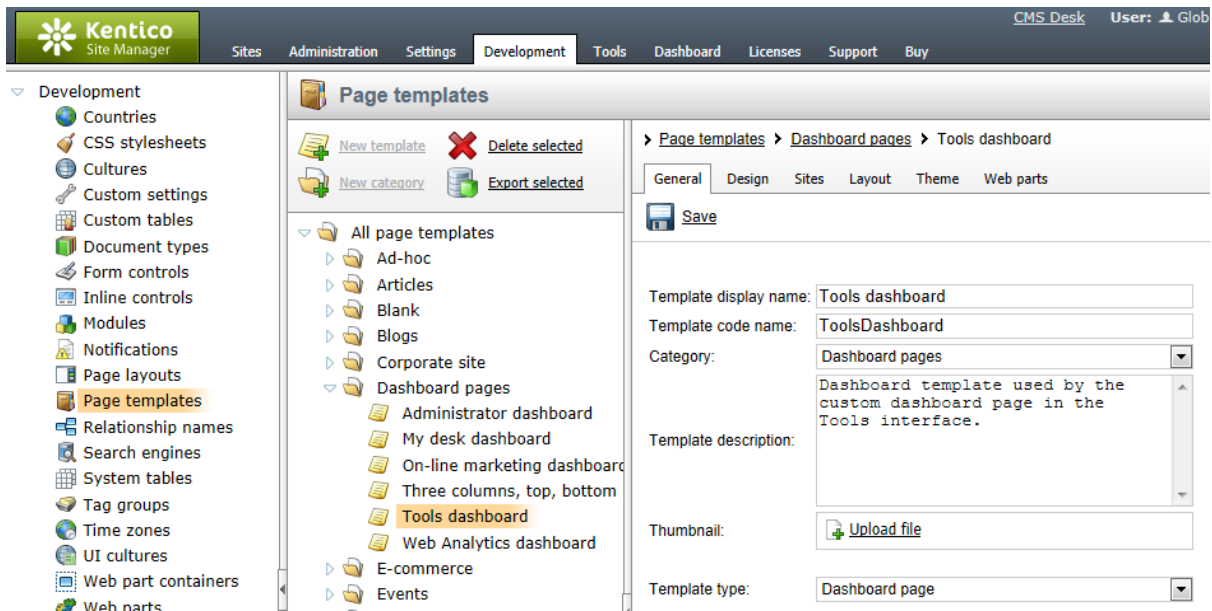

The following example demonstrates how a custom dashboard can be added to the **Tools** tab of the **CMS Desk** administration interface. The same principles can be applied when creating a dashboard in other locations.

Creating the dashboard page template

1. First, create the page template that the dashboard page will be based on. Go to **CMS Site Manager** -> **Development** -> **Page templates**, select the **Dashboard pages** category from the tree and click **New template**. Enter the following values into the available fields:

- **Template display name:** Tools dashboard
- **Template code name:** ToolsDashboard

Click **OK**, select *Dashboard page* from the **Template type** drop-down list of the new template and **Save** the change.

2. Switch to the **Design** tab and click the **Edit layout** (🛠️) button. Copy the following code into the layout to define some web part/widget zones for the template:

```
<table border="0" width="100%" cellspacing="0" cellpadding="0">
  <tr>
    <td colspan="2">
      <div class="DashboardActions PageTitleHeader">
        <cc1:CMSWebPartZone ID="zoneTop" runat="server" />
      </div>
    </td>
  </tr>
  <tr>
    <td colspan="2">
      <cc1:CMSWebPartZone ID="DashboardTop" runat="server" />
    </td>
  </tr>
  <tr valign="top">
    <td style="width:50%">
      <cc1:CMSWebPartZone ID="DashboardLeft" runat="server" />
    </td>
    <td style="width:50%">
      <cc1:CMSWebPartZone ID="DashboardRight" runat="server" />
    </td>
  </tr>
</table>
```

Click  **Save**.

3. Now open the **Design** tab again, expand the menu (▼) of the **DashboardTop** zone and select the **Properties** item. Switch the **Widget zone type** property from *None* to *Dashboard* and click **OK**. Repeat this step for the **DashboardLeft** and **DashboardRight** zones.

4. Next, click the **Add web part** (+) button of the **ZoneTop** zone, select **Widgets -> Widget actions** from the web part catalog and press **OK**. Configure the following properties of the web part:

- **Widgets -> Widget zone type:** Dashboard
- **Widgets -> Widget zone ID:** Leave empty; designates the zone where new widgets should be created when the *Add widget* button is clicked. By default, the first available zone will be used (*DashboardTop* in this case), but the ID of any other dashboard zone can be specified if required.

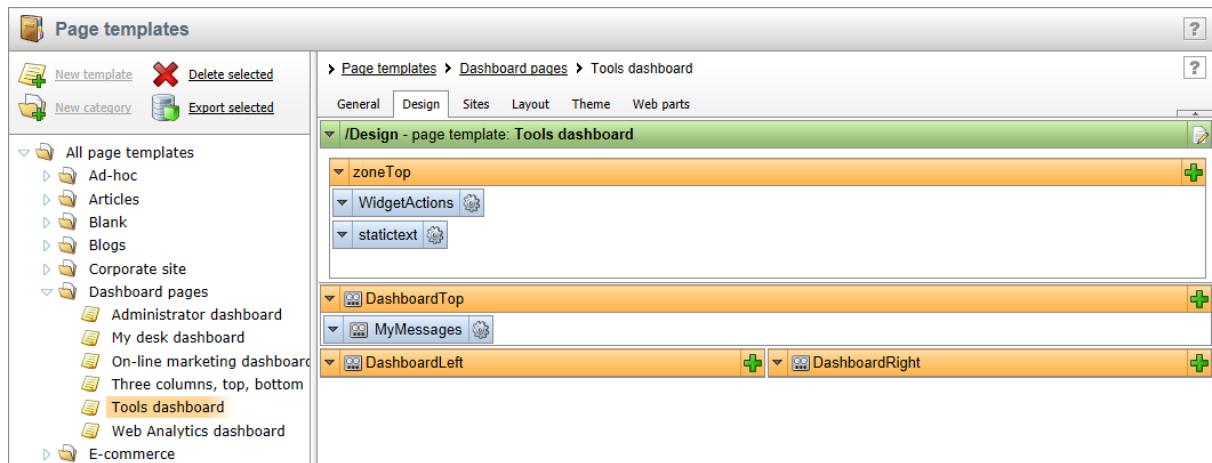

Leave the remaining properties in their default state and click **OK**.

5. Add another web part to the same zone. This time select **Text & Images -> Static text** and set the following properties:

- **Content -> Text:** This is a custom dashboard page.
- **HTML Envelope -> Content before:** <h2>
- **HTML Envelope -> Content after:** </h2>

Click **OK**.

6. Place a widget into the **DashboardTop** zone, for example **Community -> My messages** and leave the remaining two zones empty. This sets the default content of the dashboard that individual users can later configure and expand.

7. Switch to the **Sites** tab and assign the template to any websites that should carry over the new dashboard page when they are exported.

Adding the necessary UI element

8. The **CMS Desk -> Tools** section where the new dashboard will be located utilizes *User interface elements* that can be managed via the CMS. Navigate to **Site Manager -> Development -> Modules** and edit (✎) the **Tools** module. On the **General** tab, notice that the **Module code name** is *CMS.Tools*. This will be used later in the example.

9. Switch to the **User interface** tab, add a  **New element** under the root of the Tools tree and enter the values shown below:

- **Display name:** Dashboards
- **Code name:** Tools.Dashboards
- **Element is custom:** Yes (checked)

- **Caption:** Dashboards

Click **OK**. This element will only serve as a parent category in the tools menu, under which the actual dashboard will be placed. Now click  **New element** again to add an item under the **Dashboards** element and fill in the form according to the following information:

- **Display name:** Dashboard
- **Code name:** ToolsDashboardElement
- **Element is custom:** Yes (checked)
- **Caption:** *Dashboard*; this sets the text caption displayed for the element in the actual interface. In real-world scenarios, it may be preferable to specify the caption using a [localization string](#) in the appropriate macro expression format: `{${<string key>}$}`
- **Target URL:** `~/CMSGlobalFiles/ToolsDashboard.aspx?dashboardName=Tools&templateName=ToolsDashboard&{hash}`
Sets the URL of the page with the content of the UI element. The actual source file used in the URL above will be created later in this example. When creating links to dashboard pages, it is necessary to understand and correctly specify the query string parameters:
 - **dashboardName** - sets a name for the dashboard to ensure uniqueness in cases where multiple dashboards use the same page template. The content of a dashboard is unique for every user and site (when located in CMS Desk). However, if two or more dashboards share a page template and the *dashboardName* parameters in the URLs used to access them have the same value, changes made to one of the dashboards will also be applied to the others (for the given user and site).
 - **templateName** - sets the code name of the page template that the dashboard will be based on. The type of the assigned template must be *Dashboard page*. As you can see, this example uses the template created in the previous steps.
 - **hash** - the hash code will be generated automatically by the used menu control.
- **Icon path:** `CMSModules/CMS_Dashboard/module.png`; sets the path to the image used to represent the element in the actual interface.
- **Size:** Large

Click **OK** to create the new UI element once all the fields are filled in correctly.

The screenshot shows the Kentico CMS 7.0 Administration interface. The left sidebar contains a tree view of the site structure, with 'Modules' expanded to show 'Dashboards' and 'Dashboard' selected. The main area displays the 'Module properties' dialog for the 'Dashboard' element. The 'User interface' tab is active, showing the 'UI elements' section. The 'Dashboard' element is selected, and its properties are displayed in the right pane. The 'General' tab is active, showing the following settings:

- Display name: Dashboard
- Code name: ToolsDashboardElement
- Parent element: --Dashboards
- Element is custom:
- Menu item settings:
 - Caption: Dashboard
 - Target URL: ~/CMSGlobalFiles/ToolsDashboard.aspx?dashbo
 - Icon path: CMSModules/CMS_Dashboard/module.png
 - Description: (empty text area)
- Size: Large Regular

An 'OK' button is visible at the bottom right of the dialog.

Adding dashboards without using UI elements

Not all sections of the administration interface can be modified via UI elements (please refer to [UI personalization -> How does it work](#) for more information). If you wish to add a dashboard page to these other locations, the code of the used navigation components must be modified manually. Keep in mind that the dashboard page needs to be accessed through a URL with the query string parameters mentioned above in the description of the **Target URL** property.

Creating the dashboard page's source file

10. Now the **.aspx** file of the dashboard page needs to be developed and added to your web project. Open your website in Visual Studio and create a **New folder** under the root called *CMSGlobalFiles* (if it doesn't already exist). Right-click the folder and select **Add New Item**. Choose to create a **Web Form** and name it *ToolsDashboard.aspx*. As you can see, this is the file specified in the **Target URL** of the UI element created before. This location ensures that the file will be exported along with any site that includes global folders in its export package.

11. Modify the page code to match the following:

```
<%@ Page Language="C#" AutoEventWireup="true" CodeFile="ToolsDashboard.aspx.cs"
Theme="Default" EnableEventValidation="false"
Inherits="CMSGlobalFiles_ToolsDashboard" %>
```

```
<%@ Register Src="~/CMSModules/Widgets/Controls/Dashboard.ascx"
TagName="Dashboard" TagPrefix="cms" %>

<%=DocType%>

<html xmlns="http://www.w3.org/1999/xhtml" <%=XmlNamespace%>>
<head id="Head1" runat="server" enableviewstate="false">
  <title id="Title1" runat="server">Dashboard</title>
  <asp:Literal runat="server" ID="ltlTags" EnableViewState="false" />
  <style type="text/css">
    body
    {
      margin: 0px;
      padding: 0px;
      height: 100%;
      font-family: Arial;
      font-size: small;
    }
  </style>
</head>
<body class="<%=BodyClass%>">
  <form id="form1" runat="server">

    <cms:Dashboard ID="ucDashboard" runat="server" ShortID="d" />

  </form>
</body>
</html>
```

The **Dashboard** user control that you registered and placed onto the form handles the entire functionality of the dashboard. It processes the query string parameters from the URL used to access the page and displays the corresponding dashboard according to the specified dashboard name, page template and context-related data such as the current site and user.

12. Switch to the code behind of the web form and add the following references to the beginning of the code:

[C#]

```
using CMS.UIControls;
using CMS.CMSHelper;
```

13. Next, set the **CMSSGlobalFiles_ToolsDashboard** class to inherit from the **DashboardPage** class and modify it to contain the following code:

[C#]

```
public partial class CMSSGlobalFiles_ToolsDashboard : DashboardPage
{
  protected override void OnPreInit(EventArgs e)
  {
```

```
base.OnPreInit(e);

// Must be equal to the code name of the module containing the
corresponding UI element
ucDashboard.ResourceName = "CMS.Tools";

// Must be equal to the code name of the corresponding UI element
ucDashboard.ElementName = "ToolsDashboardElement";

ucDashboard.PortalPageInstance = this as PortalPage;
ucDashboard.TagsLiteral = this.ltlTags;
ucDashboard.DashboardSiteName = CMSContext.CurrentSiteName;

ucDashboard.SetupDashboard();
}

protected void Page_Load(object sender, EventArgs e)
{

    // Security access and UI personalization checks for the current user

}
}
```

In the handler of the *PreInit* event, certain properties of the **Dashboard** user control are assigned and its **SetupDashboard()** method is called. Note that the values of the **ResourceName** and **ElementName** properties must be set according to the module and code name of the UI element created in previous steps of this example.

When adding a dashboard to the interface of an actual live website, the **Page_Load** method should contain code checking that the current user has the *Read permission* for the given part of the interface and that the UI element is not disabled via *UI personalization* settings.

14. Save both files. If your CMS project was installed as a web application, **Build** your web project.

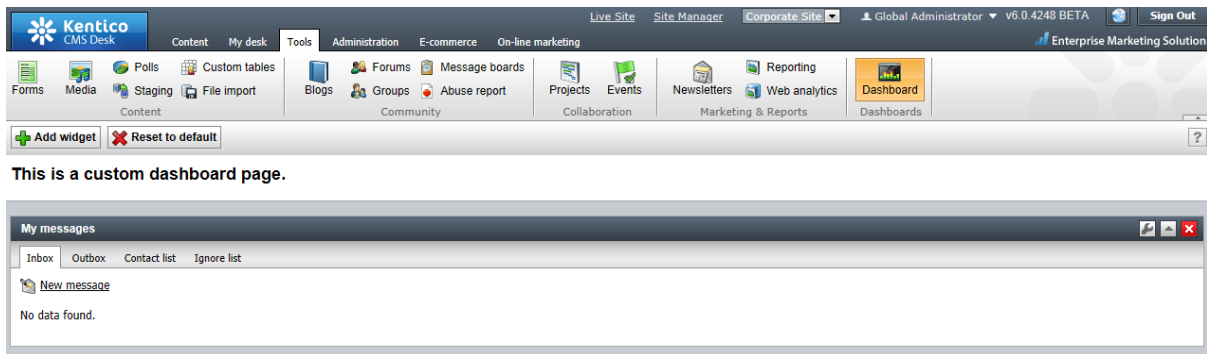

Creating dashboards in the Site Manager interface

It is not necessary to create a new aspx file for dashboards located in the Site Manager administration interface. You can simply reuse the default **~/CMSiteManager/Dashboard.aspx** file, since there is no matching UI element to be configured and the security checks should always be the same.

When adding the link to the dashboard in Site Manager navigation components, remember to appropriately set the **dashboardName** and **templateName** query string parameters in the URL.

Result

15. If you now open **CMS Desk** and switch to the **Tools** tab, you will see that there is a new **Dashboard** item in the menu. If you select it, a fully functional dashboard page based on the created page template will be displayed.

8.19 Document library

8.19.1 Overview

The Document library module enables live site users to upload and manage files stored in a pre-defined location in the [content tree](#). The module has no dedicated user interface. Its whole functionality is provided by two web parts: **Document library** and **Group document library**. Both web parts and their specific properties are described in the [Document library web parts](#) topic. The module also comes with the [Document library widget](#), which is based on the **Document library** web part.

[New document](#) [Library permissions](#)

| Document name | Modified | Workflow step |
|--|---------------------|---------------|
| ▼ Dress Code | 18/11/2010 17:02:56 | Published |
| ▼ Equal Opportunities | 18/11/2010 17:03:02 | Published |
| ▼ Intellectual Property Policy | 15/10/2010 14:50:56 | Published |

Document library files are stored in the [content tree](#) as standard *CMS.File* documents. This means that even though the module has no dedicated user interface, actions made on the live site are reflected in the content tree. Like this, the uploaded documents can also be managed by website editors or administrators in **CMS Desk -> Content**. Only flat file structure of document libraries is currently supported, i.e. you can't store files in sub-folders but only under the main document. More information about *CMS.File* documents, as well as other ways how files can be stored in Kentico CMS, can be found in [Content management -> File management](#).

A live example of use of this module can be found on the **Intranet Portal** sample website, specifically on its */Documents* page. The process of creating a similarly structured document library can be found in the [Creating a document library](#) topic. The [Managing files in document libraries](#) topic explains how the module can be used from the live site user's point of view. Finally, the [Security](#) topic explains how standard [document-level permissions](#) are applied to documents in the library and how they can be configured.

8.19.2 Document library web parts

The whole functionality of the Document library module is ensured by the following two web parts:

- **Document library** -> **Document library** - designed for general use anywhere on your website; it displays all documents from a specified location except those whose *Owner* is a community [group](#)
- **Community** -> **Group document library** - designed for use within a context of a community [group](#); displays documents whose *Owner* is the specified community [group](#) along with other documents stored under the specified path

The web parts have the following specific properties:

- **Library path** - path to the document under which the library documents are stored, e.g. */My-document-library/My-images*; only *CMS.File* documents from the first level under the entered path are displayed; using the **Set permissions** button, you can directly configure the document's permissions, as described in [Security](#)
- **Page size** - number of documents listed by the web part on a single page
- **Document form** - [Alternative form](#) that will be used for document properties editing (after choosing **Properties** from the context menu); if blank, the *CMS.File.DocumentLibrary* form will be used; if this form is not available, the *CMS.File* document type's default form will be used
- **Group name** - available only with the *Group document library* web part; documents owned by the specified group stored under the *Library path* will be displayed along with other documents under the same path
- **Combine with default culture** - if *No*, the web part only displays documents from the current culture that are stored under the *Library path*. If *Yes*, documents from the default culture are displayed along with documents from the current culture. In this case, the default culture documents are marked with the culture's flag and the **Translate** option is available in their context menu
- **Check permissions** - if enabled, only documents for which the current user has the **Read permission** are displayed by the web part; if disabled, all documents are displayed

 New document  Library permissions

| Document name ^ | Modified | Workflow step |
|--|---|---------------|
|  Dress Code | 18/11/2010 17:02:56 | Published |
|  Equal Opportunities | 18/11/2010 17:03:02 | Published |
|  Intellectual Property Policy |  15/10/2010 14:50:56 | Published |
|  Network and Software Use | 18/11/2010 17:03:09 | Published |
|  Our Core Values | 18/11/2010 17:03:18 | Published |
|  Travel Expense Report |  15/10/2010 14:51:09 | Published |
|  Travel Expense Reporting | 18/11/2010 17:03:49 | Published |

8.19.3 Document library widget

The module also comes with the **Document library** widget. The widget is stored under the **Document library** widget category and it is an editor widget, i.e. it can only be added to editor widget zones of page templates by website editors in CMS Desk.

Compared to the [Document library web parts](#), the **Document library** widget only has a limited set of properties to configure:

- **Library path** - path to the document under which the library documents are stored, e.g. */My-document-library/My-images*; only *CMS.File* documents from the first level under the entered path are displayed; using the **Set permissions** button, you can directly configure the document's permissions, as described in [Security](#)
- **Page size** - number of documents listed by the web part on a single page
- **Combine with default culture** - if *No*, only documents from the current culture that are stored under the *Library path* will be displayed; if *Yes*, documents from the default culture will be displayed

along with documents from the current culture, while default culture documents will be marked with the culture's flag and the **Translate** option is available in their context menu

Besides the fact that only a limited set of properties is available with the widget, its functionality is identical to the **Document library** web part.

New document Library permissions

8.19.4 Creating a document library

This topic explains how a document library can be created on your website. We will create a sample page with two **Document library** web parts, each of which will display files from a separate folder. Like this, we will actually have two document libraries on a single page, each for storing different types of files. The example is based on the **Intranet Portal** sample website. However, the procedure is analogical when performed on any other website.

The first step when creating a document library is to choose a location in the content tree where the files will be stored. A single document library web part can display documents from only a single location. As we want two separate libraries on a single page, we will create a page in the content tree where two **Document library** web parts will be placed. Under the page, we will create two separate folders where the actual files will be stored.

1. Go to **CMS Desk -> Content**, select the root of the content tree and click **New**. Choose the **Page (menu item)** document type. In the following dialog, enter *My document library* into the **Page name** field and choose the **Create a blank page** option. Click **Save**.

With the new document selected in the content tree, click **New** again. This time, choose the **Folder** document type and enter *My images* as its **Document name**. Repeat the same once again to create another folder, while this one should be called *My Office documents*. The final result should look as in the screenshot below.

2. Now that you have the page and folders created, we may proceed to adding the **Document library** web parts. Select the **My document library** document, switch to the **Design** mode and click the **Add web part (+)** icon of the only web part zone on the page. In the **Select web part** pop-up dialog,

choose the **Document library** web part, which is stored in the **Document library** web part category. Configure its properties as follows:

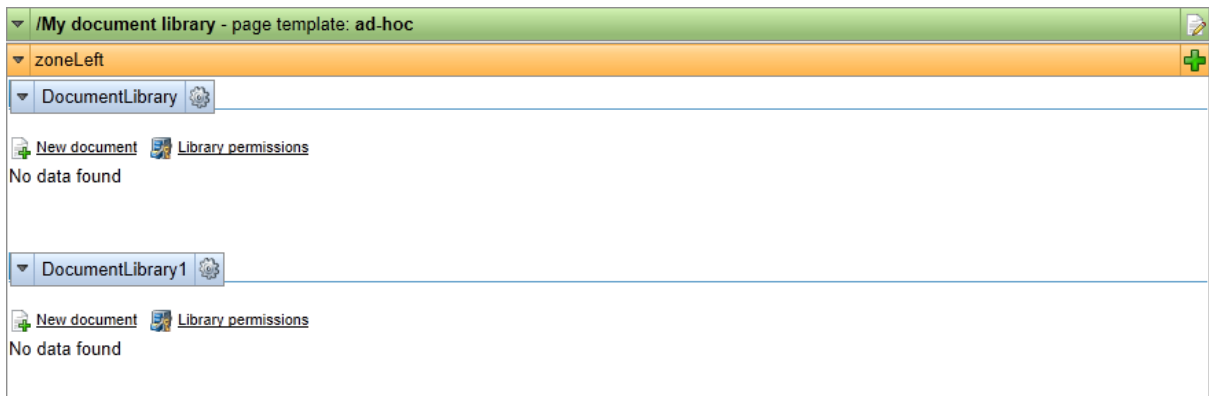

- **Library path:** /My-document-library/My-images
- **Page size:** 15
- **Document form:** leave the field blank
- **Web part container:** Intranet simple container (with header line)
- **Container title:** My images
- **Content after:**

Click **OK**.

3. Repeat step 2 and add another **Document library** web part to the page. This time, use the following values of its properties:

- **Library path:** /My-document-library/My-Office-documents
- **Page size:** 15
- **Document form:** leave the field blank
- **Web part container:** Intranet simple container (with header line)
- **Container title:** My Office documents

Click **OK**. The web part zone should now look as in the following screenshot if viewed in the **Design** mode.

4. The document libraries are now configured and ready to be used by live site users. If viewed on the live site after uploading some files into the libraries, the page should look as in the screenshot below.

The screenshot shows a document library interface with a navigation bar at the top containing links like 'Home', 'Company', 'Departments', 'Workgroups', 'Documents', 'News', 'Events', 'Media', 'Blogs', 'Forums', and 'Employees'. Below the navigation bar, there are two main sections: 'My images' and 'My Office documents'. Each section has a 'New document' and 'Library permissions' link. The 'My images' section contains a table with two rows: 'Jellyfish' (modified 11/15/2010 5:40:59 PM) and 'Penguins' (modified 11/15/2010 5:40:56 PM). The 'My Office documents' section contains a table with three rows: 'Book1' (modified 11/15/2010 5:40:21 PM), 'Document1' (modified 11/15/2010 5:40:28 PM), and 'Presentation1' (modified 11/15/2010 5:40:34 PM).

Please proceed to the [Managing files in document libraries](#) topic to learn more about how live site users can upload and manage document library files.

8.19.5 Managing files in document libraries

This topic explains particular actions that can be performed by live site users in a document library.

Permissions for particular actions

All of the actions listed below **are not always available**. They are displayed based on [document permissions](#) granted to the current user or their roles. Please consult the [Security](#) topic for more details on which permissions are required for each of the listed actions.

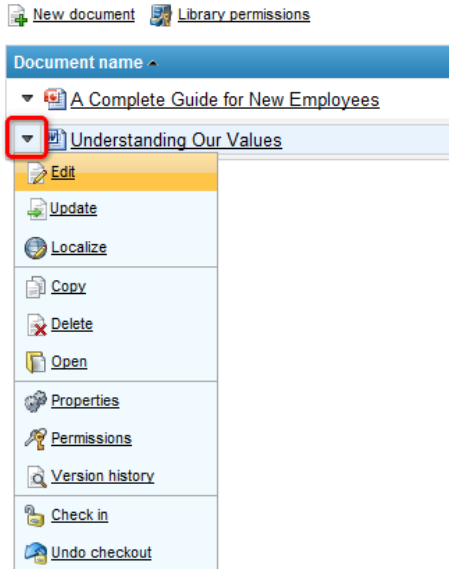

When a new document library is created, there are no files in it, so live site users can only see the web part with the following two links at the top.

-  [New document](#)
-  [Library permissions](#)

Once some files are uploaded in the document library, live site users can perform the following actions with the documents:

-  [Edit](#)
-  [Update](#)
-  [Localize](#)
-  [Copy](#)
-  [Delete](#)
-  [Open](#)
-  [Properties](#)
-  [Permissions](#)
-  [Version history](#)
- [Workflow actions](#)

These actions can be executed from a context menu, which is accessible by right-clicking anywhere in a document's row, or by left-clicking the down-arrow to the left of a document's name (as highlighted in the screenshot below).

The following text explains particular actions that can be performed in a document library:

New document

Clicking the  **New document** link in **Internet Explorer** or **Mozilla Firefox** directly opens the browser's file selection dialog. By selecting a file from a local disk and clicking **Open**, the file will be uploaded into the document library.

Library permissions

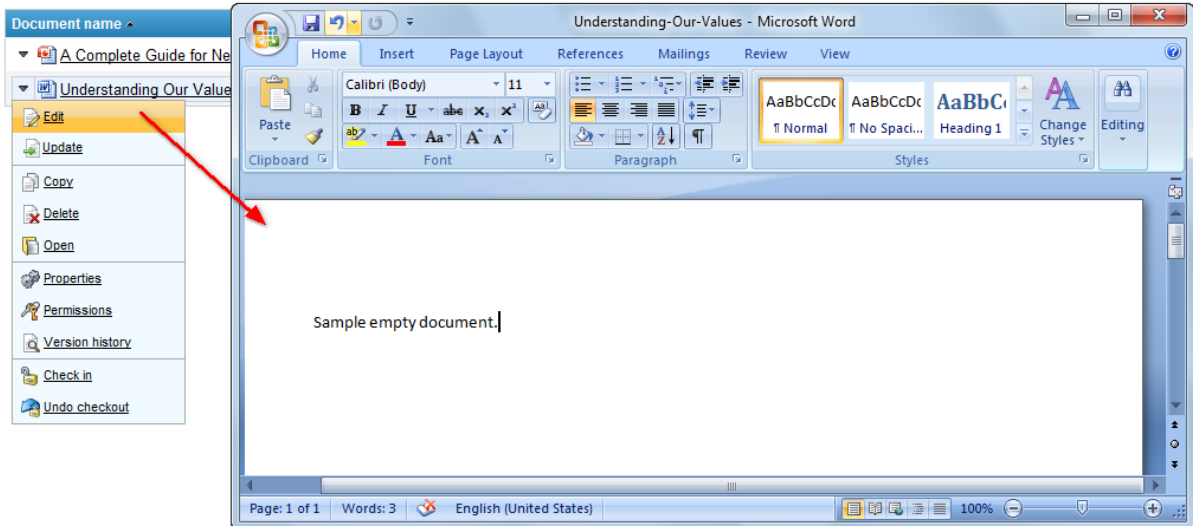

Clicking the **Library permissions** link opens a dialog for document library permissions configuration. Please refer to the **Configuring document-level permissions on the live site** section of the [Security](#) topic for more details.

Edit

The **Edit** action is only available if [WebDAV integration](#) is enabled. It opens the file in a client

application for direct editing (for example, .docx documents get opened in *MS Word*, as you can see in the screenshot below). WebDAV editing is only possible if there is an application installed on the client machine that supports WebDAV editing of the particular file type.

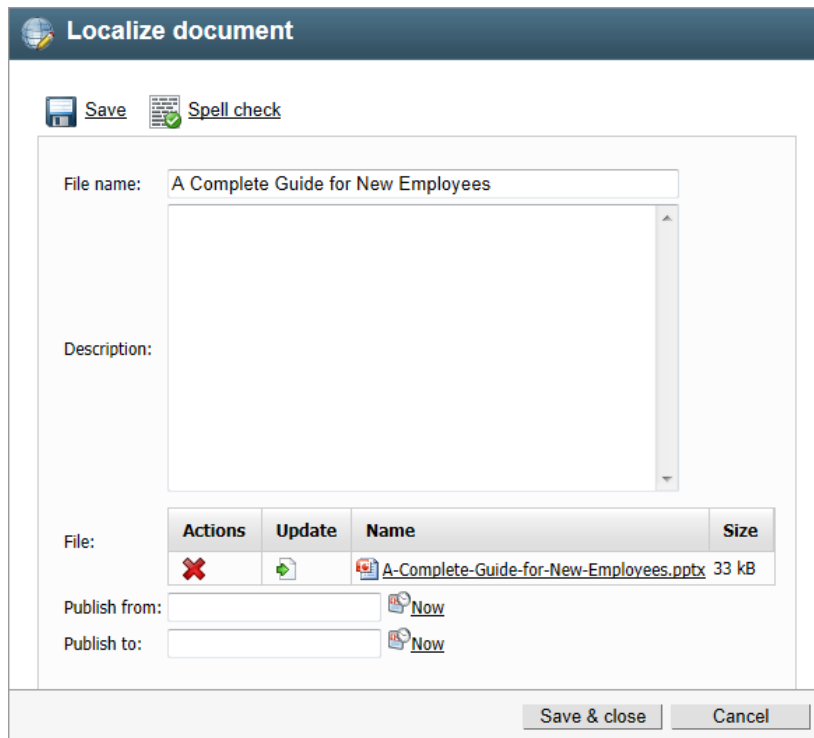

Update

Selecting the  **Update** action opens the browser's file selection dialog. Selecting a file from a local disk and clicking **Open** in the dialog replaces the original file with the selected one. In **Apple Safari** and **Opera**, there is one extra dialog displayed before the browser's file selection dialog. Please refer to the [New document](#) paragraph above for more details.

Localize

The  **Localize** option is only displayed with documents from the default culture when the **Combine with default culture** property of the web part is enabled. Clicking the action opens the dialog depicted in the screenshot below, which serves for creation of a new language version of the selected document in the current culture.

Copy

The  **Copy** action creates a copy of the file in the same document library. As only flat structure of document libraries is currently possible, a different file name needs to be entered for the copy, while the " - Copy" suffix is offered to be added to the file name automatically. When copying a linked document (marked with the  flag), the copy will be a standard document, not a linked one.

Delete

Clicking the  **Delete** action opens the dialog depicted below. Using the dialog, you can remove the document from the document library. On multilingual websites where more than one language version of

the document exists, the **Delete all culture versions of the specified document** check-box is displayed in the dialog. If you delete the document with the check-box enabled, all cultural versions of the document will be deleted.

Open

The  **Open** action works similarly as a standard file download link. The web browser's standard file download dialog is displayed and you can either open the document or save it to a local disk. The same behavior can be expected when you click the document's name in the library listing.

Properties

The  **Properties** action opens a dialog where properties of the *CMS.File* document can be configured the same way as in **CMS Desk -> Content -> Edit -> Form**. The dialog uses the [Alternative form](#) specified in the **Document form** property of the web part. If no form is specified, the *CMS.File.DocumentLibrary* form is used. If even this form is not available, *CMS.File* document type's default form is used.

The text filled in the **Description** field is displayed in a tooltip when the mouse pointer is placed above the document.

Permissions

The **Permissions** action opens a dialog for configuration of permissions for the particular document, similarly as in **CMS Desk -> Content -> Edit -> Properties -> Security**. Please refer to the **Configuring document-level permissions on the live site** section of the [Security](#) topic for more details.

Document permissions

Version history

Clicking the  **Version history** action displays an overview of the document's versions, similarly as in **CMS Desk -> Content -> Edit -> Properties -> Versions**. The following actions are available with each of the listed versions:

-  **View** - displays an overview of the document's content with the possibility of side-by-side comparison of versions
-  **Rollback** - rolls back any changes made since the particular version of the document
-  **Delete** - deletes the old version

You can also use the **Clear history** button to clear all versions except the latest one. For the action to be available, the **Destroy** permission for this document must be granted to the user.

Version history

The document has been successfully rolled back.

Workflow actions

If there is a workflow configured for documents in a document library, standard workflow actions are displayed at the bottom of the context menu, depending on workflow configuration and the current

workflow step of the document:

- **Submit to approval** - submits the document for approval to the sub-subsequent workflow step
- **Approve**¹ - approves the document and switches it to the sub-subsequent workflow step
- **Reject**¹ - rejects the document and switches it back to the previous workflow step
- **Archive** - switches the document to the Archived step
- **Check out**² - checks the document out for editing; while checked out, the document can't be edited by other users; checked-out documents are marked with the icon in the document library listing (as can be seen in the screenshot below)
- **Check in**² - checks the modified document in after editing, so that other users can edit it again
- **Undo checkout**² - takes back the check-out, while changes made to the document are not saved

¹ for these actions to be available, the user must also be in one of the roles that are allowed to approve/reject the document in the current workflow step or have the **Manage workflow** permissions for all content

² these actions are only available if the workflow applied to the document is configured to use check-in/check-out

Document libraries are typically used with [Versioning without workflow](#). In this case, document in the libraries are in the **Published** workflow step all the time and a new version of the document is created with each modification. Please refer to [Content management -> Workflow and versioning](#) for more information on workflows in Kentico CMS.

New document Library permissions

| Document name | Modified | Workflow step |
|------------------------------------|------------------------|---------------|
| A Complete Guide for New Employees | 11/4/2010 2:23:36 PM | Published |
| Understanding Our Values | 11/23/2010 10:57:07 PM | Edit |

8.19.6 Security

The Document library module leverages standard [document permissions](#). The following table explains which permissions are required to perform particular actions in the document library. These permissions can be granted to roles globally for all content or for the *CMS.File* document type, or to particular users or roles on document-level of the library's parent document or each particular document in the library.

| Action | Read | Modify | Create | Delete | Destroy | Manage workflow | Modify permissions |
|----------------------------|------|--------|--------|--------|---------|-----------------|--------------------|
| New document | • | • | • | | | | |
| Library permissions | • | | | | | | • |
| Edit | • | • | | | | | |
| Update | • | • | | | | | |
| Localize | • | • | • | | | | |
| Copy | • | • | • | | | | |
| Delete | • | | | • | | | |

| | | | | | | | |
|--|---|---|--|--|---|---|---|
|  Open | • | | | | | | |
|  Properties | • | • | | | | | |
|  Permissions | • | | | | | | • |
|  Version history | • | • | | | 1 | | |
|  Submit to approval | • | • | | | | | |
|  Approve ² | • | • | | | | 2 | |
|  Reject ² | • | • | | | | 2 | |
|  Archive | • | • | | | | | • |
|  Check out ³ | • | • | | | | | |
|  Check in ³ | • | • | | | | | |
|  Undo checkout ³ | • | • | | | | | |

¹ The **Destroy** permission is required for the user to be able to delete particular versions or the whole version history.

² For these actions to be available, the user must also be in one of the roles that are allowed to approve/reject the document in the current workflow step or have the **Manage workflow** permissions for all content.

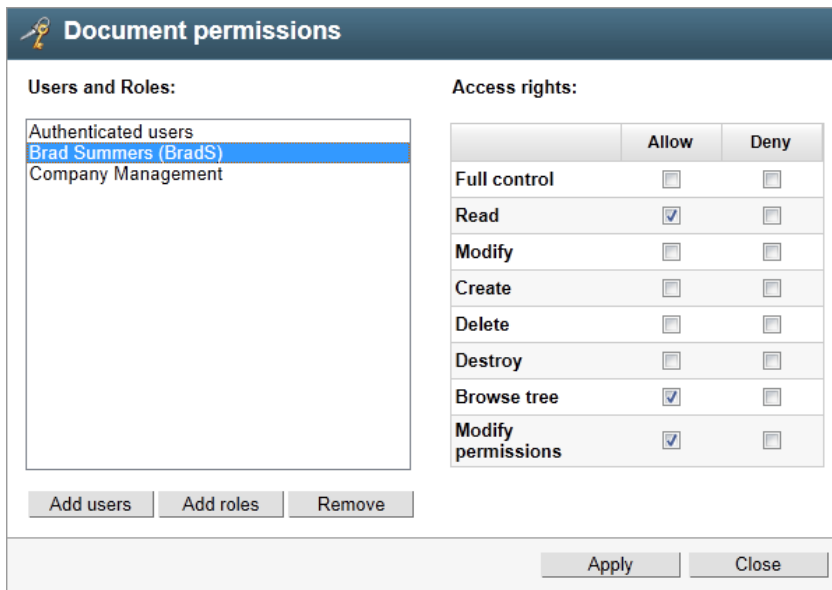

³ These actions are only available if the workflow applied to the document is configured to use check-in/check-out.

Configuring document-level permissions on the live site

Document-level permissions can be configured directly on the live site. They can be configured either globally for the document library's parent document, which results in the permissions being inherited by the child documents in the library, or separately for each particular document in the library. Permissions can be granted to users or roles. Permissions for group document libraries can also be granted to group members and [group roles](#).

The  **Library permissions** action opens a dialog for configuration of the library's parent document permissions, i.e. the permissions that can be inherited by its child documents (the actual documents stored in the library). This dialog is identical to the **Permissions** section of the **CMS Desk -> Content -> Edit -> Properties -> Security** dialog for the document. Permissions configured via the web part on the live site will be reflected in this dialog.

By choosing the  **Permissions** action from the context menu of a document in the library, the same dialog gets displayed, while this time, permissions are configured just for the particular document. Here again, the permissions configured on the live site will be reflected in the **CMS Desk -> Content -> Edit -> Properties -> Security** dialog for the document.

Permissions and workflow

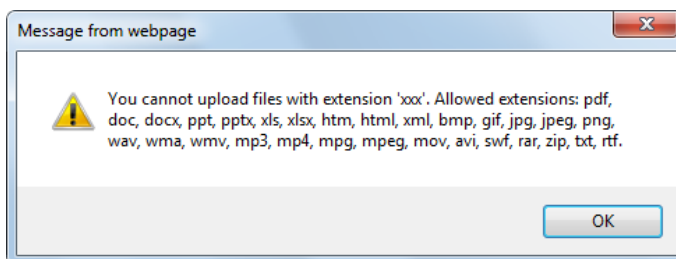

Document libraries reflect workflows applied to documents stored in them. Unless the current user has the **Modify** permission for a document, the currently published version of the document is always displayed to the user. If the document is currently archived or not published, the document is not displayed to the user at all. If the current user does have the **Modify** permission, the current version of the document (in the current workflow step) is displayed to them.

Please refer to [Content management -> Workflow and versioning](#) for more information on workflows in Kentico CMS.

Allowed file extensions

When uploading a new document into the document library using the **New document** link or updating a document using the **Update** action (both in the context menu and in the **Properties** dialog), only files with extensions defined in **Site Manager -> Settings -> System -> Files -> Upload extensions** or in the **Allowed extensions** property of the *FileAttachment* field of the *CMS.File* document type can be uploaded.

Each attempt to upload a file with an extension that is not allowed will result in the error message as displayed in the screenshot below.

8.20 E-commerce

8.20.1 Overview

For information about the **E-commerce** module please refer to [Kentico CMS E-commerce Guide](#).

8.21 E-mail queue

8.21.1 Overview

The E-mail queue module was designed to enable the sending of large amounts of e-mails, e.g. when sending newsletter issues to subscribers, without the risk of losing any of the e-mails due to errors. If an e-mail is not delivered successfully, it remains in the queue so that it can be resent later. The e-mails in the queue are sent out **automatically**, no manual sending is necessary as this is handled by the **Send queued e-mails** [scheduled task](#).

During the mail-out, e-mails in the queue are distributed to the SMTP servers defined in system. Please see the [SMTP server configuration](#) topic to learn how you can register and configure SMTP servers in Kentico CMS.

E-mails in the queue can be monitored or manually managed through the administration interface. Please see the [Adminstrating the e-mail queue](#) topic for more information.

To utilize the e-mail queue, authorized users have the option of [Sending mass e-mails](#) to large amounts of users. Certain other modules, such as [Newsletters](#), also make use of the e-mail queue. All other e-mails sent by the system can be configured to either use the e-mail queue or be sent directly to the SMTP server, as is described in the [Settings](#) topic.

8.21.2 Administrating the e-mail queue

The e-mail queue administration interface is located in **Site Manager -> Administration -> E-mail queue**. Using the **Site** drop-down list, you can choose which site you want to display the e-mail queue for. If (*global*) is selected, e-mails sent from the administration interface will be displayed. If (*all*) is selected, all e-mails in all queues will be displayed. The administration interface is divided into three tabs:

E-mail queue tab

This tab displays the actual e-mail queue. E-mails that are waiting to be sent or that haven't been sent successfully (displayed with an Error message) are displayed here. You can **Resend**  the mail, **Delete**  it or **View**  its details. There is also a number of links above the list:

-  **Resend all failed** - resends all e-mails in the queue that were unsuccessfully sent; new e-mails that have not yet been sent will not be resent
-  **Resend selected** - resends all e-mails selected by the check-boxes in the list
-  **Resend all** - resends all e-mails in the list

-  **Delete all failed** - deletes all e-mails in the queue that were unsuccessfully sent; new e-mails that have not yet been sent will not be deleted
-  **Delete selected** - deletes all e-mails selected by the check-boxes in the list
-  **Delete all** - deletes all e-mails in the list

-  **Refresh** - refreshes the content of the e-mail queue

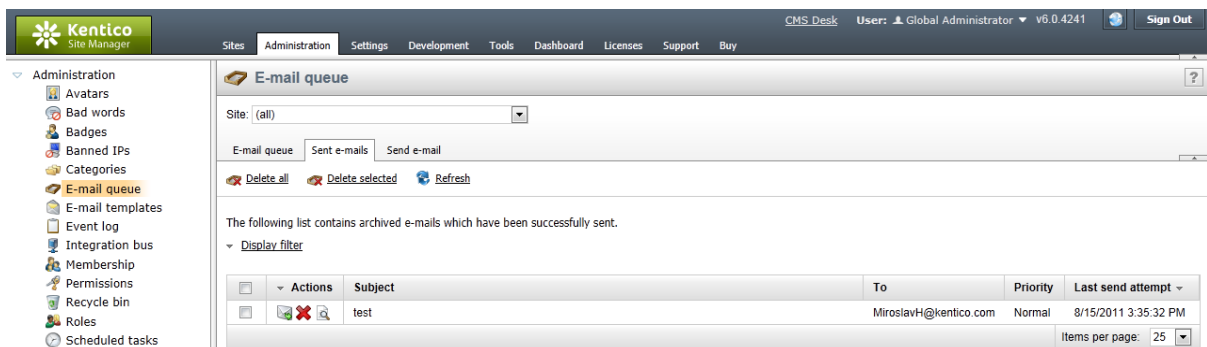

Sent e-mails tab

This tab displays a list of e-mails that have been successfully sent via the e-mail queue. You can set how long the e-mails will stay in this list through the **Site Manager -> Settings -> System -> E-mails -> Archive e-mails (days)** property.

You can **Resend** () the mail, **Delete** () it or **View** () its details. There are also three links at the top of the page:

-  **Delete all** - deletes all e-mails in the list
-  **Delete selected** - deletes e-mails selected by the check-boxes in the list
-  **Refresh** - refreshes the content of the list of sent e-mails

E-mail filter

When there is a large number of e-mails in the e-mail queue, you can easily limit which e-mails will be displayed using the filter. It can be displayed by clicking the **Display filter** link above the e-mail lists on both tabs.

Site: (all) ▼

Priority: (all) ▼

Show

Send e-mail tab

From this tab, you can easily send a single e-mail to a specified recipient (not only the site users). For sending e-mails to multiple users, we recommend using [mass e-mails](#) instead of this tab.

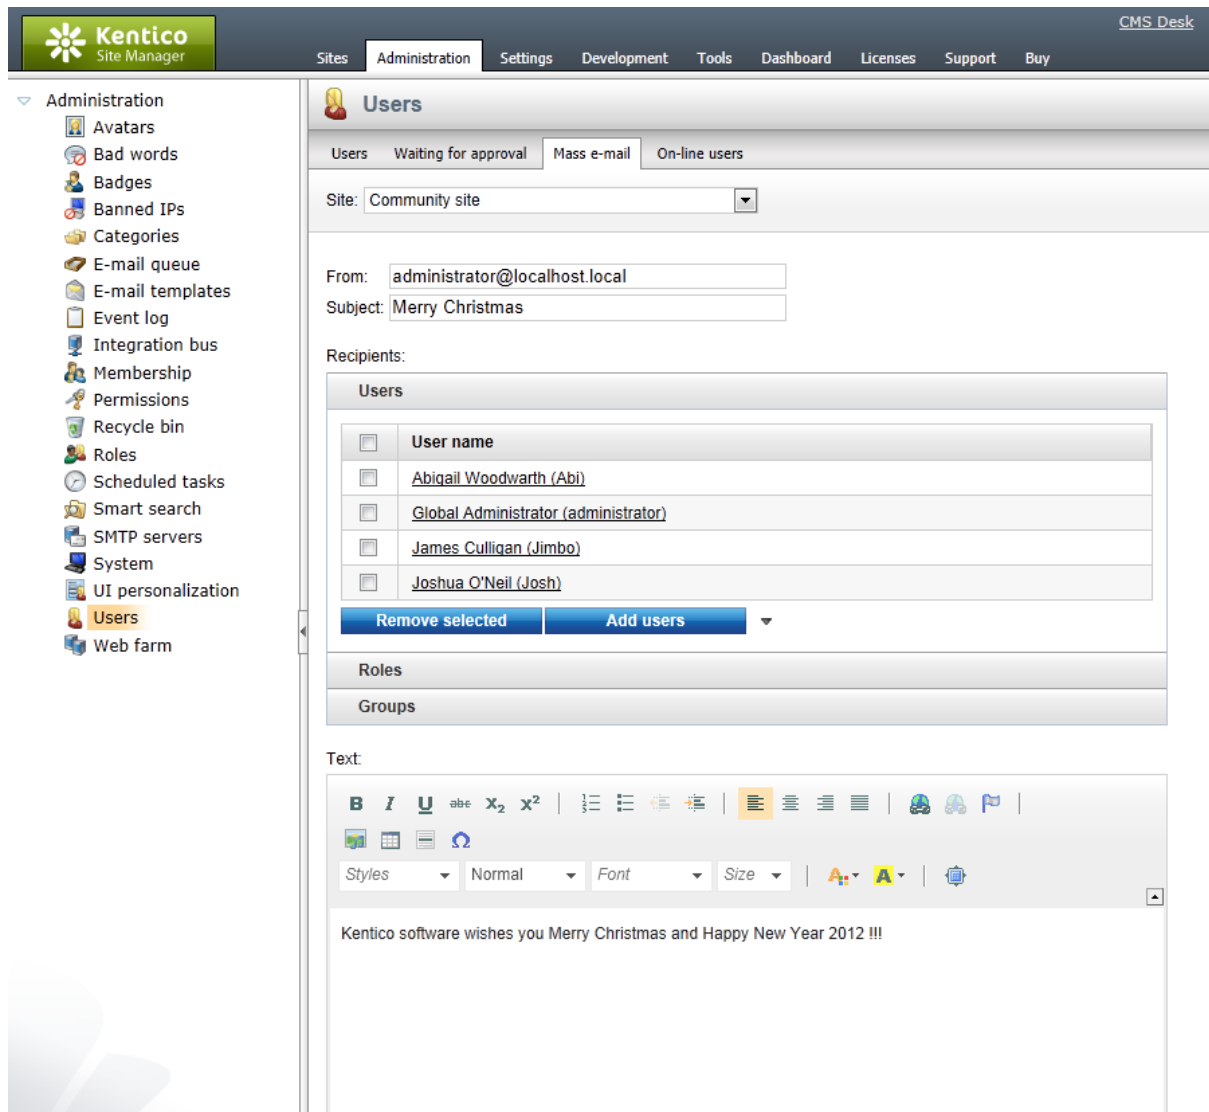

8.21.3 Sending mass e-mails

As the e-mail queue allows the sending of massive amounts of e-mails, we've implemented the Mass e-mail feature. This feature enables you to send the same e-mail to a large amount of users.

You can do this at **Site Manager -> Administration -> Users -> Mass e-mail**.

Using the **Site** drop-down list, you can select which site the recipients are related to. Based on this choice, users can be selected either directly, or according to the roles or group that they are members of by using the **Add users** buttons in the **Recipients** section. If you choose the *(all)* option from the site drop-down list, only global roles (those that are not limited to a single site) will be available and the **Groups** section will be hidden since groups are always site-related.

You can also add an attachment to the mail using the  **Attach file** link.

This tab is also available at **CMS Desk -> Administration -> Users -> Mass e-mail**, but only users of the current site can be selected.

In the e-mail queue, you will see the **Show details** link instead of a recipient's e-mail address for mass e-mails, as you can see in the screenshot below.

| <input type="checkbox"/> | Actions | Subject | To | Priority | Error message | Last send attempt | Status |
|--------------------------|---|-----------------|------------------------------|----------|---------------|-------------------|---------|
| <input type="checkbox"/> |   | Merry Christmas | Show details | Normal | | | Waiting |

Items per page: 25

After clicking the link, a window will appear as in the screenshot below. You can delete recipients from the list, so that the mass e-mail will not be delivered to them. This can be done using the **Delete** () icons or by selecting more recipients using the checkboxes and clicking **Delete selected** (.

8.21.4 Settings

E-mail settings are located at **Site Manager -> Settings -> System -> E-mails**. Among other e-mail related settings, the following three can be used to enable the e-mail queue and configure its functionality:

- **Enable e-mail queue** - if checked, the e-mail queue will be used when sending e-mails. There are certain exceptions for priority e-mails, like those containing forgotten passwords for example, that skip the queue and are sent directly.
- **Batch size** - sets the maximum number of e-mails that can be transferred from the e-mail queue to an SMTP server in one batch. If the specified value is smaller than the total amount of e-mails to be sent from the queue, a new batch is prepared and assigned to the next available server. This process is repeated until all e-mails are mailed out. The setting affects all sites in the system, so it is only available if the (*global*) option is selected from the *Site* drop-down list.
- **Archive e-mails (days)** - the number of days for which e-mails sent via the e-mail queue will remain stored on the **Sent e-mails** tab. If set to 0, e-mails will not be archived.

The screenshot shows the Kentico CMS Settings interface for the 'E-mails' module. The left sidebar contains a navigation tree with categories like Content, URLs and SEO, Security & Membership, System, Performance, Files, Health monitoring, Output filter, Search, Debug, On-line marketing, E-commerce, Community, Intranet & Collaboration, Versioning & Synchronization, Integration, and Cloud services. The main content area is titled 'E-mails' and includes a 'Save' button and a 'Reset these settings to default' link. Below this, a message states: 'These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.' The settings are organized into sections: 'General' (E-mail encoding: utf-8, E-mail format: HTML), 'E-mail processing' (Enable e-mails: checked, Enable e-mail queue: checked, Batch size: 50, Archive e-mails (days): 0), and 'SMTP server' (SMTP server: localhost, SMTP server user: empty, SMTP server password: empty, Use SSL: unchecked). The 'E-mail processing' section is highlighted with a red rectangular box.

8.22 Events

8.22.1 Overview

The Events module allows you to manage events and their attendees. It can be used to schedule various types of event like meetings, conferences, training sessions, social events, etc. Events can be displayed on your website in a calendar and you can let your website users to register for the events. Registered attendees can be managed in the module's user interface.

In the CMS, events are represented as standard documents stored in the content tree. The **Event (booking system)** document type (code name **CMS.BookingEvent**) is used for the events. Once you have some events in the content tree, you can use web parts of the module to display them on the live site and enable registration.

Web parts of the module are stored in the **Events & booking** web part category. The **Event calendar** web part appears as a standard calendar, while events located in a configured path are displayed in respective day fields. It is possible to enable registration for the events by means of the **Event registration** web part, which enables registration for the event currently selected in the calendar.

In the [Publishing events](#) topic, you can find an example demonstrating how these two web parts can be used together in a typical scenario. The example also shows how events to be displayed can be created. Another example is located in the [Using the Event calendar with other document types](#) topic — this one shows how the **Event calendar** web part can be used to display other document types than the default **Event (booking system)**. The [E-mail invitations](#) topic in the same part of the guide provides information on invitation e-mails sent to new attendees when they perform registration to an event.

User interface of the Events module can be found in **CMS Desk -> Tools -> Events**. This is where you can see an overview of all events, view registered attendees and perform other related actions. Management of event attendees is described in the [Managing attendees](#) topic. Access to this part of the user interface, as well as to creating documents, can be limited by means of permissions. Their configuration is explained in the [Security](#) topic.

The [Events internals and API](#) sub-chapter provides information about the database tables and classes used by the module, as well as examples of how booking events and their attendees can be managed using Kentico CMS API.

8.22.2 Publishing events

Events managed by the Events module are stored in the content tree as documents of the **Event (booking system)** document type (code name **CMS.BookingEvent**). The document type has the following fields:

| | |
|----------------------------------|---|
| Event name | Name of the event. |
| Event summary | Text summarizing the event. |
| Event details | Detailed text providing full details about the event. |
| Event location | Location of the event. |
| Start date | Date and time of the event's start. |
| End date | Date and time of the event's end. This value is optional and if not entered, the event will be displayed as one-day event occurring on the date specified by the Start date value. |
| All day event | Indicates if the event occurs during the whole day. |
| Capacity | Maximal number of registered attendees. |
| Allow registration over capacity | Indicates if the number of registered attendees can be higher than the defined capacity. |
| Open from | Date and time when attendee registration starts. |
| Open to | Date and time when attendee registration ends. |
| Log on-line marketing activity | Indicates if registration should be logged as an activity by the Contact management module. |
| Publish from | Date and time from when the event should be published on the website. |
| Publish to | Date and time until when the event should be published on the website. |

In a typical scenario, events are displayed using the **Event calendar** web part, while registration to the events is ensured by the **Event registration** web part. You can see an example of such setup on the **Events** page of the sample **Corporate Site**.

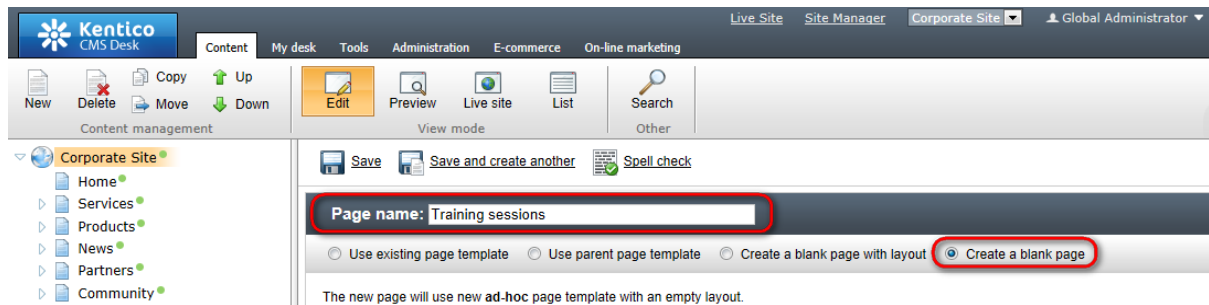

Example

In the following example, you will learn how to schedule new events and create a page where the events will be displayed in a calendar, with the possibility to register for them. For the purpose of this example, we will create a sample **Training sessions** page on the sample **Corporate Site** and use it to schedule

a few events.

Part 1: Creating the page for events

1. To get started, log on to **CMS Desk** and create a new **Page (menu item)** in the root of the content tree. When creating it, enter *Training sessions* as its **Page name** and choose the **Create a blank page** option. Finally, click **Save**.

2. Once the page is created, view it on the **Design** tab and click the **Add web part (+)** icon in the top right corner of the only web part zone on the page. In the web part selection dialog, choose the **Events & booking -> Event calendar** web part. Configure its properties as follows:

- **Path:** */Training-sessions/%*; path where displayed event documents will be stored.
- **Event start field:** *EventDate*; document field that determines the event's start date and time.
- **Event end field:** *EventEndDate*; document field that determines the event's end date and time.
- **Document types:** *cms.bookingevent*; document type used to store the displayed events in the content tree.
- **Skin ID:** *EventCalendar*; skin applied to the calendar.
- **Hide default day number:** true (checked); this needs to be enabled to avoid doubled numbers for each day, because the number is already included in the transformations that will be selected.
- **Transformation:** *CorporateSite.Transformations.CalendarEventItem*; you can use any suitable transformation, this one and the two below are chosen just to match the whole website's style.
- **No event transformation:** *CorporateSite.Transformations.CalendarNoEvent*
- **Event detail transformation name:** *CorporateSite.Transformations.CalendarEventDetail*
- **Content before:** `<div style="width: 500px;">`; this just ensures that the calendar will have limited width so that it doesn't span over the whole web part zone.
- **Content after:** `</div>`

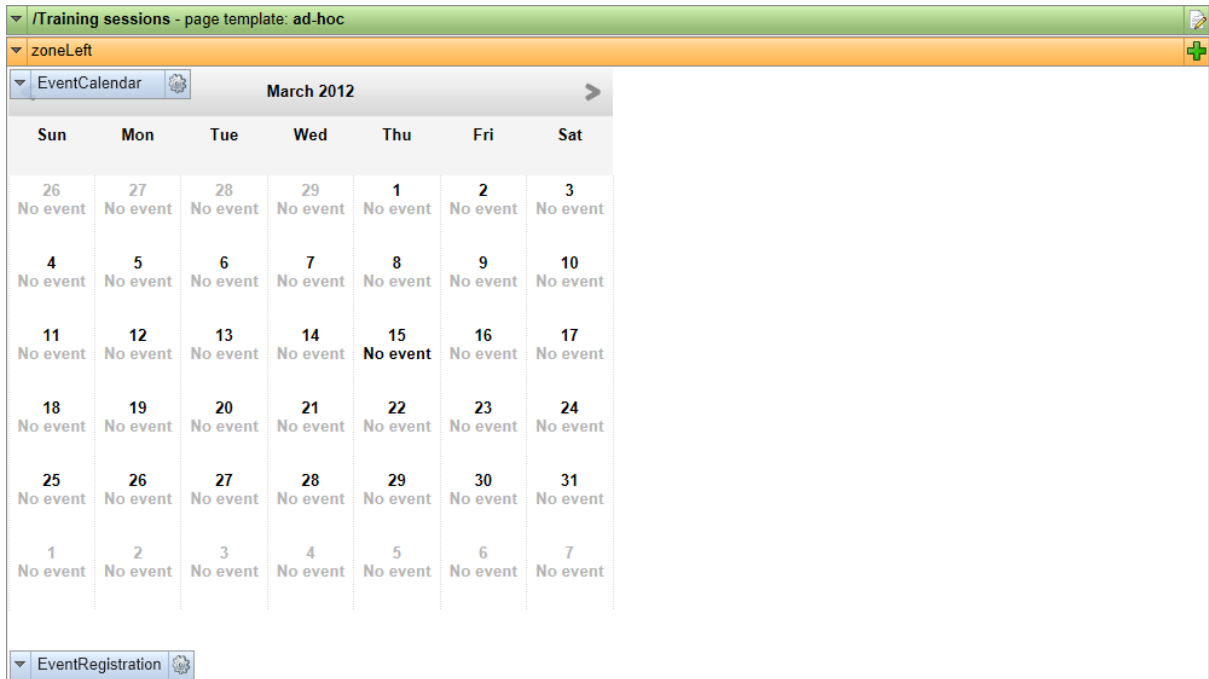

Leave the rest of the properties at their default values and click **OK**.

3. Click the **Add web part (+)** icon again and add the **Events & booking -> Event registration** web part. Configure its properties the following way:

- **Show for document types:** *CMS.BookingEvent*; this ensures that the web part will be displayed only when an event is selected in the calendar above, letting you register for the selected event.
- **Registration title:** leave the field blank as we will ensure the title in the web part container.
- **Web part container:** Corporate Site - Light gradient box
- **Container title:** Registration

Again, leave the rest of the properties at their default values and click **OK**.

4. The page is now ready. On the **Design** tab, it should look as in the following screenshot.

Part 2: Creating the events

The page is now ready to display events. But as you can see in the screenshot above, there are no events to be displayed yet. To see the required functionality working, we need to create the events now.

5. First, we will create a one-day event. Still in **CMS Desk**, select the **Training sessions** document in the content tree. Click the **New** button above and choose the **Event (booking system)** document type. Enter the following details into the form:

- **Event name:** *Training - Lesson 1*
- **Event summary:** *This is the first of the training series focused on using our product. Sign up for free!!!*
- **Event details:** *In this initial lesson, we will introduce our product and explain the basics of its use. We will also outline topics of the future lessons. All potential attendees are more than welcome, registration is for free!!!*
- **Event location:** *London Office*
- **Start date:** enter a future date and time in the current month so that you can instantly see it in the calendar.
- **End date:** enter a later time on the same day as entered above.
- **All day event:** *disabled*
- **Capacity:** *50*

Leave the rest of the fields blank or at default values and click **Save**.

6. Now let's repeat the previous step and create a multi-day event. Select the **Training sessions** document again, click the **New** button and choose the **Event (booking system)** document type. This time, enter the following details:

- **Event name:** *Training - Lesson 2*
- **Event summary:** *This is the second lesson focused on using our product. Sign up for free!!!*
- **Event details:** *In this two-day lesson, we will present some more advanced approaches to using our product. Before attending, it is recommended to be acknowledged with the information presented at the previous session. All potential attendees are more than welcome, registration is for free!!!*
- **Event location:** *London Office*
- **Start date:** enter a future date in the current month so that you can instantly see it in the calendar.
- **End date:** enter a date one day after the *Start date* so that a multi-day event is created.
- **All day event:** *disabled*
- **Capacity:** *50*

Leave the rest of the fields blank or at default values and click **Save**.

7. Switch to the live site. If you navigate to the newly created page, you should see the events in the calendar as in the screenshot below.

The screenshot shows the 'IT Company' website header with navigation links: Home, Products, News, Community, Services, Company, Media, and Training sessions. Below the header is a 'Training sessions' section with a calendar for March 2012. The calendar displays dates from 26 to 31, with events for March 15, 20, and 21. The event on March 15 is 'Training - Lesson 1', and the events on March 20 and 21 are 'Training - Lesson 2'. Red boxes highlight these event dates.

| | Partners Training | 6/21/2012 9:30:00 AM | 6/22/2012 4:00:00 PM | 30 | 0 | | |
| | Training - Lesson 2 | 8/19/2011 4:57:34 PM | 8/20/2011 4:57:35 PM | 50 | 0 | | |
| | Training - Lesson 1 | 8/17/2011 1:52:36 PM | 8/17/2011 4:52:56 PM | 50 | 0 | | |
| | Example conference | 5/7/2009 2:22:09 PM | | 10 | 0 | | |

By clicking the event name in the **Event** column, you get redirected to the event document's editing interface in **CMS Desk -> Content -> Edit**. If you click the **View** () icon next to an event, you get redirected to the event's editing interface where attendees can be managed.

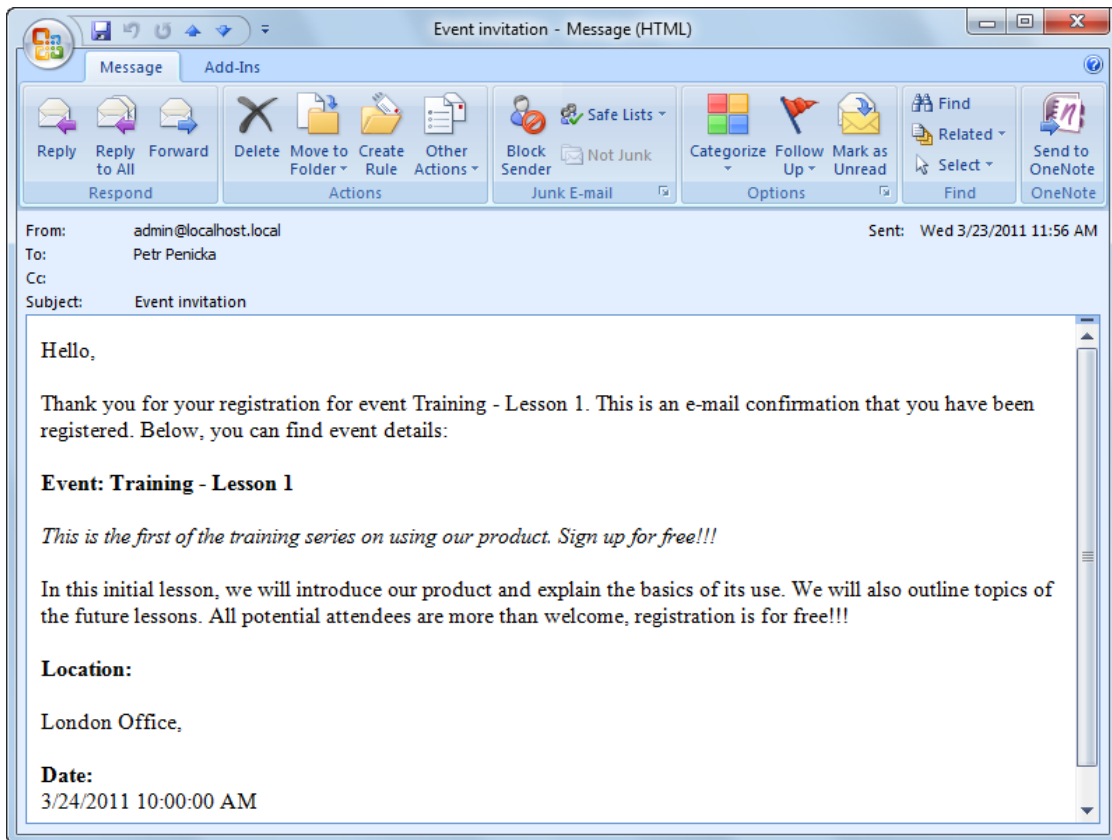

It is split into two tabs, while the **Attendees** tab will be displayed initially. Here, you can see a list of all attendees registered for the event. New attendees can be added to the event manually after clicking **New attendee** above the list. The following actions can be performed with each attendee:

- **Edit** - redirects you to the registration editing form where you can modify details submitted by the attendees on registration.
- **Delete** - clicking this icon removes the attendee from the event.
- **Resend invitation e-mail** - clicking this icon sends the invitation e-mail to the respective attendee. See [E-mail invitations](#) for more details.

| Actions | First name | Last name | E-mail | Phone |
|---------|------------|---------------|---------------------------------|-------------|
| | Cindy | Schlecker | c.schlecker@localhost.local | 354-159-768 |
| | Global | Administrator | g.administrator@localhost.local | 456-852-954 |
| | John | Jones | J.Jones@localhost.local | 152-365-159 |

Sending e-mails to all attendees

On the **Send e-mail** tab, you can send an e-mail to all attendees currently registered for the event. This may come in handy in case of changes in the event schedule, when sending additional information about the event, etc.

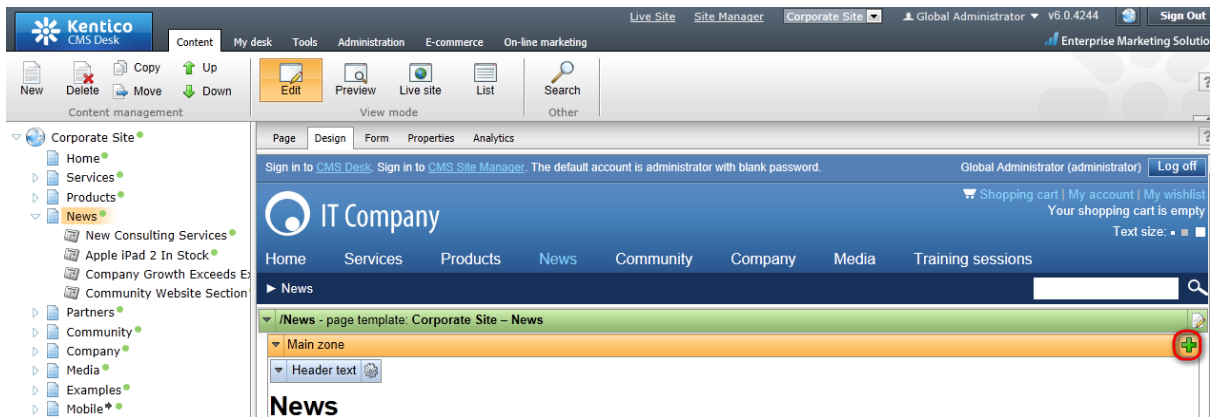

8.22.5 Using the Event calendar with other document types

The **Event calendar** web part can not only display **Event (booking system)** documents, but also documents of any other type that have a date-time field. All you have to do is specify the date-time field in the **Date field** property of the web part. This way, you can for example display news in a calendar according to their publish date.

In the following example, you will learn how to use the **Event calendar** web part to display news from the **News** section of the sample **Corporate Site**.

1. Sign in to **CMS Desk** and on the **Content** tab, select the **News** document in the content tree. View it on the **Design** tab and click the **Add web part** (+) icon of the **Main zone** web part zone.

2. Choose the **Event calendar** web part and click **OK**. In the web part properties dialog, configure its properties as follows:

- **Show for document types:** *CMS.MenuItem*; this ensures that the calendar will only be displayed in the list of news and not when a particular news item is viewed.
- **Path:** */News/*; path to the news documents to be displayed.
- **Event start field:** *NewsReleaseDate*; news will be displayed in respective calendar days based on the value in this field.
- **Document types:** *CMS.News*; this ensures that only news documents stored in the path will be displayed.
- **Skin ID:** *EventCalendar*, skin applied to the calendar.
- **Transformation:** click the New button and create the following transformation: `## GetDocumentUrl() %>"><## Eval("NewsTitle", true) %>
`
- **Content before:** `<div style="width: 600px;">`; this just ensures that the calendar will have limited width so that it doesn't span over the whole web part zone.
- **Content after:** `</div>`

Leave the rest of the properties at their default values and click **OK**.

3. Now if you go to the live site and view the **News** page, you should see the calendar below the list of news. If you browse to the appropriate month where the sample news are published (or if you create your own sample news with a current date), you should see the news in the calendar. After clicking the news title, you should be redirected to the particular news item's detailed view.

8.22.6 Security

Security settings of the Events module can be configured at two levels:

Management of events

Since the events are standard documents, the users who manage them need to have appropriate **document permissions** configured on the three levels of the document permissions hierarchy, as described in [Development -> Membership -> Permissions -> Document permissions](#).

Management of attendees

Event attendees can be managed in **CMS Desk -> Tools -> Events**. In the **Administration -> Permissions** section of both **CMS Desk** and **Site Manager**, permissions for this module need to be granted to the roles that should be able to manage event attendees. You can assign the following permissions to the roles:

- **Modify** - allows users to modify (add, update, delete) lists of attendees and attendee details, as well as re-send invitation messages and send e-mails to all attendees.
- **Read** - allows users to read the lists of events and attendees of particular events.

 **Permissions**

Site:

Permissions for:

Report for user: Show only this user's roles

8.22.7 Events internals and API

8.22.7.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Events module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.22.7.2 Database tables

The following database tables are used in the Events module:

- **CONTENT_BookingEvent** - the *CMS.BookingEvent* is a standard Kentico CMS document type, therefore, it has this associated database table where records representing particular booking events are stored.
- **Events_Attendee** - contains records representing booking event attendees. It is bound to a record in the *CMS_Tree* table which represents the booking event's document in the content tree.

8.22.7.3 API classes

If you are not familiar with the database table data management by Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

Classes for management of documents can be found in the **CMS.DocumentEngine** namespace. Classes for management of event attendees are located in the **CMS.EventManager** namespace.

Events management API

Because booking events are standard documents stored in the content tree, their management is carried out the same way as management of any other documents using the following classes:

- **TreeNode** - represents one content tree node.
- **TreeProvider** - provides functionality manipulation with tree nodes.

For more information on documents management API, please refer to [Content management -> Content management internals and API](#).

Events_Attendee table API:

- **EventsAttendeeInfo** - represents one event attendee object.
- **EventsAttendeeInfoProvider** - provides functionality for management of event attendees.

8.22.7.4 API examples

8.22.7.4.1 Overview

These topics show examples of how the Events module API can be used:

- [Managing events](#)
- [Managing attendees](#)

Please note

All API examples can be simulated in the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Tools\Events\Default.aspx.cs**.

The Events module API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.EventManager;
using CMS.DocumentEngine;
using CMS.WorkflowEngine;
using CMS.PortalEngine;
```

8.22.7.4.2 Managing events

The following example creates an event.

```
private bool CreateEvent()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get root document
    TreeNode root = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/", null, true);

    // Create a new CMS Page (menu item) document
    TreeNode node = TreeNode.New("CMS.MenuItem", tree);

    // Set values
    node.DocumentName = "MyNewDocument";
}
```

```
node.DocumentCulture = CMSContext.PreferredCultureCode;

// Get page template
PageTemplateInfo template = PageTemplateInfoProvider.GetPageTemplateInfo
("cms.empty");
if (template != null)
{
    node.SetDefaultPageTemplateID(template.PageTemplateId);
}

// Insert the document
DocumentHelper.InsertDocument(node, root.NodeID, tree);

// Create new Event (booking system) document
TreeNode eventNode = TreeNode.New("CMS.BookingEvent", tree);

// Set values
eventNode.DocumentName = "MyNewEvent";
eventNode.DocumentCulture = CMSContext.PreferredCultureCode;
eventNode.SetValue("EventSummary", "My event summary");
eventNode.SetValue("EventDetails", "My event details");
eventNode.SetValue("EventLocation", "My location");
eventNode.SetValue("EventDate", DateTime.Now);
eventNode.SetValue("EventCapacity", 100);

// Get page template
PageTemplateInfo eventTemplate = PageTemplateInfoProvider.GetPageTemplateInfo
("cms.empty");
if (eventTemplate != null)
{
    eventNode.SetDefaultPageTemplateID(eventTemplate.PageTemplateId);
}

// Insert the Event (booking system) document
DocumentHelper.InsertDocument(eventNode, node.NodeID, tree);

return true;
}
```

The following example gets and updates an event.

```
private bool GetAndUpdateEvent()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get event document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/"
MyNewDocument/MyNewEvent", null, true);

    if (node != null)
    {
        // Update value
    }
}
```

```
node.SetValue("EventDetails", "My event details were updated.");
node.SetValue("EventCapacity", 200);
DocumentHelper.UpdateDocument(node, tree);

return true;
}

return false;
}
```

The following example deletes an event.

```
private bool DeleteEvent()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get event document
    TreeNode eventNode = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/
MyNewDocument/MyNewEvent", null, true);

    // Get events parent document
    TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/
MyNewDocument", null, true);

    if (eventNode != null && node != null)
    {
        // Delete event document
        DocumentHelper.DeleteDocument(eventNode, tree, true, true, true);

        // Delete document
        DocumentHelper.DeleteDocument(node, tree, true, true, true);

        return true;
    }

    return false;
}
```

8.22.7.4.3 Managing attendees

The following example creates an attendee.

```
private bool CreateAttendee()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get event document
    TreeNode eventNode = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/
MyNewDocument/MyNewEvent", null, true);
```

```
if (eventNode != null)
{
    // Create new attendee object
    EventAttendeeInfo newAttendee = new EventAttendeeInfo();

    // Set the properties
    newAttendee.AttendeeEmail = "MyNewAttendee@localhost.local";
    newAttendee.AttendeeEventNodeID = eventNode.NodeID;
    newAttendee.AttendeeFirstName = "My firstname";
    newAttendee.AttendeeLastName = "My lastname";

    // Save the attendee
    EventAttendeeInfoProvider.SetEventAttendeeInfo(newAttendee);

    return true;
}

return false;
}
```

The following example gets and updates an attendee.

```
private bool GetAndUpdateAttendee()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get event document
    TreeNode eventNode = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/
MyNewDocument/MyNewEvent", null, true);

    if (eventNode != null)
    {
        // Get the attendee
        EventAttendeeInfo updateAttendee =
        EventAttendeeInfoProvider.GetEventAttendeeInfo(eventNode.NodeID,
        "MyNewAttendee@localhost.local");
        if (updateAttendee != null)
        {
            // Update the properties
            updateAttendee.AttendeeEmail = updateAttendee.AttendeeEmail.ToLower();

            // Save the changes
            EventAttendeeInfoProvider.SetEventAttendeeInfo(updateAttendee);

            return true;
        }
    }

    return false;
}
```

The following example gets and bulk updates attendees.

```
private bool GetAndBulkUpdateAttendees()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get event document
    TreeNode eventNode = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/
MyNewDocument/MyNewEvent", null, true);

    if (eventNode != null)
    {
        // Prepare the parameters
        string where = "AttendeeEmail LIKE N'MyNewAttendee%'";

        // Get the data
        DataSet attendees = EventAttendeeInfoProvider.GetEventAttendees
(eventNode.NodeID, where, null, null, 0);

        if (!DataHelper.DataSourceIsEmpty(attendees))
        {
            // Loop through the individual items
            foreach (DataRow attendeeDr in attendees.Tables[0].Rows)
            {
                // Create object from DataRow
                EventAttendeeInfo modifyAttendee = new EventAttendeeInfo
(attendeeDr);

                // Update the properties
                modifyAttendee.AttendeeEmail =
modifyAttendee.AttendeeEmail.ToUpper();

                // Save the changes
                EventAttendeeInfoProvider.SetEventAttendeeInfo(modifyAttendee);
            }

            return true;
        }
    }

    return false;
}
```

The following example deletes an attendee.

```
private bool DeleteAttendee()
{
    TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);

    // Get event document
    TreeNode eventNode = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/
MyNewDocument/MyNewEvent", null, true);
```

```

    if (eventNode != null)
    {
        // Get the attendee
        EventAttendeeInfo deleteAttendee =
        EventAttendeeInfoProvider.GetEventAttendeeInfo(eventNode.NodeID,
        "MyNewAttendee@localhost.local");

        // Delete the attendee
        EventAttendeeInfoProvider.DeleteEventAttendeeInfo(deleteAttendee);

        return (deleteAttendee != null);
    }

    return false;
}

```

8.23 Event log

8.23.1 Overview

The Event log module stores information about all events that occur in the system. A log of these events can then be displayed and inspected. It is useful in case that some unwanted behavior occurs in the system and you want to find out where the problem originates or some other details about it.

The event log can be viewed in the **Administration -> Event log** section of both **CMS Desk** and **Site Manager**. In **CMS Desk**, only events related to the currently edited website can be viewed, while in **Site Manager**, you can view all events that occurred in the whole system. More details about these interfaces can be found in the [Viewing logged events](#) topic. Access to the interfaces and actions performed there can be restricted by means of permissions. To learn more, please see the [Security](#) topic.

In the [Event log internals and API](#) sub-chapter, you can find information about database tables and classes that are used for event logging, as well as several examples of how events can be logged and how the log can be managed using Kentico CMS API.

8.23.2 Viewing logged events

The event log can be viewed in the **Administration -> Event log** section of both **CMS Desk** and **Site Manager**. In **CMS Desk**, only events related to the currently edited website can be viewed, while in **Site Manager**, you can view all events that occurred in the whole system.

In the top row, you can select from the following options:

| | |
|-------------|---|
| Select site | <p>Using this drop-down list, you can select what events will be displayed. You can either select a particular website to display only event that occurred on the website, or you have the following extra options:</p> <ul style="list-style-type: none"> • (all) - displays all events that occurred in the whole system. |
|-------------|---|

| | |
|-----------|---|
| | <ul style="list-style-type: none"> • (only global events) - displays only global, i.e. not website specific events. <p>This option is only available in Site Manager. In CMS Desk, only events related to the current website are displayed in the log.</p> |
| Clear log | Deletes all records currently displayed in the log. |

The filter above the list enables you to display only records that match specified criteria. The **Display advanced filter** and **Display simplified filter** links switch the filter between simple and advanced mode, while the advanced one offers more filtering criteria to be specified.

The following details are displayed with each logged event. Some extra information is logged but not displayed in the grid. It can be viewed after clicking the **Display event** (🔍) icon, which displays a pop-up window with full details about the event. More information can be found [below](#).

| | |
|---------------|--|
| Type | Type of the event. There are three types of events that can occur: <ul style="list-style-type: none"> • Information - standard event. • Warning - standard event with higher importance, e.g. application restart. • Error - critical error event, e.g. an unfinished operation, unhandled exception, etc. |
| Event time | Time when the event occurred. |
| Source | Source module where the event occurred. |
| Event code | Code of the event. These codes depend on the type of performed action. |
| User ID | ID of the user who performed the action that raised the event. |
| User name | Username of the user who performed the action that raised the event. If blank, the event was not raised by a user action, but was raised by the system itself. |
| IP address | IP address of the user who performed the action. If blank, the event was not raised by a user action, but was raised by the system itself. |
| Document name | Name of the document to which the event is related. If blank, the event was not document-related. |
| Site | Name of the website where the event occurred. |
| Machine name | Name of the server where the event occurred. Useful e.g. when running the system in a web farm. |

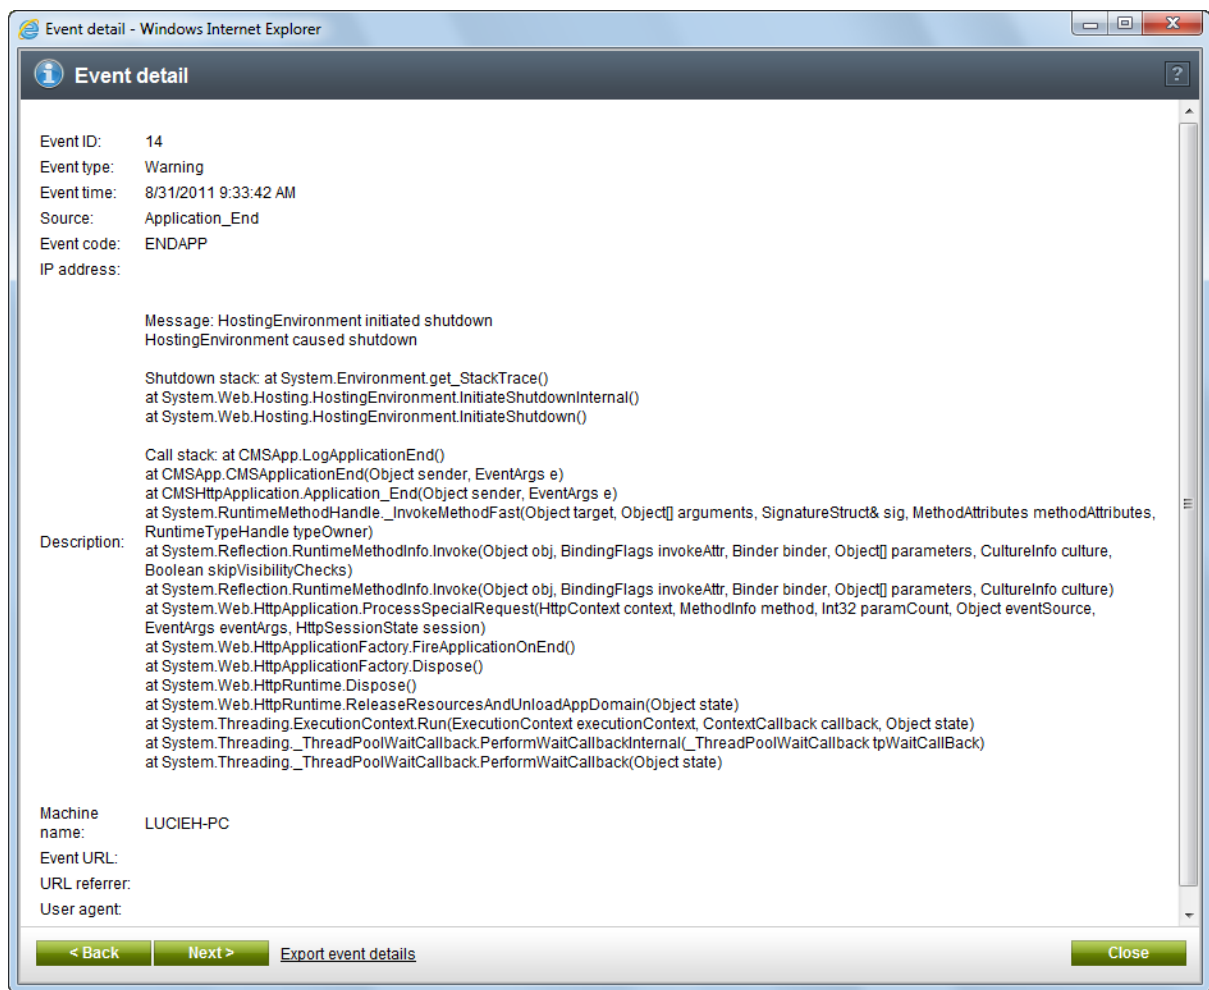

| Actions | Type | Event time | Source | Event code | User name | IP address | Document name | Site | Machine name |

Event details

If you click the **Display event** () icon in an event's row, a pop-up window with full details about the event is displayed. The following details are displayed in the window, while some of them may not be displayed if not applicable.

| | |
|------------|--|
| Event ID | Identifier of the event. |
| Event type | Type of the event. There are three types of events that can occur: <ul style="list-style-type: none"> • Information - standard event. • Warning - standard event with higher importance, e.g. application restart. • Error - critical error event, e.g. an unfinished operation, unhandled exception, etc. |
| Event time | Time when the event occurred. |
| Source | Source module where the event occurred. |
| Event code | Code of the event. These codes depend on the type of performed action. |
| User ID | ID of the user who performed the action that raised the event. |
| User name | Username of the user who performed the action that raised the event. If blank, the event was not raised by a user action, but was raised by the system itself. |
| IP address | IP address of the user who performed the action. If blank, the event was not raised by a user action, but was raised by the |

| | |
|---------------|---|
| | system itself. |
| Document name | Name of the document to which the event is related. If blank, the event was not document-related. |
| Description | Text describing the event. |
| Site name | Name of the website where the event occurred. |
| Machine name | Name of the server where the event occurred. Useful e.g. when running the system in a web farm. |
| Event URL | URL of the page where the event occurred. |
| URL referrer | URL of the page from which the event was raised. |
| User agent | User agent of the browser used when the event was raised. |

8.23.3 Related settings

The following settings in **Site Manager -> Settings** are related to the Event log module:

| Settings category | Description |
|-------------------|-------------|
|-------------------|-------------|

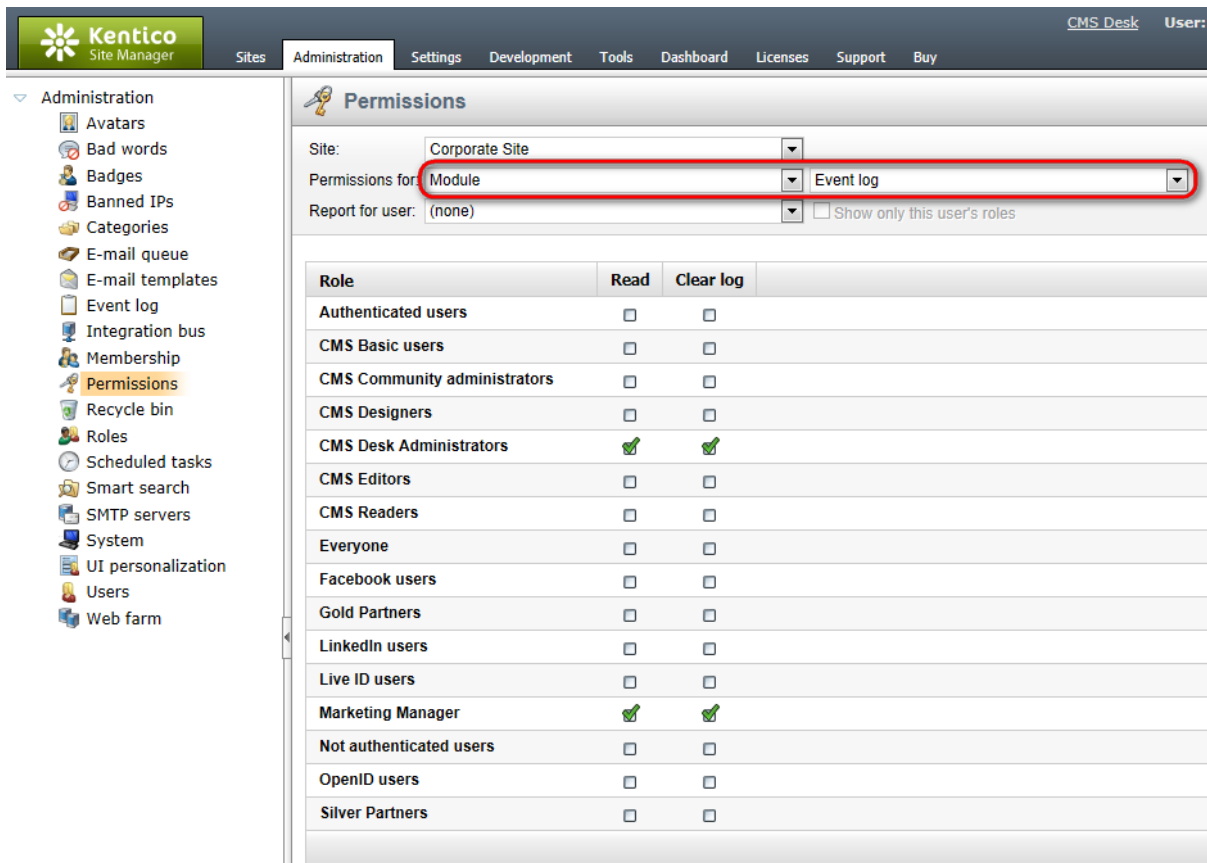

| | |
|---|---|
| Content -> Log page not found exception | If enabled, page not found (404) exceptions will be logged as a warning in the event log. |
| System -> Event log size | Number of events stored in the event log. When exceeded by 10% (or a different percentage set by means of the <i>CMSLogKeepPercent</i> web.config key), the percentage of the oldest events is deleted from the log in a batch. If 0, no events are logged. |
| System -> Log metadata changes | If enabled, changes of object and document metadata (i.e. when an object or document is created, edited or deleted) are logged in the Event log. |
| System -> Error notification e-mail address | If an e-mail address is entered, e-mail notifications about errors logged in the event log will be sent to the address. |

There are also several special keys that can be added to the *appSettings* section of the *web.config* file that provide an extra level of event logging settings in combination with the settings listed above. For more information on the keys, please refer to [Appendix B - Web.config parameters](#).

8.23.4 Security

Access to the Event log and actions that can be performed in it can be restricted by means of permissions. There is a dedicated **Module -> Event log** permission matrix in the **Administration -> Permissions** section of **CMS Desk** and **Site Manager**. In the matrix, you can grant the following permissions to particular roles:

- **Read** - allows members of the role to view the event log and details of particular logged events.
- **Clear log** - allows members of the role to clear the event log (i.e. use the **Clear log** button).

8.23.5 Event log internals and API

8.23.5.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Events module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.23.5.2 Database tables

The Event log module uses the following database table:

- **CMS_EventLog** - contains records representing logged events.

8.23.5.3 API classes

If you are not familiar with the database table data management by Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Event log module use the **CMS.EventLog** namespace.

CMS_EventLog table API:

- **EventLogInfo** - represents one log event object.
- **EventLogInfoProvider** - provides functionality for management of log events.

8.23.5.4 API examples

8.23.5.4.1 Overview

These topics show examples of how the Event log module API can be used:

- [Managing log events](#)

**Please note**

All API examples can be simulated in the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Administration\EventLog\Default.aspx.cs**.

The Event log module API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.EventLog;
```

8.23.5.4.2 Managing log events

The following example logs an event in the event log.

```
private bool LogEvent()
{
    // Create new event object
    EventLogInfo newEvent = new EventLogInfo();

    // Set the properties
    newEvent.EventType = "I";
    newEvent.EventDescription = "My new logged event.";
    newEvent.EventCode = "APIEXAMPLE";
    newEvent.EventTime = DateTime.Now;
    newEvent.Source = "API Example";
    newEvent.SiteID = CMSContext.CurrentSiteID;

    // Create new instance of event log provider
    EventLogProvider eventLog = new EventLogProvider();

    // Log the event
    eventLog.LogEvent(newEvent);

    return true;
}
```

The following example gets and updates the event created by the example above.

```
private bool GetAndUpdateEvent()
{
    // Create new instance of event log provider
    EventLogProvider eventLog = new EventLogProvider();

    // Get top 1 event matching the where condition
    string where = "EventCode = 'APIEXAMPLE'";
    int topN = 1;
    DataSet events = eventLog.GetAllEvents(where, null, topN, null);

    if (!DataHelper.DataSourceIsEmpty(events))
    {
        // Create the object from DataRow
        EventLogInfo updateEvent = new EventLogInfo(events.Tables[0].Rows[0]);

        // Update the properties
        updateEvent.EventDescription = updateEvent.EventDescription.ToLower();

        // Save the changes
        eventLog.SetEventLogInfo(updateEvent);

        return true;
    }

    return false;
}
```

The following example gets multiple events based on a WHERE condition and bulk updates them.

```
private bool GetAndBulkUpdateEvents()
{
    // Create new instance of event log provider
    EventLogProvider eventLog = new EventLogProvider();

    // Get events matching the where condition
    string where = "EventCode = 'APIEXAMPLE'";
    DataSet events = eventLog.GetAllEvents(where, null);

    if (!DataHelper.DataSourceIsEmpty(events))
    {
        // Loop through the individual items
        foreach (DataRow eventDr in events.Tables[0].Rows)
        {
            // Create the object from DataRow
            EventLogInfo updateEvent = new EventLogInfo(eventDr);

            // Update the properties
            updateEvent.EventDescription = updateEvent.EventDescription.ToUpper();

            // Save the changes
            eventLog.SetEventLogInfo(updateEvent);
        }
    }
}
```

```
        return true;
    }

    return false;
}
```

The following example clears the event log.

```
private bool ClearLog()
{
    // Create new instance of event log provider
    EventLogProvider eventLog = new EventLogProvider();

    // Clear event log for current site
    eventLog.ClearEventLog(CMSContext.CurrentUser.UserID,
        CMSContext.CurrentUser.UserName, HTTPHelper.GetUserHostAddress(),
        CMSContext.CurrentSiteID);

    return true;
}
```

8.24 File import

8.24.1 Overview

The file import module allows you to import files including their entire folder structure from the disk to the Kentico CMS content repository (content tree). When files are uploaded this way, they are stored as **CMS.File** (or **CMS.Folder**) documents. The module allows large amounts of files to be selected, which eliminates the need to create documents and upload files in the content tree manually one-by-one.

The module's user interface can be found in **CMS Desk -> Tools -> File import**. The label at the top shows the path to the file import folder, which is where all files that you wish to import must be located. If the folder doesn't exist, you may need to create it on the disk. The default file import folder is **~/CMSImportFiles**. You can define your custom file import path in **Site Manager -> Settings -> System -> Files -> File import folder**.

For a more specific example of using this module to import files, please continue in the [Importing files](#) topic.

The [Security](#) topic shows how permissions can be set for this module. The use of this module should usually only be allowed for site administrators, as it doesn't check certain security settings from **Site Manager -> Settings -> System -> Files**, such as allowed file extensions.

The file import module isn't the only way files can be uploaded to the Kentico CMS system. For other options and information about general file management, please refer to the [Content management -> File Management](#) chapter of this guide.

8.24.2 Importing files

The following is a step-by-step guide through the process of importing files:

1. Copy your files into the specified import folder.
2. Go to **CMS Desk -> Tools -> File import**. You should see a list of files that are currently in the import folder.
3. Choose which files should be imported using the checkbox next to each file and specify the following properties:
 - **Target alias path:** path within the content tree where the files will be imported
 - **Culture:** culture to which the uploaded files (documents) will be assigned
 - **Delete imported files from disk:** if enabled, files in the import folder will be deleted after a successful import
 - **Include file extension in name:** if enabled, the file extension is included in the *Document name* of the newly imported files

Click **Start import**.

Delete imported files from disk:

Include file extension in name:

4. Now if you switch to the **Content** tab and locate the alias path that you specified in the previous step, you should see the files uploaded.

Please note

If you are importing files from your computer (on the **Import from your computer** tab), you need to:

1. Click the **Select files** button to specify the files that you wish to import.
2. Click the **Upload** button to upload the selected files to the Kentico CMS content repository (content tree).

8.24.3 Security

Access rights to the file import module can be configured in **CMS Site Manager -> Administration -> Permissions**, after you select the **Modules -> File import** permission matrix. This can also be done in **CMS Desk -> Administration -> Permissions**, but only for the current site. The File import module only has one single permission:

- **Import files** - members of the specified roles are allowed to import files using the File import module

Permissions

Site:

Permissions for:

| Not authenticated users | <input type="checkbox"/> |

8.25 Forms

8.25.1 Overview

The Forms module enables non-technical users (content editors) to easily create and publish [on-line forms](#). These forms can be used to gather structured data from website users. A typical example of such form is the **Contact Us** form, which can be found on the **Company** page of the sample Corporate Site. The form is depicted in the screenshot below.

Contact Us

First name:

Last name:

E-mail:

Phone number: () -

Your message:

The administration interface of the module is located in **CMS Desk -> Tools -> Forms**. This is where new forms can be created, as described in the [Creating a new form](#) topic. Once a form is created via the user interface, it can be added to a live site page. This can be done either via the WYSIWYG editor, or by means of the **On-line form** web part or widget. Both options are described in the [Displaying a form on the live site](#) topic.

Each form has its own separate database table where submitted data is stored. The submitted data can be viewed and managed in **CMS Desk -> Tools -> Forms**. Data records can even be exported to a **Microsoft Excel** spreadsheet in this part of the user interface. Please refer to the [Managing form data](#) topic for more information on which actions can be performed with the submitted data.

You may want to notify the person who is responsible for management of forms data when a new record is submitted. For this purpose, you can configure the form to send automatic notification e-mails about new records. The user who submitted the new record may also be notified that the record was submitted successfully and that it will be processed soon. This can be achieved by configuring autoresponder e-mails. Both options are described in the [Notification and autoresponder e-mails](#) sub-chapter. Macros can be used largely with notification and autoresponder e-mails, as well as when you want to localize field captions in the form. Please refer to the [Using macros with forms](#) topic to learn more.

Access to forms may be restricted, so that only members of selected roles can perform certain operations with the forms themselves or with the data in them. The [Security](#) topic gives you an overview of how to configure forms permissions both globally and separately for each particular form.

Layout of each form is fully customizable. The [Defining custom form layout](#) topic explains how it can be achieved. You may also customize behavior of the forms module with your custom code. These possibilities are explained in the [Forms internals and API](#) sub-chapter, along with an overview of where form records are stored and which API classes contain methods for their management. It also provides a series of code examples showing how methods from these classes may be used in your custom code.

8.25.2 Creating a new form

In this topics, we will create a new sample form via the Forms module's user interface. This topic doesn't explain all options that are available in the user interface. For a detailed description of each option, please refer to the built-in context help, which is accessible by clicking the  icon in the top-right corner of the user interface.

1. Go to **CMS Desk -> Tools -> Forms** and click the  **New form** button. Type *Event registration* into the **Form display name** field.

Click  **Save**.

2. You will be redirected to the **General** tab of the new form's editing interface. Specify the following values:

- **After the form is submitted:** Select the **Display text** option and enter the following text into the field next to it: *Thank you for your registration. We will confirm it shortly by e-mail.*
- **Submit button text:** Register

The screenshot shows the 'Form Properties' configuration page in Kentico CMS. The 'General' tab is active, displaying the following configuration:

- Form display name: Event registration
- Form code name: EventRegistration
- Table name: Form_CorporateSite_EventRegistration
- After the form is submitted:
 - Display text: Thank you for your registration. We will confirm it :
 - Redirect to URL:
 - Clear form
 - Continue editing
- Submit button text: Register
- Submit button image:

Click **Save**.

3. Now we will define the form's fields. Go to the **Fields** tab. Add the following fields using the **Add attribute** (+) button. For each field, enter the values shown below, click **Save** and repeat the procedure until you have all the listed fields defined.

- **Column name:** FirstName
- **Show on public form:** enabled
- **Field caption:** First name
- **Field type:** TextBox
- **Maximum length:** 100
- **Allow empty value:** disabled

- **Column name:** LastName
- **Show on public form:** enabled
- **Field caption:** Last name
- **Field type:** TextBox
- **Maximum length:** 100
- **Allow empty value:** disabled

- **Column name:** Phone
- **Show on public form:** enabled
- **Field caption:** Phone
- **Field type:** U.S. phone number
- **Maximum length:** 14
- **Allow empty value:** enabled

- **Column name:** Email
- **Show on public form:** enabled

- **Field caption:** E-mail
- **Field type:** E-mail
- **Maximum length:** 100
- **Allow empty value:** disabled

- **Column name:** Presentations
- **Show on public form:** enabled
- **Field caption:** Presentations you want to visit
- **Field type:** Multiple choice
- **Editing control settings -> Data source:** Select the **Options** radio button and enter the following into the textbox below:
 - ASP.NET;ASP.NET
 - ATLAS;ATLAS
 - WPF;Windows Presentation Foundation
- **Allow empty value:** enabled

Each form field and its functionality is based on an object called a *form control*, which is selected through the **Field type**. This gives you almost unlimited form flexibility and customization options.

When editing the properties of a field, you can switch between **Simple** and **Advanced** mode using the appropriate button at the top of the dialog. In advanced mode, the full configuration options of the field editor are available. Simple mode offers a more straightforward editing dialog and is recommended for non-technical users. In simple mode, only form controls that are configured to have **High priority** are offered among the **Field type** options.

Please see the [Development -> Form controls](#) chapter for detailed information about form fields and their types.

4. The last item will be used only by site editors to mark the processed registration forms. This will be done exclusively via the user interface. Therefore, it has the **Show on public form** property disabled.

- **Column name:** RegistrationProcessed
- **Show on public form:** disabled
- **Field caption:** Registration processed
- **Field type:** Check box
- **Allow empty value:** enabled

5. With all the fields defined, the form is ready to be published on the live site. This can be done several different ways, all of which are described in the [Displaying a form on the live site](#) topic.

Please note

If you click the **Switch to advanced mode** link below the field editor, an extended user interface will be displayed. There you can configure additional options such as input validation rules or CSS classes used for the fields.

8.25.3 Displaying a form on the live site

In the [Creating a new form](#) topic, you have learned how to create a new form via the module's user interface. This topic will give you an overview of how you can add the form to the live site.

Content editors can add a form to any page with editable text regions. It can be done either using the **Insert Form** (📄) button on the [WYSIWYG editor](#) toolbar. A form can also be added directly into text by typing a macro in the following format: `%%control: BizFormControl?BizFormCodeName%%`. The *BizFormCodeName* part of the macro needs to be replaced with the code name of the particular form.

Website designers or developers can add a form to any web part or widget zone by adding the **On-line form** web part or widget. In this case, code name of the form needs to be entered in the **Form name** property of the web part or widget.

The examples below explain both options of adding forms to your live site pages.

Example 1: Adding a form via the WYSIWYG editor

In this example, we will add the *Event registration* form, created in the [Creating a new form](#) topic, to a

page using the **Insert Form** (📄) button on the WYSIWYG editor toolbar. Any other form can be added to a page exactly the same way.

1. Go to **CMS Desk -> Content** and select some page with editable regions (the **Editable text** web part). View the page in **Edit mode** on the **Page** tab.
2. Click the **Insert Form** (📄) button on the WYSIWYG editor toolbar, which will create an On-line form inline widget.

3. The configuration dialog of the widget will be opened. Click the **Select** button next to the **Form name** field and choose the **Event registration** form.

 A screenshot of the 'Widget properties (On-line form)' configuration dialog. The dialog has a title bar with a gear icon and window controls. It is divided into three sections:

- BizForm settings:** Contains a 'Form name*' field with the value 'EventRegistration'. To the right are 'Select' and 'Clear' buttons.
- Conversion tracking:** Contains a 'Track conversion name:' field with 'Select', 'Edit', and 'New' buttons. Below it is a 'Conversion value:' field.
- Widget container:** Contains a 'Widget container:' dropdown menu with '(none)' selected and 'Edit' and 'New' buttons. Below it is a 'Container title:' field.

 At the bottom right, there are 'OK' and 'Cancel' buttons.

Click **OK**.

A placeholder image will be pasted into the text. The properties of the On-line form inline widget can be edited at any time by double clicking this image.

4. Click **Save** and switch to the **Live site** mode. You will see the form on the page.

First name:

Last name:

Phone: () -

E mail:

ASP.NET

Presentations you want to visit: ATLAS

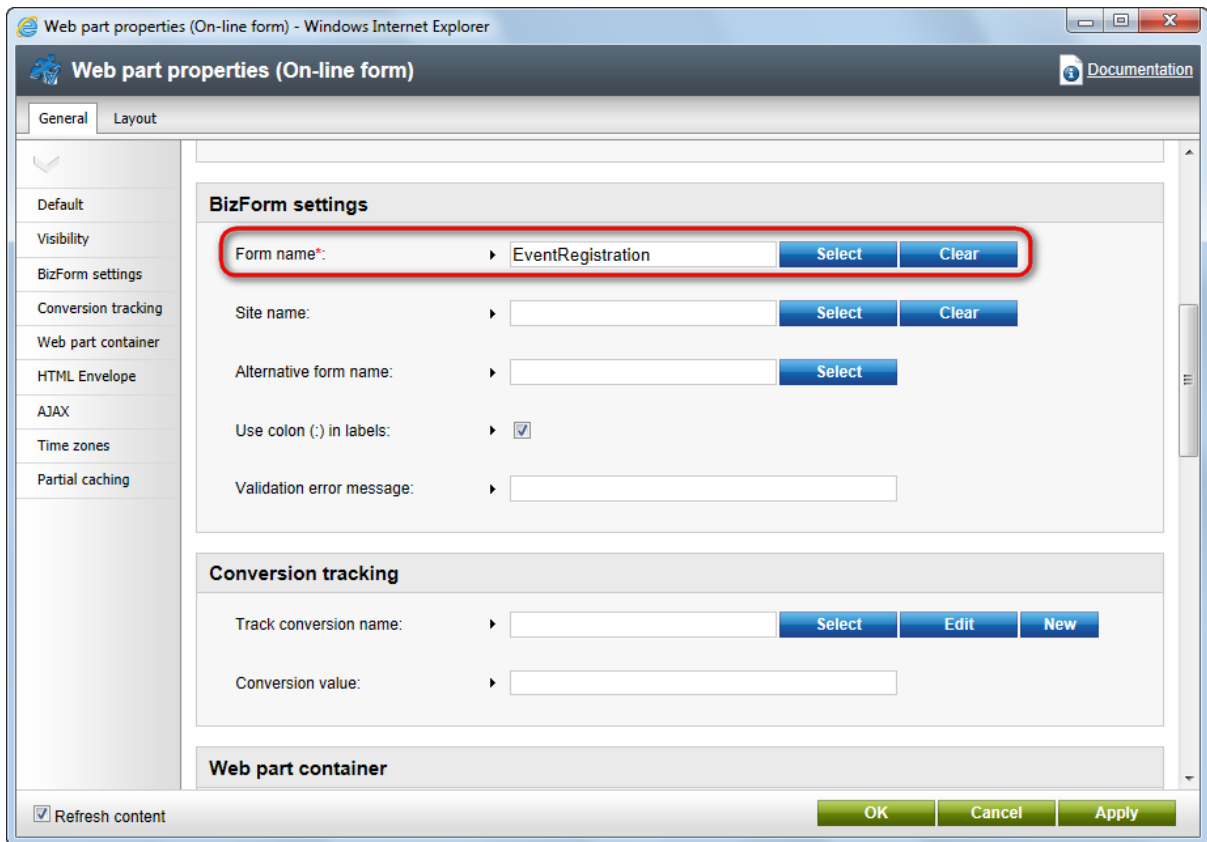

Windows Presentation Foundation

5. Try entering some values and submitting the filled-in form. After doing that, you may proceed to the [Managing form data](#) topic, where management of submitted data is explained.

Example 2: Adding a form using the On-line form web part

This example demonstrates how to add the *Event registration* form, created in the [Creating a new form](#) topic, to a page using the **On-line form** web part. Any other form can be added to a page exactly the same way. The same applies to using the **On-line form** widget - the only difference is that the widget can only be added to a widget zone, not a web part zone.

1. Go to **CMS Desk -> Content** and select any page with a web part zone. View the page in the **Edit -> Design** mode.
2. Click the **Add web part (+)** button at the top-right corner of the zone and choose the **Forms -> On-line form** web part. Click **OK**.
3. In the web part properties dialog, you only need to enter *EventRegistration* (the code name of the form) into the **Form name** property and click **OK**.

4. Click **Save** and switch to the **Live site** mode. You will see the form on the page.

First name:

Last name:

Phone: () -

E mail:

Presentations you want to visit: ASP.NET ATLAS Windows Presentation Foundation

5. Try entering some values and submitting the filled-in form. After doing that, you may proceed to the [Managing form data](#) topic, where management of submitted data is explained.

8.25.4 Managing form data

Form records (data submitted by website users) can be viewed and managed in **CMS Desk -> Tools -> Forms**. In the list of forms, you need to click the **Edit** (✎) icon next to a particular form. You will get redirected to the **Data** tab of the form's editing interface, where particular records are listed.

Each of the records listed in the grid has the following actions available:

- **Edit record** (✎) - allows you to alter the record.
- **Delete record** (✖) - allows you to delete the record.

You can also perform the following actions using the buttons in the tab's header:

- **New record** (➕) - used to manually add records to the current form.
- **Select displayed fields** (🔍) - enables you to select which of the form's fields should be displayed in the grid.

| Actions | ContactUsID | Form inserted | Form updated | First name | Last name | E-mail | Phone number | Your message |
|---------|-------------|---------------------|----------------------|------------|-----------|------------------------------|----------------|---|
| ✎ ✖ | 8 | 5/4/2012 3:00:11 PM | 5/7/2012 11:29:04 AM | Brad | Summers | brad.summers@example.com | (123) 456-7890 | Hi, I am contacting you to find out if this form works. |
| ✎ ✖ | 9 | 5/7/2012 7:47:08 AM | 5/7/2012 11:29:17 AM | Sheryl | Cox | sheryl.cox@example.com | (897) 654-3214 | Hi, could you please send me your latest price list? |
| ✎ ✖ | 10 | 5/7/2012 7:47:48 AM | 5/7/2012 11:29:28 AM | David | Silver | david.silver@localhost.local | (123) 456-4561 | Hi, I like your new website! |
| ✎ ✖ | 11 | 5/7/2012 7:48:05 AM | 5/7/2012 11:30:04 AM | John | Smith | john.smith@localhost.local | (123) 123-1231 | Hello, please contact me as soon as possible. |

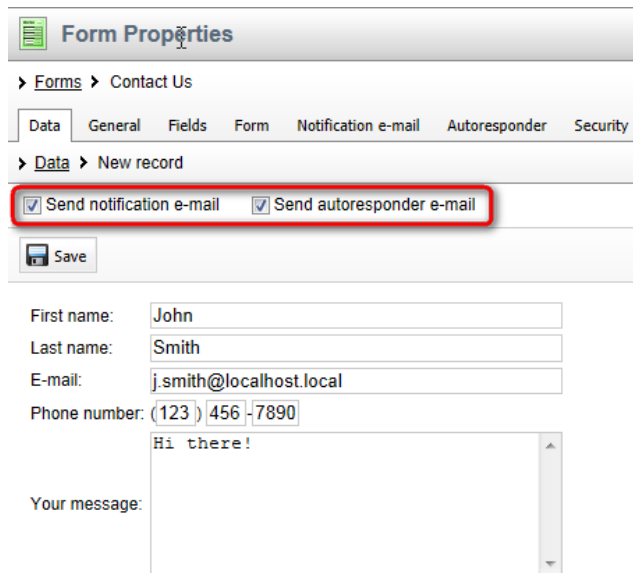

A form's records may be exported into an external file using either the XLSX (Excel), CSV or XML format. This can be done by clicking the ▼ icon in the header of the **Actions** column in the grid and then selecting the appropriate option from the context menu.

| Actions | ContactUsID | Form inserted | Form updated | First name |
|-----------------|-------------|---------------------|----------------------|------------|
| Export to Excel | | 5/4/2012 3:00:11 PM | 5/7/2012 11:29:04 AM | Brad |
| Export to CSV | | 5/7/2012 7:47:08 AM | 5/7/2012 11:29:17 AM | Sheryl |
| Export to XML | | 5/7/2012 7:47:48 AM | 5/7/2012 11:29:28 AM | David |
| Advanced export | | 5/7/2012 7:48:05 AM | 5/7/2012 11:30:04 AM | John |

The **Advanced export** option opens a dialog where you can specify which rows and columns should be included in the exported data. For detailed information about exporting data to files, please refer to the [Modules -> UI data export](#) chapter.

In cases where a large number of records is displayed, you can create a filter for limiting which records should be displayed. To learn more about this possibility, please refer to [Modules -> Alternative forms -> Creating filter forms](#).

When editing (✎) or creating (➕) a record via the administration interface, the form is displayed the same way as on the live site, letting you enter or change the values. Additionally, you can decide if [notification and autoresponder e-mails](#) should be sent when you save the record.

Your message: Hi there!

8.25.5 Notification and autoresponder e-mails

8.25.5.1 Notification and autoresponder e-mails

The Forms module allows you to send two types of e-mails automatically when a new record is added:

- [Notification e-mail](#) - e-mails notifying the person responsible for form data management (content editor, administrator, ...) about the new submitted record.
- [Autoresponder](#) - e-mail to the person who submitted the new record, typically confirming that the record has been received and will be processed.

When a record is added on the live site, the e-mails are sent out based on settings described in the following topics. When a record is added or modified via the administration interface, the person who is entering the record can decide whether these e-mails will be sent, as described in [Managing form data](#).

8.25.5.2 Notification e-mails

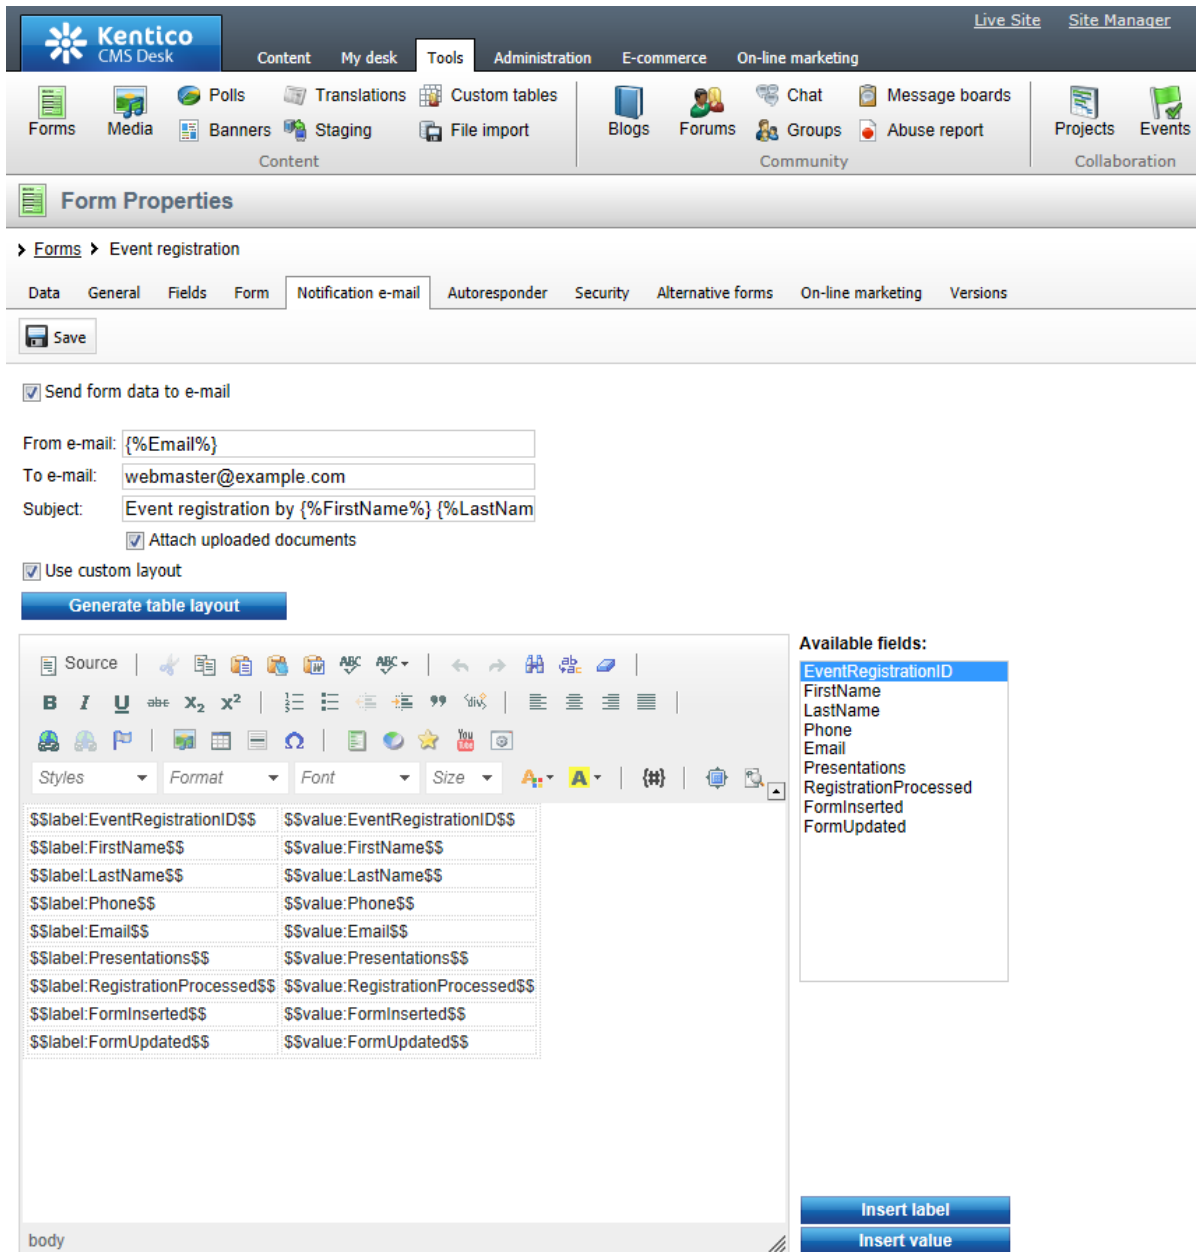

Notification e-mails can be configured on the **Notification e-mail** tab of a form's editing interface. To enable them, you first need to enable the **Send form data to e-mail** option. Then you need to configure the following settings:

- **From e-mail** - the e-mail address from which the notifications will be sent. A typical option is to use the address of the user who submitted the form. This can be done by entering a macro expression, which retrieves the value from the field in the form where users enter their e-mail address, as described in the [Using macros with forms](#) topic.
- **To e-mail** - e-mail address where notification e-mails should be sent. Typically the address of the person responsible for management of form records. You can specify multiple addresses separated by semicolons.
- **Subject** - subject of the notification e-mails.
- **Attach uploaded documents** - enable this option if you want to attach files submitted via the form (if there are any) to the notification e-mails.
- **Use custom layout** - if disabled, the body of the notification e-mails will contain all field names with the entered values, each on a single line. If enabled, you can define a custom layout for the

notifications in the text area displayed below.

- **Generate table layout** - this button generates a table containing all field names in the left column and their values in the right column. Macros for particular field names and values can also be entered separately by selecting a field from the *Available fields* listbox and clicking the *Insert label* or *Insert value* buttons.

Macros may be utilized in the values of any of these fields. Once all the options are configured, click  **Save** to save your configuration.

8.25.5.3 Autoresponder e-mails

Autoresponder e-mails can be configured on the **Autoresponder** tab of a form's editing interface.

When you navigate to the tab for the first time, only the **Confirmation e-mail source field** drop-down list will be visible. Expand it and choose the form field where users will enter their e-mail address, so that the system knows where to send the automatic response. This means that autoresponder e-mails can only be used with forms where such a field is present (however, this should be the case with most real-world on-line forms).

Once a field is chosen, the following additional options will be displayed:

- **From e-mail** - e-mail address from which the autoresponder e-mails will be sent (the *From* field of the e-mail message).
- **Subject** - subject of the autoresponder e-mails.

You can then define the body content of the e-mails through the text area and WYSIWYG editor. The **Generate table layout** button generates a table with all field names in the left column and their values in the right column. Particular field names and their values can also be entered separately by selecting a field from the **Available fields** listbox and clicking the **Insert label** or **Insert value** buttons

Macros may be utilized in the values of these fields, as described in the [Using macros with forms](#) topic.

The screenshot displays the 'Form Properties' dialog for an 'Event registration' form. The 'Autoresponder' tab is selected, showing configuration for an email sent upon form submission. The 'Confirmation e-mail source field' is set to 'Email', the 'From e-mail' is 'autoresponder@example.com', and the 'Subject' is 'Event registration form submitted'. Below the configuration fields is a 'Generate table layout' button. The main area of the dialog shows a table with placeholder text for labels and values, and an 'Available fields' list on the right.

| Label | Value |
|-----------------------|-----------------------|
| EventRegistrationID | EventRegistrationID |
| FirstName | FirstName |
| LastName | LastName |
| Phone | Phone |
| Email | Email |
| Presentations | Presentations |
| RegistrationProcessed | RegistrationProcessed |
| FormInserted | FormInserted |
| FormUpdated | FormUpdated |

Available fields:

- EventRegistrationID
- FirstName
- LastName
- Phone
- Email
- Presentations
- RegistrationProcessed
- FormInserted
- FormUpdated

Buttons: Insert label, Insert value

The **Attachments** button in the header of the tab allows you to add files to the autoresponder e-mail, such as a detailed event agenda, white papers, etc. You can see the current number of attachments in the button's caption. Clicking the button opens a dialog where you can manage the attachments. The **Paste to text** action may be used to insert image attachments directly into the body of the e-mail (to the current cursor position).

When everything is configured as required, click **Save** to save the autoresponder settings.

8.25.6 Defining custom form layout

If you're not satisfied with the standard table layout of the form, the forms module allows you to define custom form layout. This can be achieved on the **Form** tab of a form's editing interface in **CMS Desk -> Tools -> Forms**.

Example

To modify the default layout of the sample *Event registration* form created in the [Creating a new form](#) topic, please take the following steps:

1. Go to **CMS Desk -> Tools -> Forms** and click the **Edit** () icon next to the form.
2. In its editing interface, go to the **Form** tab and check the **Use custom form layout** checkbox.
3. Click the **Generate table layout** button. This will generate a table containing all fields of the form, with appropriate labels, input controls and validation controls. Alternatively, you may use the **Insert label**, **Insert input** and **Insert validation label** buttons on the right to achieve the same result. This gives you the option to include just the fields that you want to appear in the form.
4. With the table generated, you may try altering the appearance of the form using actions on the [WYSIWYG editor](#) toolbar. For the purpose of this example, add a heading saying *Event registration* above the form, select it and apply the **Heading 2** format through the WYSIWYG editor toolbar. You may also delete the first line of the table (*EventRegistrationID*), which does not need to be displayed on the public form. The result should look as in the screenshot below.

8.25.7 Using macros with forms

Values of the fields that you need to fill in when configuring a form can be obtained dynamically from the submitted forms. The following table shows which macro types can be used for particular values of form configuration.

| | Localization | Context | Query String | Cookie | Custom | Path | Context (Data) macros |
|--------------------------------------|--------------|---------|--------------|--------|--------|------|-----------------------|
| General tab - Form display name | • | | | | | | |
| General tab - Display text | • | | | | | | • |
| General tab - Redirect to URL | | • | | | | | • |
| General tab - Submit button text | • | | | | | | |
| Fields tab - Default value | • | • | • | • | • | • | |
| Fields tab - Field caption | • | | | | | | |
| Fields tab - Table layout | • | | | | | | |
| Notification e-mail tab - all fields | • | • | • | • | • | | • |
| Autoresponder tabs - all fields | • | • | • | • | • | | • |

Context (data) macros

You can use values from current context when configuring a form. This can be achieved using a data macro in the `{%column_name%}` format. The `column_name` part of the macro is the value of the **Column name** property of a particular form field. When the form is submitted, the macros are

automatically resolved and replaced with particular data from the form.

These macros can be used in the following fields:

- **General tab**
 - Display text
 - Redirect to URL
- **Notification e-mails**
 - From e-mail
 - To e-mail
 - Subject
 - E-mail body
- **Autoresponder e-mails**
 - From e-mail
 - Subject
 - E-mail body

Example 1

When configuring notification e-mails for the sample form created in the [Creating a new form](#) topic, you may use the following values:

- **From e-mail:** `{%Email%}`;
- **Subject:** `Event registration by {%FirstName%} {%LastName%}`;

This will result in the e-mail having the user's e-mail address as the sender address, which enables the recipient to easily reply to the e-mail. The subject of the e-mail will have the first and last name of the user, which will help identifying the sender of the e-mail.

Example 2

If you entered the **Display text** value on the **General** tab of the same form like this:

- *Dear {%FirstName%}, thank you for your message. We will contact you shortly.*

The text will be resolved as the following when "Jane" was entered in the **First name** field by the user:

- *Dear Jane, thank you for your message. We will contact you shortly.*

Form text localization

If you need to display the form on a multi-lingual website, you can localize field captions and other text strings using localization macros, e.g.:

- `{$myform.fullname$}`
- `{$=Hello|de-de=Hallo|it-it=Ciao$}`

You can find more details in [Development -> Multilingual and international support -> Localization expressions](#).

Detailed overview of all macros in Kentico CMS can be found in [Development -> Macro expressions](#).

8.25.8 Security

Access to the Forms module can be managed in **CMS Desk -> Administration -> Permissions**, after you select the **Module -> Forms** permission matrix. The Forms module has the following permissions:

- **Read form** - members of the roles are allowed to view form configuration, fields and layout (not the actual records).
- **Create form** - members of the roles are allowed to create new forms.
- **Edit form** - members of the roles are allowed to edit form configuration, fields and layout (not the actual records).
- **Delete form including data** - members of the roles are allowed to delete forms including stored records.
- **Read data** - members of the roles are allowed to view form records.
- **Edit data** - members of the roles are allowed to create and edit form records
- **Delete data** - members of the roles are allowed to delete existing form records
- **Destroy form** - members of the roles are allowed to delete the version history of forms.
- **Edit SQL Queries** - some types of fields (form controls) offer the possibility of specifying an SQL query that will be used to retrieve the offered options. Users who belong to the specified roles will be allowed to write the code of these queries (please note that this can be a security risk).

| Permissions | | | | | | | | | | |
|------------------------------|-------------------------------------|--|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|--|
| Site: | Corporate Site | | | | | | | | | |

Security for individual forms

The roles which are authorized to read and modify a form and its data can also be specified for individual forms. To do this, edit (✎) a particular form in **CMS Desk -> Tools -> Forms** and switch to its **Security** tab. The following two options are available:

- **All form users** - all users with access to the *Tools -> Forms* section will be allowed to manage the form.
- **Only authorized roles** - only members of the roles added to the box will be allowed to manage the form.

Please note: General module permissions for the Forms module (described above) must be granted to the role first. Then, you can further customize access to particular forms using the form-level settings. The fact that a role has permissions to access a particular form is not sufficient — the form-level settings only define if the particular form will be listed in **Tools -> Forms**.

8.25.9 Form file settings

Files may be submitted as part of form records, typically when a form contains an uploader type field (specifically the *Upload file* field type/form control). In **Site Manager -> Settings -> System -> Files**, you can adjust the following settings related to files submitted through forms and their storage in the file system:

| Storage | |
|---|---|
| Custom form files folder | <p>Folder where files uploaded via forms are stored. You can use:</p> <ul style="list-style-type: none"> • physical disk path: e.g. c:\myfiles\ • virtual path: ~/UploadedFiles • UNC path: \\server\folder <p>If no value is entered, the files are stored under the <code>~/<site code name>/BizFormFiles/</code> folder.</p> |
| Use site-specific subfolders for custom form files folder | <p>This setting is only applied when a Custom form files folder is configured. If enabled, attachment files will be stored in a sub-folder named according to the code name of the site where the form is placed, i.e. <code><custom form files folder>/<site code name></code>. It is useful for better orientation in files when multiple sites are running in the system.</p> |
| Security | |

| | |
|-------------------|---|
| Upload extensions | <p>Specifies which extensions are allowed for uploaded files in general, including forms. You can restrict the types of uploaded files by entering a limited list of extensions separated by semicolons, for example: <i>gif;jpg;doc;pdf</i></p> <p>This allows you to block users from uploading potentially dangerous files, such as ASPX scripts. If no value is specified, uploading will be allowed for all file types.</p> <p>Allowed extensions can also be set for individual uploader form fields. Each field of this type has an Extensions setting, which can be configured on the Fields tab of the given form. You may either have the field inherit from the site settings or specify a different list of extensions.</p> |
|-------------------|---|

8.25.10 Forms internals and API

8.25.10.1 Database tables and API classes

The Forms module uses the following database tables:

- **Form_<site code name>_<table name>** - each form has its own database table. for example: *BizForm_CorporateSite_EventRegistration*. The table contains all fields that you specified on the form's **Fields** tab and you can modify stored data using direct access to the table (there are no dependencies).
- **CMS_Class** - each form has an associated record in the CMS_Class table. You can recognize form records by the *BizForm.* prefix in the *ClassName* column.

The Forms API is provided by the following classes from the **CMS.FormEngine** namespace:

- **BizFormInfo**, **BizFormInfoProvider** - these classes provide functionality for managing forms.

The following topics show examples of how these classes can be used:

- [Creating a new record](#)
- [Updating a record](#)
- [Deleting a record](#)
- [Customization possibilities](#)

The [API programming and Kentico CMS internals](#) section of this guide contains more API related information, so please refer to it if required.

For detailed API documentation, such as a list of all methods from the classes above, please refer to [Kentico CMS API Reference](#).

8.25.10.2 Creating a new record

The sample code below demonstrates how to add a new record to a form using the API.

[C#]

```
using CMS.SettingsProvider;
```

```
using CMS.FormEngine;

...

string bizFormName = "ContactUs";
string siteName = "CorporateSite";

// Read from definition
BizFormInfo bfi = BizFormInfoProvider.GetBizFormInfo(bizFormName, siteName);

if (bfi != null)
{
    // Read data type definition
    DataClassInfo dci = DataClassInfoProvider.GetDataClass(bfi.FormClassID);

    if (dci != null)
    {
        BizFormItemProvider bProvider = new BizFormItemProvider();
        // Create a new record in memory
        BizFormItem formRecord = BizFormItem.New(dci.ClassName, bProvider);

        // Insert some data
        formRecord.SetValue("FirstName", "Alice");
        formRecord.SetValue("LastName", "Cooper");
        formRecord.SetValue("Email", "alice@email.com");
        formRecord.SetValue("Message", "Hello world");
        formRecord.SetValue("PhoneNumber", "(123) 123-4567");
        formRecord.SetValue("FormInserted", DateTime.Now);
        formRecord.SetValue("FormUpdated", DateTime.Now);

        // Insert the new record in the database
        formRecord.Insert();

        // Update number of entries in BizFormInfo
        BizFormInfoProvider.RefreshDataCount(bfi.FormName, bfi.FormSiteID);
    }
}
```

8.25.10.3 Updating a record

This code example shows how an existing form record can be modified.

[C#]

```
using System.Data;

using CMS.FormEngine;
using CMS.SettingsProvider;
using CMS.DataEngine;
using CMS.GlobalHelper;

...

string bizFormName = "ContactUs";
```

```
        string siteName = "CorporateSite";

        // Read Form definition
        BizFormInfo bfi = BizFormInfoProvider.GetBizFormInfo(bizFormName,
siteName);

        if (bfi != null)
        {
            // Read data type definition
            DataClassInfo dci = DataClassInfoProvider.GetDataClass
(bfi.FormClassID);

            if (dci != null)
            {
                // Get all Form data
                GeneralConnection genConn = ConnectionHelper.GetConnection();
                DataSet ds = genConn.ExecuteQuery(dci.ClassName + ".selectall",
null, null, null);

                if (!DataHelper.DataSourceIsEmpty(ds))
                {
                    // Get ID of the first record
                    int formRecordID = ValidationHelper.GetInteger(ds.Tables[0]
.Rows[0][0], 0);

                    BizFormItemProvider bProvider = new BizFormItemProvider();

                    // Get the record with ID of the first row record
                    BizFormItem formRecord = bProvider.GetItem(formRecordID,
dci.ClassName);

                    if (formRecord != null)
                    {
                        // Set new field values
                        formRecord.SetValue("FirstName", "Bob");
                        formRecord.SetValue("LastName", "Marley");
                        formRecord.SetValue("Email", "bob@email.com");
                        formRecord.SetValue("Message", "Good job:");
                        formRecord.SetValue("FormUpdated", DateTime.Now);

                        // Save updates in the database
                        formRecord.Update();

                        lblInfo.Text = "The first record was updated
successfully.";
                    }
                }
                else
                {
                    lblInfo.Text = "No data found.";
                }
            }
        }
    }
```

8.25.10.4 Deleting a record

This code example shows how a form record can be deleted.

[C#]

```
using System.Data;

using CMS.FormEngine;
using CMS.SettingsProvider;
using CMS.DataEngine;
using CMS.GlobalHelper;

...

string bizFormName = "ContactUs";
string siteName = "CorporateSite";

// Get Form definition
BizFormInfo bfi = BizFormInfoProvider.GetBizFormInfo(bizFormName,
siteName);

if (bfi != null)
{
    // Get data type definition
    DataClassInfo dci = DataClassInfoProvider.GetDataClass
(bfi.FormClassID);
    if (dci != null)
    {
        // Get all Form data
        GeneralConnection genConn = ConnectionHelper.GetConnection();
        DataSet ds = genConn.ExecuteNonQuery(dci.ClassName + ".selectall",
null, null, null);

        if (!DataHelper.DataSourceIsEmpty(ds))
        {
            // Get ID of the first record
            int formRecordID = ValidationHelper.GetInteger(ds.Tables[0].Rows
[0][0], 0);

            BizFormItemProvider bProvider = new BizFormItemProvider();
            // Get the record with specified ID
            BizFormItem formRecord = bProvider.GetItem(formRecordID,
dci.ClassName);

            if (formRecord != null)
            {
                // Delete the first record
                formRecord.Delete();

                // Update number of entries in BizFormInfo
                BizFormInfoProvider.RefreshDataCount(bfi.FormName,
bfi.FormSiteID);

                lblInfo.Text = "The record was deleted successfully.";
            }
        }
    }
}
```

```
        else
        {
            lblInfo.Text = "No data found.";
        }
    }
}
```

8.25.10.5 Customization possibilities

This topic provides information on how forms behavior can be modified with your custom code.

Event Handling

You can run custom actions when a form record is created, updated or deleted. There are two ways how you can handle these events:

1. Handling BizForm control events

In this case, you can place the **BizForm** control into the markup of a user control or web part and specify the code name of the required Form in its **FormName** property. Then, you can handle the BizForm events, such as **OnAfterSave**, **OnBeforeValidate**, etc.

In these handlers, you can retrieve the values of form fields using the **BasicForm.GetFieldValue(string fieldName)** method, which may be called through the corresponding property of the BizForm control. For example:

[C#]

```
BizForm.BasicForm.GetFieldValue( "FirstName" );
```

The data of the entire form may be accessed as a data container through the **BizForm.BasicForm.Data** property. This allows you to insert values into fields programmatically using the **SetValue(string fieldName, object value)** method. For example:

[C#]

```
BizForm.BasicForm.Data.SetValue( "TimeStamp", DateTime.Now );
```

Please note that field values need to be set at the appropriate time in the BizForm control's life cycle. A suitable place is in the handler of the **OnBeforeSave** event.

If you wish to set up special behavior in the form during the editing process, individual controls that make up the fields, labels and validation error messages in the form can be accessed through the hash tables provided by the **BizForm.BasicForm.FieldControls**, **BizForm.BasicForm.FieldLabels** and **BizForm.BasicForm.FieldErrorLabels** properties.

If necessary, you can stop further processing (saving) of the form at any point by setting the **BizForm.StopProcessing** property to *true*.

An example of this type of customization can be found in [Development -> Web parts -> Modifying web parts -> Modifying code of standard web parts](#).

2. Handling global data events

You can write a custom data handler as described in the [API programming and Kentico CMS internals -> Data handler \(CustomDataHandler class\)](#) topic. This type of handler will allow you to run custom code whenever a database record is inserted, updated or deleted. You can use the `dataItem.ClassName` property to check if the record being updated matches the code name of your form (you can find it in the **Form code name** field on the **General** tab of a form's editing interface).

Custom field controls

You can create your own field controls as described in the [Form controls](#) chapter. If you want to make a form control available in the field editor of the Forms module, you need to check the **Show control in Forms** box in the given control's editing dialog (in **Site Manager -> Development -> Form controls**) and also choose a **Default data type**. To ensure that the form control is also offered in the simple mode of the form field editor, it is also necessary to enable its **High priority** flag.

8.26 Forums

8.26.1 Overview

This module allows you to integrate full-featured forums into your website. The forums are highly configurable and allow you to:

- Organize forums into [forum groups](#)
- Open/lock forums
- Perform SQL or index-based full-text [searches](#) of forum content
- [Manage](#) all forum posts and threads of a particular forum
- Choose to require and/or display e-mails of the forum users
- [Subscribe](#) to receive notifications about all posts added to a forum or thread by e-mail
- Create [moderated forums](#) (posts need to be approved before they are displayed on-line)
- Configure standard forum functions such as [post attachments](#), [BBCode support](#), adding posts to [favorites](#), user avatars and more
- Set forums to use [Friendly URLs](#)
- Use your own [custom forum layouts](#)
- Enable a forum only for authenticated users
- Specify user roles that are allowed to use various forum functions via [Security](#) settings

Forums

This section represents sample discussion forums created using the **Forums** module. You can set up any number of forum groups and each forum group may contain multiple forums on particular topics. The forums are organized into threads. You can also use the **Forums** module for article comments if you use so called "ad-hoc" forums that are bound to a particular document (article, product, etc.). For more information on the **Forums** module, please refer to [Kentico CMS Developer's Guide -> Modules -> Forums](#).

Search forums: [Advanced search](#)

| Forum | Threads | Posts | Last post |
|--|---------|-------|---|
| Site forums | | | |
| Website forums
This is a forum group for sample forums on the sample Corporate Site.
Lock | 2 | 11 | Susanne Paige
(6/21/2011 8:18:39 PM) |

There are two basic types of forums:

- [Pre-defined forums](#) - created by the administrator and then displayed on the website.
- [Ad-hoc forums](#) (article comments) - created for a single document when a visitor posts the first comment to the given document.

The Message boards module provides another option that allows users to post comments on your website. Please refer to the [Modules -> Message boards](#) chapter to learn more about it.

The Forums module can be managed in **CMS Desk -> Tools -> Forums**. Further settings can be found at **Site Manager -> Settings -> Community -> Forums** and are described in more detail in the [Settings](#) topic.

The [Forums internals and API](#) sub-chapter provides information about the database tables and classes used by the module and examples of how forums can be managed using the API.

Kentico CMS Community Site Guide contains some additional forum examples and tutorials:

- [Part 1 -> Forums](#): Examples of the functionality and customization of groups.
- [Part 2 -> Creating the Forums section](#): A step-by-step tutorial on how to create a sample forum section of a website.

You will need to have the sample Community Site installed to follow Kentico CMS Community Site Guide.

8.26.2 Creating a forum group

All forums are a part of some forum group. Pre-defined forums need to be created within some particular forum group and ad-hoc forums are automatically placed into the **AdHoc forum group** upon creation. A **forum group** usually contains forums related to the same topic. For example:

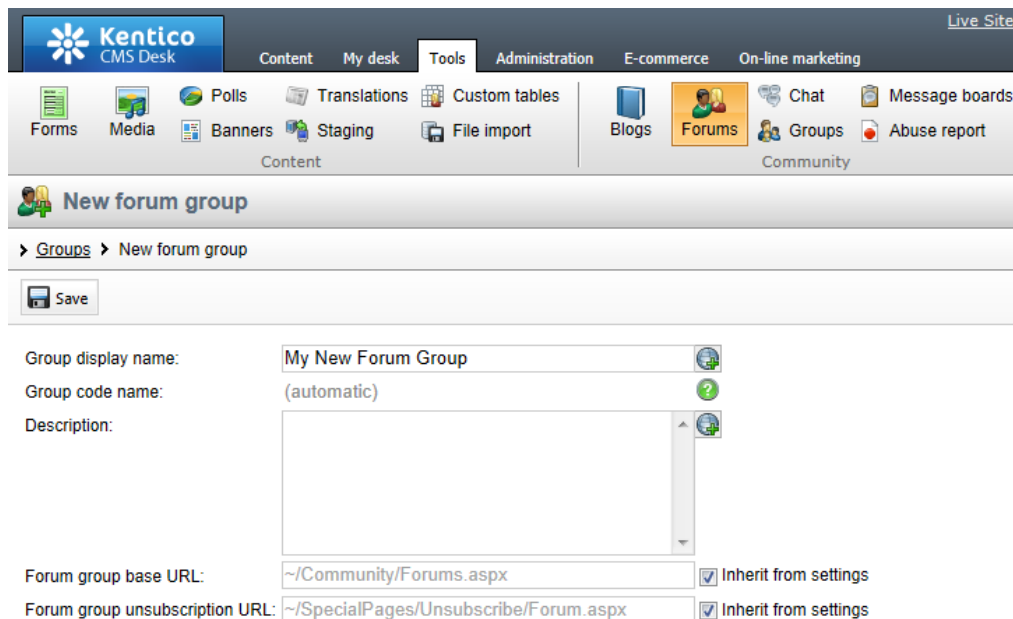

- Computers (forum group)
 - Announcements (forum)
 - Technical questions (forum)
 - FAQ's (forum)
- Web design (forum group)
 - CSS (forum)
 - XHTML (forum)

Creating a new forum group

Go to **CMS Desk -> Tools -> Forums** and click the  **New forum group** button. Fill in the following fields:

- **Group display name** - sets the name displayed for the forum group on the website.
- **Group code name** - assigns a unique name to the forum group that can be used to identify it, e.g. in the API. You can leave the *(automatic)* option to have the system generate an appropriate code name based on the display name.
- **Description** - may be used to enter a text description of the forum group, which will be displayed on the website.
- **Forum group base URL** - enter the URL of the page where the forum group will be placed, for example: `~/MyForum.aspx`. This is used by the system when creating absolute URLs leading to the given forum group.
- **Forum group unsubscription URL** - sets the URL of the page where users can unsubscribe from forums under the given group.

Click  **Save** to confirm the creation of the group.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The 'Tools' menu is expanded, showing options like 'Forms', 'Media', 'Polls', 'Translations', 'Custom tables', 'Blogs', 'Forums', 'Groups', 'Chat', 'Message boards', 'Staging', 'File import', and 'Abuse report'. The 'Forums' option is highlighted. Below the navigation, the 'New forum group' form is displayed. The form has a 'Save' button at the top left. The fields are: 'Group display name' (My New Forum Group), 'Group code name' (automatic), 'Description' (empty text area), 'Forum group base URL' (~/Community/Forums.aspx), and 'Forum group unsubscription URL' (~/SpecialPages/Unsubscribe/Forum.aspx). Both URL fields have 'Inherit from settings' checked.

Continue to the [Creating a pre-defined forum](#) topic to learn how to create individual forums within a forum group or the [Adding an ad-hoc forum to the web](#) topic to find out more about ad-hoc forums.

8.26.3 Creating a pre-defined forum

Pre-defined forums need to be created within a forum group before you can publish them on the website. See the [Creating a forum group](#) topic to learn how to create a forum group.

Creating a new forum

Go to **CMS Desk -> Tools -> Forums** and click **Edit** (✎) for some forum group. Go to the Forums tab and click **Add forum**. Enter the following details:

- **Forum display name** - the name of the forum that will be displayed on your website.
- **Forum code name** - assigns a unique name to the forum that can be used to identify it, e.g. in the API. You can leave the (*automatic*) option to have the system generate an appropriate code name based on the display name.
- **Description** - the description displayed on your website.
- **Forum base URL** - URL displayed when the user accesses the forum; e.g. *~/MyForums.aspx*.
- **Forum unsubscription URL** - URL of the page where users can unsubscribe from the given forum.

- **Require e-mail address** - indicates if e-mail address should be required from the post author.
- **Display e-mail addresses** - indicates if e-mail address of the post author should be displayed to other site visitors.
- **Enable WYSIWYG editor** - indicates if the visitors can use the WYSIWYG editor for entering text.
- **Use security code (CAPTCHA)** - indicates if the user needs to retype the security code displayed as an image. This feature can help avoid spam in the forums.

- **Forum is open** - indicates if the forum is visible and can be accessed.
- **Forum is locked** - if checked, users will not be able to add new posts to the forum, but it will remain accessible for viewing.
- **Forum is moderated** - indicates if the posts need to be approved by a forum moderator.

The **Inherit from forum group** checkboxes or radio button options displayed next to the properties are used to automatically load values from the settings of the parent forum group. To configure unique properties for a forum, simply clear the appropriate checkbox and enter the desired value.

Click **Save** to add the forum.

Forum is locked:

Forum is moderated:

Now that the forum is created, it may be configured in more detail. Switch to its **General** tab, where you can edit the options that were entered when the forum was created, as well as the following additional properties:

- **Forum type** - determines the overall type of the forum. The following three types may be selected:
 - **User can choose** - when creating a new thread, users can choose from the following two types.
 - **Discussion forum** - news threads use a standard discussion format where users reply to previous posts.
 - **Question-Answer forum** - in forums of this type, the initial post of a thread is usually a question and the replies are attempts to answer it. The forum includes a voting feature that allows users to mark individual replies as helpful answers. Once a post receives the amount of votes specified in the *Minimum votes to mark post as answer* property, it will be designated as a valid answer and displayed accordingly.
- **Minimum votes to mark post as answer** - determines the minimum amount of votes that a post must receive before it is marked as an answer in *Question-Answer* type forums.
- **Maximum image side size** - sets the maximum side size in pixels of images inserted into forum posts. If a larger picture is included in a forum post, it will be resized so that its larger side is equal to the entered value.
- **Attachment max. file size (kB)** - sets the maximum file size of forum post attachments in kB.
- **User can edit own posts** - indicates whether users are allowed to edit their own existing posts.
- **User can delete own posts** - indicates whether users are allowed to delete their own existing posts.

The properties in the **Editor settings** section determine which BB code macros may be used by forum users to format the text of forum posts. Further details may be found in the [BBCode support](#) topic.

Once everything is configured as necessary, the forum can be placed on a website. The [Publishing a pre-defined forum on the website](#) topic describes how.

8.26.4 Publishing a pre-defined forum on the website

When you want to publish a forum on your website, you can use the built-in web parts on your page templates. You can find more details about each web part in the [Kentico CMS Web Parts](#) reference.

Web parts and ASPX page templates

If you are using ASPX page templates, you can simply drag and drop the controls that implement the forum web parts located in the `~/CMSWebParts/Forums` folder onto your page and use them in a similar way.

Publishing a forum group on the website

You can publish an entire forum group on the website using the **Forum group** (ForumGroup.ascx) web part. All you need to do is to select the appropriate **Group name** value in the web part properties. The default forum looks like this:

| Forum | Threads | Posts | Last post |
|---|---------|-------|---|
| Site forums
Site forums | | | |
| Sample forum
Lock | 1 | 1 | Frank Stevens
(8/18/2011 11:16:10 AM) |
| Website forums
This is a forum group for sample forums on the sample Corporate Site.
Lock | 2 | 11 | Susanne Paige
(6/21/2011 8:18:39 PM) |

The forum threads in the selected forum can be displayed in two ways:

1. As a list of threads

- set the **Forum layout** property to **Flat**

Website forums
This is a forum group for sample forums on the sample Corporate Site.

[New thread](#) | [Subscribe to forum](#) | [Site forums](#) > Website forums

| Thread | Created by | Posts | Views | Last post |
|--|---------------|-------|-------|---|
| Services feedback
Lock Stick thread | administrator | 5 | 26 | Susanne Paige
(6/21/2011 8:18:39 PM) |
| Products requests
Lock Stick thread | administrator | 6 | 2 | Trevor Lloyd
(6/21/2011 8:00:58 PM) |

1

2. As a tree of threads and posts
- set the **Forum layout** property to **Tree**

Website forums
This is a forum group for sample forums on the sample Corporate Site.

[New thread](#) | [Subscribe to forum](#) | [Site forums](#) > Website forums

- Website forums
 - Products requests
 - Apple iPad 2
 - More smartphones
 - RE:More smartphones
 - Services feedback
 - Consulting exceeding all expectations
 - Web development - London Office

8.26.5 Adding an ad-hoc forum to the web

Ad-hoc forums are useful if you want to enable users to add comments to some page or article, but you do not want to create the forum for each document manually. You may also consider using [Message boards](#) for this purpose if you don't need a structured forum.

Ad-hoc forums can be added using the **Forum (Single forum - General)** web part.

If you place the **Forum (Single forum - General)** web part to a page and set its **Forum name** property to *ad-hoc forum* (or *ad_hoc_forum* if you are using ASPX templates), the forum will be displayed on the website, but it will be actually created after some visitor adds a first post to the forum. After that, the forum will be created in the **AdHoc forum group** forum group in **CMS Desk -> Tools -> Forums**.

Ad-hoc forums are uniquely identified by the document they belong to.

The following two web parts are **deprecated**, and they are available only because of **backward compatibility** with versions prior to 4.0:

- **Forum (Single forum - Flat layout)** - this web part ensures backward compatibility with the former **Forum thread list** web part
- **Forum (Single forum - Tree layout)** - this web part ensures backward compatibility with the former **Forum tree** web part

8.26.6 Adding forum searching

If you want to let users search forum posts for some given text, you can use the **Forum search box** (ForumSearch.ascx) and **Forum search results** (ForumSearchResults.ascx) web parts. You will typically place them both on the same page. However, if you need to place the forum search box on a different page, you can set its **Redirect to URL** property to the page where you have the **Forum search**

results web part, such as `~/SearchForum.aspx`.

Search forums:
[Advanced search](#)

Search results for shop in forum group Site forums : 3 occurrences found.

Web development - London Office
 Hi, I am a representative of one of your first customers in London. We are currently having a lot of praise and only praise can be said to their job so far. Clear communication, reasonable pricing and good right company to take care of our website.

Guest

Can't wait for the project to be finished and for the re-vamped website to go live!

1

If you wish to use the basic search box by default, but want to let users have the option of using the advanced dialog as well, you can do so by entering the path to the page containing the **Forum search - advanced dialog** web part into the **Advanced search path** property of the **Forum search box** web

part. The **Advanced search** link will then be displayed as seen in the first image.

These web parts use the SQL search engine.

If you prefer index-based searching, this can be provided by various Smart search web parts from the **Full-text search** category if they have a forums type search index set. Please refer to the [Modules -> Smart search](#) chapter for more details.

8.26.7 Managing forum posts

Threads and posts can be managed on the **Posts** tab when editing the forum that contains them.

Creating a new thread

When you navigate to the tab, you can initially see the **New thread** page, letting you add a new thread to the current forum group. The following details need to be filled in:

- **User name:** user name which will be used for the thread author
- **E-mail:** e-mail of the thread author
- **Subject:** subject of the initial post of the thread
- **Post:** text of the initial post of the thread
- **Signature:** signature under the initial post
- **Subscribe to post:** if enabled, notification e-mails about new posts in the thread will be sent to the e-mail address specified in the *E-mail* field

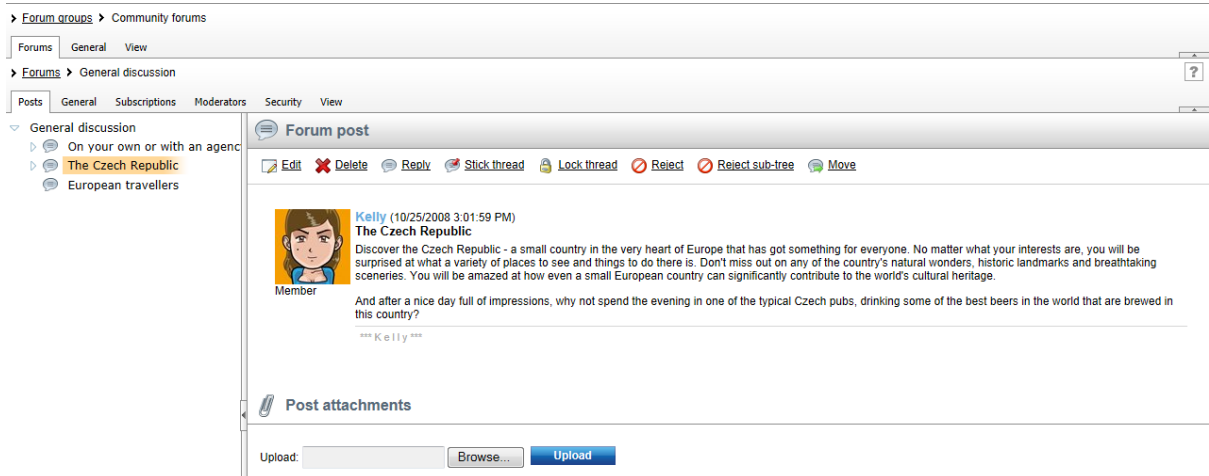

The screenshot shows the 'New thread' form in a forum application. The form is titled 'New thread' and is part of the 'Forum group properties' interface. It shows a tree view on the left with 'General discussion' selected. The form fields include: User name (administrator), E-mail (administrator@localhost), Subject (empty), Post type (Discussion selected, Question unselected), Post (text area), Signature (text area), and Subscribe to post (checkbox). Buttons for OK, Cancel, and Preview are at the bottom.

Managing particular posts

If you select a post from the tree on the left, you can perform the following actions:

- **Edit** - opens the post for editing - you can edit the post text, user's name, signature, etc.
- **Delete** - deletes the post
- **Reply** - opens a dialog using which you can send a reply to the post

-  **Stick thread** - sticks this thread so that it will be displayed at the beginning of the forum
-  **Split thread** - moves the post and its replies to a new thread
-  **Lock thread** - locks the thread so that no more posts can be added to it
-  **Reject** - rejects the post so that it is not displayed and needs approval to be displayed
-  **Reject sub-tree** - performs the Reject action for the current posts and all its children
-  **Move** - moves a thread to a new forum

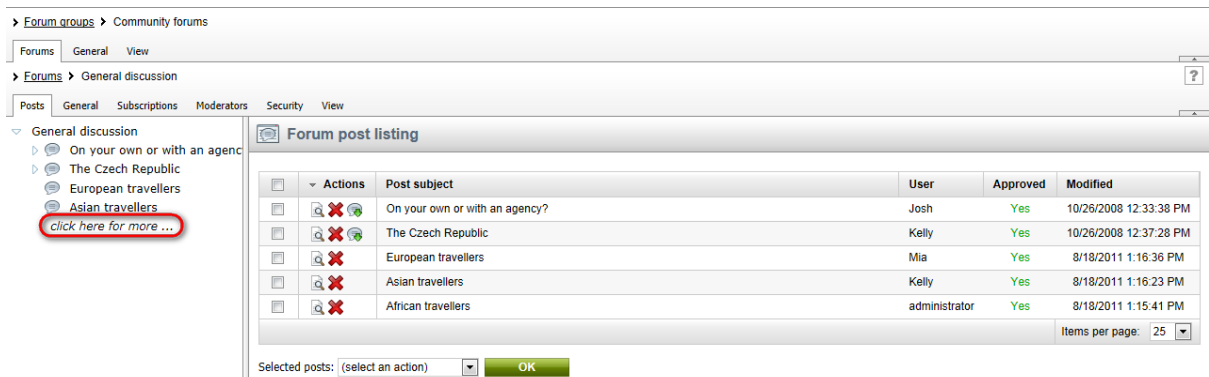

Forum post listing

In case that there are too many threads in the forum, you can limit the number of displayed threads using the **Max forum post nodes** settings key in **Site Manager -> Settings -> Community -> Forums**. If you use this key and there are more threads in the forum than the set value, the **Click here for more...** link is displayed at the bottom of the tree. After clicking this link, the **Forum post listing** page is displayed in the main area.

The **Forum posts listing** page initially displays all threads in the forum, while the following actions can be performed:

-  **View** - displays the thread's initial post in the main area (this action is identical to clicking the post in the tree)
-  **Delete** - deletes the whole thread including all child posts
-  **Sub-posts** - displays sub-posts of the post in the grid in the main area
-  **Parent post** - displays a list of sub-posts of the parent post in the main area (goes up one level)

| Actions | Post subject | User | Approved | Modified |
|---|--------------------------------|---------------|----------|------------------------|
|    | On your own or with an agency? | Josh | Yes | 10/26/2008 12:33:38 PM |
|    | The Czech Republic | Kelly | Yes | 10/26/2008 12:37:28 PM |
|    | European travellers | Mia | Yes | 8/18/2011 1:16:36 PM |
|    | Asian travellers | Kelly | Yes | 8/18/2011 1:16:23 PM |
|    | African travellers | administrator | Yes | 8/18/2011 1:15:41 PM |

8.26.8 Subscriptions

Subscriptions allow users to receive e-mail notifications when a new post is added to a selected forum or as a reply to a specific post. Users may subscribe directly while browsing through forums on the live site.

When viewing the thread list of a forum, the **Subscribe to forum** link displayed at the top provides a way to subscribe to the entire forum (all of its threads).

| Website forums | | | | | |
|--|---------------|-------|-------|---|--|
| This is a forum group for sample forums on the sample Corporate Site. | | | | | |
| New thread Subscribe to forum Site forums > Website forums | | | | | |
| Thread | Created by | Posts | Views | Last post | |

Apple iPad 2

Hi, how about the new iPad 2? I've already got the first version, but I just can't wait to the new one, it seems advanced and trendy!!!

[Reply](#) | [Quote](#) | [Subscribe to post](#)

Both of these actions open a dialog where users can submit their e-mail address.

Please note

The subscription functionality may be disabled through the properties of the web part used to publish the forum or forum group.

Additionally, the [Security](#) settings of specific forums may be configured to only allow subscription for certain types of users or roles.

Enabling double opt-in

To make users confirm that the e-mail address they're subscribing with really exists and belongs to them, you can enable the double opt-in functionality. With double opt-in enabled, subscribers will be sent an e-mail with a confirmation link. They will have to click the link to create their subscription.

To enable double opt-in globally for all forums:

1. Go to **Site Manager -> Settings -> Community -> Forums**.
2. Turn on the **Enable double opt-in for forums** setting.
3. Specify how long you want the confirmation links to be valid in the **Double opt-in interval** setting.

The following two steps are optional. If you omit them, the system will use the default approval page located in `~/CMSModules/Forums/CMSPages/SubscriptionApproval.aspx`.

4. Place the **Forum subscription confirmation** web part on a new page. Adjust its properties according to your needs.
5. Enter the page's path into the **Double opt-in approval page path** setting.

Double opt-in should now be configured for all forums. You can override the settings for each forum group in its properties in **CMS Desk -> Tools -> Forums**. You can also define specific settings for particular forums.

The functionality uses the **Forums - Subscription request e-mail template**. You can insert the confirmation link into the template using the `{%SubscriptionLink%}` macro.

Unsubscription

Users can cancel their forum subscriptions at any time by clicking on the unsubscription link included in every notification e-mail about a new post (when using the default e-mail template).

This is a notification of a new post added to the forum you subscribed to:

Forum: Website forums
Subject: RE:More smartphones
Posted by: administrator
Date and time: 4/10/2012 10:21:09 AM
Text: Hi Jane, we are working on this at the moment. If everything goes well, you should be able to see many more models from various suppliers soon. You can expect more cost-savvy models, more manufacturers and a larger variety of operating systems.

[Click here to view forum on-line](#) [Click here to unsubscribe](#)

The link leads to a page that automatically processes the unsubscription request and deletes the appropriate subscription (it is identified using a parameter passed in the query string of the link's URL).

This is either handled by the `~/CMSPages/Unsubscribe.aspx` system page, or by a custom unsubscription page created for the website. If you wish to use a custom page, it is necessary to place the [Forum unsubscription](#) web part onto it, which ensures all the required functionality. The URL of this page then needs to be entered into the **Forum unsubscription URL** field of the given forum or forum group (the value can also be inherited from the website's **Forum unsubscription URL** setting, which can be specified in **Site Manager -> Settings -> Community-> Forums**).

Subscription e-mails and the Forum base URL

It is important to set a correct **Forum base URL** value in the forum configuration so that the subscription notifications and other related e-mails contain valid links leading to the appropriate forum.

When entering the value, you can use the relative URL of the page where the forum is located, for example: `~/Community/Forums.aspx`

Alternatively, users with access to CMS Desk can view all of their active forum subscriptions in **My Desk** -> **My profile** -> **Subscriptions** and manually **Unsubscribe** (✘) as needed.

The screenshot shows the 'My profile' page with a navigation menu on the left and a main content area. The 'Subscriptions' tab is selected. The main content area is divided into several sections:

- Newsletter subscriptions:** Shows the user's email address (administrator@localhost.local) and a list of selected newsletters (none). An 'Add newsletters' button is present.
- Blog post subscriptions:** States the user is not currently subscribed to receive notifications about any blog comments.
- Message board subscriptions:** States the user is not currently subscribed to receive notifications about any board messages.
- Forum subscriptions:**
 - States the user is currently subscribed to receive notifications on new posts added to the following forums:
 - Table with columns: Actions, Forum name. Row: ✘, Website_forums.
 - States the user is currently subscribed to receive notifications on new posts added to the following forum posts:
 - Table with columns: Actions, Forum name, Post subject. Row: ✘, Feedback, How can we improve the website?

For live site users, the same options can be provided by the [My account](#) web part, as long as its **Display my subscriptions** and **Display forum subscriptions** properties are enabled.

Managing subscriptions

When editing a forum in **CMS Desk** -> **Tools** -> **Forums**, administrators can manage all of the given forum's subscriptions on the **Subscriptions** tab.

Forum group properties

> Forum groups > Site forums

Forums General View

> Forums > Website forums

New subscription

| Actions | E-mail | Thread | Approved |
|---------|-----------------------|------------------|----------|
| | andy@localhost.local | More smartphones | Yes |
| | seang@localhost.local | | No |

Send confirmation e-mail to subscriber

The **Delete** () action may be used to remove existing subscriptions. If this is done with the **Send confirmation e-mail to subscriber** checkbox enabled, a notification e-mail will be sent to the given address, informing about the unsubscription.

The **New subscription** button provides a way to subscribe a user to the whole forum. When clicked, the dialog depicted in the screenshot below is opened. All that needs to be done is enter the e-mail address of the user that should be subscribed and then click **OK**.

> Forum groups > Site forums

Forums General View

> Forums > Website forums

Posts General Subscriptions Moderators Security View

> Subscriptions > New subscription

E-mail:

Send confirmation e-mail to subscriber

Like when removing subscriptions, the checkbox at the bottom of the dialog indicates if a confirmation e-mail should be sent to the address of the new subscriber. These confirmation e-mails are sent automatically to users who subscribe on-site.

E-mail templates

The post notification e-mails are sent to the subscribed users based on the **Forums - New post** e-mail template, which can be edited in **Site Manager -> Administration -> E-mail templates**. The notifications informing users about their forum subscriptions or unsubscriptions are based on the **Forums - Subscription confirmation** and **Forums - Unsubscription confirmation** templates respectively. If you have double opt-in enabled for forums, the e-mail that is sent upon requesting subscription is based on the **Forums - Subscription request** template.

You can use the following specific [context macros](#) in forum subscription e-mail templates:

- **{% ForumDisplayName %}** - display name of the related forum.
- **{% ForumName %}** - code name of the related forum.
- **{% ForumDescription %}** - resolves into the description text of the forum.
- **{% GroupDisplayName %}** - display name of the related forum group.
- **{% GroupName %}** - code name of the related forum group.
- **{% GroupDescription %}** - description text of the forum group.
- **{% PostSubject %}** - the subject of the new forum post that caused the notification to be sent.
- **{% PostText %}** - resolves into the HTML content of the new post.
- **{% PostTextPlain %}** - resolves into the plain text version of the new post's content.
- **{% PostUsername %}** - name of the user who created the post.
- **{% PostTime %}** - the date and time when the new post was added.
- **{% Link %}** - resolves into a link to the new post.
- **{% UnsubscribeLink %}** - generates a link that can be used to unsubscribe from the given forum.

The two macros below are available for (un)subscription notifications:

- **{% Subject %}** - if the user is subscribed to a specific post, this resolves into the subject of the given post. Otherwise it returns an empty string.
- **{% Separator %}** - if the user is subscribed to a specific post, this returns the value of the `forums.confirmationtemplateseparator` resource string (" - " by default). This can be placed between the name of the forum and the subject of the post to cover both possible subscription scenarios.

You can use the following macro when double opt-in is enabled:

- **{% SubscribeLink %}** - contains the URL of the page used to confirm subscriptions.

You can also access the following related objects and their properties (e.g. `{% ForumPost.PostViews %}`):

- **{% ForumPost %}** - *ForumPostInfo* object of the post to which the user is subscribed (if applicable).
- **{% Forum %}** - *ForumInfo* object representing the forum to which the user is subscribed.
- **{% ForumGroup %}** - *ForumGroupInfo* object of the forum group containing the given forum.
- **{% Subscriber %}** - *ForumSubscriptionInfo* object representing subscription of the recipient to the given forum. Only available for the *New post* template.

8.26.9 Forum moderation

You can configure a forum so that it is moderated. It means that all posts must be approved by one of the forum moderators before they are published in the forum.

Configuring forum moderation

You can enable forum moderation and configure the list of moderators under the **Forum properties -> Moderators** tab. Even when this option is disabled, approval of posts might be required, e.g. when a [Bad word](#) is detected or when a post has been rejected.

The moderators automatically receive an e-mail notification when a new item is waiting for approval. The e-mail template can be modified in **Site Manager -> Administration -> E-mail templates -> Forums - Moderator notification**. To insert dynamic values into the template, you may use the same macro expressions as are described for the *Forums - New post* notification in the [Subscriptions](#) topic.

8.26.10 Forum post attachments

Users can attach files to forum posts. To enable users to do this, you have to assign the **Attach files** permission on the forum's **Security** tab to the desired user roles or all authenticated users. See the [Security](#) topic for more details. There are also some additional settings related to attachments:

In **Site Manager -> Settings -> Community -> Forums**, you can make the following setting:

- **Forum attachments allowed extensions** - you can specify which file extensions can be attached to forum posts. Extensions should be entered without dots and separated by semicolons. If blank, all extensions are allowed.

In web part properties of the **Forum group** web part, you can make the following settings:

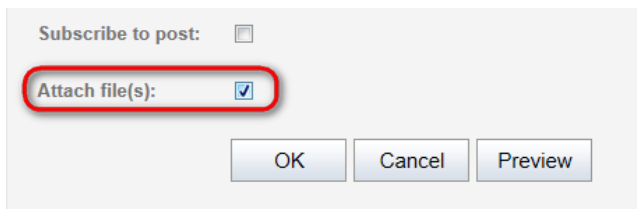

- **Display attachment image** - if checked, attached images will be displayed as images, not only as links.
- **Attachment image maximal side size** - if an attached image is larger than the entered value, it will be resized so that its larger side's size is equal to the entered value.

When editing a forum in **CMS Desk -> Tools -> Forums**, you can set the following property on the **General** tab:

- **Attachment max. file size (kB)** - you can define the maximum size of an attached file in kB.

Adding attachments to a forum post

When adding a post to a forum, users can check the **Attach file(s)** check box at the bottom of the post adding dialog.

The image shows a dialog box with the following elements:

- A checkbox labeled "Subscribe to post:" which is unchecked.
- A checkbox labeled "Attach file(s):" which is checked and highlighted with a red circle.
- Three buttons at the bottom: "OK", "Cancel", and "Preview".

After clicking **OK**, a new dialog will be displayed, where users can upload the attachments. When all desired images are uploaded, users can click the **Back** button, which will take them back to the forum.

Attachments
Maximum allowed file size is 1024 kB.

| Filename | File size | |
|------------------------------|-----------|------------------------|
| Desert.jpg | 845941 B | Delete |
| Koala.jpg | 780831 B | Delete |
| Penguins.jpg | 777835 B | Delete |
| Penguins.jpg | 777835 B | Delete |

Back in the forum thread, links to uploaded attachments will be displayed with the post, as you can see in the screenshot below.

8.26.11 BBCode support

[Bulletin Board code](#) (the *BBCode* abbreviation is commonly used) is a lightweight markup language designed to let users format text of their messages. It is used in many forums on the web, not just on websites created with Kentico CMS. Its tags are similar to HTML tags and are entered in square brackets.

Users can use BBCode in their forum posts only if it is enabled. You have to allow use of BBCode when editing () a forum or forum group, on the **General** tab of its editing interface in **CMS Desk -> Tools -> Forums**.

The following table explains particular BBCode tags. The first column shows icons on the BB editor toolbar. Clicking one of these icons encloses the selected text within the respective tags. The second column shows examples of text enclosed within the tags. The **Description** column explains what effects the tags have on the formatting. The last column lists respective properties on the **General** tab that have to be enabled in order for the tags to be functional.

| Icon | Example | Description | Property on the General tab |
|---|--|---|-----------------------------|
|  | [url]http://example.org[/url]
[url=http://example.com]Example[/url] | Makes the text a link leading to the URL.

One of the following three options can be selected:

No - the macros are not functional | Enable links in posts |

| | | | |
|---|--|--|--|
| | | <p>and the icon is not displayed</p> <p>Simple dialog - clicking the icon displays a simple dialog where the URL of the link can be entered manually</p> <p>Advanced dialog - clicking the icon displays the insert link dialog where the URL can be selected in various ways</p> | |
|  | <p>[img]http://www.imagesxy.com/img.bmp[/img]</p> <p>[img=200x50]http://www.imagesxy.com/img.bmp[/img]</p> <p>[img=200]http://www.imagesxy.com/img.bmp[/img]</p> | <p>Displays an image located at the URL. The optional parameter resizes the image. It can be added either in format <code><width>x<height></code> or <code><max side size></code>.</p> <p>One of the following three options can be selected:</p> <p>No - the macros are not functional and the icon is not displayed</p> <p>Simple dialog - clicking the icon displays a simple dialog where the URL of the link can be entered manually</p> <p>Advanced dialog - clicking the icon displays the insert image dialog where the image can be selected in various ways</p> | <p>Enable image macros in posts</p> |
|  | <p>[quote]quoted text[/quote]</p> <p>[quote=Administrator]quoted text[/quote]</p> | <p>Displays text in a grey box; used for quotations.</p> <p>The optional parameter displays <i>Administrator wrote:</i> and the quoted text on a new line.</p> | <p>Enable quote macros in posts</p> |
|  | <p>[code]code example[/code]</p> | <p>Displays text in monospaced format; used for code snippets.</p> | <p>Enable code snippet macros in posts</p> |
|  | <p>[b]bold text[/b]</p> <p>[strong]bold text[/strong]</p> | <p>Makes the text bold.</p> | <p>Enable bold font macros in posts</p> |
|  | <p>[i]italicized text[/i]</p> <p>[em]italicized text[/em]</p> | <p>Makes the text italic.</p> | <p>Enable italics font macros in posts</p> |
|  | <p>[u]underlined text[/u]</p> | <p>Underlines the text.</p> | <p>Enable underline font macros in posts</p> |
|  | <p>[s]strikethrough text[/s]</p> | <p>Strikes the text through.</p> | <p>Enable strike font macros in posts</p> |
|  | <p>[color=red]Red Text[/color]</p> <p>[color=#f00]Red Text[/color]</p> <p>[color=f00]Red Text[/color]</p> <p>[color=#ff0000]Red Text[/color]</p> <p>[color=ff0000]Red Text[/color]</p> | <p>Sets the text color.</p> | <p>Enable font color macros in posts</p> |

URLs in BBCode macros

All URLs in macros (URL, IMG) are validated as a URL to avoid XSS and resolved into their absolute URL equivalents. The following URL formats can be used:

- **www.google.com** – URL starting with www.
- **http://devnet.kentico.com** – URL starting with protocol
- **~/CMSDesk/default.aspx** – Virtual path
- **../default.aspx** – Relative URLs
- **/KenticoCMS/default.aspx** – Server relative URL

API for BBcode macros

There is an easy way to resolve macros in ASPX or codebehind code. To resolve all the macros (recommended), use the following method:

```
string CMS.CMSHelper.CMSContext.ResolveDiscussionMacros(string inputText)
```

Or you can use the **CMS.GlobalHelper.DiscussionMacroHelper** class to resolve macros with particular settings using the **ResolveMacros** method from an object of this class.

8.26.12 Forum favorites

If you enable the **Enable favorites** web part property of the **Forum group** web part, forum posts will be displayed with the **Add post to favorites** link, as you can see in the screenshot below.

If a user clicks this link, the post will be added to their favorite posts.

If you place the **Forum favorites** web part to some page, the web part will display links to favorite posts of the current user. You can see the appearance of the web part with two favorite posts in the screenshot below.

8.26.13 Friendly URLs

Forums display content based on the current values of the **forumid** and **threadid** query string parameters. By default, the URL of a forum thread might look like the following:

- **<domain>/Forums.aspx?forumid=3&threadid=12**

A friendly URL of the same forum thread looks like the following:

- `<domain>/Forums/f4/t13/Frequently-asked-questions.aspx`

Having your forum URLs in this format is a good practice when it comes to SEO (Search Engine Optimization).

Enabling friendly URLs

For this to be enabled, you have to do the following two tasks:

1. Set the following properties of the **Forum group** web part:

- **Use friendly URLs** - check to enable the Friendly URLs feature.
- **Friendly base URL** - enter the base part of the URL, which is displayed after the domain name, e.g. `/Forums` for the example above and for the document aliases listed below.
- **URL extension** - extension that will be used at the end of the friendly URL.

2. Assign the following [document aliases](#) to the document containing the Forum group web part. The `/Forums` part of each alias must be equal to the value in the **Friendly base URL** property of the Forum group web part:

- `/Forums/{forumid}/{whatever}`
- `/Forums/{forumid}/fp{fpage}/{whatever}`
- `/Forums/{forumid}/t{threadid}/{whatever}`
- `/Forums/{forumid}/fp{fpage}/t{threadid}/{whatever}`
- `/Forums/{forumid}/t{threadid}/tp{tpage}/{whatever}`
- `/Forums/{forumid}/fp{fpage}/t{threadid}/tp{tpage}/{whatever}`

Single forum friendly URLs

If you want to enable friendly URLs for a [single forum](#), the **Forum (Single forum - General)** web part should be set the same way as described in step 1, but only the following two document aliases need to be added to the document:

- `/Forums/t{threadid}/{whatever}`
- `/Forums/t{threadid}/tp{tpage}/{whatever}`

8.26.14 Customizing forum design

Forum layouts are stored in `<web project>\CMSModules\Forums\Controls\Layouts`. The folder contains three sub-folders by default.

| ↑ Name | Ext | Size |
|--|-----|-------|
|  [..] | | <DIR> |
|  [Custom] | | <DIR> |
|  [Flat] | | <DIR> |
|  [Tree] | | <DIR> |

The **Flat** and **Tree** folders contain controls for the identically named layouts. The **Custom** folder can be used for defining custom layouts.

To **create a custom layout**, you need to create a sub-folder inside the **Custom** folder. The name of this sub-folder will be used as the name of the layout. The sub-folder has to contain controls with the same

names as included in the Flat or Tree folders. You can see a screenshot of these files below. When writing the controls' code, make sure that they inherit from **ForumViewer**.

| ↑ Name | Ext |
|-----------------------|------|
| ↑ [..] | |
| Attachments | ascx |
| Attachments.ascx | cs |
| Forums | ascx |
| Forums.ascx | cs |
| SearchResults | ascx |
| SearchResults.ascx | cs |
| SubscriptionEdit | ascx |
| SubscriptionEdit.ascx | cs |
| Thread | ascx |
| Thread.ascx | cs |
| ThreadEdit | ascx |
| ThreadEdit.ascx | cs |
| Threads | ascx |
| Threads.ascx | cs |

8.26.15 Security

The security model of the Forums module has two parts:

1. Security of the Forums module administration interface.
2. Security of the forums published on the website.

Forums module administration interface

Access to the Forums module administration interface in **CMS Desk -> Tools** can be managed in the **Modules -> Forums** permission matrix at **CMS Site Manager -> Administration -> Permissions** (or **CMS Desk -> Administration -> Permissions**; only applies to the current site):

- **Modify** - allows users to modify forum settings
- **Read** - allows users to only read forum settings

Users without any permissions who are moderators of at least one forum are allowed to access the **Posts waiting for my approval** dialog only.

 **Permissions**

Site:

Permissions for:

Report for user: Show only this user's roles

| Role | Read | Modify |
|------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Editors | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Readers | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> |
| Facebook users | <input type="checkbox"/> | <input type="checkbox"/> |
| Gold Partners | <input type="checkbox"/> | <input type="checkbox"/> |
| LinkedIn users | <input type="checkbox"/> | <input type="checkbox"/> |
| Live ID users | <input type="checkbox"/> | <input type="checkbox"/> |
| Marketing Manager | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Not authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |
| OpenID users | <input type="checkbox"/> | <input type="checkbox"/> |
| Silver Partners | <input type="checkbox"/> | <input type="checkbox"/> |

Security of forums published on a website

If you **Edit** () some forum and switch to its **Security** tab, the permission matrix displayed in the screenshot below will be displayed.

Columns of the matrix represent the following actions:

- **Access to forum** - defines who can enter the forum and view posts
- **Attach files** - defines who can attach files to forum posts
- **Mark as answer** - defines who can mark posts as answers in Question - Answer forums
- **Post** - defines who can add posts to the forum
- **Reply** - defines who can reply to forum posts
- **Subscribe** - defines who can subscribe for receiving notifications about new posts in the forum

Rows in the top part of the matrix have the following meanings:

- **Nobody** - the action can't be performed by anyone
- **All users** - anybody can perform the action
- **Authenticated users** - only signed-in registered users can perform the action
- **Authorized roles** - only members of roles specified in the lower part of the matrix can perform the action

Below the permission matrix, there is one more check-box:

Allow user to change the name - if checked, users can change their name displayed with a forum post when entering the post; if unchecked, their user name will be used

| | Access to forum | Attach files | Mark as answer | Post | Reply | Subscribe |
|---------------------|----------------------------------|----------------------------------|----------------------------------|----------------------------------|----------------------------------|----------------------------------|
| Nobody | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| All users | <input checked="" type="radio"/> | <input type="radio"/> | <input checked="" type="radio"/> | <input checked="" type="radio"/> | <input type="radio"/> | <input checked="" type="radio"/> |
| Authenticated users | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Authorized roles | <input type="radio"/> | <input checked="" type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input checked="" type="radio"/> | <input type="radio"/> |

Please select the authorized roles (available only when you select the "Authorized roles" option above):

| | Access to forum | Attach files | Mark as answer | Post | Reply | Subscribe |
|------------------------------|--------------------------|-------------------------------------|--------------------------|--------------------------|-------------------------------------|--------------------------|
| Authenticated users | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Editors | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Readers | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Facebook users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Gold Partners | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| LinkedIn users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Live ID users | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Marketing Manager | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

The following properties of the **Forum group** web part are also related to forum security:

- **Hide forum to unauthorized users** - indicates whether forums for which the user has no permissions are visible for them in the list of forums in a forum group
- **Redirect unauthorized users** - determines whether to redirect unauthorized users to the logon page or whether to display only an info message
- **Access denied page URL** - URL where the user is redirected when trying to access forum for which they are not authorized

8.26.16 Settings

Settings of the Forums module are located in **Site Manager -> Settings -> Community-> Forums**. The following settings are available:

- **Send forum e-mails from** - sets the e-mail address that will be used as the sender for forum notifications and confirmation e-mails.
- **Forum base URL** - this setting should contain the relative URL of the page where the website's forums are located, for example `~/Community/Forum.aspx`. Forum groups and individual forums can either inherit this value from the settings or use their own. Having a correct base URL is important for generating valid links in forum-related e-mails.
- **Forum attachments allowed extensions** - allows you to specify a list of file extensions that will be allowed for forum post attachments. The extensions should be entered without dots and separated by semicolons. If blank, all extensions are allowed.
- **Max forum post nodes** - determines the maximum number of forum post nodes displayed in the forum post tree when editing a forum in *CMS Desk* -> *Tools* -> *Forums*. If there are more nodes than allowed by this value, the *click here for more...* link will be displayed at the bottom of the tree, letting you display a list of all nodes in the main area.
- **Forum unsubscription URL** - sets the URL of the page that unsubscribes users from receiving notifications about new forum posts. The [Forum unsubscription](#) web part must be placed on the page in order for the unsubscriptions to work. The value of this setting can be inherited by forum groups and through them by particular child forums. If left empty, the `~/CMSPages/Unsubscribe.aspx`

system page is used.

- **Enable double opt-in for forums** - indicates if double opt-in should be enabled for forum objects. When enabled, users are required to confirm their subscription by clicking a link that is sent to them in an e-mail.
- **Double opt-in approval page path** - path to the page that contains the Forum subscription confirmation web part. The subscription confirmation link that will be sent to users will point to this page.
- **Double opt-in interval (hours)** - amount of time in hours, during which a user has to confirm their subscription request.
- **Send double opt-in confirmation** - indicates if an e-mail confirmation should be sent to user after they approve a subscription. If double opt-in is disabled, these confirmation e-mails are always sent.

8.26.17 Forums internals and API

8.26.17.1 Overview

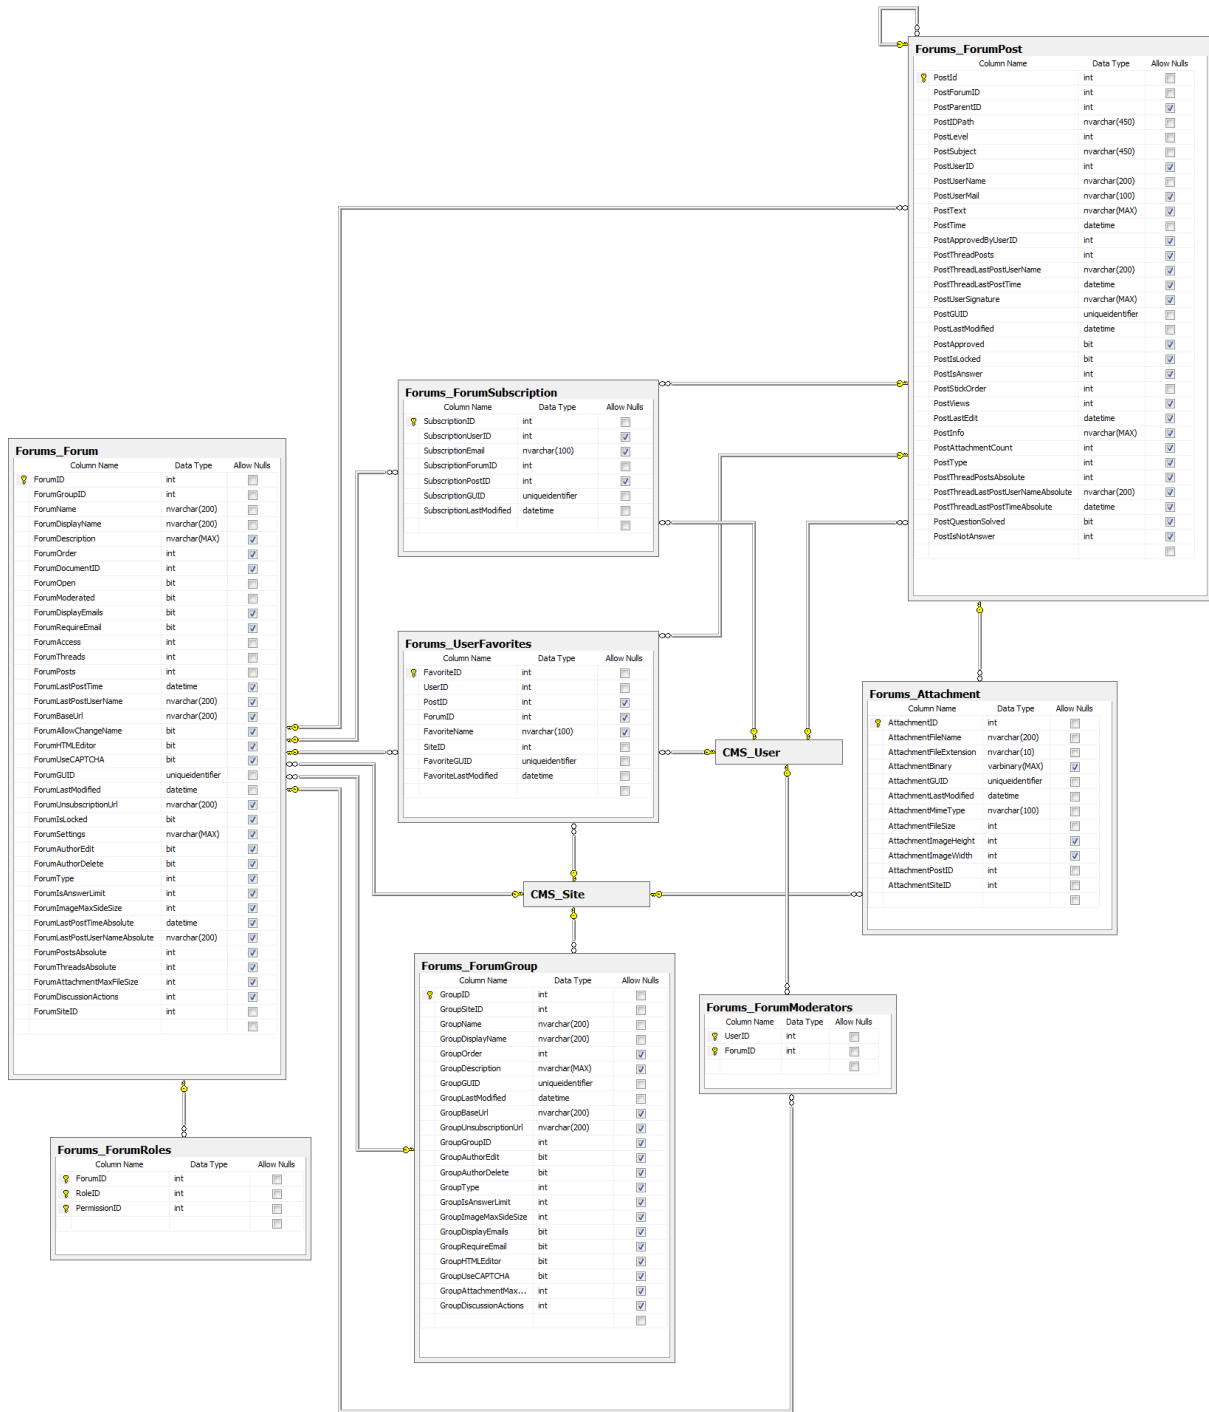

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Forums module. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the module's classes, please refer to [Kentico CMS API Reference](#).

8.26.17.2 Database tables

The following database tables are used to store information about forums and their content:

- **Forums_ForumGroup** - contains records representing forums groups and their settings.
- **Forums_Forum** - contains records representing individual forums and their settings.
- **Forums_ForumPost** - contains records of forum posts and their content.
- **Forums_ForumModerators** - stores relationships between forums and users. Each entry in this table indicates that a user is a moderator of a specific forum.
- **Forums_ForumRoles** - stores relationships between forums and roles as well as a permission type. Each entry in this table indicates that users of the given role have the specified permission for a forum.
- **Forums_ForumSubscription** - stores information about user subscriptions to forums.
- **Forums_Attachment** - contains records representing forum post attachments.
- **Forums_UserFavorites** - stores relationships between users and the forums or posts marked by them as favorite.

8.26.17.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

**Please note**

The classes of the Forums module can be found in the **CMS.Forums** namespace.

Forums_ForumGroup table API:

- **ForumGroupInfo** - represents one forum group object.
- **ForumGroupInfoProvider** - provides management functionality for forum groups.

Forums_Forum table API:

- **ForumInfo** - represents one forum object.
- **ForumInfoProvider** - provides management functionality for forums.

Forums_ForumPost table API:

- **ForumPostInfo** - represents one forum post.
- **ForumPostInfoProvider** - provides management functionality for forum posts.

Forums_ForumModerator table API:

- **ForumModeratorInfo** - represents a relationship between a user and a forum, indicating that the user is the forum's moderator.
- **ForumModeratorInfoProvider** - provides management functionality for user-forum moderator relationships.

Forums_ForumRoles table API:

- **ForumRoleInfo** - represents a relationship between a forum, role and permission.
- **ForumRoleInfoProvider** - provides management functionality for forum-role relationships.

Forums_ForumSubscription table API:

- **ForumSubscriptionInfo** - represents a subscription of a user to a forum.
- **ForumSubscriptionInfoProvider** - provides management functionality for forum subscriptions.

Forums_Attachment table API:

- **ForumAttachmentInfo** - represents one forum post attachment.
- **ForumAttachmentInfoProvider** - provides management functionality for forum post attachments.

Forums_UserFavorites table API:

- **ForumUserFavoritesInfo** - represents a relationship between a user and a forum or post marked as favorite.
- **ForumUserFavoritesInfoProvider** - provides management functionality for forum favorites.

Other classes:

- **ForumContext** - provides forum-related information for the current user.

8.26.17.4 API examples

8.26.17.4.1 Overview

These topics show examples of how the API of the Forums module can be used:

- [Managing forum groups](#)
- [Managing forums](#)
- [Managing forum posts](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Community\Forums\Default.aspx.cs**.

The forum API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.Forums;
```

8.26.17.4.2 Managing forum groups

The following example creates a forum group.

```
private void CreateForumGroup()
{
    // Create new forum group object
    ForumGroupInfo newGroup = new ForumGroupInfo();

    // Set the properties
    newGroup.GroupDisplayName = "My new group";
    newGroup.GroupName = "MyNewGroup";
    newGroup.GroupSiteID = CMSContext.CurrentSiteID;
    newGroup.GroupAuthorDelete = true;
    newGroup.GroupAuthorEdit = true;
    newGroup.GroupDisplayEmails = true;
}
```

```
// Save the forum group
ForumGroupInfoProvider.SetForumGroupInfo(newGroup);
}
```

The following example gets and updates a forum group.

```
private bool GetAndUpdateForumGroup()
{
    // Get the forum group
    ForumGroupInfo updateGroup = ForumGroupInfoProvider.GetForumGroupInfo
("MyNewGroup", CMSContext.CurrentSiteID);
    if (updateGroup != null)
    {
        // Update the properties
        updateGroup.GroupDisplayName = updateGroup.GroupDisplayName.ToLower();

        // Save the changes
        ForumGroupInfoProvider.SetForumGroupInfo(updateGroup);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates forum groups.

```
private bool GetAndBulkUpdateForumGroups()
{
    // Prepare the parameters
    string where = "GroupName LIKE N'MyNewGroup%'";
    string orderBy = "";
    string columns = "";
    int topN = 10;

    // Get the data
    DataSet groups = ForumGroupInfoProvider.GetGroups(where, orderBy, topN,
columns);
    if (!DataHelper.DataSourceIsEmpty(groups))
    {
        // Loop through the individual items
        foreach (DataRow groupDr in groups.Tables[0].Rows)
        {
            // Create object from DataRow
            ForumGroupInfo modifyGroup = new ForumGroupInfo(groupDr);

            // Update the properties
            modifyGroup.GroupDisplayName = modifyGroup.GroupDisplayName.ToUpper();

            // Save the changes
        }
    }
}
```

```
        ForumGroupInfoProvider.SetForumGroupInfo(modifyGroup);
    }

    return true;
}

return false;
}
```

The following example deletes a forum group.

```
private bool DeleteForumGroup()
{
    // Get the forum group
    ForumGroupInfo deleteGroup = ForumGroupInfoProvider.GetForumGroupInfo
("MyNewGroup", CMSContext.CurrentSiteID);

    // Delete the forum group
    ForumGroupInfoProvider.DeleteForumGroupInfo(deleteGroup);

    return (deleteGroup != null);
}
```

8.26.17.4.3 Managing forums

The following example creates a forum.

```
private bool CreateForum()
{
    // Get the forum group
    ForumGroupInfo group = ForumGroupInfoProvider.GetForumGroupInfo("MyNewGroup",
CMSContext.CurrentSiteID);

    if (group != null)
    {
        // Create new forum object
        ForumInfo newForum = new ForumInfo();

        // Set the properties
        newForum.ForumDisplayName = "My new forum";
        newForum.ForumName = "MyNewForum";
        newForum.ForumGroupID = group.GroupID;
        newForum.ForumSiteID = group.GroupSiteID;
        newForum.AllowAccess = SecurityAccessEnum.AllUsers;
        newForum.AllowAttachFiles = SecurityAccessEnum.AuthenticatedUsers;
        newForum.AllowPost = SecurityAccessEnum.AllUsers;
        newForum.AllowReply = SecurityAccessEnum.AllUsers;
        newForum.AllowSubscribe = SecurityAccessEnum.AllUsers;
        newForum.ForumOpen = true;
        newForum.ForumModerated = false;
    }
}
```

```
        newForum.ForumThreads = 0;
        newForum.ForumPosts = 0;

        // Save the forum
        ForumInfoProvider.SetForumInfo(newForum);

        return true;
    }

    return false;
}
```

The following example gets and updates a forum.

```
private bool GetAndUpdateForum()
{
    // Get the forum
    ForumInfo updateForum = ForumInfoProvider.GetForumInfo("MyNewForum",
CMSContext.CurrentSiteID);
    if (updateForum != null)
    {
        // Update the properties
        updateForum.ForumDisplayName = updateForum.ForumDisplayName.ToLower();

        // Save the changes
        ForumInfoProvider.SetForumInfo(updateForum);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates forums.

```
private bool GetAndBulkUpdateForums()
{
    // Prepare the parameters
    string where = "ForumName LIKE N'MyNewForum%'";
    string orderBy = "";
    string columns = "";
    int topN = 10;

    // Get the data
    DataSet forums = ForumInfoProvider.GetForums(where, orderBy, topN, columns);
    if (!DataHelper.DataSourceIsEmpty(forums))
    {
        // Loop through the individual items
        foreach (DataRow forumDr in forums.Tables[0].Rows)
        {
            // Create object from DataRow
        }
    }
}
```

```
        ForumInfo modifyForum = new ForumInfo(forumDr);

        // Update the properties
        modifyForum.ForumDisplayName = modifyForum.ForumDisplayName.ToUpper();

        // Save the changes
        ForumInfoProvider.SetForumInfo(modifyForum);
    }

    return true;
}

return false;
}
```

The following example deletes a forum.

```
private bool DeleteForum()
{
    // Get the forum
    ForumInfo deleteForum = ForumInfoProvider.GetForumInfo("MyNewForum",
CMSContext.CurrentSiteID);

    // Delete the forum
    ForumInfoProvider.DeleteForumInfo(deleteForum);

    return (deleteForum != null);
}
```

8.26.17.4.4 Managing forum posts

The following example creates a forum post.

```
private bool CreateForumPost()
{
    // Get the forum
    ForumInfo forum = ForumInfoProvider.GetForumInfo("MyNewForum",
CMSContext.CurrentSiteID);
    if (forum != null)
    {
        // Create new forum post object
        ForumPostInfo newPost = new ForumPostInfo();

        // Set the properties
        newPost.PostUserID = CMSContext.CurrentUser.UserID;
        newPost.PostUserMail = CMSContext.CurrentUser.Email;
        newPost.PostUserName = CMSContext.CurrentUser.UserName;
        newPost.PostForumID = forum.ForumID;
        newPost.PostTime = DateTime.Now;
        newPost.PostApproved = true;
    }
}
```

```
newPost.PostText = "This is my new post";
newPost.PostSubject = "My new post";

// Save the forum post
ForumPostInfoProvider.SetForumPostInfo(newPost);

return true;
}

return false;
}
```

The following example gets and updates a forum post.

```
private bool GetAndUpdateForumPost()
{
    // Prepare the parameters
    string where = "PostSubject LIKE N'My new post%'";
    string orderBy = "";
    string columns = "";
    int topN = 10;

    // Get the data
    DataSet posts = ForumPostInfoProvider.GetForumPosts(where, orderBy, topN,
columns);
    if (!DataHelper.DataSourceIsEmpty(posts))
    {
        ForumPostInfo updatePost = new ForumPostInfo(posts.Tables[0].Rows[0]);

        // Update the properties
        updatePost.PostSubject = updatePost.PostSubject.ToLower();

        // Save the changes
        ForumPostInfoProvider.SetForumPostInfo(updatePost);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates forum posts.

```
private bool GetAndBulkUpdateForumPosts()
{
    // Prepare the parameters
    string where = "PostSubject LIKE N'My new post%'";
    string orderBy = "";
    string columns = "";
    int topN = 10;
```

```
// Get the data
DataSet posts = ForumPostInfoProvider.GetForumPosts(where, orderBy, topN,
columns);
if (!DataHelper.DataSourceIsEmpty(posts)
{
    // Loop through the individual items
    foreach (DataRow postDr in posts.Tables[0].Rows)

    {
        // Create object from DataRow
        ForumPostInfo modifyPost = new ForumPostInfo(postDr);

        // Update the properties
        modifyPost.PostSubject = modifyPost.PostSubject.ToUpper();

        // Save the changes
        ForumPostInfoProvider.SetForumPostInfo(modifyPost);
    }

    return true;
}

return false;
}
```

The following example deletes a forum post.

```
private bool DeleteForumPost()
{
    // Prepare the parameters
    string where = "PostSubject LIKE N'My new post%'";
    string orderBy = "";
    string columns = "";
    int topN = 10;

    // Get the data
    DataSet posts = ForumPostInfoProvider.GetForumPosts(where, orderBy, topN,
columns);
    if (!DataHelper.DataSourceIsEmpty(posts))
    {
        // Get the forum post
        ForumPostInfo deletePost = new ForumPostInfo(posts.Tables[0].Rows[0]);

        // Delete the forum post
        ForumPostInfoProvider.DeleteForumPostInfo(deletePost);

        return true;
    }

    return false;
}
```

8.27 Friends

8.27.1 Overview

The Friends module is one of the social-networking features of Kentico CMS. It allows you to add the Facebook-style friendship functionality to your site. The module enables registered website users to request another user's friendship. When the friendship gets approved by the second user, the two users become friends. The process of requesting a friendship is described in the [Requesting friendships](#) topic. Requests are sent to users based on e-mail templates, which are listed and described in the [Related e-mail templates](#) topic.

Management of friendships can be performed either by the users themselves, or by the site administrators. Both options are described in the [Friends management](#) topic. Users can manage only their own friendships, while users with appropriate permissions (described in the [Security](#) topic) can manage friendships of all users in the system.

The module comes with several web parts. Using these, you can add the friendship management functionality to the live site. All web parts related to the module are listed in the [Available web parts](#) topic.

By default, becoming friends brings just some improvements to the way the users can communicate and publish details about themselves, as described in the [Examples of use](#) topic. However, the friendship functionality may be leveraged largely in your custom code, enabling you to use these relationships between users for your specific purposes.

In the [Friends internals and API](#) sub-chapter, you can find information about database tables and classes that are used by the Friends module, as well as several examples of how friendships can be managed using Kentico CMS API.

8.27.2 Requesting friendships

How to make the request?

There are several ways how users can request other users' friendship:

Context menus

As described in [Development -> Document types and transformations -> Context menus in transformations](#), the **Users viewer** web part may be equipped with a context menu when an appropriately written transformation is used. This context menu contains the **Add as friend** option, enabling registered website users to request this user's friendship.

Request friendship and My friends web parts

The **Request friendship** web part is just a tiny link with customizable text. Clicking it opens the **Add a new friend** pop-up dialog.

[Request friendship](#)

Requesting friendships on the live site is also possible via the **My friends** web part. It contains the **Add a friend** link, which opens the same **Add a new friend** dialog mentioned above.

My pending requests Rejected friends **My friends**

[Add a friend](#)

CMS Desk -> My Desk -> Friends

Users with access to **CMS Desk** can request friendships from within **My desk -> Friends**. Here again, they can find the **Add a friend** button, which opens the **Add a new friend** dialog.

|--------------------------|---------|-----------|--------------|----------|---------|
| <input type="checkbox"/> | | David | David Silver | David | |
| <input type="checkbox"/> | | Kelly | Kelly Taylor | Kelly | |

Add a new friend dialog

After clicking one of the options mentioned above, the **Add a new friend** dialog appears. In the dialog, you can specify the following:

- **User** - the user whose friendship you are requesting. This options is not available when requesting a friendship from the context menu as friendship of the user whose context menu was displayed is requested in this case.
- **Comment** - comment sent to the user along with the friendship request.
- **Send e-mail** - the user will be notified by a standard e-mail message.
- **Send message** - the user will be notified by a Messaging module message.
- **Automatically approve** - global administrators and users with the **Manage** permission for the Friends module can use this check-box, which creates the requested friendship without the other user's approval; not available on the live site.

In case that the **Send e-mail** or **Send message** options are enabled, the **Friends - Friend request** e-mail template mentioned in the section below is used for the notification e-mail or Messaging module message. When the **Automatically approve** option is enabled along with the previously mentioned ones, the **Friends - Friend approval** template is used.

8.27.3 Related e-mail templates

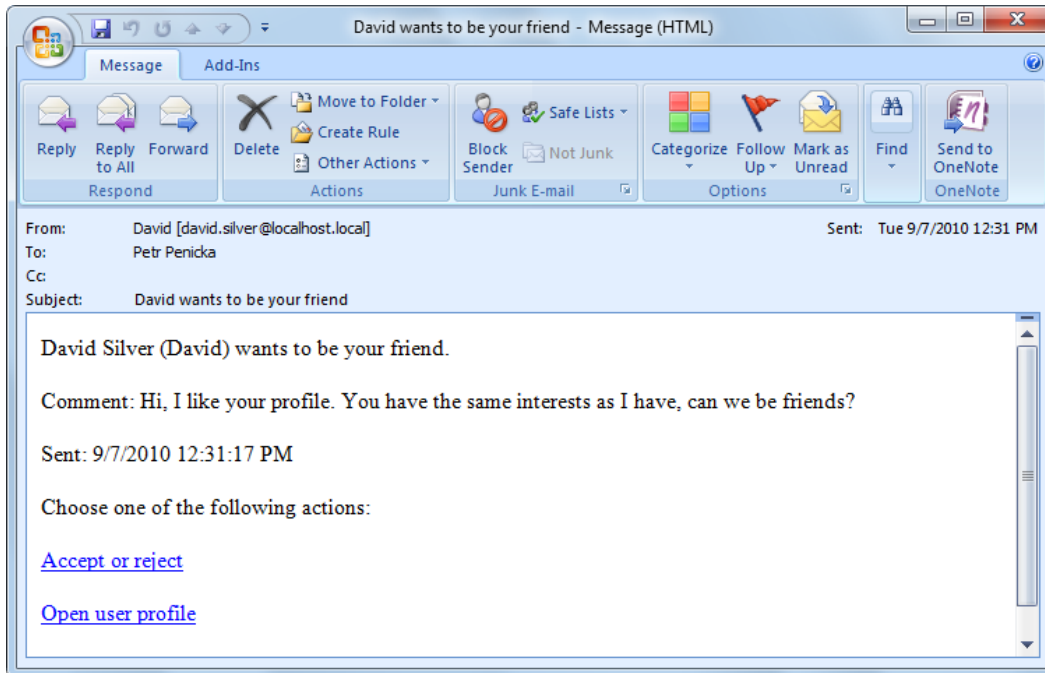

In **Site manager -> Administration -> E-mail templates**, you can find the following e-mail templates related to the Friends module:

- **Friends - Friend approval** - template for e-mail or message confirming that a user approved your friendship request.
- **Friends - Friend rejection** - template for e-mail or message confirming that a user rejected your friendship request.
- **Friends - Friend request** - template for e-mail or message notifying you about the fact that some user requested your friendship.

If you choose to **Edit** (✎) some of the templates, you will see two large text fields:

- **Text** - text of the template used for e-mails.
- **Plain text** - text of the template used for [Messaging](#) module messages.

Links in these e-mails need to be handled by a special page containing the **Friendship management** web part, which is a special web part that ensures handling of these requests.

Macros in friendship e-mail templates

In both fields, you can use the following specific [context macros](#) to include dynamic values in their text:

- **{% managementurl %}** - returns the friendship management page URL. See **Friend management path** in [Settings](#) for more details.
- **{% profileurl %}** - returns URL of the user who requested the friendship.
- **{% formattedsendername %}** - returns the name of the user who is requesting the friendship in format *username (fullname)*.
- **{% formattedrecipientname %}** - returns the name of the user whose friendship is being requested in format *username (fullname)*.

You can also access the following objects and their properties (e.g. `{% Sender.UserName %}`):

- **{% Sender %}** - *UserInfo* object of the user who is requesting the friendship.
- **{% Recipient %}** - *UserInfo* object of the user whose friendship is being requested.
- **{% Friendship %}** - *FriendInfo* object containing information about the current friendship.

Besides these special ones, you can also use all other standard macro expressions in the templates. See the [Development -> Macro expressions](#) chapter of this guide for more information about macro expressions in Kentico CMS.

8.27.4 Friends management

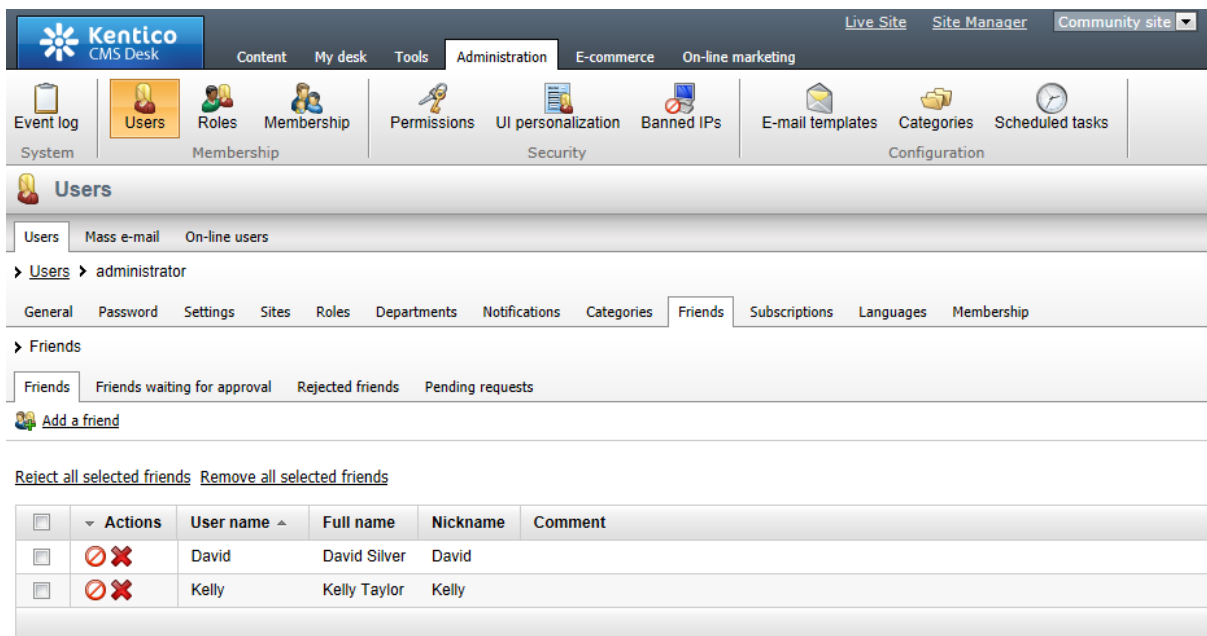

Users with access to **CMS Desk -> My desk -> Friends** can manage their own friendships from within this section of the administration interface.

Site administrators can manage all users' friends in both **CMS Desk** and **Site Manager**, in the **Administration -> Users** section, after choosing **Edit** (✎) next to some user and switching to their **Friends** tab.

In both cases, the four tabs described below are available. On the live site, the same functionality can be provided by the web parts described in the [Available web parts](#) topic.

Friends (My friends)

On this tab, you can see a list of all your current friends. New friendships can be requested using  **Add a friend**. You also can **Remove** (✖) or **Reject** (🚫) friends in the list. The difference between the two is that rejected friends can't request your friendship anymore while they are in the rejected status, while removed friends can request the friendship again. By checking some of the check-boxes and clicking one of the **Reject all selected friends** and **Remove all selected friends** buttons, you can reject or remove more friends at once.

The screenshot shows the Kentico CMS Desk Administration interface. The top navigation bar includes 'Live Site', 'Site Manager', and 'Community site'. The main navigation menu has 'Administration' selected. Below it, the 'Users' section is active, with 'Friends' selected in the sub-menu. The interface includes buttons for 'Add a friend', 'Reject all selected friends', and 'Remove all selected friends'. A table lists two users: David Silver and Kelly Taylor, both with 'Reject' and 'Remove' icons.

| <input type="checkbox"/> | Actions | User name | Full name | Nickname | Comment |
|--------------------------|---|-----------|--------------|----------|---------|
| <input type="checkbox"/> |   | David | David Silver | David | |
| <input type="checkbox"/> |   | Kelly | Kelly Taylor | Kelly | |

Friends waiting for approval (Friends waiting for my approval)

On this tab, you can see a list of all users who requested your friendship. You can either **Approve** (✔) or **Reject** (🚫) their request. By checking some of the check-boxes and clicking one of the **Approve all selected friends** and **Reject all selected friends** links, you can approve or reject more requests at once.

The screenshot shows the Kentico CMS Administration interface. The top navigation bar includes 'Live Site', 'Site Manager', and 'Community site'. The main menu has 'Administration' selected. Below the menu, there are icons for 'Event log', 'Users', 'Roles', 'Membership', 'Permissions', 'UI personalization', 'Banned IPs', 'E-mail templates', 'Categories', and 'Scheduled tasks'. The 'Users' section is active, showing 'Users', 'Mass e-mail', and 'On-line users' tabs. The 'Users' > 'administrator' path is shown. The 'Friends' tab is selected, showing 'Friends', 'Friends waiting for approval', 'Rejected friends', and 'Pending requests' sub-tabs. The 'Rejected friends' sub-tab is active, displaying a table of rejected users.

| <input type="checkbox"/> | Actions | User name ^ | Full name | Nickname | Comment |
|--------------------------|--|-------------|---------------|----------|---------|
| <input type="checkbox"/> | <input checked="" type="checkbox"/> <input type="checkbox"/> | Josh | Joshua O'Neil | Josh | |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> <input type="checkbox"/> | Turbo | Noel Turpin | Turbo | |

Rejected friends

On this tab, you can see a list of all users whose friendship you rejected. Once in the rejected status, the user can't request your friendship anymore. You can either **Approve** (✓) some user's friendship, which makes them your friend, or **Remove** (✗) the user from the list of rejected, which enables them to request your friendship again. By checking some of the check-boxes and clicking one of the **Approve all selected friends** or **Remove all selected friends**, you can approve or remove more users at once.

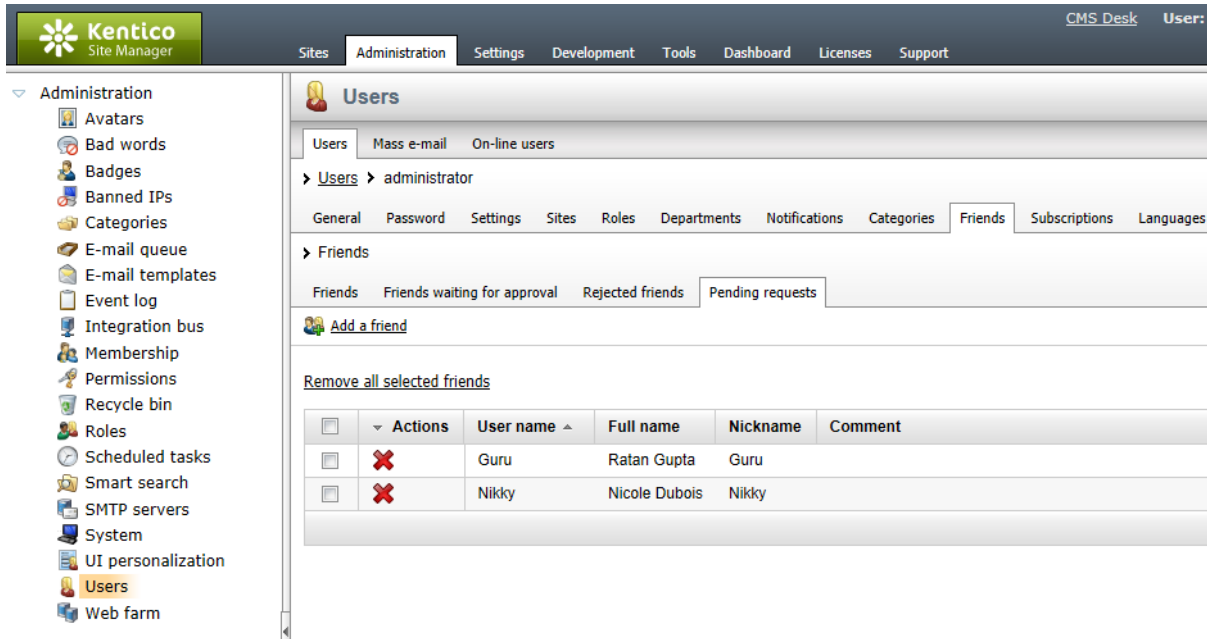

The screenshot shows the Kentico CMS Administration interface. The top navigation bar includes 'CMS Desk' and 'User:'. The main menu has 'Administration' selected. Below the menu, there are icons for 'Avatars', 'Bad words', 'Badges', 'Banned IPs', 'Categories', 'E-mail queue', 'E-mail templates', 'Event log', 'Integration bus', 'Membership', 'Permissions', 'Recycle bin', 'Roles', 'Scheduled tasks', 'Smart search', 'SMTP servers', 'System', 'UI personalization', 'Users', and 'Web farm'. The 'Users' section is active, showing 'Users', 'Mass e-mail', and 'On-line users' tabs. The 'Users' > 'administrator' path is shown. The 'Friends' tab is selected, showing 'Friends', 'Friends waiting for approval', 'Rejected friends', and 'Pending requests' sub-tabs. The 'Rejected friends' sub-tab is active, displaying a table of rejected users with comments.

| <input type="checkbox"/> | Actions | User name ^ | Full name | Nickname | Comment |
|--------------------------|---|-------------|---------------|----------|-----------------------------------|
| <input type="checkbox"/> | <input checked="" type="checkbox"/> <input checked="" type="checkbox"/> | Josh | Joshua O'Neil | Josh | I don't like you |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> <input checked="" type="checkbox"/> | Turbo | Noel Turpin | Turbo | You are my enemy not my friend!!! |

Pending requests (My pending requests)

On this tab, you can see a list of friends whose friendship you requested. New friendships can be requested using **Add a friend**. You can cancel a request by clicking the **Remove** (✗) icon or you can

select more users using the check-boxes and click the **Remove all selected friends** link, which cancels more friendship requests at once.

8.27.5 Available web parts

The Friends module comes with the following web parts. All of them are located in the **Community -> Friends** web part category. This page brings just a brief overview of them. For a detailed description of each web part's properties please see [Kentico CMS Web parts reference](#).

Friends viewer

This web part can typically be used on user's profile page for viewing their friends. If you right-click the user's avatar image, you will be offered several tasks, as you can see in the screenshot below.

The following web parts are actually on-site equivalents of the friends management administration interface described in the [Friends management](#) topic:

Friends list

This web part displays a list of all friends of the current user.

[Reject all selected friends](#) [Remove all selected friends](#)

| <input type="checkbox"/> | Actions | User name ^ | Full name | Nickname | Comment | Approved |
|--------------------------|---|-------------|--------------|----------|---------|-----------------------|
| <input type="checkbox"/> |   | Kelly | Kelly Taylor | Kelly | | 12/18/2008 6:42:46 PM |
| <input type="checkbox"/> |   | Tessie | Iman Teshome | Tessie | | 11/21/2008 3:41:16 PM |

Items per page: 25 ▼

Friends waiting for approval

This web part displays a list of all users waiting for the current user's friendship approval.

[Approve all selected friends](#) [Reject all selected friends](#)

| <input type="checkbox"/> | Actions | User name ^ | Full name | Nickname | Comment | Requested |
|--------------------------|---|-------------|--------------|----------|---------|-----------------------|
| <input type="checkbox"/> |   | Mia | Mia Lee | Mia | | 9/13/2010 12:44:49 PM |
| <input type="checkbox"/> |   | Tessie | Iman Teshome | Tessie | | 9/13/2010 12:44:36 PM |

Items per page: 25 ▼

Rejected friends

This web part displays a list of all users whose friendship the current user rejected. These users can't request the current user's friendship while they are in this list.

[Approve all selected friends](#) [Remove all selected friends](#)

| <input type="checkbox"/> | Actions | User name ^ | Full name | Nickname | Comment | Rejected |
|--------------------------|---|-------------|---------------|----------|------------------------------------|-----------------------|
| <input type="checkbox"/> |   | Josh | Joshua O'Neil | Josh | I don't like you | 9/13/2010 12:30:40 PM |
| <input type="checkbox"/> |   | Turbo | Noel Turpin | Turbo | you are my enemy, not my friend!!! | 9/13/2010 12:31:26 PM |

Items per page: 25 ▼

My pending requests

This web part displays a list of all users whose friendship the current user requested.

[Remove all selected friends](#)

| <input type="checkbox"/> | Actions | User name ^ | Full name | Nickname | Comment | Status |
|--------------------------|---|-------------|---------------|----------|---------|---------|
| <input type="checkbox"/> |  | Guru | Ratan Gupta | Guru | | Waiting |
| <input type="checkbox"/> |  | Nikky | Nicole Dubois | Nikky | | Waiting |

Items per page: 25 ▼

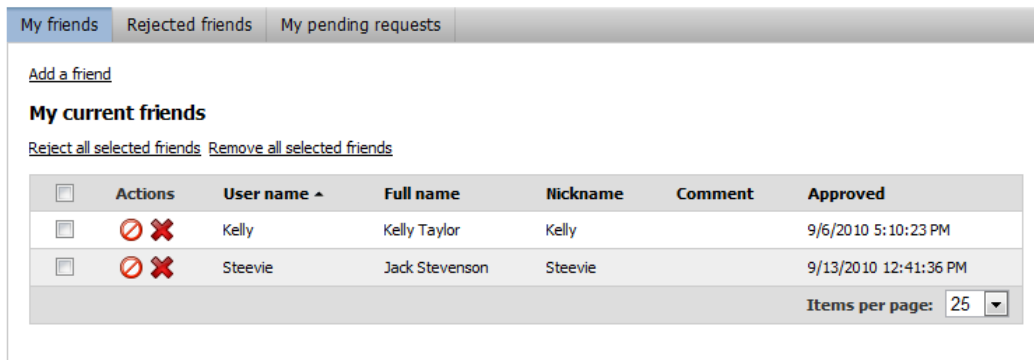

Request friendship

This web part displays only a link that, when clicked, opens the **Add a new friend** dialog.

[Request friendship](#)

My friends

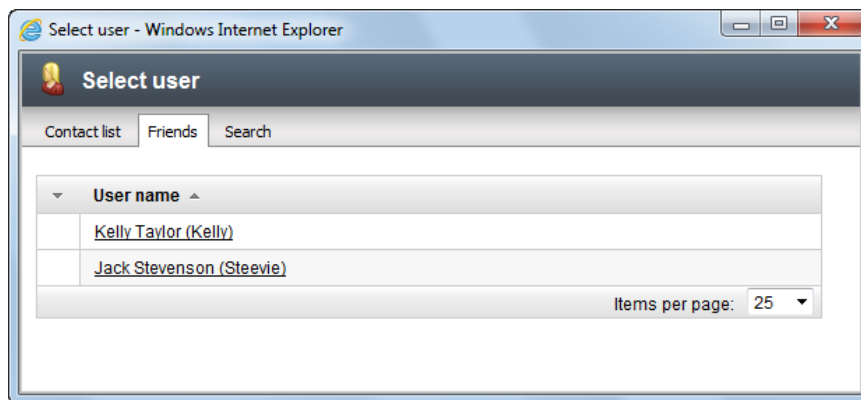

This web part combines the five previously mentioned web parts in one single web part. It's functionality is fully equal to the UI in **CMS Desk -> My Desk -> Friends**.

8.27.6 Examples of use

Messaging module

When selecting a recipient of a messaging module message, you can conveniently switch to the **Friends** tab and select one of your friends just by clicking their user name.

Fields visibility

Users can set the visibility of some fields on their public profile to **Display to friends**, which makes the field visible only to their friends. For more information on this feature, please refer to [Development -> Membership, security and permissions -> Custom fields visibility](#).

8.27.7 Security

Permissions of the Friends module can be set in both **Site manager** and **CMS Desk**, in the **Administration -> Permissions** section. There, you need to select the **Modules -> Friends** permission matrix.

The following permissions can be assigned to particular roles:

- **Manage** - members of the role can manage Friends of particular users in *CMS Desk -> Administration -> Users*
- **Read** - members of the role can view friends of particular users in *CMS Desk -> Administration -> Users*

 **Permissions**

Site:

Permissions for:

Report for user: Show only this user's roles

| Role | Read | Manage |
|------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Editors | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Readers | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> |
| Facebook users | <input type="checkbox"/> | <input type="checkbox"/> |
| Gold Partners | <input type="checkbox"/> | <input type="checkbox"/> |
| LinkedIn users | <input type="checkbox"/> | <input type="checkbox"/> |
| Live ID users | <input type="checkbox"/> | <input type="checkbox"/> |
| Marketing Manager | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Not authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |
| OpenID users | <input type="checkbox"/> | <input type="checkbox"/> |
| Silver Partners | <input type="checkbox"/> | <input type="checkbox"/> |

8.27.8 Settings

The following two settings available in **Site Manager -> Settings -> Community** are related to the Friends module:

| | |
|------------------------|--|
| Enable friends | Indicates if the Friends functionality should be available in other modules on the live site. |
| Friend management path | <p>Node alias path of the page on that the Friendship management web part is placed. This is a special web part that handles friendship management actions from friendship request e-mails.</p> <p>If some user receives an e-mail with friendship request, there are links for friendship approval or rejection included in the mail. When the user clicks one of the links, they are redirected to this page and the user guid and type of action is transferred in form of querystring parameters. The Friendship management web part processes the received parameters and performs the necessary tasks for friendship approval or rejection.</p> <p>On the Community Starter Site, the <i>Special-pages/Friend-management</i> page serves exactly this purpose. More information on how such page can be created can be found in Community Site Guide -> Part 2 -> Creating the Special pages -> Creating the friend management page.</p> |

The screenshot shows the Kentico Site Manager Administration interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The user is logged in as 'Global Administrator' (v6.0.4233). The left sidebar shows a tree view of settings categories, with 'Community' selected. The main content area is titled 'Community' and contains several sections of settings:

- Groups:**
 - Group template path: [Select]
 - Groups security access denied path: [Select]
 - Group management path: [Select]
 - Group profile path: [Select]
- Group invitation:**
 - Invitation acceptance path: [Select]
 - Group invitation expires after (days): 0
- Members:**
 - Member management path: [Select]
 - Member profile path: [Select]
 - Enable friends:** (highlighted with a red box)
 - Friend management path: /Special-pages/Friend-manageme [Select]
- Activity points:**
 - Enable user activity points:

8.27.9 Friends internals and API

8.27.9.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Abuse report module. You will also see the most common [API examples](#).

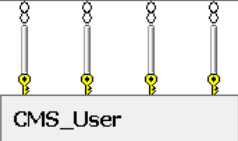

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.27.9.2 Database tables

The Friends module uses the following database tables:

- **Community_Friend** - contains friendship records, while each row in the table represents a friendship between two users.
- **CMS_User** - contains records representing user accounts.

| Community_Friend | | | |
|-----------------------|------------------|-------------------------------------|---|
| Column Name | Data Type | Allow Nulls | |
| FriendID | int | <input type="checkbox"/> |  |
| FriendRequestedUserID | int | <input type="checkbox"/> | |
| FriendUserID | int | <input type="checkbox"/> | |
| FriendRequestedWhen | datetime | <input type="checkbox"/> | |
| FriendComment | nvarchar(MAX) | <input checked="" type="checkbox"/> | |
| FriendApprovedBy | int | <input checked="" type="checkbox"/> | |
| FriendApprovedWhen | datetime | <input checked="" type="checkbox"/> | |
| FriendRejectedBy | int | <input checked="" type="checkbox"/> | |
| FriendRejectedWhen | datetime | <input checked="" type="checkbox"/> | |
| FriendGUID | uniqueidentifier | <input type="checkbox"/> | |
| FriendStatus | int | <input type="checkbox"/> | |

8.27.9.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Friends module can be found in the **CMS.Community** namespace.

CommunityFriend table API:

- **FriendInfo** - represents one friendship object.
- **FriendInfoProvider** - provides friendship management functionality.

8.27.9.4 API examples

8.27.9.4.1 Overview

The following topic show examples of how the API of the Friends module can be used:

- [Managing friendships](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project**

```
folder>\CMSAPIExamples\Code\Community\Friends\Default.aspx.cs
```

The Friends API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.Community;
```

8.27.9.4.2 Managing friendships

The following example demonstrates how a friendship request can be created.

```
private bool RequestFriendship()
{
    // First create a new user which the friendship request will be sent to
    UserInfo newFriend = new UserInfo();
    newFriend.UserName = "MyNewFriend";
    newFriend.FullName = "My new friend";
    newFriend.UserGUID = Guid.NewGuid();

    UserInfoProvider.SetUserInfo(newFriend);

    // Create new friend object
    FriendInfo newFriendship = new FriendInfo();

    // Set the properties
    newFriendship.FriendUserID = CMSContext.CurrentUser.UserID;
    newFriendship.FriendRequestedUserID = newFriend.UserID;
    newFriendship.FriendRequestedWhen = DateTime.Now;
    newFriendship.FriendComment = "Sample friend request comment.";
    newFriendship.FriendStatus = FriendshipStatusEnum.Waiting;
    newFriendship.FriendGUID = Guid.NewGuid();

    // Save the friend
    FriendInfoProvider.SetFriendInfo(newFriendship);

    return true;
}
```

The following example approves the friendship requested in the previous code example.

```
private bool ApproveFriendship()
{
```

```
// Get the users involved in the friendship
UserInfo user = CMSContext.CurrentUser;
UserInfo friend = UserInfoProvider.GetUserInfo("MyNewFriend");

if (friend != null)
{
    // Get the friendship with current user
    FriendInfo updateFriendship = FriendInfoProvider.GetFriendInfo
(user.UserID, friend.UserID);
    if (updateFriendship != null)
    {
        // Set its properties
        updateFriendship.FriendStatus = FriendshipStatusEnum.Approved;
        updateFriendship.FriendRejectedBy = 0;
        updateFriendship.FriendApprovedBy = user.UserID;
        updateFriendship.FriendApprovedWhen = DateTime.Now;

        // Save the changes to database
        FriendInfoProvider.SetFriendInfo(updateFriendship);

        return true;
    }
}

return false;
}
```

The following example rejects the friendship requested in the first code example on this page.

```
private bool RejectFriendship()
{
    // Get the users involved in the friendship
    UserInfo user = CMSContext.CurrentUser;
    UserInfo friend = UserInfoProvider.GetUserInfo("MyNewFriend");

    if (friend != null)
    {
        // Get the friendship with current user
        FriendInfo updateFriendship = FriendInfoProvider.GetFriendInfo
(user.UserID, friend.UserID);

        // Set its properties
        updateFriendship.FriendStatus = FriendshipStatusEnum.Rejected;
        updateFriendship.FriendApprovedBy = 0;
        updateFriendship.FriendRejectedBy = user.UserID;
        updateFriendship.FriendRejectedWhen = DateTime.Now;

        // Save the changes to database
        FriendInfoProvider.SetFriendInfo(updateFriendship);

        return true;
    }
}
```

```
else
{
    return false;
}
}
```

The following example demonstrates how multiple friendships can be get based on a WHERE condition and bulk updated.

```
private bool GetAndBulkUpdateFriends()
{
    // Get the user
    UserInfo friend = UserInfoProvider.GetUserInfo("MyNewFriend");

    if (friend != null)
    {
        // Prepare the parameters
        string where = "FriendRequestedUserID = " + friend.UserID;

        // Get the data
        DataSet friends = FriendInfoProvider.GetFriends(where, null);
        if (!DataHelper.DataSourceIsEmpty(friends))
        {
            // Loop through the individual items
            foreach (DataRow friendDr in friends.Tables[0].Rows)
            {
                // Create object from DataRow
                FriendInfo modifyFriend = new FriendInfo(friendDr);

                // Update the properties
                modifyFriend.FriendStatus = FriendshipStatusEnum.Approved;
                modifyFriend.FriendRejectedBy = 0;
                modifyFriend.FriendApprovedBy = CMSContext.CurrentUser.UserID;
                modifyFriend.FriendApprovedWhen = DateTime.Now;

                // Save the changes
                FriendInfoProvider.SetFriendInfo(modifyFriend);
            }

            return true;
        }
    }

    return false;
}
```

The following example shows how friendships can be selected based on a WHERE condition and bulk deleted.

```
private bool DeleteFriends()
{
```

```
// Get the user
UserInfo friend = UserInfoProvider.GetUserInfo("MyNewFriend");

if (friend != null)
{
    // Prepare the parameters
    string where = "FriendRequestedUserID = " + friend.UserID;

    // Get all user's friendships
    DataSet friends = FriendInfoProvider.GetFriends(where, null);
    if (!DataHelper.DataSourceIsEmpty(friends))
    {
        // Delete all the friendships
        foreach (DataRow friendDr in friends.Tables[0].Rows)
        {
            FriendInfo deleteFriend = new FriendInfo(friendDr);

            deleteFriend.Delete();
        }
    }
    else
    {
        // Change the info message
        apiDeleteFriends.InfoMessage = "The user 'My new friend' doesn't have any friends. The user has been deleted.";
    }

    // Finally delete the user "My new friend"
    UserInfoProvider.DeleteUser(friend);

    return true;
}

return false;
}
```

8.28 Geo mapping

8.28.1 Overview

The Geo mapping module allows you to display maps on your site. You can display also content on these maps.

The module has no administration interface and consists only of nine web parts and three widgets derived from the static group of these web parts. The web parts and widgets can be found under the **Maps** category in the web part and widget selection dialogs.

You can see the web parts configured and working on the sample Corporate Site, under the **/Examples/ Webparts/Maps** node of the content tree.

What purpose it has

The module can be used for many scenarios in which a geographical position is the key information:

- show your offices
- show your stores
- show your partners
- show real estates you offer
- etc.

You can use it to display virtually any content that has a location. The only requirement is that you tag your content with [longitude and latitude](#).

How to get longitude and latitude for a given place

You can use an on-line service that allows you to enter the country, city and street and shows you the respective longitude and latitude. One such service is available for example at [http:// world.maporama.com](http://world.maporama.com).

Available providers

You can choose from the following map providers:

- [Bing Maps](#) (originally Live Maps)
- [Google Maps](#)

Each of these providers has its dedicated web parts and a widget. Please click the particular map provider to learn more.

8.28.2 Bing maps

The **Bing maps web parts** enable displaying a map with defined location markers using the Bing maps service. They use the **Bing maps API**, which is described in detail in the following location: <http://www.microsoft.com/maps/isdk/ajax/>.

The maps show the location markers and are zoomed according to the settings made by the **Large view scale** property. For a document-related map and for a map with a data source, the center is on the coordinates specified by the **Default latitude** and **Default longitude** properties of the corresponding web part. However, a static map has its center on the location marker.

Static Bing maps

The **Static Bing maps** web part is used. Geographical location is displayed based on manually entered coordinates. Only one location can be displayed at a time. Learn [here](#) how to display a location marker on the map.

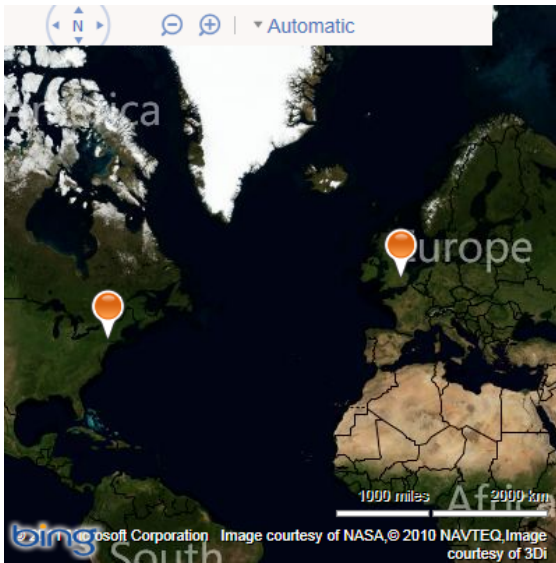

In the screenshot below, you can see how the web part looks on page load.

Document-related Bing maps

The **Bing maps** web part is used. Geographical location is displayed dynamically based on the properties of the document. More locations can be displayed at a time. Learn [here](#) how to display location markers on the map.

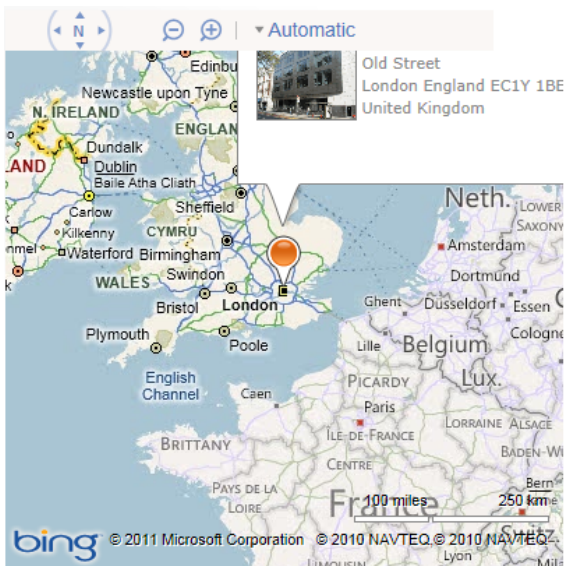

In the screenshot below, you can see how the web part looks on page load.

Bing maps with a data source

The **Basic Bing maps** web part in combination with a data source web part is used. Geographical location is displayed dynamically based on the data source, e.g. documents data source, query data source, xml data source etc. More locations can be displayed at a time. Learn [here](#) how to display location markers on the map.

The screenshot below shows how any of the web parts looks when one of the location markers is clicked. Regardless of its type, the map is zoomed according to the value of the **Detailed view scale** property and a tooltip is displayed. It shows the heading loaded from a document type field specified in the **Tooltip field** property and the rest of the content loaded using a transformation specified in the **Transformation** property.

If you enable the **Enable keyboard shortcuts** property, the following shortcuts can be used to control the map:

- R - switch to Road view.
 - A - switch to Aerial view.
 - H - switch to Aerial view with labels.
 - O - switch to Bird's eye view.
 - B - switch to Bird's eye view with labels.
-
- Plus Sign (+) - zoom the map in.
 - Minus Sign (-) - zoom the map out.

Detailed descriptions of all properties of the web parts can be found in the [Kentico CMS Web Parts Reference](#) or directly in the web part properties dialog after clicking the  **Documentation** link at the top right corner of the dialog.

**Please note**

Certain Bing maps services, e.g. [location translations](#), require that you have your Bing maps account. As a Bing map account holder, you can create keys to use these services.

The **Bing maps widget** is derived from the **Static Bing maps** web part. It provides the same functionality and look as this web part, while only a limited set of properties can be configured.

8.28.3 Google maps

The **Google maps web parts** enable displaying a map with defined location markers using the Google maps service. They use the **Google maps API v3**, which is described in detail in the following location: <http://code.google.com/intl/cs-CZ/apis/maps/documentation/v3/controls.html>.

The maps show the location markers and are zoomed according to the settings made by the **Large view scale** property. For a document-related map and for a map with a data source, the center is on the coordinates specified by the **Default latitude** and **Default longitude** properties of the corresponding web part. However, a static map has its center on the location marker.

Static Google maps

The **Static Google maps** web part is used. Geographical location is displayed based on manually entered coordinates. Only one location can be displayed at a time. Learn [here](#) how to display a location marker on the map.

In the screenshot below, you can see how the web part looks on page load.

Document-related Google maps

The **Google Maps** web part is used. Geographical location is displayed dynamically based on the properties of the document. More locations can be displayed at a time. Learn [here](#) how to display location markers on the map.

In the screenshot below, you can see how the web part looks on page load.

Google maps with a data source

The **Basic Google maps** web part in combination with a data source web part is used. Geographical location is displayed dynamically based on the data source, e.g. documents data source, query data source, xml data source etc. More locations can be displayed at a time. Learn [here](#) how to display location markers on the map.

The screenshot below shows how any of the web parts looks when one of the location markers is

clicked. Regardless of its type, the map is zoomed according to the value of the **Detailed view scale** property and a tooltip is displayed. It shows the heading loaded from a document type field specified in the **Tooltip field** property and the rest of the content loaded using a transformation specified in the **Transformation** property.

If you enable the **Enable keyboard shortcuts** property, the following shortcuts can be used to control the map:

- **Up Arrow** - move a little north.
- **Down Arrow** - move a little south.
- **Left Arrow** - move a little west.
- **Right Arrow** - move a little east.

- **Page Up** - move a large step north.
- **Page Down** - move a large step south.
- **Home** - move a large step west.
- **End** - move a large step east.

- **Plus Sign (+)** - zoom the map in.
- **Minus Sign (-)** - zoom the map out.

Detailed descriptions of all properties of the web parts can be found in the [Kentico CMS Web Parts Reference](#) or directly in the web part properties dialog after clicking the  **Documentation** link at the top right corner of the dialog.

The **Google maps widget** is derived from the **Static Google maps** web part. It provides the same functionality and look as this web part, while only a limited set of properties can be configured.

8.28.4 Example: Static maps

This example will show you how to display one object, e.g. an office, on a map. The **Static Google maps** web part will be used. However, the procedure is identical for the [Static Bing maps](#) web part, too. You can use any Kentico CMS sample site for the purpose of this example.

How to do it in general

To display one object on a map, you will need to add a static map web part to a page and configure its properties. Specifically, you will need to fill in **two fields for the geographical coordinates** - one for **longitude** and one for **latitude** - or, alternatively, a **location field** in human-readable form, e.g. an address. This will ensure that the location marker is displayed on the map.

Example

1. Sign in as an administrator to **CMS Desk -> Content** and click the root of the content tree.
2. Click  **New** and choose to create a new  **Page (menu item)**. Enter *Office* for **Page name**, choose the **Create a blank page with layout** option and select the **Simple** layout. Click  **Save**.
3. Now switch to the **Design** tab, add the **Maps/Static/Static Google maps** web part to the **zoneLeft** web part zone and set the following properties:
 - **Latitude:** 40.76 (The field containing the latitude position.)
 - **Longitude:** -73.98 (The field containing the longitude position.)
 - **Tooltip:** New York Office (The field used for the heading of tooltips.)
 - **Marker content:** 1290 Avenue of the Americas, New York, 10104, NY (The field containing details of the displayed object. You can use the built-in [WYSIWYG editor](#) to edit the details and you can also insert an image.)
 - **Large view scale:** 3 (The zoom used on page load.)
 - **Icon URL** - if you don't want to use the default location marker icon, you can **alternatively** choose your custom location marker icon. Click the **Select** button to open the **Insert link** dialog and set your custom location marker icon URL. For more details on how to insert a URL, please refer to the [WYSIWYG editor -> Insert link](#) chapter.
 - **Detailed view scale:** 10 (The zoom used if the location marker is clicked.)
 - **Width:** 500 (In pixels.)
 - **Height:** 400 (In pixels.)

Geolocation values are valid in the following intervals:

- **Latitude:** from -90 to 90
- **Longitude:** from -180 to 180

Alternatively, you can leave the **Latitude** and **Longitude** fields undefined or set to zero and use the **Location or address** field instead to enter the location value in a human-readable form, e.g. an address.

Important!

Using geolocation values in a human-readable form involves some processing overhead and can even lead to inaccurate results. To ensure maximum performance and accuracy, it is therefore recommended to use the latitude and longitude coordinates when defining a geographical location.

Please note

You can enable geolocation translations, i.e. addresses to coordinates, on the server side by checking the **Use server processing** checkbox. If you decide to do so, please check that the maps services query limits (IP-based) are sufficient for your needs.

To ensure maximum efficiency, maps services results are cached if the **Use server processing** option is enabled. What is more, separate cache keys are used for the live site mode and for other modes.

Click **OK**.

4. Sign out and view the page. It will look like this:

You can see one balloon on the map - this is the location marker. If you mouse-over the balloon, you will see the office name. If you click the balloon, you will see the detailed view:

8.28.5 Example: Document-related maps

This example will show you how to display a list of offices and their location on a map. The **Google maps** web part will be used in the example. However, the procedure is identical for [Bing maps](#) web part, too.

The Corporate Site sample website will be used and you will create a page for offices directly under the website root. However, if you don't have this site installed, you can use any other available site.

How to do it in general

To display content on a map, you need to have this content stored in the content tree as standard documents. These documents can be of any document type as long as the document type contains **two fields for the geographical coordinates** - one for **longitude** and one for **latitude** - or, alternatively, a human-readable **location field**, e.g. an address.

Then you need to configure properties of the map web part to display documents stored within the desired location, and specify which fields of the document type contain the coordinates or human-readable location. This ensures that the location markers are displayed.

Step 1 - Creating a new page with offices

1. Sign in as an administrator to **CMS Desk** -> **Content** and click the root of the content tree.

2. Click  **New** and choose to create a new  **Page (menu item)**. Enter *Offices* for **Page name**, choose the **Create a blank page with layout** option and select the **Two columns** layout. Click  **Save**.

3. First you need to add a list of offices. Switch to the **Design** tab and add the **Listings and viewers/ Documents/DataList** web part to the **zoneLeft** web part zone. Set the following properties:

- **Path:** `{{0}}%`
- **Document types:** CMS.Office
- **Transformation:** CMS.Office.Simple
- **Selected item transformation:** CMS.Office.Default
- **Repeat columns:** 1
- **Repeat direction:** Vertical
- **Repeat layout:** Table
- **Content before:** `
 <div class="GeneralList">`
- **Content after:** `</div>`

Click **OK**.

Step 2 - Geo-coding your information

4. Now you will create two documents of the **Office** type under the document created in Step 1. Click the *Offices* page and click  **New**. Choose to create a new  **Office** and enter the following values:

- **Office name:** New York Office
- **Address line 1:** 1290 Avenue of the Americas
- **City:** New York
- **ZIP code:** 10104
- **State:** NY
- **Country:** U.S.A.
- **Phone:** 123456789
- **E-mail:** ny@example.com
- **Latitude:** 40.76
- **Longitude:** -73.98
- **Office photo** - please choose an image from your disk.
- **Icon URL** - if you don't want to use the default location marker icon for this particular document on the map, you can **alternatively** set URL of your custom location marker icon. Click the **Select** button to open the **Insert link** dialog and set your custom location marker icon URL. For more details on how to insert a URL, please refer to the [WYSIWYG editor -> Insert link](#) chapter.

Please note

The **Office** document type already contains the **Latitude** and **Longitude** fields. These are the fields that you will later specify in the map web part properties as the **source for the geographical position** of the location markers. If you use a custom document type, you will need to define these fields manually. They must be of the **decimal number** type. You can give them any names you want and only need to specify them in the web part properties.

Values are valid in the following intervals:

- **Latitude:** from -90 to 90
- **Longitude:** from -180 to 180

Click  **Save**.

5. Create another office:

- **Office name:** San Francisco Office
- **Address line 1:** 835 Market Street
- **City:** San Francisco
- **ZIP code:** 94103
- **State:** CA
- **Country:** U.S.A.
- **Phone:** 123456789
- **E-mail:** sf@example.com
- **Latitude:** 37.78
- **Longitude:** -122.41
- **Office photo** - please choose an image from your disk.

- **Icon URL** - if you don't want to use the default location marker icon for this particular document on the map, you can **alternatively** set URL of your custom location marker icon. Click the **Select** button to open the **Insert link** dialog and set your custom location marker icon URL. For more details on how to insert a URL, please refer to the [WYSIWYG editor -> Insert link](#) chapter.

Click  **Save**.

Step 3 - Displaying the content on the map

6. If you view the *Offices* page now, it displays only a list of offices. Switch to the **Design** tab and add the **Maps/Documents/Google maps** web part to the **zoneRight** web part zone.

First, you need to configure which documents should be displayed on the map. Set the following properties:

- **Path:** `/{0}%`
- **Document types:** CMS.Office

It ensures that all offices in the current site section will be shown. Now you need to specify the transformation used for the text displayed in the balloon:

- **Transformation:** CMS.Office.Preview

Next, you will set the values that specify how the map is displayed:

- **Default latitude:** 39.27 (Latitude of the map center when the large view map is displayed on page load.)
- **Default longitude:** -98.20 (Longitude of the map center when the large view map is displayed on

page load.)

- **Latitude field:** OfficeLatitude (The field of the document containing the latitude position.)
- **Longitude field:** OfficeLongitude (The field of the document containing the longitude position.)
- **Large view scale:** 3 (The zoom used on page load.)
- **Detailed view scale:** 10 (The zoom used if a location marker is clicked.)
- **Width:** 500 (In pixels.)
- **Height:** 400 (In pixels.)
- **Tooltip field:** OfficeName (The field used for the heading of tooltips.)
- **Icon field** - contains the code name of the source field whose content will be used as URL for your custom location marker icon; i.e. *OfficeIconURL* for the purpose of this example. If not set for a particular document or left empty, the default location marker icon will be used.

Alternatively, you can leave the **Default latitude** and **Default longitude** fields for the large view map center undefined or set to zero and use the **Default location or address** field instead to enter the location value in a human-readable form, e.g. an address. Similarly, you can do this for the **Latitude field** and **Longitude field** fields related to the location markers using the alternative **Location field** field.

Important!

Using geolocation values in a human-readable form involves some processing overhead and can even lead to inaccurate results. To ensure maximum performance and accuracy, it is therefore recommended to use the latitude and longitude coordinates when defining a geographical location.

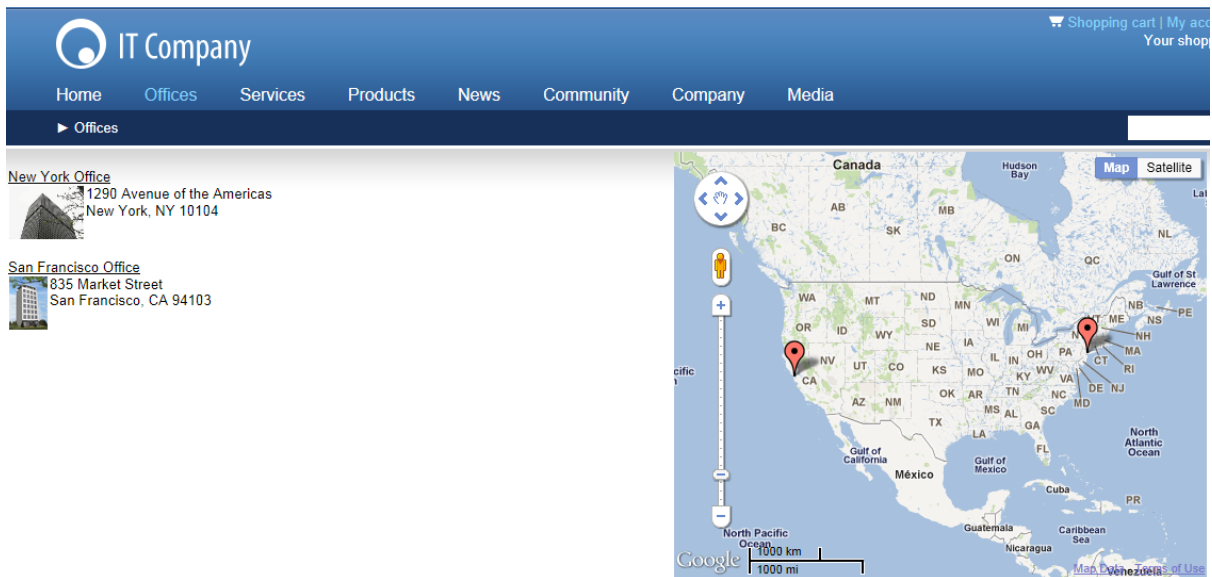

Please note

You can enable geolocation translations, i.e. addresses to coordinates, on the server side by checking the **Use server processing** checkbox. If you decide to do so, please check that the maps services query limits (IP-based) are sufficient for your needs.

To ensure maximum efficiency, maps services results are cached if the **Use server processing** option is enabled. What is more, separate cache keys are used for the live site mode and for other modes.

Click **OK**.

7. Sign out and view the page. It will look like this:

You can see two balloons on the map - these are the location markers. If you mouse-over a balloon, you will see the office name. If you click a balloon, you will see the office detailed view:

8.28.6 Example: Maps with a data source

This example will show you how to display a list of offices and their location on a map using a data source. The **Basic Google maps** web part in combination with the **Documents data source** web part will be used in the example. However, the procedure is identical for [Basic Bing maps](#) web part, too.

The Corporate Site sample website will be used and you will create a page for offices directly under the website root. However, if you don't have this site installed, you can use any other available site.

How to do it in general

To display content on a map, you need to have a data source web part configured that will provide this content for the map web part. For the purpose of this example, documents content will be used. It will be stored in the content tree as standard documents. These documents can be of any document type as long as the document type contains **two fields for the geographical coordinates** - one for **longitude** and one for **latitude** - or, alternatively, a human-readable **location field**, e.g. an address.

When you have the documents created and stored within the desired location, you will need to configure properties of the data source and map web parts to display them on a map. You will also need to specify which fields of the document type contain the coordinates or human-readable location. This ensures that location markers are displayed.

Step 1 - Creating a new page with offices

1. Sign in as an administrator to **CMS Desk -> Content** and click the root of the content tree.
2. Click  **New** and choose to create a new  **Page (menu item)**. Enter *Offices* for **Page name**, choose the **Create a blank page with layout** option and select the **Two columns** layout. Click  **Save**.
3. First you need to add a list of offices. Switch to the **Design** tab and add the **Listings and viewers/ Documents/Datalist** web part to the **zoneLeft** web part zone. Set the following properties:

- **Path:** `/{0}/%`
- **Document types:** CMS.Office
- **Transformation:** CMS.Office.Simple
- **Selected item transformation:** CMS.Office.Default
- **Repeat columns:** 1
- **Repeat direction:** Vertical
- **Repeat layout:** Table
- **Content before:** `
 <div class="GeneralList">`
- **Content after:** `</div>`

Click **OK**.

Step 2 - Geo-coding your information

4. Now you will create two documents of the **Office** type under the document created in Step 1. Click the *Offices* page and click  **New**. Choose to create a new  **Office** and enter the following values:

- **Office name:** New York Office
- **Address line 1:** 1290 Avenue of the Americas
- **City:** New York
- **ZIP code:** 10104
- **State:** NY
- **Country:** U.S.A.
- **Phone:** 123456789
- **E-mail:** ny@example.com
- **Latitude:** 40.76
- **Longitude:** -73.98
- **Office photo** - please choose an image from your disk.
- **Icon URL** - if you don't want to use the default location marker icon for this particular document on

the map, you can **alternatively** set URL of your custom location marker icon. Click the **Select** button to open the **Insert link** dialog and set your custom location marker icon URL. For more details on how to insert a URL, please refer to the [WYSIWYG editor -> Insert link](#) chapter.

Please note

The **Office** document type already contains the **Latitude** and **Longitude** fields. These are the fields that you will later specify in the map web part properties as the **source for the geographical position** of the location markers. If you use a custom document type, you will need to define these fields manually. They must be of the **decimal number** type. You can give them any names you want and only need to specify them in the web part properties.

Values are valid in the following intervals:

- **Latitude:** from -90 to 90
- **Longitude:** from -180 to 180

Click  **Save**.

5. Create another office:

- **Office name:** San Francisco Office
- **Address line 1:** 835 Market Street
- **City:** San Francisco
- **ZIP code:** 94103
- **State:** CA
- **Country:** U.S.A.
- **Phone:** 123456789
- **E-mail:** sf@example.com
- **Latitude:** 37.78
- **Longitude:** -122.41
- **Office photo** - please choose an image from your disk.
- **Icon URL** - if you don't want to use the default location marker icon for this particular document on the map, you can **alternatively** set URL of your custom location marker icon. Click the **Select** button to open the **Insert link** dialog and set your custom location marker icon URL. For more details on how to insert a URL, please refer to the [WYSIWYG editor -> Insert link](#) chapter.

Click  **Save**.

Step 3 - Configuring the data source

6. If you view the *Offices* page now, it displays only a list of offices. Switch to the **Design** tab and add the **Data sources/Documents data source** web part to the **zoneRight** web part zone.

You only need to configure which documents should be used by this web part to be displayed on the map. Set the following properties:

- **Path:** `/{0}/%`
- **Document types:** CMS.Office

It ensures that all offices in the current site section will be shown.

Click **OK**.

Step 4 - Displaying the content on the map

7. On the **Design** tab, add the **Maps/Basic/Basic Google maps** web part to the **zoneRight** web part zone.

First, you will need to configure which data source should be used. Set the following properties:

- **Data source name:** DocumentsDataSource

Now you need to specify the transformation used for the text displayed in the balloon:

- **Transformation:** CMS.Office.Preview

Finally, you will set the values that specify how the map is displayed:

- **Default latitude:** 39.27 (Latitude of the map center when the large view map is displayed on page load.)
- **Default longitude:** -98.20 (Longitude of the map center when the large view map is displayed on page load.)
- **Latitude field:** OfficeLatitude (The field of the document containing the latitude position.)
- **Longitude field:** OfficeLongitude (The field of the document containing the longitude position.)
- **Large view scale:** 3 (The zoom used on page load.)
- **Detailed view scale:** 10 (The zoom used if a location marker is clicked.)
- **Width:** 500 (In pixels.)
- **Height:** 400 (In pixels.)
- **Tooltip field:** OfficeName (The field used for the heading of tooltips.)
- **Icon field** - contains the code name of the source field whose content will be used as URL for your custom location marker icon; i.e. *OfficeIconURL* for the purpose of this example. If not set for a particular document or left empty, the default location marker icon will be used.

Alternatively, you can leave the **Default latitude** and **Default longitude** fields for the large view map center undefined or set to zero and use the **Default location or address** field instead to enter the location value in a human-readable form, e.g. an address. Similarly, you can do this for the **Latitude field** and **Longitude field** fields related to the location markers using the alternative **Location field** field.

Important!

Using geolocation values in a human-readable form involves some processing overhead and can even lead to inaccurate results. To ensure maximum performance and accuracy, it is therefore recommended to use the latitude and longitude coordinates when defining a geographical location.

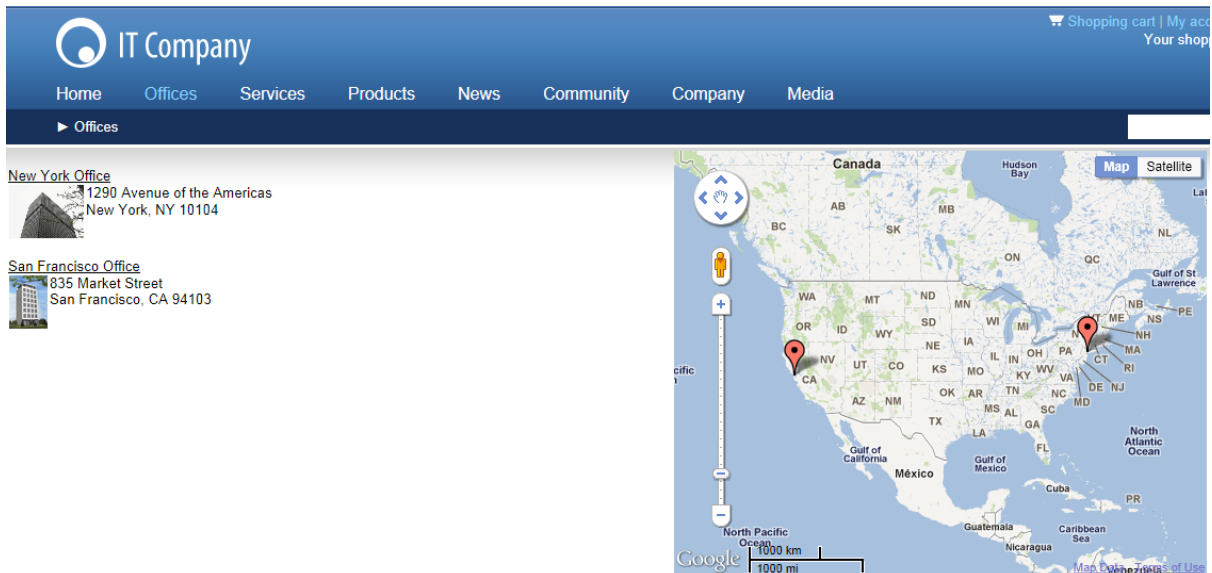

Please note

You can enable geolocation translations, i.e. addresses to coordinates, on the server side by checking the **Use server processing** checkbox. If you decide to do so, please check that the maps services query limits (IP-based) are sufficient for your needs.

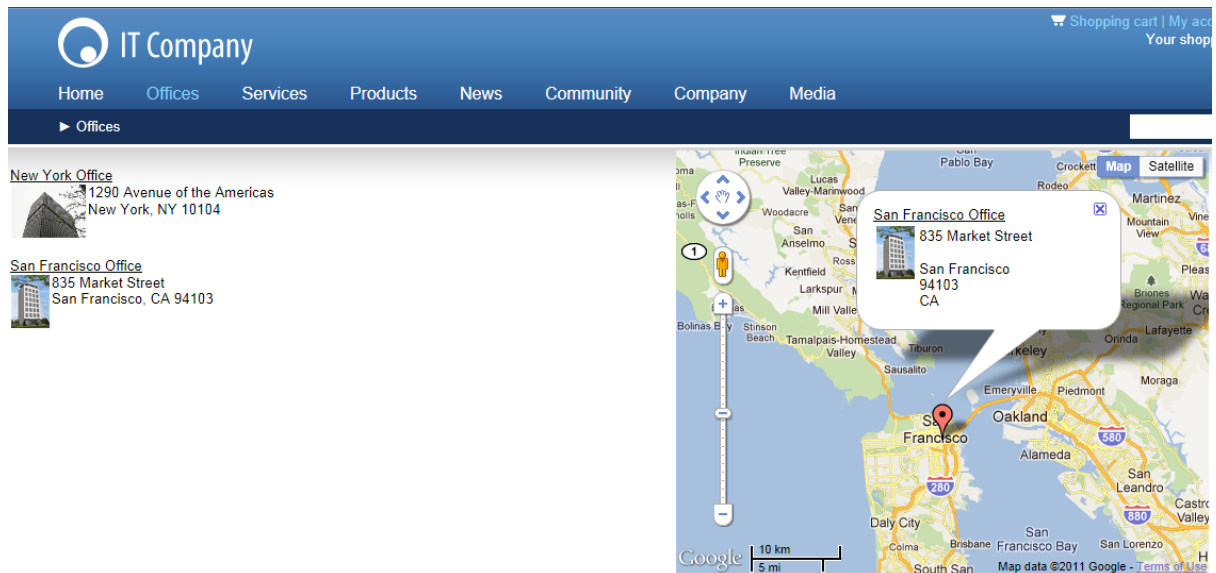

To ensure maximum efficiency, maps services results are cached if the **Use server processing** option is enabled. What is more, separate cache keys are used for the live site mode and for other modes.

Click **OK**.

8. Sign out and view the page. It will look like this:

You can see two balloons on the map - these are the location markers. If you mouse-over a balloon, you will see the office name. If you click a balloon, you will see the office detailed view:

8.29 Groups

8.29.1 Overview

The groups module allows site members who share an interest in a certain topic or field to access related information and share their own experiences on a subsection of your website. Site users can create new groups or join already existing ones. Groups may contain their own documents section, [forums](#), [message boards](#), [media libraries](#), [polls](#) and [projects](#) and have the option of defining group roles. Groups can also be useful for managing access control.

Site administrators can manage groups of a given site through the CMS Desk interface. Learn more in the [Groups management](#) topic.

Both site administrators and users who are in authorized roles can edit the content and various settings of groups. Learn more about this in the [Editing a group](#) topic. Further settings available only to global administrators are described in the [Settings](#) topic.

To allow users to interact with the groups module, you have to place some group web parts, which can be found in the **Community** web part category, somewhere on your site. An example of this that describes how to enable users to create groups can be found in the [Enabling users to create groups](#) topic. A full list of group web parts and their function and properties can be found in the [Kentico CMS Web Parts](#) reference.

The [Groups internals and API](#) sub-chapter provides information about the database tables and classes used by the module and examples of how groups can be managed using the API.

Kentico CMS Community Site Guide contains some additional group examples and tutorials:

- [Part 1 -> Groups](#): Examples of the functionality and customization of groups.
- [Part 2 -> Creating the Groups section](#): A step-by-step tutorial on how to create a sample group pages section of a website.

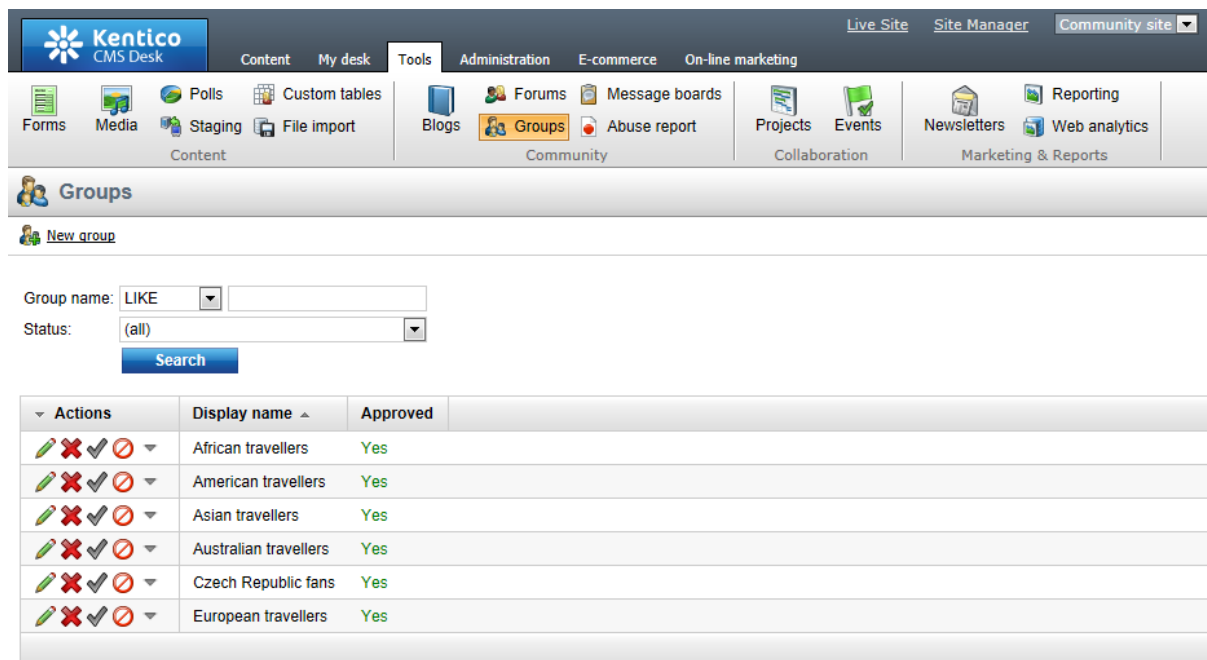

You will need to have the sample Community Site installed to follow Kentico CMS Community Site Guide.

8.29.2 Groups management

In the screenshot below, you can see the groups management interface located in **CMS Desk -> Tools -> Groups**. On this page, you can see a list of all groups on the site. You can filter displayed groups using the filter above the list. Filtration is possible by the group's **display name** and approval **Status**.

Even though groups are typically created by site users on the live site, you can create new groups in this section of the administration interface too. It can be done by clicking  **New group** at the top part of the page. Groups in the list can be **Edited** () or **Deleted** (). The [Editing a group](#) topic describes editing in more detail.

If an administrator's approval is needed after a user creates a new group, the approval can be done by clicking the **Approve** () icon. By clicking the **Reject** () icon, groups can be switched back to the state they were in before they were approved. If you do this to an existing group, the group will not be displayed on the live site.

| Actions | Display name | Approved |
|---|-----------------------|----------|
|     | African travellers | Yes |
|     | American travellers | Yes |
|     | Asian travellers | Yes |
|     | Australian travellers | Yes |
|     | Czech Republic fans | Yes |
|     | European travellers | Yes |

All Kentico CMS documents can be set to be owned by a group. To do this select a document from the content tree, switch to **Edit** mode and go to **Properties -> General -> Owned by group**. Then click **Change** and choose a group from the drop-down list. This property is used to identify which group a

document belongs to and is used by various group context sensitive web parts to display the correct content. It also influences the editing permissions of Group administrator widget zones. See [Enabling users to create groups](#) for more information.

8.29.3 Editing a group

There are two ways how group properties can be edited:

- On-site management using the [Group profile](#) web part; this is typically used by group administrators
- Administration interface in **CMS Desk -> Tools -> Groups**, after choosing to **Edit** () a group; this is typically used by site administrators

Both of the two approaches provide the same tabs layout, with the difference that there are some extra settings in the administration interface compared to on-site management. These will be marked as **AI only** in the descriptions below.

General tab

On this tab, you can set the general properties of the group:

- **Display name** - name of the group displayed on the site and in the administration interface; *AI only*
- **Code name** - name of the group used in site code; *AI only*
- **Description** - text describing the group
- **Group pages location** - node alias path of the location where group pages of the group are stored
- **Theme** - allows the selection of one of the website [CSS stylesheets](#) that will be used by the pages of the group
- **Avatar** - group avatar image

- **Approve members** - determines if users can join the group with or without a group admin's approval; the last option allows invited members to join without approval
- **Content access** - determines who can view content of the group pages
- **Notify group admins when a user joins/leaves** - if checked, group administrators will receive a notification e-mail when a user joins/leaves the group
- **Notify group admins on pending members** - if checked, group administrators will receive a notification e-mail when a user requests to join the group and admin's approval is needed

- **Created by** - displays who created the group
- **Approved by** - displays who approved the group to be created on the site

Security tab

On this tab, you can use the matrix to set permissions for group pages. The following permissions can be assigned:

- **Create pages** - users can create group pages
- **Delete pages** - users can delete group pages
- **Edit pages** - users can edit group pages

These permissions can be assigned to:

- **Nobody** - nobody can perform the action
- **All users** - all users can perform the action
- **Authenticated users** - only signed-in users can perform the action, i.e. anonymous public users cannot perform it

- **Group members** - only group members can perform the action, i.e. authenticated non-group members and anonymous users cannot perform it
- **Authorized roles** - only members of the group roles selected below can perform the action

Group admin's permissions

Group administrators can perform any of these actions, even if they don't have the permissions assigned.

Members tab

On this tab, you can see a list of all members of the group. You can **Edit** (✎) or **Delete** (✖) users in the list. You can also **Approve** (✔) members' requests for joining the group or **Reject** (⊘) them from the group. Once rejected, the user cannot request to join the group until they are approved again.

Group properties

> Groups > Asian travellers

General Security Members Roles Forums Media libraries Message boards Polls Projects

[Add member](#) [Invite member](#)

Username: LIKE

Status: (all)

| Actions | User name | Full name | Member approved | Member rejected |
|---|-----------|-------------|-----------------------|-----------------|
| <input checked="" type="checkbox"/> <input checked="" type="checkbox"/> <input checked="" type="checkbox"/> <input checked="" type="checkbox"/> | Guru | Ratan Gupta | 10/23/2008 4:00:32 PM | |
| <input checked="" type="checkbox"/> <input checked="" type="checkbox"/> <input checked="" type="checkbox"/> <input checked="" type="checkbox"/> | Mia | Mia Lee | 10/23/2008 4:00:43 PM | |

Clicking [Add member](#), you can add users to the group directly, without sending an invitation to them. This is possible only in the administration interface. On the live site, only [Invite member](#) is displayed. When adding a user to a group, you have the following options:

- **User** - select an existing site user who you want to add to the group
- **Comment** - text comment that you can add to the user; this comment is not sent to the user, it is only displayed in the administration interface
- **Approve** - if checked, the user will be automatically approved; if not, a user will need a group admin's approval before they become members of the group
- **Add roles** - you can use this button to assign the user to group roles; a dialog where you can select from a list of available group roles is opened

The screenshot shows the 'Group properties' window for the 'Asian travellers' group. The 'Members' tab is active, and the 'New member' dialog is open. The 'User' field contains 'Joshua O'Neil (Josh)' with a 'Select' button and a 'Clear' button. Below it is a dropdown menu showing 'Josh from Australia.'. The 'Comment' field is empty. The 'Approve' checkbox is checked. There is an 'OK' button at the bottom left. On the right, there is a section titled 'Add member to roles' with the text 'No roles selected.' and an 'Add roles' button.

After clicking **Invite member**, the dialog displayed in the screenshot below will be displayed. There are two ways of invitation:

- **Invite existing site member** - after selecting an existing site user in the **User name** field, an invitation e-mail will be sent to the user's e-mail address. The text entered into the **Comment** field will be included in the e-mail. Users can then join the group either by clicking a link in the e-mail, or via the **My sent invitations** web part.
- **Invite via e-mail** - this way, you can send the invitation to any e-mail address that you enter into the **E-mail** field. In this case, user will be required to register to the site after clicking the join link in the e-mail. Text entered to the **Comment** field will be included in the e-mail.

The screenshot shows the 'Group properties' window for the 'Asian travellers' group. The 'Members' tab is active, and the 'Invite member' dialog is open. At the top, there are two radio buttons: 'existing site member' (selected) and 'via e-mail'. The 'User name' field contains 'Jack Stevenson (Steevie)' with a 'Select' button and a 'Clear' button. The 'Comment' field contains the text 'Hi, do you want to join to our group?'. There is an 'Invite' button at the bottom.

Roles tab

On this tab, you can see a list of roles defined for the group. These roles are applicable only in the context of the group. Don't confuse them with website roles, which can be set in **Site Manager -> Administration -> Roles**.

Roles in the list can be **Edited** (✎) and **Deleted** (✖).

Forums tab

On this tab, you can create and manage the group's forums. As these forums are standard Kentico CMS forums set into the context of the group, please refer to the [Modules -> Forums](#) chapter of this guide for more information on their management.

Media libraries tab

On this tab, you can create and manage the group's media libraries. As these are standard Kentico CMS media libraries set into the context of the group, please refer to the [Modules -> Media libraries](#) chapter of this guide for more information on their management.

Message boards tab

On this tab, you can manage the group's message boards. As these are standard Kentico CMS message boards set into the context of the group, please refer to the [Modules -> Message boards](#) chapter of this guide for more information on their management.

Polls tab

On this tab, you can manage the group's polls. As these are standard Kentico CMS polls set into the context of the group, please refer to the [Modules -> Polls](#) chapter of this guide for more information on their management.

Projects tab

On this tab, you can manage the group's projects. As these are standard Kentico CMS projects set into the context of the group, please refer to the [Modules -> Project management](#) chapter of this guide for more information on their management.

8.29.4 Enabling users to create groups

You can enable site users to create new groups by placing the [Community -> Groups -> Group registration](#) web part on your site. You have to set the following properties of the web part:

- **Template source alias path** - alias path of the document that will be used, together with the documents stored under it, as a template for groups created by the web part. If left empty, the value of the *Site Manager* -> *Settings* -> *Community* -> *Group template path* field will be used.
- **Template target alias path** - alias path where the documents copied from the *Template source alias path* will be loaded when a group is created.
- **Automatically create forum** - if checked, a forum group and a General discussion forum are automatically added under the created group.
- **Automatically create media library** - if checked, a media library is automatically added under the created group.
- **Automatically create smart search indexes** - if checked, a smart search index is automatically created for the documents of the created group, as well as for the new forum if the *Automatically create forum* property is enabled.
- **Group profile URL path** - alias path of the page containing the group profile. The *{groupname}* wildcard can be used to substitute for the name of the current group.
- **Combine with default culture** - if checked, the default culture will be used when creating group pages under a culture where the source or target nodes were not found.
- **Group name label text** - text that will be displayed in the form before the field where the group name is entered.
- **Text after successful registration** - text displayed when a group is successfully created.
- **Text after successful registration with approving** - text displayed when a group is successfully created, but requires an administrator's approval to be published on the web.

- **Require approval** - if checked, the group will have to be approved by a site administrator before it is published on the site.
- **Redirect to URL** - URL where the user will be redirected after creating the group.
- **Hide form after registration** - if checked, the form will be hidden after creating the group.

Group pages templates

Each group has its own section on the website where its content is stored - so called group pages. When adding the **Group registration** web part to your site, you have to specify the **Template source alias path** and **Template target alias path** properties. These two properties are essential when creating the **group pages section** of each group.

The page specified by the **Template source alias path** and all its sub-pages are copied to the location specified by the **Template target alias path**.

To get a better idea of how this works, you can take a look at our sample **Community Starter site**. On the site, the **Group registration** web part is configured the following way:

- **Template source alias path:** /Groups/Template
- **Template target alias path:** /Group-pages

As you can see in the screenshot below, there is the **/Groups/Template** page with one sub-page: **Pages**. When a new group is created, its title page is created under **/Group-pages** and the **Pages** page is created under it. As you have probably noticed, the web parts placed on the title page are identical to those placed on the **Template** page. Web parts on the **Pages** page are also identical to the source **Pages** page. Under **Pages**, all group documents will be stored.

All Kentico CMS documents can be set to be owned by a group. This can be done by signing into CMS Desk, selecting a document from the content tree, switching to **Edit** mode and going to **Properties -> General -> Owned by group** and choosing a group from the drop-down list displayed after clicking the **Change** button. This property is used to identify which group a document belongs to and is used by various group context sensitive web parts to display the correct content. It also influences the editing permissions of Group administrator widget zones.

In **Site Manager -> Settings -> Community**, you can enable or disable the **Use parent community group for new documents** option. If you have it enabled, all newly created documents will inherit the group assignment from their parent document.

The screenshot displays the Kentico CMS 7.0 Developer's Guide interface. The top navigation bar includes 'Live Site', 'Site Manager', and 'Community site' tabs. Below the navigation bar is a toolbar with 'New', 'Delete', 'Move', 'Up', 'Down', 'Edit', 'Preview', 'Live site', 'List', and 'Search' buttons. The left sidebar shows a tree view of the site structure, with 'Czech_Republic_fans' selected under 'Group pages'. The main content area displays the 'Properties' tab for the selected group page, showing fields for 'Design', 'Other properties', 'Owner', and 'Output cache'. The 'Owner' section is highlighted with a red box, showing 'Global Administrator (administrato)' as the owner and 'Czech Republic fans' as the group, with 'Change' and 'Select' buttons.

Please refer to [Community Site Guide -> Part 2 -> Creating the Groups section](#) for a step-by-step tutorial on how to create a sample group pages section of a website.

8.29.5 How site users create a new group

When a user wants to create a new group on the live site using the **Group registration** web part, they have to fill in the following details:

- **Group name** - name of the group displayed on the site and in the administration interface
- **Description** - text describing the group
- **Approve members** - determines if users can join the group with or without the group admin's approval; the last options allows invited members to join without the approval
- **Content access** - determines who can view content of the group pages

After clicking **OK**, the group will be created and group pages added to the site. In case that site administrator's approval is needed, these actions will be performed after the approval.

Create new group

By entering the details into the form below, you can create your new user group. Make sure you give the group a name and description according to the group's field of interest. It is a good way of attracting site users with the same interest to join your group.

Group name:

Description:

Approve members:

- Any site member can join
- Only approved members can join
- Only approved members can join except for invited members

Content access:

- Anybody can view the content
- Site members can view the content
- Only group members can view the content

8.29.6 Related e-mail templates

In **Site manager -> Administration -> E-mail templates**, you can find the [E-mail templates](#) used for the automatic group-related e-mail notifications. Messages based on the following templates are sent to users when they attempt to join a group or invite a new member:

- **Groups - Member joined confirmation** - sent to users who join a group that does not require membership approval.
- **Groups - Member joined waiting for approval** - sent to users who apply to groups where approval is needed.
- **Groups - Member approved** - informs users that their group membership has been approved.
- **Groups - Member rejected** - sent to users if their attempt to join a group was rejected by the group's administrators.
- **Groups - Member invitation** - sent to users who are invited to a group by an existing member.
- **Groups - Member accepted invitation** - used to inform group members that their invitation was accepted by the recipient.

The templates below are used for notifications sent to group or community administrators:

- **Groups - Member join** - notifies group administrators when a new member joins their group.
- **Groups - Member waiting for approval** - lets administrators know that a new group member is waiting for their approval.
- **Groups - Member leave** - notifies group administrators when a member leaves their group.
- **Groups - Waiting for approval** - sent to community administrators when a new group is created (if it requires approval) .

Any of these templates can be edited as needed, so you may fully customize the content of the notifications. You can use the following [context macros](#) to include dynamic values in their text. Please note that some of the macros are only available in certain templates, e.g. invitation values and objects can only be accessed in templates related to invitation notifications.

- **{% AcceptionURL %}** - resolves into the URL of a page where users can accept an invitation to join a group. See *Invitation acceptance path* in [Settings](#) for more details.
- **{% InvitedBy %}** - returns the name of the user who sent the invitation.

You can also access the following objects and their properties (e.g. `{% MemberUser.FullName %}`):

- **{% Group %}** - *GroupInfo* object of the group related to the notification.
- **{% MemberUser %}** - *UserInfo* object of the user who is attempting to join the group.
- **{% Invitation %}** - *InvitationInfo* object that can be used to access the properties of the group invitation.
- **{% Sender %}** - *UserInfo* object representing the user who accepted the invitation (usable in the *Member accepted invitation* template).
- **{% Recipient %}** - *UserInfo* object of the user who originally sent the invitation (usable in the *Member accepted invitation* template)..
- **{% GroupMember %}** - *GroupMemberInfo* object representing the new member who accepted the invitation to join the group.

In addition to the special ones listed above, you can also use all other standard macro expressions in the templates. See the [Development -> Macro expressions](#) chapter of this guide for more information about macro expressions in Kentico CMS.

8.29.7 Security

Permissions of the Groups module can be set in **Site Manager -> Administration -> Permissions**. The following permissions can be assigned to members of the particular roles:

- **Manage** - allows managing of groups via the administration interface
- **Read** - allows viewing group settings, but does not allow any changes to be made to them

 **Permissions**

Site: ▼

Permissions for: ▼ Groups ▼

Report for user: ▼ Show only this user's roles

| Role | Read | Manage |
|------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |

Group pages permissions

- **Create pages** - users can create group pages
- **Delete pages** - users can delete group pages
- **Edit pages** - users can edit group pages

These permissions can be assigned to:

- **Nobody** - nobody can perform the action
- **All users** - all users can perform the action
- **Authenticated users** - only signed-in users can perform the action, i.e. anonymous public users can't perform it
- **Group members** - only group members can perform the action, i.e. authenticated non-group members and anonymous users can't perform it
- **Authorized roles** - only members of the group roles selected below can perform the action

Group admin's permissions

Group administrators can perform any of these actions, even if they haven't the permissions assigned.

| | Create pages | Delete pages | Edit pages |
|---------------------|----------------------------------|----------------------------------|----------------------------------|
| Nobody | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| All users | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Authenticated users | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Group members | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Authorized roles | <input checked="" type="radio"/> | <input checked="" type="radio"/> | <input checked="" type="radio"/> |

Please select the authorized roles (available only when you select the "Authorized roles" option above):

| | Create pages | Delete pages | Edit pages |
|-------------|--------------|--------------|------------|
| Group admin | | | |

Items per page: 20

8.29.8 Settings

Settings of the groups module are located in **Site Manager -> Settings -> Community**. The following settings can be adjusted:

- **Group template path** - alias path of the document that will be used, together with the documents stored under it, as a template for newly created groups; e.g. */Groups/Template*
- **Groups security access path** - alias path of a document to which users will be redirected when they try to access pages of a group to which they don't have permissions; this page should contain the Group security message web part; e.g. */Groups/{GroupName}/Access*
- **Group management path** - alias path of the group management page, containing the Group profile web part; e.g. */Groups/{GroupName}/Management*
- **Group profile path** - alias path of the group profile page; e.g. */Groups/{GroupName}*
- **Invitation acceptance path** - alias path of the document containing the Group invitation web part; this is a special web part handling requests for joining a group when a user clicks the joining link in a group invitation e-mail; e.g. */Special-pages/Invitation-acceptation*.
- **Group invitation expires after (days)** - when some user receives a group invitation e-mail, the link for joining the group included in the e-mail will be active for the number of days entered here. After the specified duration, the link will no longer be functional; when 0 is entered, the link will be functional permanently.
- **Use parent community group for new documents** - indicates if new documents should inherit the value of the *Owned by group* property from their parent document.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The 'Settings' tab is active, and the 'Community' module is selected. The left sidebar shows a tree view of settings categories, with 'Community' highlighted. The main content area displays the 'Community' settings. A red box highlights the 'Groups' section, which contains the following settings:

- Group template path: /Groups/Template
- Groups security access denied path: /Groups/{GroupName}/Access
- Group management path: /Groups/{GroupName}/Managem
- Group profile path: /Groups/{GroupName}

Below the 'Groups' section is the 'Group invitation' section with the following settings:

- Invitation acceptance path: /Special-pages/Invitation-acceptat
- Group invitation expires after (days): 0

The 'Members' section includes the following settings:

- Member management path: [empty]
- Member profile path: [empty]
- Enable friends:
- Friend management path: [empty]

8.29.9 Groups internals and API

8.29.9.1 Overview

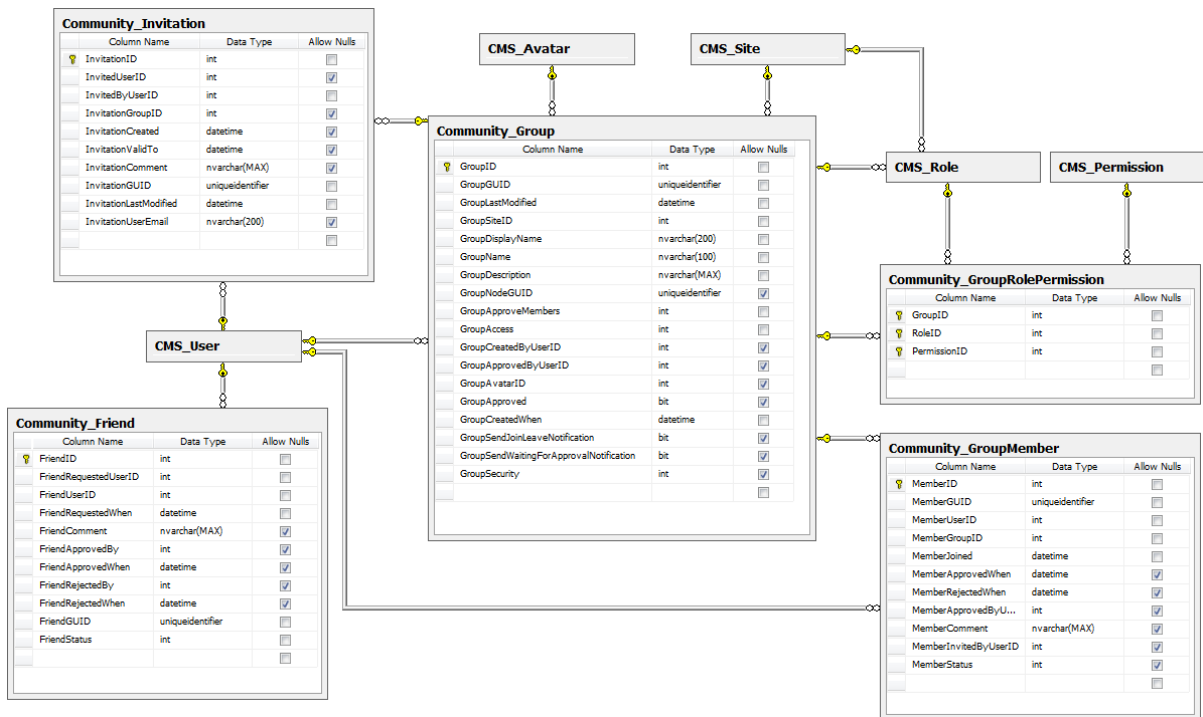

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Groups module. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the module's classes, please refer to [Kentico CMS API Reference](#).

8.29.9.2 Database tables

The following database tables are used to store information about groups:

- **Community_Group** - contains records representing groups and their settings.
- **Community_GroupMember** - stores relationships between groups and users and other group membership data.
- **Community_GroupRolePermission** - stores relationships between groups and roles as well as a permission type. Each entry in this table indicates that users belonging to the given role have the specified permission for a group.
- **Community_Invitation** - stores invitations for group membership.

Group role storage

Group roles are stored along with standard roles in the **CMS_Role** table. Records representing group roles have a value in their **RoleGroupID** field that is equal to the ID of the group that they belong under, while standard roles have it set to *NULL*.

8.29.9.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Groups module can be found in the **CMS.Community** namespace.

Community_Group table API:

- **GroupInfo** - represents one group object.
- **GroupInfoProvider** - provides management functionality for groups.

Community_GroupMember table API:

- **GroupMemberInfo** - represents one group member.

- **GroupMemberInfoProvider** - provides management functionality for group members.

Community_GroupRolePermission table API:

- **GroupRolePermissionInfo** - represents a relationship between a group, role and permission.
- **GroupRolePermissionInfoProvider** - provides management functionality for group-role relationships.

Community_Invitation table API:

- **InvitationInfo** - represents an invitation to become a member of a group.
- **InvitationInfoProvider** - provides management functionality for group invitations.

Other classes:

- **CommunityContext** - this class can be used to provide group-related data of the current request.

8.29.9.4 API examples

8.29.9.4.1 Overview

These topics show examples of how the API of the Groups module can be used:

- [Managing groups](#)
- [Managing group members](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Community\Groups\Default.aspx.cs**.

The group API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.Community;
```

8.29.9.4.2 Managing groups

The following example creates a group.

```
private void CreateGroup()
{
    // Create new group object
    GroupInfo newGroup = new GroupInfo();

    // Set the properties
    newGroup.GroupDisplayName = "My new group";
    newGroup.GroupName = "MyNewGroup";
    newGroup.GroupSiteID = CMSContext.CurrentSiteID;
    newGroup.GroupDescription = "";
    newGroup.GroupApproveMembers = GroupApproveMembersEnum.AnyoneCanJoin;
    newGroup.GroupAccess = CMS.SiteProvider.SecurityAccessEnum.AllUsers;
    newGroup.GroupApproved = true;
    newGroup.GroupApprovedByUserID = CurrentUser.UserID;
    newGroup.GroupCreatedByUserID = CurrentUser.UserID;
    newGroup.AllowCreate = SecurityAccessEnum.GroupMembers;
    newGroup.AllowDelete = SecurityAccessEnum.GroupMembers;
    newGroup.AllowModify = SecurityAccessEnum.GroupMembers;
    newGroup.GroupNodeGUID = Guid.Empty;

    // Save the group
    GroupInfoProvider.SetGroupInfo(newGroup);
}
```

The following example gets and updates a group.

```
private bool GetAndUpdateGroup()
{
    // Get the group
    GroupInfo updateGroup = GroupInfoProvider.GetGroupInfo("MyNewGroup",
CMSContext.CurrentSiteName);
    if (updateGroup != null)
    {
        // Update the properties
        updateGroup.GroupDisplayName = updateGroup.GroupDisplayName.ToLower();

        // Save the changes
        GroupInfoProvider.SetGroupInfo(updateGroup);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates groups.

```
private bool GetAndBulkUpdateGroups()
{
    // Prepare the parameters
    string where = "GroupName LIKE N'MyNewGroup%'";
}
```

```
// Get the data
DataSet groups = GroupInfoProvider.GetGroups(where, null);
if (!DataHelper.DataSourceIsEmpty(groups))
{
    // Loop through the individual items
    foreach (DataRow groupDr in groups.Tables[0].Rows)
    {
        // Create object from DataRow
        GroupInfo modifyGroup = new GroupInfo(groupDr);

        // Update the properties
        modifyGroup.GroupDisplayName = modifyGroup.GroupDisplayName.ToUpper();

        // Save the changes
        GroupInfoProvider.SetGroupInfo(modifyGroup);
    }

    return true;
}

return false;
}
```

The following example deletes a group.

```
private bool DeleteGroup()
{
    // Get the group
    GroupInfo deleteGroup = GroupInfoProvider.GetGroupInfo("MyNewGroup",
CMSContext.CurrentSiteName);

    // Delete the group
    GroupInfoProvider.DeleteGroupInfo(deleteGroup);

    return (deleteGroup != null);
}
```

8.29.9.4.3 Managing group members

The following example adds a user as a member of a group.

```
private bool CreateGroupMember()
{
    // Get the group
    GroupInfo group = GroupInfoProvider.GetGroupInfo("MyNewGroup",
CMSContext.CurrentSiteName);

    if (group != null)
    {
```

```
        // Get the user
        UserInfo user = UserInfoProvider.GetUserInfo
(CMSContext.CurrentUser.UserName);

        if (user != null)
        {
            // Create new group member object
            GroupMemberInfo newMember = new GroupMemberInfo();

            //Set the properties
            newMember.MemberGroupID = group.GroupID;
            newMember.MemberApprovedByUserID = CurrentUser.UserID;
            newMember.MemberApprovedWhen = DateTime.Now;
            newMember.MemberInvitedByUserID = CurrentUser.UserID;
            newMember.MemberUserID = user.UserID;
            newMember.MemberJoined = DateTime.Now;
            newMember.MemberComment = "New member added by API example.";

            // Save the member
            GroupMemberInfoProvider.SetGroupMemberInfo(newMember);
        }

        return true;
    }

    return false;
}
```

The following example gets and updates a group member.

```
private bool GetAndUpdateGroupMember()
{
    // Get the group
    GroupInfo group = GroupInfoProvider.GetGroupInfo("MyNewGroup",
CMSContext.CurrentSiteName);

    if (group != null)
    {
        // Get the user
        UserInfo user = UserInfoProvider.GetUserInfo
(CMSContext.CurrentUser.UserName);

        if (user != null)
        {
            // Get the group member
            GroupMemberInfo updateMember =
GroupMemberInfoProvider.GetGroupMemberInfo(user.UserID, group.GroupID);
            if (updateMember != null)
            {
                // Update the properties
                updateMember.MemberComment = updateMember.MemberComment.ToLower();

                // Save the changes
            }
        }
    }
}
```

```
        GroupMemberInfoProvider.SetGroupMemberInfo(updateMember);

        return true;
    }
}

return false;
}
```

The following example gets and bulk updates group members.

```
private bool GetAndBulkUpdateGroupMembers()
{
    // Prepare the parameters
    string where = "MemberUserID =" + CMSContext.CurrentUser.UserID;

    // Get the data
    DataSet members = GroupMemberInfoProvider.GetGroupMembers(where, null);
    if (!DataHelper.DataSourceIsEmpty(members))
    {
        // Loop through the individual items
        foreach (DataRow memberDr in members.Tables[0].Rows)
        {
            // Create object from DataRow
            GroupMemberInfo modifyMember = new GroupMemberInfo(memberDr);

            // Update the properties
            modifyMember.MemberComment = modifyMember.MemberComment.ToUpper();

            // Save the changes
            GroupMemberInfoProvider.SetGroupMemberInfo(modifyMember);
        }

        return true;
    }

    return false;
}
```

The following example removes a member from a group.

```
private bool DeleteGroupMember()
{
    // Get the group
    GroupInfo group = GroupInfoProvider.GetGroupInfo("MyNewGroup",
    CMSContext.CurrentSiteName);

    if (group != null)
    {
        // Get the user
```

```
        UserInfo user = UserInfoProvider.GetUserInfo
(CMSContext.CurrentUser.UserName);

        if (user != null)
        {
            // Get the group member
            GroupMemberInfo deleteMember =
GroupMemberInfoProvider.GetGroupMemberInfo(user.UserID, group.GroupID);
            if (deleteMember != null)
            {
                // Save the changes
                GroupMemberInfoProvider.DeleteGroupMemberInfo(deleteMember);

                return true;
            }
        }

        return false;
    }
}
```

The following example creates an invitation to a group for a user.

```
private bool CreateInvitation()
{
    // Get the group
    GroupInfo group = GroupInfoProvider.GetGroupInfo("MyNewGroup",
CMSContext.CurrentSiteName);

    if (group != null)
    {
        // Create new invitation
        InvitationInfo newInvitation = new InvitationInfo();

        // Set properties
        newInvitation.InvitationComment = "Invitation created by API example.";
        newInvitation.InvitationGroupID = group.GroupID;
        newInvitation.InvitationUserEmail = "admin@localhost.local";
        newInvitation.InvitedByUserID = CMSContext.CurrentUser.UserID;
        newInvitation.InvitationCreated = DateTime.Now;
        newInvitation.InvitationValidTo = DateTime.Now.AddDays(1);

        // Save object
        InvitationInfoProvider.SetInvitationInfo(newInvitation);

        return true;
    }

    return false;
}
```

8.30 Health monitoring

8.30.1 Overview

The Health monitoring module enables website administrators to monitor and record load and performance of a Kentico CMS instance. Monitoring itself is not integrated in Kentico CMS user interface — the module only stores monitored values about the system in Windows performance counters and therefore provides support for monitoring using an external application, e.g. the built-in [Performance monitor](#) in Microsoft Windows 7, Windows Vista or Windows Server 2008 R2. The module can be used only if the Kentico CMS instance is running in Full Trust environment.

As mentioned above, monitored values are stored in Windows performance counters. The [Performance counters overview](#) topic provides overview of default performance counters that can be used out-of-the-box, as well as information on counters definition XML files, categories where the counters are stored, etc. While Kentico CMS comes with a pre-defined set of default counters, you are not limited to use just the default ones - in the [Adding custom counters](#) topic, you can learn how to implement custom performance counters tailored for your specific purposes.

The first thing to do when enabling Health monitoring of an instance of Kentico CMS is registration of the performance counters in Windows. This can be done in three different ways, each of which is described in the [Registering performance counters](#) topic. Once the counters are registered, it is also necessary to enable Health monitoring in Kentico CMS settings, as explained in [Enabling Health monitoring](#). When counters are registered and Health monitoring enabled, you can start using an external application to monitor the values. Basics of monitoring using the built-in [Performance monitor](#) are explained in the [Monitoring using Performance monitor](#) topic.

While most values are monitored and written to the counters by the Kentico CMS application itself, monitoring of some of them requires database access. To optimize performance in this case, it is possible to install a dedicated Windows service and let it handle monitoring of these values instead of the application. To learn more about the installation of Windows service, please refer to the [Installing Health monitoring Windows service](#) topic.

8.30.2 Performance counters overview

This topic provides an overview of default Kentico CMS performance counters, their definition XML file and categories where the counters are stored.

Application name `web.config` key

Before getting to the counters, it is important to explain the following key in the `appSettings` section of the instance's `web.config` file:

```
<add key="CMSApplicationName" value="Default Web Site/CMS" />
```

This key is added to the `web.config` file automatically during installation. In case of IIS installation, path to the instance in IIS is used as its value. In case of Visual Studio web server installation, name of the target web project root folder is used. The value must be less than 60 characters long. In general, the value of the key is used by Kentico CMS Windows services to identify the Kentico CMS instance. Specifically for Health monitoring, the value is used to identify performance counters to which monitored values about the instance should be written.

Important!

In case of Visual Studio web server installation, it is possible that multiple instances running on a single server may have identical values of the key (if the instances are installed into folders with the same names). In this case, you need to ensure that the keys have different values. Otherwise, values from these instances may be written to the same counters.

Performance counter categories

Kentico CMS performance counters are stored in two categories:

- **Kentico - General (<CMSApplicationName>)** - contains general counters monitoring the Kentico CMS instance as a whole. It contains single-instance counters, which means each of the counters can be added to the to the list of monitored counters just once. If a counter is present in this category as well as in the Sites category, its value in this category is a sum of values of all site instances of the counter in the Sites category.
- **Kentico - Sites (<CMSApplicationName>)** - contains site specific counters monitoring particular websites running in the Kentico CMS instance. It contains multi-instance counters, i.e. each of the counters can be added to the list of monitored counters multiple times — once for each website running in the instance. These counters are used only if the *Enable site counters* option is enabled in *Site Manager -> Settings -> System -> Health monitoring*.

The `<CMSApplicationName>` part of the category names is the value of the `CMSApplicationName` `web.config` key explained above. In case of IIS installation, the value is reversed in the category names so that website name is stated first and the IIS path after it. For example, if the IIS path is **Default Web**

Site/CMS, you would have **CMS/Default Web Site** in the name of the category. This should provide better orientation in the category list in Performance Monitor.

Performance counters definition XML

In `~\AppData\CMSModules\HealthMonitoring`, you can find the **counters.xpc** file. This is a file in XML format which contains definitions of default performance counters for the respective instance of Kentico CMS. It contains definitions of both General and Site counters. When performance counters are registered in Windows, this file is accessed to get the list of counters to be registered.

Apart from this default file, the whole folder structure under `~\AppData\CMSModules\` is also searched for other files with the **.xpc** extension when counters are registered. The other files can contain definitions of additional performance counters and when found, the counters are registered as well.

The following code is an extract from the **counters.xpc** file:

```
<?xml version="1.0" encoding="utf-8"?>
<Counters>
  <Counter Key="allocatedmemory" Name="Allocated memory in MB" Description="The
size of allocated memory in megabytes." Type="NumberOfItems32" Enabled="True"
OnlyGlobal="True" />
  <Counter Key="pendingrequestsperssecond" Name="Pending requests/sec"
Description="The number of pending requests per second." Type="NumberOfItems32"
Enabled="True" OnlyGlobal="True" PerSecond="True" />
  ...
</Counters>
```

As you can see in the code extract above, each counter element has the following attributes:

- **Key** – counter key used for its identification.
- **Name** – name of the counter displayed in Performance Monitor or another monitoring tool.
- **Type** – type of the counter, all types are listed and explained at: <http://msdn.microsoft.com/en-us/library/system.diagnostics.performancecountertype.aspx>.
- **Enabled** – indicates if the counter should be enabled.
- **OnlyGlobal** – indicates if the counter will be included in the *General* category (true) or in both *General* and *Sites* categories (false).

Default performance counters

The following table lists the default counters that are pre-defined in the **counters.xpc** file and registered in Windows by default:

| Counter name | Category | Description | Values written by |
|-------------------------|----------|---|-------------------|
| Allocated memory in MB | Global | The size of memory allocated by the application in Megabytes. | Application |
| Cache expired items/sec | Global | The number of expired cache items per second. | Application |
| Cache removed items/sec | Global | The number of items removed from cache per second. | Application |

| | | | |
|-------------------------------|------------------|---|---|
| Cache underused items/sec | Global | The number of underused cache items per second. | Application |
| Content page views/sec | Global and Sites | The number of content pages viewed per second. | Application |
| E-mails in queue | Global and Sites | The number of e-mails in E-mail queue. | Application or Windows service ¹ |
| Error e-mails in queue | Global and Sites | The number of e-mails in E-mail queue whose sending failed. | Application or Windows service ¹ |
| Errors | Global | The number of errors in event log since last application restart. | Application |
| File downloads/sec | Global and Sites | The number of files downloaded per second. | Application |
| Non-page requests/sec | Global | The number of non-page requests per second. | Application |
| On-line users – total | Global and Sites | The total number of on-line users. | Application |
| On-line users – authenticated | Global and Sites | The number of authenticated on-line users. | Application |
| On-line users – anonymous | Global and Sites | The number of anonymous on-line users. | Application |
| Pages not found/sec | Global and Sites | The number of not found pages (404 error) per second. | Application |
| Pending requests/sec | Global | The number of pending page requests per second. | Application |
| Robots.txt views/sec | Global and Sites | The number of <i>robots.txt</i> page requests per second.

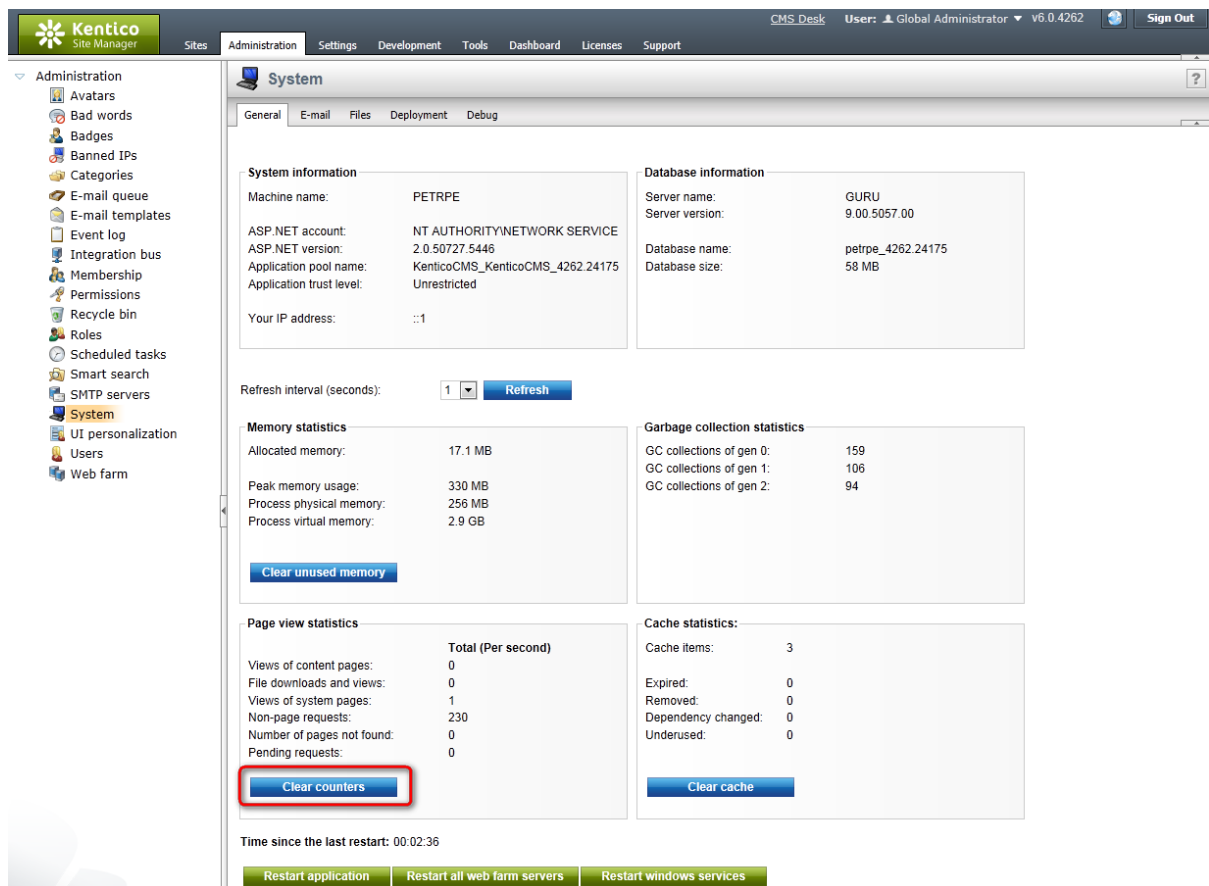

Important: For values to be written to this counter, IIS must be configured to handle <i>.txt</i> extensions. This can be ensured by following a part of the procedure used when configuring custom URL extensions. The procedure is different for IIS 6 (perform all steps on the page) and for IIS 7 or higher (perform only step 1 of Required configuration). | Application |
| Running SQL queries | Global | The number of running SQL queries. | Application |
| Running threads | Global | The number of running threads. | Application |
| Scheduled tasks running | Global | The number of running scheduled tasks. | Application |
| Scheduled tasks in queue | Global | The number of scheduled tasks in queue. | Application or Windows service ¹ |
| System page views/sec | Global | The number of system pages viewed per second. | Application |

| | | | |
|--|--------|---|-------------|
| Warnings | Global | The number of warnings in event log since last application restart. | Application |
| ¹ The Windows service is used to write values to these counters only if it is installed and if the Use external service option is enabled in Site Manager -> Settings -> System -> Health monitoring . | | | |

It is also possible to define custom counters to monitor other system values according to your specific needs. For more information on this, please refer to the [Adding custom counters](#) topic.

Clearing counter values

By clicking the **Clear counters** button in **Site Manager -> Administration -> System**, it is possible to clear values stored in all counters registered for the current Kentico CMS instance. Due to the fact that Health monitoring is only functional in Full Trust environment, the button is only present in this section if the application is running in Full Trust environment.

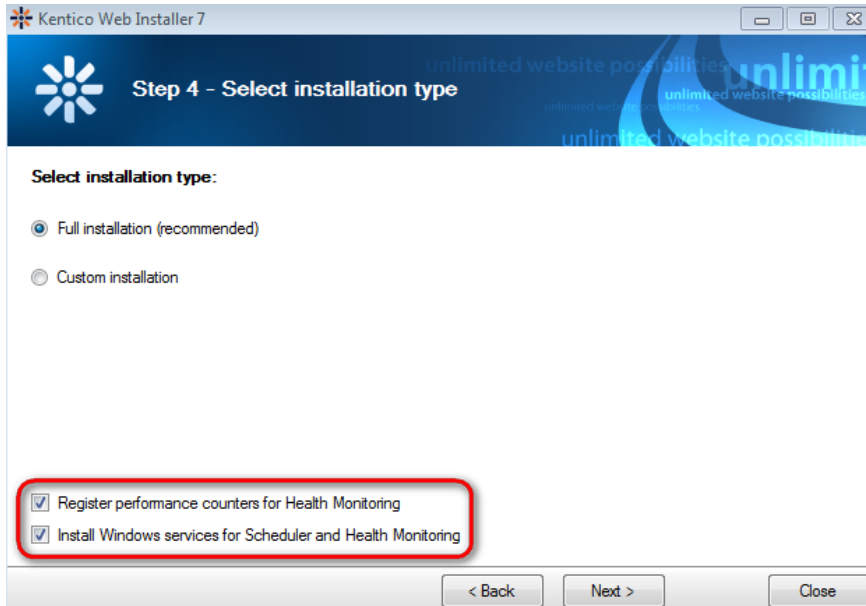

8.30.3 Registering performance counters

There are three ways how performance counters for a Kentico CMS instance can be registered in Windows.

Registration of counters in Web Installer

The first option of registering performance counters for an instance of Kentico CMS is in Step 4 of the [Web Installer](#). In this step, you can see the **Register performance counters for Health Monitoring** check-box. If you enable it, performance counters will be registered for the currently installed instance of Kentico CMS.

Check the **Install Windows services for Scheduler and Health Monitoring** option to install the **Kentico CMS Scheduler** and **Kentico CMS Health Monitor** services. Installing the service can optimize your application's performance.

| | | | | |
|--|-----------------------------------|---------|-----------|-----------------|
| IPsec Policy Agent | Internet Protocol security (IP... | Started | Manual | Network Service |
| Kentico CMS Health Monitor (Default Web Site/KenticoCMS) | Registers categories with co... | Started | Automatic | Local System |
| Kentico CMS Scheduler (Default Web Site/KenticoCMS) | Processes Kentico CMS sche... | Started | Automatic | Local System |
| KtmRm for Distributed Transaction Coordinator | Coordinates transactions be... | | Manual | Network Service |

Automatic registration of counters by the Windows service

When the Windows service is launched or restarted, it checks if performance counter categories for the respective Kentico CMS instance are registered. If it detects that they are not registered, it performs their registration automatically.

When the Windows service is running, it also monitors creation, editing and deletion of **.xpc** files located anywhere in the folder structure under `~\App_Data\CMSModules\`. When an **.xpc** file in this location is created, edited or deleted, the Windows services performs reload of all counters in both counter categories, ensuring that registered counters match the counters defined in the **.xpc** files.

Manual registration/removal of counters using the Windows service

It is also possible to register performance counters manually. This can be done by going to the **Bin** folder of your current Kentico CMS project folder (typically `C:\inetpub\wwwroot\KenticoCMS\bin`) and executing the **HealthMonitoringService.exe** file from Windows command line with the following parameters:

```
HealthMonitoringService.exe /webpath="<disk path to web project root>" /
createcounters
```

Similarly, you can use the **HealthMonitoringService.exe** file to remove already registered counters. This is done by executing the file with parameters as follows:

```
HealthMonitoringService.exe /webpath="<disk path to web project root>" /
deletecounters
```

Performance counters in Windows registry

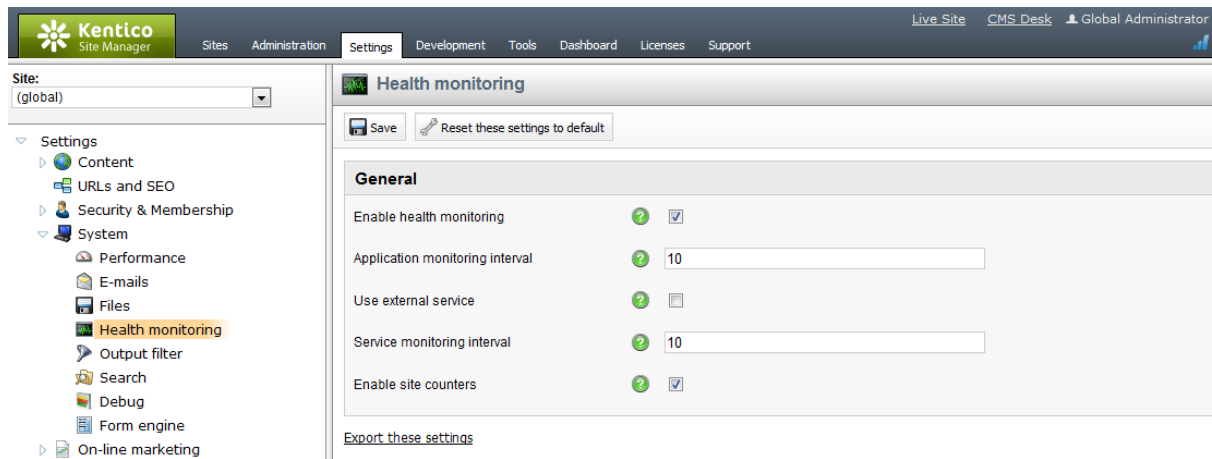

Registration of performance counters is technically performed by adding specific keys to Windows registry. In the registry, they are located in *HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services*. The keys represent individual registered counter categories and have the same names as the respective registered counter categories. By deleting the registry keys, you perform removal of the respective counter categories so that they are no longer registered.

8.30.4 Enabling Health monitoring

Once you have Kentico CMS performance counters registered in Windows as described in the [Registering performance counters](#) topic, you need to adjust Health monitoring settings in order for monitored values to be written to the counters and to specify how exactly it will be performed.

This can be done in **Site Manager -> Settings -> System -> Health monitoring**, where the following settings can be adjusted:

| | |
|---------------------------------|---|
| Enable health monitoring | Indicates if Health monitoring is enabled. i.e. if monitored values are written to both General and Site performance counters related to this instance of Kentico CMS. If disabled, no values are written to any of these performance counters. |
| Application monitoring interval | Time interval (in seconds). In this periodic interval, the application reads monitored values and writes them to performance counters. |
| Use external service | Indicates if external Windows service should be used to read and write monitored values to the <i>Scheduled tasks in queue</i> , <i>E-mails in queue</i> and <i>Error e-mails in queue</i> performance counters. As these counters require database access to get their values, using the external service may optimize your application's performance. |
| Service monitoring interval | Time interval (in seconds). In this periodic interval, the external Windows service reads monitored values and writes them to performance counters. If you are using the Health Monitoring Windows service and change this value, it is necessary to restart the Windows service in order for the new value to be used. |
| Enable site counters | Indicates if values are written to site specific performance counters. If disabled, values are written to general counters only. |

8.30.5 Monitoring using Performance monitor

When you have performance counters for your instance of Kentico CMS [registered in Windows](#) and [Health monitoring settings](#) adjusted, you can start monitoring values written to the counters. There is a number of applications that can be used for this purpose. In this topic, we will use the built-in [Performance monitor](#) that is a native part of Windows 7, Windows Server 2008 R2 and Windows Vista.

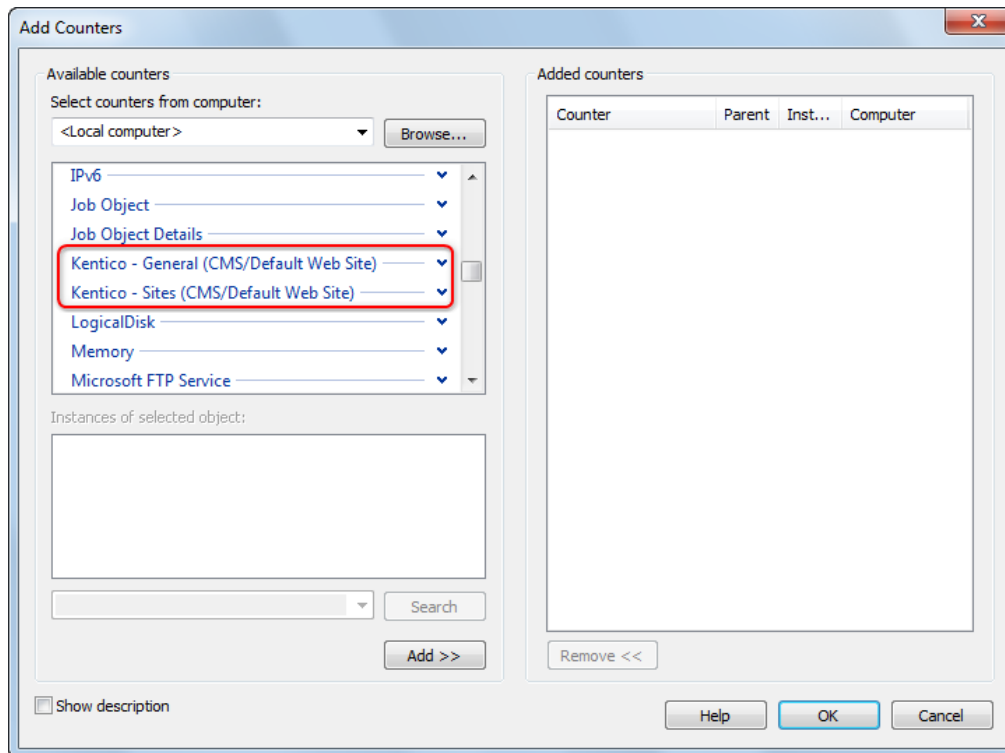

To execute Performance monitor, type *perfmon* in Windows Start menu search box and press *Enter*.

Performance monitor will be launched. In the tree on the left, select **Monitoring Tools -> Performance monitor**. As you can see, only the default **% Processor Time** counter is monitored initially. To add the Kentico CMS counters, click the **Add (+)** icon in the toolbar at the top, as highlighted in the following screenshot.

The **Add Counters** window pops up. From the **Select counters from computer** drop-down list, choose **<Local computer>**. In the section below, you will see a list of all counter categories currently registered in Windows. Among them, you will find two counter categories for each Kentico CMS instance with registered performance counters — **Kentico - General (<IIS path>/<IIS website>)** and **Kentico - Sites (<IIS path>/<IIS website>)**.

If you click the down-arrow next to a category name, you will expand all counters present in the category (1. in the screenshot below). You can either add all counters in a category by selecting the category and clicking **Add >>**, or just individual counters by selecting the counter and clicking the **Add >>** button.

When a counter from the **Site** category is selected, you can add it either for an individual website, or for all websites running in the instance. To add it for all websites, select the counter, then choose **<All instances>** in the **Instances of selected objects** section (2. in the screenshot below) and click **Add >>**. To add it for an individual website, select the counter, then choose the website's code name in the **Instances of selected objects** section and click **Add >>**.

Added counters will be listed in the **Added counters** section on the right. Once you have all counters added, click **OK** to return back to the monitoring UI.

Back in **Monitoring Tools -> Performance Monitor**, you can see that values in counters are now shown in a graph and reflect the real activity of the Kentico CMS instance. You can switch between different ways how monitored values are displayed using the **Graph type** drop-down list highlighted in the screenshot below.

8.30.6 Installing Health monitoring Windows service

Kentico CMS comes with a dedicated Windows service for Health monitoring purposes. This service can be used to additionally register performance counters and to write values to the *Scheduled tasks in queue*, *E-mails in queue* and *Error e-mails in queue* performance counters. As these three counters require database access to get their values, using the Windows service for their monitoring instead of the application itself can provide better performance.

The following text describes how the service can be installed. Please note that a specific configuration is also required for the service to write values to the mentioned performance counters. See [Enabling Health monitoring](#) for more details.

Installing and uninstalling the Health monitoring Windows service using Kentico CMS Service Manager

The easiest way to install or uninstall the Health monitoring Windows service is to use the [Kentico Service Manager](#) utility. The utility can either be launched from Kentico CMS program group in Windows Start menu, or from [Kentico Installation Manager](#), as shown in the screenshot below.

Installing the Health monitoring Windows service from the command line

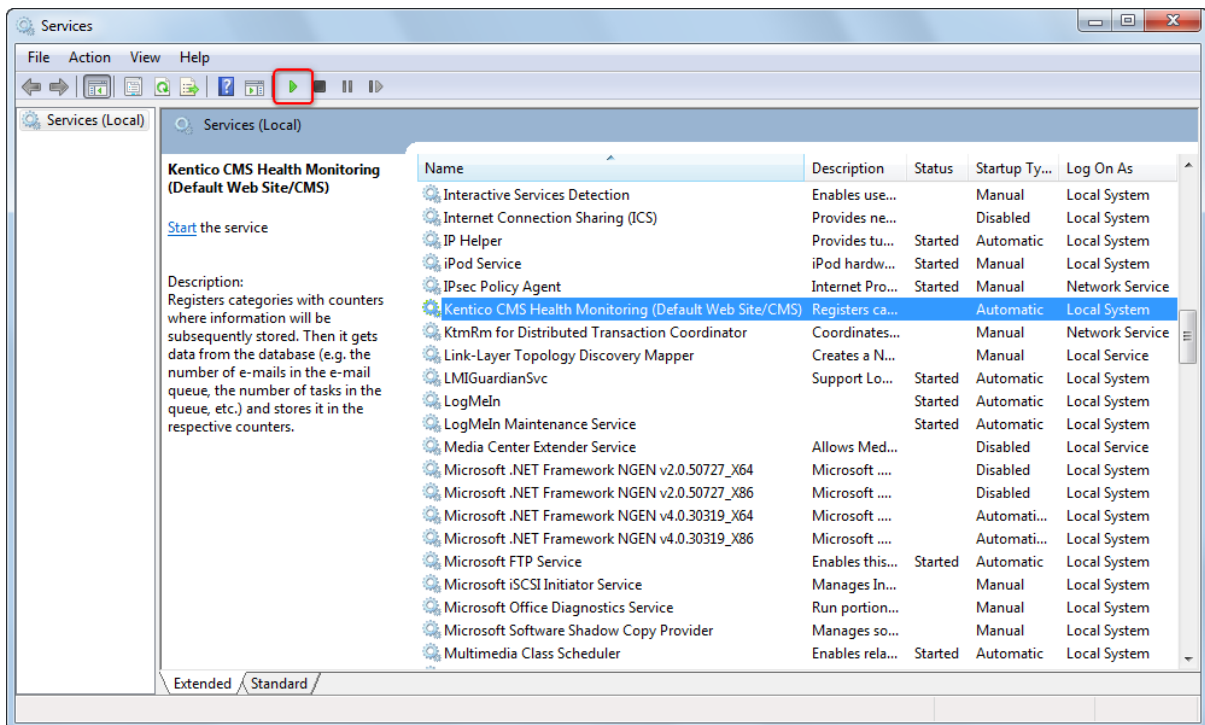

To install the Windows service from the command line, you need to use [Installer Tool \(InstallUtil.exe\)](#), which is a native part of the .NET Framework. The following steps describe installation of the Windows service using the Installer Tool.

1. Open Windows command line (type *cmd* in the Start menu search box) and navigate to the .NET folder containing *InstallUtil.exe* (e.g. *c:\Windows\Microsoft.NET\Framework64\v4.0.30319*).
2. Execute *InstallUtil.exe* from Windows command line with parameters as shown below. The parameters mean the following:

- **/webpath** - path to the root folder of the Kentico CMS instance for that you want to install the Windows service.
- **second parameter** - path to the *HealthMonitoringService.exe* file in the *Bin* folder inside application root (typically *c:\inetpub\wwwroot\KenticoCMS\bin\HealthMonitoringService.exe*).
- **/LogToConsole** - optional parameter defining if installation progress will be logged to console.
- **/i** - if this parameter is used, the Installer Tool performs installation of the Windows service.

```
InstallUtil /webpath="C:\inetpub\wwwroot\KenticoCMS" "c:\inetpub\wwwroot\KenticoCMS\bin\HealthMonitoringService.exe" /LogToConsole=true /i
```

3. To verify that the service is installed successfully, open Services management console (type *services.msc* into the Start menu search box). In the list of installed services, you should see the **Kentico CMS Health Monitoring (<CMSApplicationName web.config key value>)** service. The service is not running initially. To start it, click the **Start Service** button in the top toolbar, as highlighted in the screenshot below.

Uninstalling the Health monitoring Windows service from the command line

Uninstalling the Health monitoring Windows service can be performed exactly the same way as described above, while you only need to use the `/u` parameter instead of `/i` at the end of the command:

```
InstallUtil /webpath="C:\inetpub\wwwroot\KenticoCMS" "c:\inetpub\wwwroot\KenticoCMS\bin\HealthMonitoringService.exe" /LogToConsole=true /u
```

After executing this command, the Health monitoring Windows service for the instance of Kentico CMS specified by the `/webpath` parameter will be uninstalled.

8.30.7 Adding custom counters

Besides the default performance counters listed in the [Performance counters overview](#) topic, it is also possible to implement custom performance counters to monitor other values according to your specific needs.

In the following example, you will learn how to implement a custom performance counter to monitor the number of accesses to the **Home.aspx** page of any website running in the system. The counter will be available in both the **General** and the **Sites** counter categories, enabling you to monitor access to the **Home.aspx** page of each individual website or globally for all websites in the Kentico CMS instance.

1. Create a new XML file where the custom counter's definition will be located. Give it the name e.g. *MyCounters.xpc* and add it to `~\App_Data\CMSModules\HealthMonitoring` (or any other folder under `~\App_Data\CMSModules\`). Its content should be as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<Counters>
  <Counter Key="requestshomepage" Name="Home.aspx page requests" Description="The number of Home.aspx page requests." Type="NumberOfItems32" Enabled="True" OnlyGlobal="False" />
</Counters>
```

2. We need to create a new module class in **App_Code** (or **Old_App_Code** if you installed the project as a web application), e.g. `~\App_Code\Custom\CustomCounterModule.cs`, which will extend the **CMSModuleLoader** partial class. The code extract below shows what the class should look like for the purpose of this example.

At first, a private attribute `mTotalHomePageRequests` is added to the class, which will hold the value logged in the counter. Its value is made accessible by the `TotalHomePageRequests` public property. The code within the `Init()` method, which is executed on each application start, ensures registration of the method in the `OnLogCustomCounter` event. When the event occurs, the `HealthMonitoringLogHelper_OnLogCustomCounter` method is executed.

```
using System;

using CMS.GlobalHelper;
using CMS.SettingsProvider;
```

```
using CMS.SiteProvider;

[CustomCounterModuleLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Counter of total Home.aspx page requests.
    /// </summary>
    private static CMSPerformanceCounter mTotalHomePageRequests = null;

    /// <summary>
    /// Counter of total home page requests.
    /// </summary>
    public static CMSPerformanceCounter TotalHomePageRequests
    {
        get
        {
            if (mTotalHomePageRequests == null)
            {
                mTotalHomePageRequests = new CMSPerformanceCounter();
            }

            return mTotalHomePageRequests;
        }
    }

    /// <summary>
    /// Module registration
    /// </summary>
    private class CustomCounterModuleLoaderAttribute : CMSLoaderAttribute
    {
        /// <summary>
        /// Initializes the module
        /// </summary>
        public override void Init()
        {
            CMS.CMSHelper.HealthMonitoringLogHelper.OnLogCustomCounter += new
            CMS.CMSHelper.HealthMonitoringLogHelper.LogCustomCounterHandler
            (HealthMonitoringLogHelper_OnLogCustomCounter);
        }

        /// <summary>
        /// Handles custom event of health monitoring.
        /// </summary>
        /// <param name="counter">Counter</param>
        /// <returns>CMS performance counter</returns>
        private static CMSPerformanceCounter
        HealthMonitoringLogHelper_OnLogCustomCounter(Counter counter)
        {
            if (counter.Key.ToLower() == "requestshomepage")
            {
                return TotalHomePageRequests;
            }

            return null;
        }
    }
}
```

```
}  
}
```

3. Add the *OnLoad* method below to *~\CMSPages\PortalTemplate.aspx.cs*. The code ensures that the counter value is incremented each time a page with the */home* node alias path is accessed.

```
protected override void OnLoad(EventArgs e)  
{  
    // Increment Home.aspx page requests counter  
    if (CMS.CMSHelper.CMSContext.CurrentPageInfo.NodeAliasPath.Equals("/home",  
StringComparison.InvariantCultureIgnoreCase))  
    {  
        CMSModuleLoader.TotalHomePageRequests.Increment  
(CMS.CMSHelper.CMSContext.CurrentSiteName);  
    }  
  
    base.OnLoad(e);  
}
```

4. At this point, the process is different depending on if the Windows service was running at the time when you performed step 1 of this example.

4.a If it was running, the counters should be already registered in both categories as the Windows service performs automatic reload of counters when an **.xpc** file in the folder structure under *~\AppData\CMSModules* is created, edited or deleted.

4.b If the Windows service was not running when you performed step 1, you will need to register the counters manually by executing the Windows service with respective parameters, as explained in the [Registering performance counters](#) topic. To do it, open Windows command line, navigate to the **Bin** folder inside the Kentico CMS installation folder (typically *C:\Program Files\Kentico CMS\<version>\Bin*) and execute the **HealthMonitoringService.exe** file with the following parameters:

```
HealthMonitoringService.exe /webpath="<disk path to web project root>" /  
createcounters
```

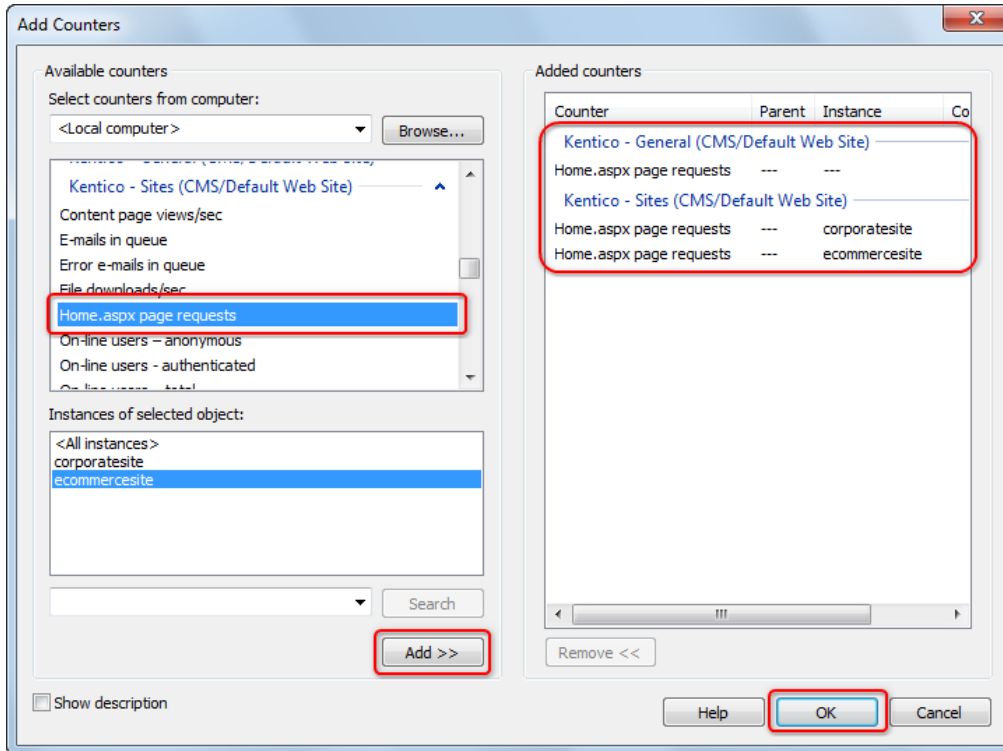

This action will reload all counters in both categories, including the newly added one.

Custom counters and Health Monitoring Windows service

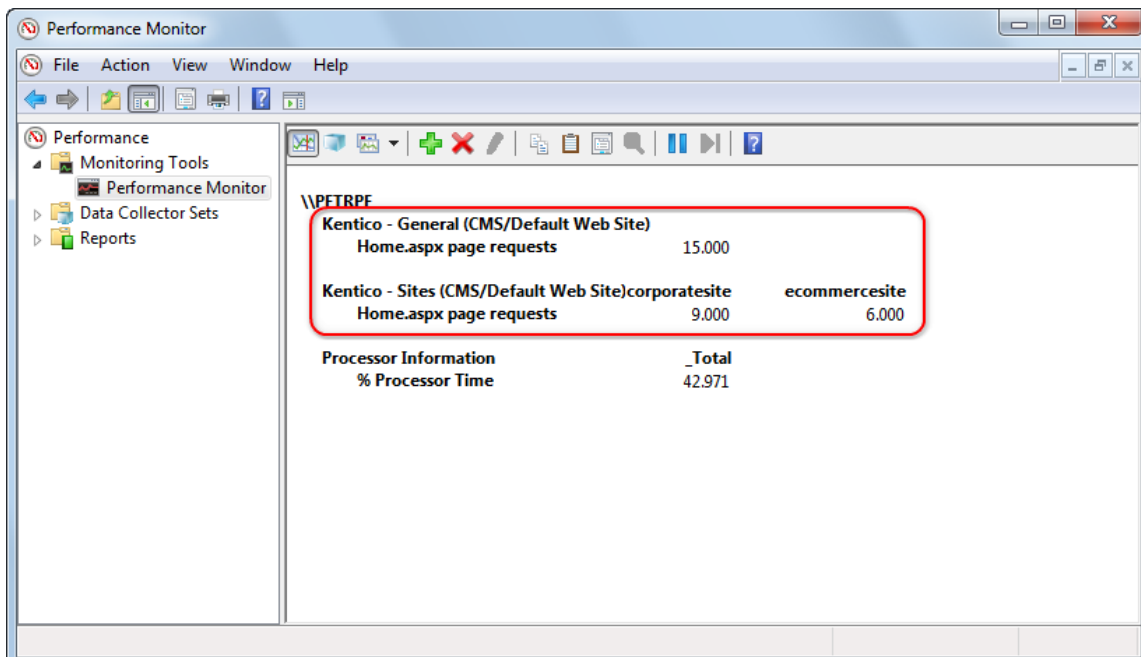

Values of all custom counters can be logged only by the application itself, i.e. it is not possible for values of custom counters to be logged by the Windows service. The only purpose of using the service in this step is to register the added counter, as described in the [Registering performance counters](#) topic.

5. Verify that you have Health monitoring settings adjusted correctly in **Site Manager -> Settings -> System -> Health monitoring**, launch Performance monitor and open the dialog for adding monitored counters (as explained in [Monitoring using Performance monitor](#)). You should see the new counter

present in both counter categories of the current Kentico CMS instance. Add the counter using the **Add >>** button, once from the **General** category and once for each website (if you have more than in your Kentico CMS instance) from the **Sites** category. Then click **OK**.

6. Before trying out the functionality, go to **Site Manager -> Administration -> System** and restart the application using the **Restart application** button. Now try accessing the **Home.aspx** page multiple times and see how the value gets incremented after each access.

8.31 Image gallery

8.31.1 Overview

The Image gallery module is used for effortless creating of image gallery pages. By means of this module, you can display images which are saved in the content tree as documents. The module encompasses four page templates and three web parts suitable for creating image galleries.

However, using the Image gallery module is not the only way to display images on your web pages. You can achieve similar functionality by using the [Media libraries](#) module. The Media libraries module provides an alternative way of creating a gallery and is suitable if large numbers of stored images are to be displayed or if you want to make audio, video and other file types accessible from your web pages. Another option consists in attaching an image to a document using the [Attachment image gallery](#) web part.

In the Image gallery chapter, you can learn what web parts are available in the Image gallery module (learn [here](#) how to do it), what page templates can be used (as explained [here](#)), you can learn how to import files or even the whole folder structure from the disk to Kentico CMS content repository (as referenced [here](#)) and you can also learn how to use transformations to alter the appearance of your gallery (as explained [here](#)).

8.31.2 Available web parts

There are three web parts suitable for creating image galleries. From the **Select web part** dialog window, you can select the **Image gallery**, **Lightbox gallery** and **Content slider** web parts in the **Listings and viewers** category.

Image gallery

This is the basic web part for image galleries. In its initial view, it displays a set of picture thumbnails:

After clicking one of the thumbnails, the detail view will be displayed:

[Previous](#)

5 Of 28 [Thumbnails](#)

[Next](#)

Besides the usual parameters common to all web parts, these properties can be set to customize the appearance of the gallery:

| Transformations | |
|--------------------------|--|
| Detail transformation | Transformation used for displaying a selected image. |
| Thumbnail transformation | Transformation used for displaying gallery thumbnails. |
| Layout | |

| | |
|-----------------------------|--|
| Number of columns | Number of thumbnail columns in the thumbnail view. |
| Rows per page | Number of thumbnail rows per page in the thumbnail view. |
| Repeat direction | Determines the direction in which items should be displayed when multiple columns are used - can be either vertical or horizontal. |
| Paging | |
| Paging mode | Paging parameter transfer type:
<u>Query string</u> - the paging parameter is transferred through URL
<u>PostBack</u> - the actual page is transferred through ViewState, no URL parameter is used |
| Query string key | Name of the URL parameter containing the page number. |
| Show first and last buttons | If checked, buttons leading to the first and last pages of the gallery will be displayed. |
| Show buttons on top | If checked, paging buttons will be shown above the thumbnails. Otherwise, they will be displayed below them. |

Lightbox gallery

This web part's thumbnail view is similar to that of the **Image gallery** web part:

Displaying results 1-8 (of 28)

|< < 1 - 2 - 3 - 4 > >|

After clicking one of the thumbnails, the whole page will be grayed out and a lightbox with the selected image will be displayed on the top of it, as you can see in the screenshot below:

Here is a list of properties specific to the **Lightbox gallery** web part:

| Transformations | |
|------------------------------|--|
| Transformation | Transformation used for displaying the list of thumbnails. |
| Alternating transformation | Transformation used for even items in the thumbnail view. |
| Selected item transformation | Transformation used in the detail view mode. |
| Item separator | Separator displayed between thumbnails. |
| Nested controls ID | <p>Sets the nested controls IDs. Use ';' as a separator; Example: myRepeaterID;myDataListID;myRepeaterID2</p> <p>This property replaces the previously used NestedRepeaterID and NestedDataListID properties. If you are still using these properties, no changes to functionality will occur, but it is advisable to rewrite your code to use the new property instead.</p> |
| Paging | |
| Enable paging | Indicates if paging is enabled. If unchecked, all thumbnails in the gallery will be displayed on a single page. |
| Paging mode | Paging parameter transfer type:
<u>Query string</u> - the paging parameter is transferred through URL
<u>Postback</u> - the actual page is transferred through ViewState, no URL parameter is used |
| Pager position | Determines position of the pager. Available options are <i>Bottom</i> , <i>Top</i> and <i>Top and bottom</i> . |
| Page size | Number of thumbnails displayed per page. |

| | |
|-----------------------------------|---|
| Query string key | Name of the URL parameter containing the page number. |
| Show first and last buttons | If checked, buttons leading to the first and last page of the gallery will be displayed. |
| LightBox Configuration | |
| Always visible navigation buttons | Indicates whether the navigation buttons are always visible, not only on mouse over. |
| Frame width | Width of the LightBox frame. |
| Frame height | Height of the LightBox frame. |
| Path to external CSS file | URL path to the external CSS file required by LightBox. |
| Overlay opacity | Opacity of LightBox background. Enter values ranging from 0 (transparent) to 1 (opaque black). |
| Animate | Enables LightBox animation. |
| Load delay | Load delay time (in milliseconds). If you are using automatic resizing, this value indicates how long the lightbox will take to reach the element size. If you have problems with displaying lightbox content, try to use a higher value. |
| Resize speed | Defines the speed of resizing images. Choose values ranging from 1 (slowest) to 10 (fastest). |
| Border size | Size of the image border. |
| Loading image | Image displayed while loading the LightBox image. |
| Close button image | Image of the Close button. |
| Previous button image | Image of the Previous button. |
| Next button image | Image of the Next button. |
| Group name | Name of the LightBox group. |

Content slider

The **Content slider** is a web part that can be used for displaying various document types, hence it is also very suitable for displaying images. Contrary to the previous two web parts, the **Content slider** provides no thumbnail view. It displays a full sized image slide show with a pager below. The pager allows for browsing through the images using the numbered buttons. After clicking any of these buttons, the slide show stops and the **Start** button appears. This button launches the slide show again.

Specific properties of the **Content slider** web part:

| Transformations | |
|-----------------------------|--|
| Transformation | Transformation used for displaying the list of thumbnails. |
| Alternating transformation | Transformation used for even items in the thumbnail view. |
| Item separator | Separator displayed between thumbnails. |
| Nested controls ID | Sets the IDs of nested controls as specified in the transformation code. |
| Div options | |
| Width (px) | Width of the scrolling text area in pixels. |
| Height (px) | Height of the scrolling text area in pixels. |
| Style | Style assigned to the DIV tag of the area. |
| JavaScript options | |
| FadeIn time (milliseconds) | Fade in time of the image. |
| FadeOut time (milliseconds) | Fade out time of the image. |
| Break time (milliseconds) | Time for which the image will be displayed. |
| Auto start | If checked, the slide show will automatically start from the beginning. |

8.31.3 Available page templates

There are three basic page templates that can be used for image galleries. In **CMS Desk -> Content**, create a new **Page (menu item)** using a page template. From the **Use page template** dialog window, you can select the **Image gallery**, **Lightbox gallery**, **Sliding gallery** and **List of galleries** templates in the **Images** category.

List of galleries

This page template is used for displaying a list of all galleries under a selected path. For each gallery, it displays a thumbnail with a gallery name above it. By clicking one of the thumbnails, you will be redirected to the main page of the gallery.

The **Teaser image** of each gallery's menu item is used as the thumbnail in the list of galleries. To change some of the thumbnails, select the appropriate gallery's menu item in the content tree and switch to **CMSDesk -> Edit -> Form**. On the displayed page, select a new **Teaser image** and click  **Save**. The selected image will now be displayed as a thumbnail of the gallery in the list of galleries.

Images

Image gallery

This is a basic page template used for displaying image galleries. It uses the **Image gallery** web part for displaying images under a given path in the content tree. See the [Available web parts](#) chapter for detailed info.

Lightbox gallery

This page template uses the **Lightbox gallery** web part for displaying images. See the [Available web parts](#) chapter for detailed info.

Sliding gallery

Displays images using the **Content slider** web part.

8.31.4 Importing images

Images used in galleries are imported the same way as any other files, as described in the [File import](#) chapter.

8.31.5 Transformations

Use of transformations is essential for all **Image gallery** web parts. You can view and alter transformations in the **Transformations** section of a web part's property configuration dialog. For each transformation property, you can **Select** a predefined transformation from a list, **Edit** the current transformation or create a **New** one by means of the respective buttons.

Here are some examples of how you can alter the appearance of the **Image gallery** web part. This is the default thumbnail transformation code of the **Image gallery** web part:

```
<a href="?imagepath=<%# System.Web.HttpUtility.UrlEncode(DataBinder.Eval
(Container, "DataItem.NodeAliasPath").ToString()) %>">
<%# IfEmpty(Eval("FileAttachment"), "no image", "<img alt=\"\" + Eval("FileName") +
\"\" src=\"\" + GetFileUrl("FileAttachment") + "?maxsize=180\" border=\"0\" /
```

```
>" ) %>
</a>
```

And this is how the gallery created using this transformation looks like:

In the following example, we will add a red border around each thumbnail.

```
<div style="border: solid 3px Red">
<a href="?imagepath=<## System.Web.HttpUtility.UrlEncode(DataBinder.Eval
(Container, "DataItem.NodeAliasPath").ToString()) %>">
<## IfEmpty(Eval("FileAttachment"), "no image", "<img alt=\"\" + Eval("FileName") +
\"\" src=\"\" + GetFileUrl("FileAttachment") + "?maxsidesize=180\" border=\"0\" /
>") %>
</a>
</div>
```

This is how the result looks like:

This example shows how to display the file name and date and time of creation for each thumbnail in the gallery:

```

<a href="?imagepath=<%# System.Web.HttpUtility.UrlEncode(DataBinder.Eval
(Container, "DataItem.NodeAliasPath").ToString()) %>">
<%# IfEmpty(Eval("FileAttachment"), "no image", "<img alt=\"\" + Eval("FileName") +
\"\" src=\"\" + GetFileUrl("FileAttachment") + "?maxsize=180\" border=\"0\" /
>") %>
</a>
<%# Eval("DocumentName") %> <br/>
<%# GetDateTime("DocumentCreatedWhen") %>
    
```

Transformations for the Lightbox gallery web part

When writing a custom transformation for the **Lightbox gallery** web part, it is necessary to use the 'rel' and 'rev' parameters as highlighted in the transformation code below. The 'title' parameter is used to determine the description of the image displayed in the lightbox.

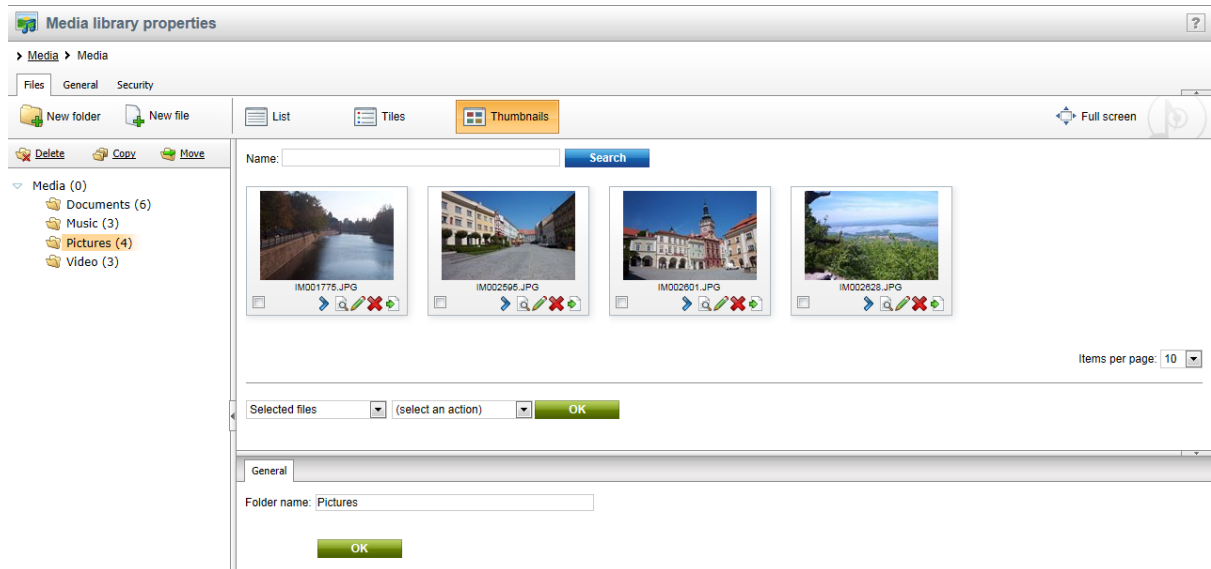

```

<a href="<# GetDocumentUrl() %>" rel="lightbox[group]" rev="<# Eval
("NodeAliasPath") %>"
title="<# Eval("FileDescription") %>">?maxsize=150"
alt="<# Eval("FileName") %>" /></a>
  
```

8.32 Media

8.32.1 Overview

The Media libraries module enables storing of various files, such as photos, sound, videos, package files, presentation files, etc. This means that not only media files, but also other types of files can be stored in media libraries. Media libraries can either be global or related to a particular [group](#).

However, the Media libraries module is not the only way to store files of various kinds within the system. Please refer to the [Content management -> File management](#) chapter of this guide for more details.

- To learn how to create media libraries, please refer to the [Creating media library](#) topic.
- To learn how to upload files to your media libraries, how to manage these files and what file types are supported, please refer to the [Media library content](#) chapter.
- To learn how to use the Media library web part and the built-in WYSIWYG editor in your media libraries, please refer to the [Displaying files from media library](#) chapter.
- To learn how to adjust your media library settings and how to configure your media library custom storage, custom file types and the maximal uploaded file size, please refer to the [Settings](#) chapter.
- To learn how to assign media library permissions and how to deal with secured and non-secured libraries on your site, please refer to the [Security](#) chapter.

More examples of the use of the Media libraries module are available in Kentico CMS Community Site Guide, as describe [here](#).

8.32.2 Community site examples

More examples of the use of the Media libraries module are available in Kentico CMS Community Site Guide. Please note that these practical examples do not concern the whole functionality of the module but focus on its use in a broader context of the Community Site sample website:

- See [Part 1 -> Media libraries -> Current functionality](#) in Kentico CMS Community Site Guide: A brief description of the functionality of the Media libraries module.
- See [Creating custom media libraries](#) in the same section of the Community Site Guide: An example of creating a new global media library and publishing it on the site.
- See [Publishing more than one global media library](#) in the same section of the Community Site Guide: An example of how to publish more than one global media library on the site.
- See [Community Site Guide -> Part 2 -> Pre-development tasks -> Creating a sample Media library](#) in Kentico CMS Community Site Guide: An example of creating a sample media library.
- See [Creating the Blogs section -> Creating the Media page](#) in the same section of the Community Site Guide: An example of creating the Media page using the Media gallery web part under the Blogs section.
- See [Creating the Groups section -> Creating the Media page](#) in the same section of the Community

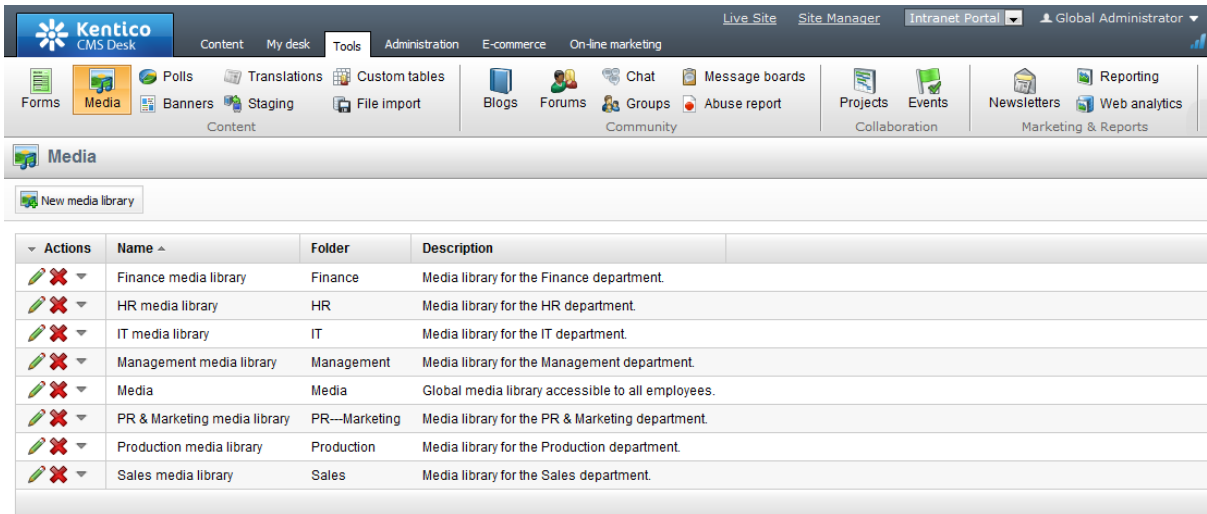

Site Guide: An example of creating the Media page using the Media gallery web part under the Groups section.

8.32.3 Creating media library

There are two ways how media libraries can be created:

- **Live site** - group administrators can create group media libraries on the live site using the **Group profile** web part.
- **Administration interface** - site administrators can create global media libraries in **CMS Desk -> Tools -> Media libraries** or group media libraries in **CMS Desk -> Tools -> Groups -> Edit (✎) -> Media libraries**.

1. In all of these cases, media libraries can be created by clicking  **New media library** above the list of libraries, as you can see in the screenshot below.

| Actions | Name ^ | Folder | Description |
|---|------------------------------|----------------|---|
|   | Finance media library | Finance | Media library for the Finance department. |
|   | HR media library | HR | Media library for the HR department. |
|   | IT media library | IT | Media library for the IT department. |
|   | Management media library | Management | Media library for the Management department. |
|   | Media | Media | Global media library accessible to all employees. |
|   | PR & Marketing media library | PR---Marketing | Media library for the PR & Marketing department. |
|   | Production media library | Production | Media library for the Production department. |
|   | Sales media library | Sales | Media library for the Sales department. |

2. After clicking the link, the following details need to be entered:

- **Display name** - the name of the media library displayed in the administration interface and on the live site.
- **Code name** - the name of the media library used by developers in the code.
- **Description** - the text describing the media library.
- **Teaser image** - the image used as the media library teaser.
- **Folder name** - the name of the folder where files will be stored. This folder will be created under `<web project>\<site name>\media\` or [custom location](#).

3. Click **OK** to create the library. After doing so, you will be redirected to the **Media library properties** interface - just as if you clicked the **Edit** (✎) icon in the list of libraries.

The **Files** tab allows the management of the media library content as described in more detail in the [Media library content](#) subchapter. The **General** tab is used to edit media library general properties that you entered in step 2. Finally, the **Security** tab enables you to adjust permissions to work with folders and files in the given media library. For more details on how to adjust permissions in media libraries, please refer to the [Media library permissions](#) topic.

8.32.4 Media library content

8.32.4.1 Overview

In this subchapter you will learn how to deal with content in a media library.

- To learn how to upload files into media libraries, please refer to the [Uploading files](#) topic.
- To learn how to manage files stored in a media library, please refer to the [Files and folders](#)

[management](#) topic.

- For a brief overview of file types that can be played or viewed on your site by default, please refer to the [Supported file types](#) topic.
- To learn about file size supported in media libraries, please refer to the [Supported file size](#) topic.
- To learn about names of files uploaded to media libraries and about these files thumbnails, please refer to the [File naming conventions](#) topic.

8.32.4.2 Uploading files

There are three ways how files can be uploaded into a media library:

- **By means of the administration interface**
- **On the live site using the Media gallery or Media file uploader web parts**
- **Externally, directly into the file system - e.g. via FTP**

In the following examples, you will learn how to add files into media libraries via the administration interface, on the live site and using FTP.

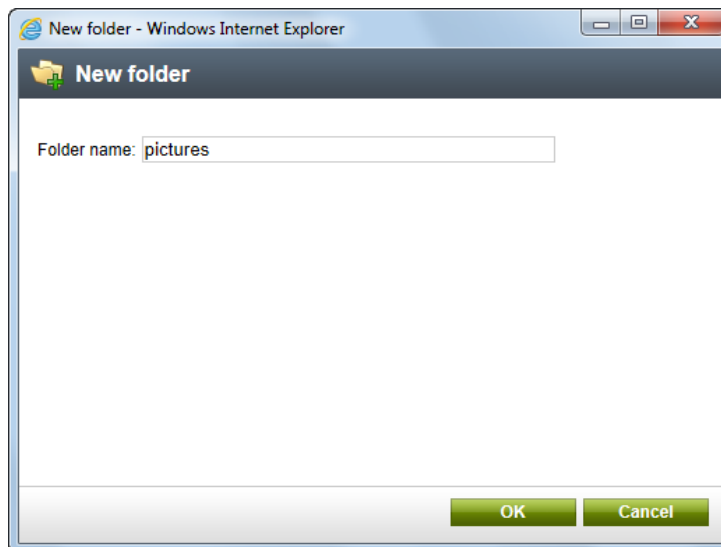

Uploading files via the administration interface

If you choose to **Edit** (✎) a media library in **CMS Desk -> Tools -> Media libraries**, you can manage files in the library on the **Files** tab.

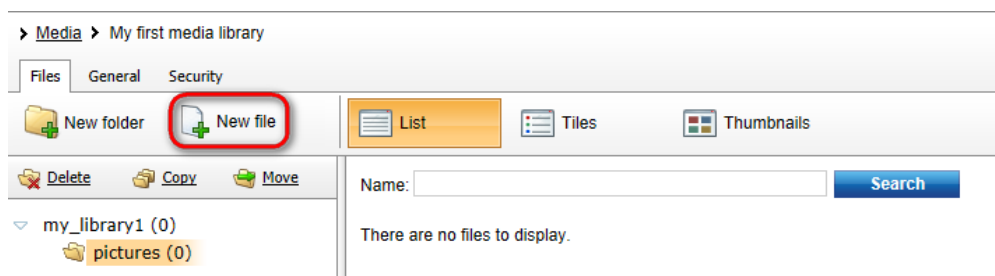

1. It is a good idea to keep your files organized in folders within the media library. To create a new folder, click the **New folder** button in the top left corner of the page.

2. Enter the name of the folder, e.g. *pictures*, and click **OK**.

3. The folder is now created. You can upload files into the selected folder by clicking the  **New file** button.

4. A dialog appears, letting you upload the file. Just select the right folder and the file to be uploaded, then click the **Open** button.

5. Now if you go to the site folder in your file system, you will find the media library under the **media** folder, as you can see the screenshot below. The location of the folder may be customized as described [here](#).

On-site upload via the Media gallery and Media file uploader web parts

The **Media gallery** web part has the following two properties enabling on-site file upload:

- **Allow upload** - enables on-site upload of files.
- **Allow upload thumbnail** - enables on-site upload of file thumbnails.

If these properties are enabled, the controls highlighted in the screenshot below will be displayed in the web part, letting users upload files and thumbnails:

Media gallery

The screenshot shows a 'Media gallery' interface. On the left is a navigation tree with 'Media' expanded, containing 'Documents', 'Music', 'Pictures', and 'Video'. The main area displays a grid of files, sorted by Name, Date, or Size. The files listed are:

- MS Word document**: Size: 9.7 kB, Uploaded: 8/15/2011
- HTML document**: Size: 271 B, Uploaded: 8/15/2011
- PDF document**: Size: 27 kB, Uploaded: 8/15/2011
- MS PowerPoint doc...**: Size: 32 kB, Uploaded: 8/15/2011
- MS Excel document**: Size: 8.9 kB, Uploaded: 8/15/2011
- XML document**: Size: 64 B, Uploaded: 8/15/2011
- WIN XP startup so...**: Size: 76 kB, Uploaded: 8/15/2011
- WIN XP startup so...**: Size: 415 kB, Uploaded: 8/15/2011

Below the grid is a pagination control: '< < 1 2 > >|'. At the bottom is an upload control with a red border, containing 'File:' and 'Browse...' buttons, and 'Preview:' and 'Browse...' buttons, with an 'Upload' button to the right.

The **Media file uploader** web part is also used for uploading files to your media libraries; it has the following property that enables on-site upload of file thumbnails:

- **Enable upload thumbnail** - enables on-site upload of file thumbnails.

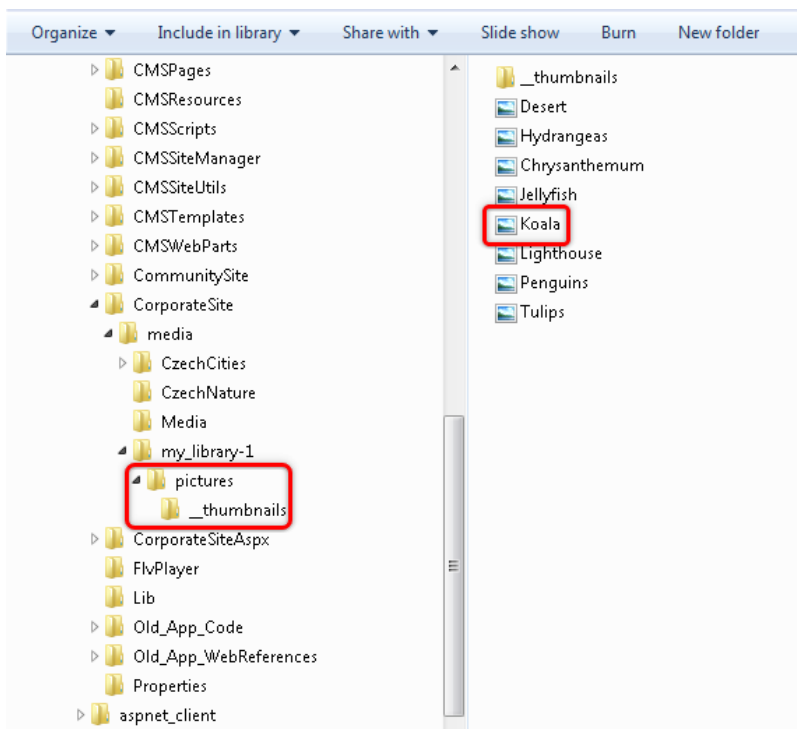

If the property is enabled, the users are allowed to upload both files and their thumbnails. Otherwise, only the control enabling users to browse for and upload files will be available:

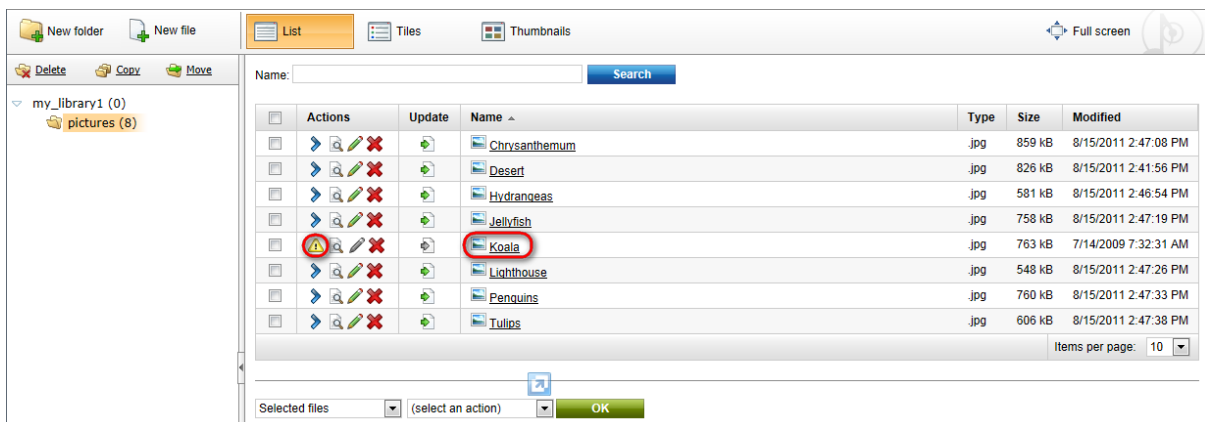

External upload

Files can also be uploaded **externally**, without any use of Kentico CMS administration interface or on-site web parts, e.g. using **FTP**. To do this, you simply need to copy the files into the appropriate folder of the media library.

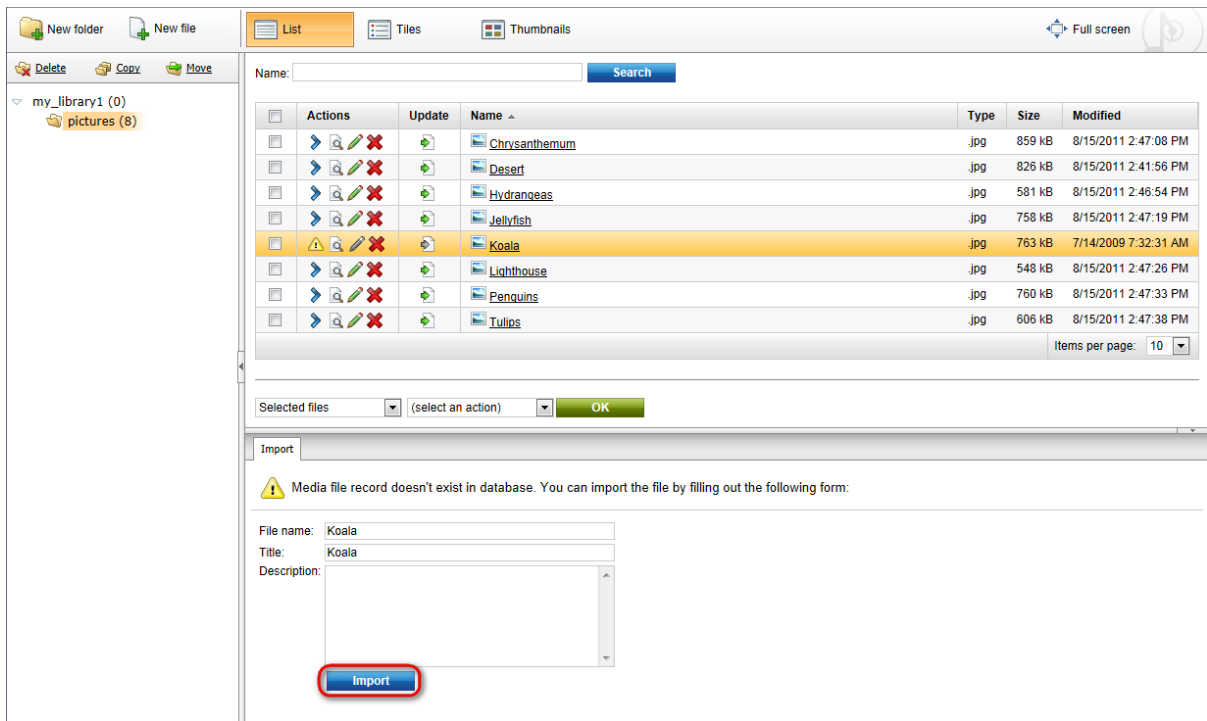

1. For the purposes of this example, try uploading another file into the **pictures** folder by copying it using Windows Explorer or any other file manager.

2. If you go back to the Media library administration interface, you will see the file present in the list. As you can notice, this file is marked with the warning (⚠) icon indicating that the file has not been imported yet. This means that the file **has not yet been registered in the database**. Such files can't be used on the site and have to be registered first. This happens only to externally uploaded files, files uploaded via the administration interface are registered in the database automatically.

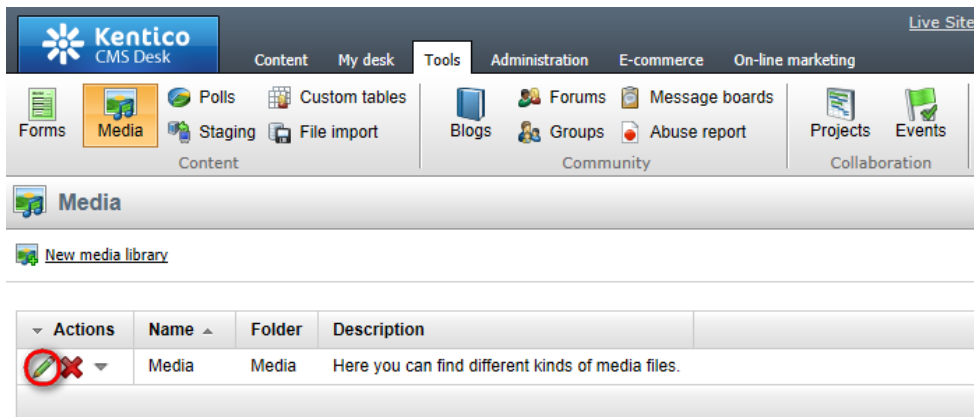

To register the file, you have to click the **Import** button, which creates the file's record in the database. Please note that the files are not physically copied into the database, they remain in the file system only and a record linking to the physical file is created in the database.

Multiple files can also be imported conveniently as a batch. See [Batch operations](#) in the **Files and folders management** topic for more details.

8.32.4.3 Files and folders management

To manage files stored in a media library, you need to go to **CMS Desk -> Tools -> Media libraries** and click the **Edit** (✎) icon next to the appropriate media library.

The library editing interface will be displayed on the **Files** tab where the files can be managed.

Folder operations

The following actions can be performed with the folders in the media library:

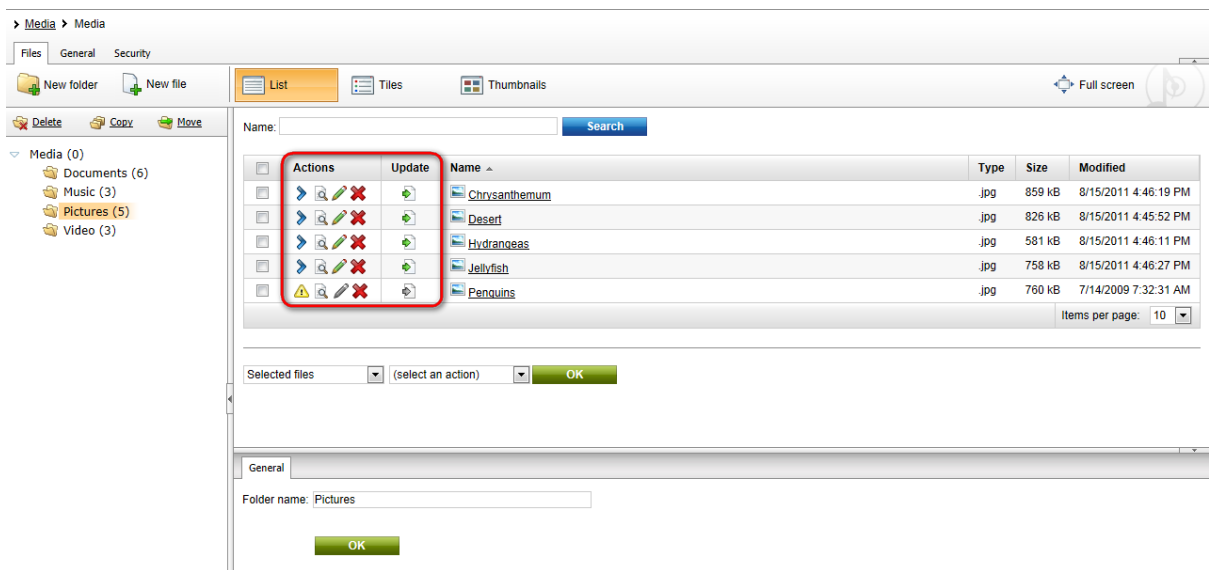

- **New folder** - creates a new folder under the currently selected folder.

-  **Delete** - deletes the currently selected folder.
-  **Copy** - uploads the folder and its content to another location and keeps the original folder.
-  **Move** - uploads the folder into another location and deletes the original folder.

Single file operations

You can perform the following operations by clicking the icons next to particular files:

-  **New file** - uploads a file from the local or network file system to the currently selected folder.
-  **Select** - selects the file and opens its editing interface in the bottom section.
-  **View** - downloads the file and opens it in your default application for the file type.
-  **Edit** - if you click the icon next to an image, the image gets opened in the built-in [image editor](#). If the icon is clicked next to a non-image file, the [metadata editor](#) is opened.
-  **Delete** - deletes the file.
-  **Update** - replaces the file with another file. The original file gets deleted and replaced by the new one.
-  **Import** - this icon is displayed only with files that have been uploaded to the library folder externally (e.g. via FTP) and have not yet been registered in the database. By clicking the icon, you register the file in the database as described [here](#).

Batch file operations

You can also perform the  **Copy**,  **Move**,  **Delete** and  **Import** operations for multiple files at once. To perform a batch operation, take the following steps:

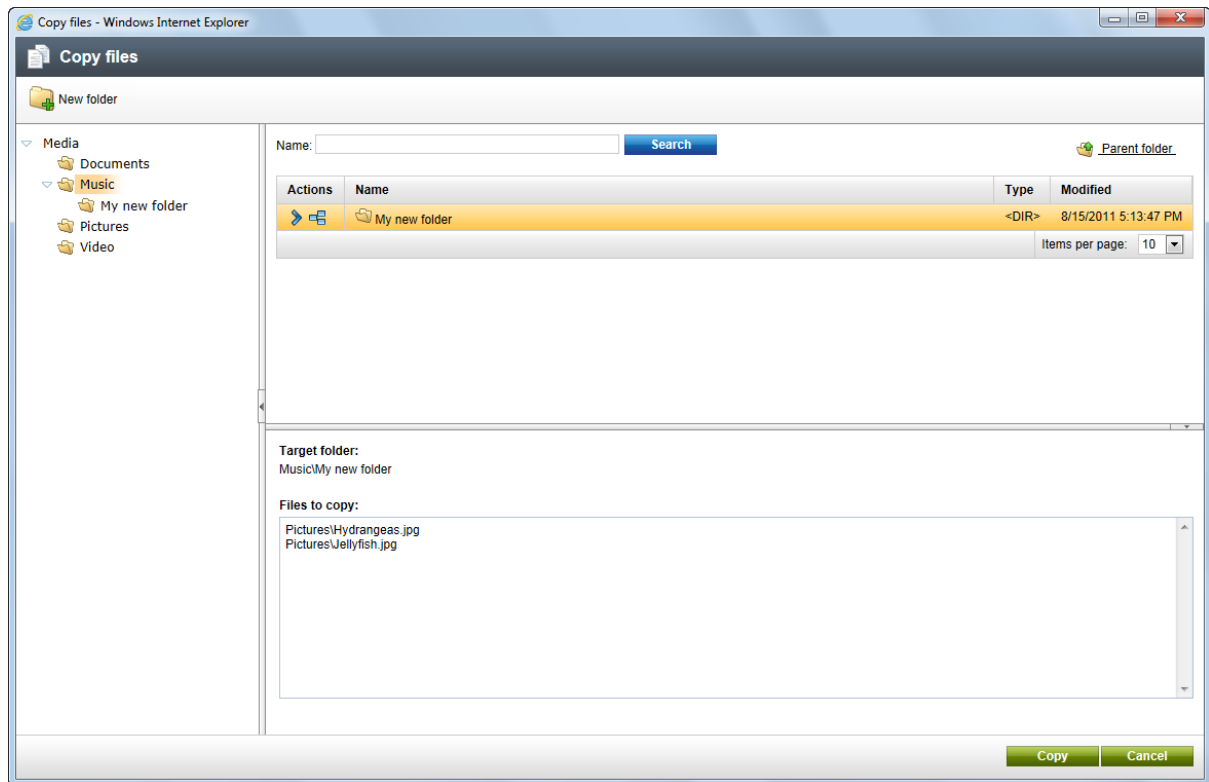

1. Use the first drop-down list (1. in the screenshot) to select if you want to perform the operation for:
 - **All files** - performs the operation for all files in the current folder.
 - **Selected files** - performs the operation only for files selected by the check-boxes ()
2. If you selected **Selected files** in the previous step, use the check-boxes (2. in the screenshot) to select the files with which to perform the operation.

3. Choose the operation to perform using the second drop-down list (3. in the screenshot) and click **OK**.

| Actions | Update | Name ▲ | Type | Size | Modified |
|-------------------------------------|--------|---------------|------|--------|----------------------|
| <input type="checkbox"/> | | Chrysanthemum | .jpg | 859 kB | 8/15/2011 4:46:19 PM |
| <input checked="" type="checkbox"/> | | Desert | .jpg | 826 kB | 7/14/2009 7:32:31 AM |
| <input checked="" type="checkbox"/> | | Hydrangeas | .jpg | 581 kB | 8/15/2011 4:46:11 PM |
| <input checked="" type="checkbox"/> | | Jellyfish | .jpg | 758 kB | 8/15/2011 4:46:27 PM |
| <input checked="" type="checkbox"/> | | Koala | .jpg | 763 kB | 7/14/2009 7:32:31 AM |

Selected files **1.** Import **3.** **OK**

4.a If you are performing the **Copy** or **Move** operation, the following dialog is displayed. Choose the target folder (or create a new one using the **New folder** button if needed) and click the **Copy**/
 Move button.

4.b If you are performing the **Delete** operation, you will be prompted to confirm the deletion. Click **OK** to delete the files.

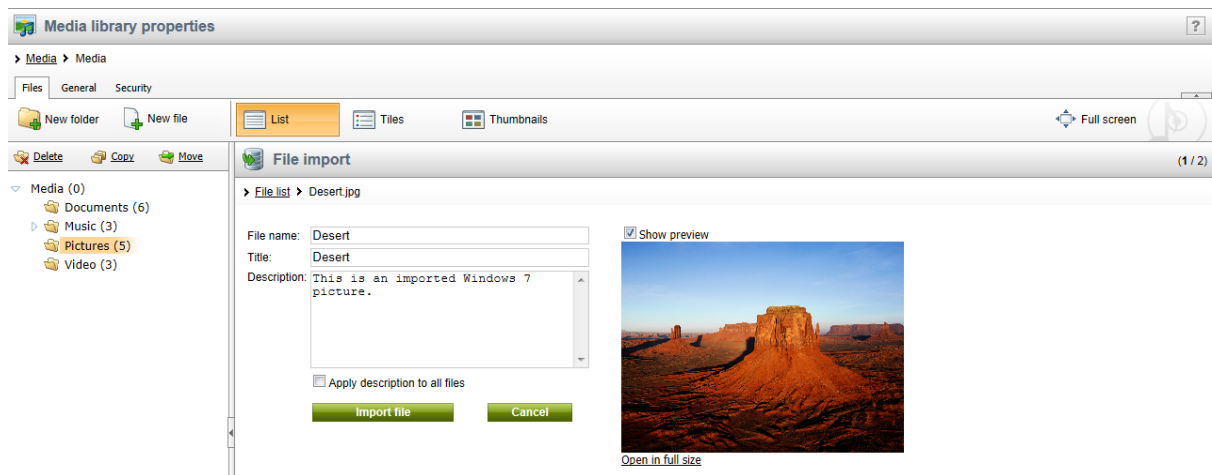

4.c If you are performing a batch  **Import** operation, the dialog as in the following screenshot will appear for each imported file. Please specify the following details for each imported file:

- **File name** - the name of the file displayed in the administration interface.
- **Title** - the name of the file displayed on the live site.
- **Description** - the text describing the image. You can leave blank.

Click the **Import file** button to proceed to the following file.

You can also enable the **Apply description to all files** option, which imports all files in one click on the **Import all files** button. All files will have the entered **Description** and the **File name** and **Title** fields will contain the names of the physical files without extension.

Important!

Because of ASP.NET architecture, **site restart** will occur when:

- a media library is deleted
- a group containing a media library is deleted
- one of the following actions is performed when editing a library in **CMS Desk** -> **Tools** -> **Media libraries** -> **Files** or on the live site:
 - folder is deleted
 - folder is renamed
 - folder is moved
 - large number of files is deleted (100 by default, this can be set in the `<system.web>` section of your web.config by the following key: `<compilation debug="true" numRecompilesBeforeAppRestart="100">`)

Because of this, it is highly recommended to allow performing of these actions only to system administrators or to the least possible number of users. The recommended practice is for the site administrators to pre-define the folder structure of the libraries when they are created and not to allow users to further modify it.

8.32.4.4 Supported file types

The following file types are supported and can be played or displayed on your site by default:

- **Images** - bmp, gif, png, wmf, jpg, jpeg, tiff, tif.
- **Audio** - wav, wma, mp2, mp3, mid, midi, mpga.
- **Video** - avi, mp4, mpg, mpeg, wmv, qt, mov, rm.
- **Flash** - swf.

Custom file types can also be defined, as described in [this chapter](#).

Please note

All other file types will be recognized as **documents**, which means that they can't be played as videos, displayed as pictures, etc., but they can still be stored in the library and downloaded by users on the live site.

8.32.4.5 Supported file size

Media libraries in Kentico CMS support the upload of large files (audio files, video files etc.) However, if you would like to enable this functionality for your media libraries, you need to **increase the maximal uploaded file size**, as described in [this](#) topic.

8.32.4.6 File naming conventions

When a file is being uploaded to a media library, users can upload the file itself and its thumbnail. The **thumbnail** will be displayed in the file list in the **Media gallery** web part. Thumbnails are typically used if you want to upload some non-image file and attach an image which will be displayed as the file's thumbnail in the file list. For image files, the thumbnail can but doesn't have to be done, as the image itself will be used for this purpose.

When the thumbnail image or the image itself is larger than the required thumbnail image size, its resized copy will be created with the required size. Both thumbnails and resized copies are stored in a **hidden folder** in the root of the media library folder. The name of the hidden folder can be set in **Site Manager -> Settings -> Content -> Media -> Media file hidden folder**.

Format of media library files on the disk

- **File** - <file name>.<file extension>.
- **Resized file** - <hidden folder>/<file name>_<file extension>_<width>_<height>.<extension>.
- **Thumbnail** - <hidden folder>/<file name>_<file extension><thumbnail suffix>.<thumbnail extension>.
- **Resized thumbnail** - <hidden folder>/<file name>_<file extension><thumbnail suffix>_<width>_<height>.<thumbnail extension>.

Example

If you upload the following files:

- **Uploaded file** - *MyImage.jpg*.
- **Uploaded thumbnail** - *MyPhoto.bmp*.

with the following settings defined in [Site Manager -> Settings -> Content -> Media](#):

- **Media file hidden folder** - *__thumbnails*.
- **Media file thumbnail suffix** - *_preview*.

the uploaded files will be stored in the following locations in the media library folder, with the following names:

- **File** - *MyImage.jpg*.
- **Resized file** - *__thumbnails/MyImage_jpg_100_200.jpg*.
- **Thumbnail** - *__thumbnails/MyImage_jpg_preview.bmp*.
- **Resized thumbnail** - *__thumbnails/MyImage_jpg_preview_20_30.bmp*.

8.32.5 Displaying files from media library

8.32.5.1 Overview

In this subchapter you will learn how to display files from a media library.

- If you would like to learn how to display media gallery content on your site, please follow the [Using Media gallery web part](#) topic.
- If you would like to learn about integration of media library files into text using the built-in WYSIWYG editor, please refer to the [Using WYSIWYG editor](#) topic.
- If you would like to learn how to use files from various sources (from Document attachments, Content and Media libraries) in your document types, please refer to the [Using the Media selection control](#) topic.

8.32.5.2 Using Media gallery web part

The **Media gallery** web part can be used to display content of media libraries on the live site.

1. If you need to use the **Media gallery** web part, navigate to **Content -> Edit**. Switch to the **Design** tab and click any of the available **Add web part** (+) icons on the page you have selected from the content tree of the current site. Now select **Media library -> Media gallery** and click **OK**.

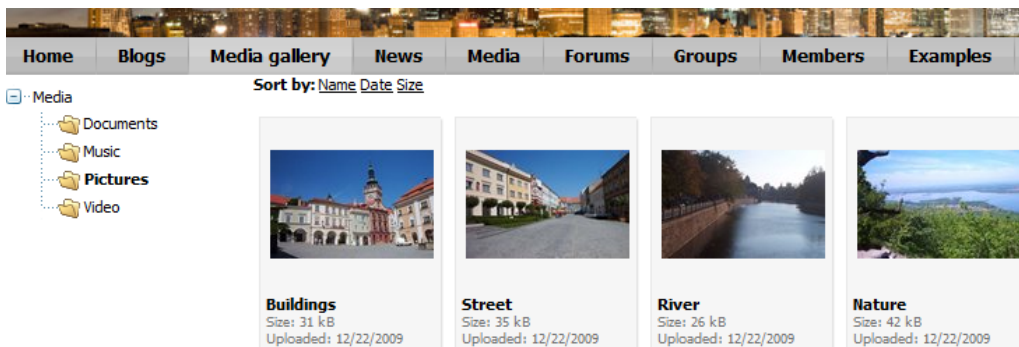

2. In the web part properties window, you only have to choose the media library that you want to display:

- **Media library** - *Media*.

Click **OK**.

3. If you now switch to the live site, and select **Pictures** for instance, you should see the web part displaying content of the selected media library.

8.32.5.3 Using WYSIWYG editor

If you are editing a text using the WYSIWYG editor, you can easily insert an image, video, flash etc. from your media library into the text via the  **Insert image or media** dialog (please refer to the [Insert image or media](#) chapter for more details) or you can insert a link to any file from your media library via the  **Insert link** dialog (please refer to the [Insert link](#) chapter for more details).

8.32.5.4 Using the Media selection control

The **Media selection** form control can be used to enable users to select files on the **Form** tab of a document. It allows to use any file from any source (from Document attachments, Content and Media libraries) in your documents. To follow an example which demonstrates how this can be achieved, please refer to the [topic of the same name](#) in the **File management** chapter in the **Content management** section of this guide.

8.32.6 Settings

8.32.6.1 Overview

In this subchapter you will learn how to adjust general media library settings.

- If you would like to adjust the settings of the Media libraries module, please refer to the [Media library settings](#) topic.
- If you would like to learn how to customize the location of all libraries of a particular site, please refer to the [Configuring custom storage for media library](#) topic.
- If you would like to read a more detailed explanation of how to enable any media types to be recognized by the system, please refer to the [Configuring custom file types](#) topic.
- If you would like to learn how to configure maximal uploaded file size, please refer to the [Configuring maximal uploaded file size](#) topic.

8.32.6.2 Media library settings

Settings related to the Media libraries module are located in **Site Manager -> Settings -> Content -> Media**. The following settings are related to the module:

| General | |
|-------------------------------|--|
| Use permanent URLs | If true, URLs of media library files will be generated in permanent format (<i>~/getmedia/<file guid>/<file name>.<file extension>.<files friendly URL extension></i>), otherwise a direct path to the file will be used (e.g.: <i>~/MySite/Media/MyLibrary/MyImage.jpg</i>). |
| Max subfolders | The maximum number of folders that can be displayed under an expanded folder node in the tree view. |
| Security | |
| Media file allowed extensions | Extensions of files which can be uploaded to media libraries; should be divided by semicolons. |
| Check files permissions | Indicates if the See media library content permission is checked when retrieving media files using permanent URLs. |
| Storage | |

| | |
|--|---|
| Custom media libraries folder | The folder where media library files are stored. If no value is entered, the default location is <code>~/<site code name>/media</code> . If you would like to learn how to configure custom storage for your media library, please refer to this topic. |
| Use site-specific subfolders for custom media libraries folder | This setting is applied only when a <i>Custom media libraries folder</i> is configured. If enabled, media library files will be stored in a sub-folder named using the site code name under the custom files folder, i.e. <code><custom media libraries folder>/<site code name></code> . It is useful for better orientation in files when multiple sites are running in the system. |
| Media file hidden folder | The name of the folder where thumbnails of media files will be stored. This folder is hidden in the file system by default and thumbnails are generated within it. |
| Media file thumbnail suffix | The suffix added to thumbnail files. Thumbnail files names are in the following format:
<code><file name>_<file extension><thumbnail suffix>.<thumbnail extension></code> |

Please note

If the **Custom media libraries folder** settings are inherited from global settings and the **Use site-specific subfolders for custom media libraries folder** property is set to TRUE, only the folder of the site you are about to delete will be removed from the custom folder.

The screenshot displays the Kentico Site Manager Administration interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The user is logged in as 'Global Administrator'. The left sidebar shows a tree view of settings categories: Content, Content management, Media, Blogs, Polls, URLs and SEO, Security & Membership, System, On-line marketing, E-commerce, Community, Intranet & Collaboration, Versioning & synchronization, Integration, and Cloud services. The main content area is titled 'Media' and contains the following settings:

- General**
 - Use permanent URLs:
 - Max subfolders: 100
- Security**
 - Media file allowed extensions: pdf,doc;docx;ppt;pptx;xls;xlsx;htm;html+xml;bmp;g
 - Check files permissions:
- Storage**
 - Media libraries folder:
 - Use site-specific subfolders for custom media libraries folder:
 - Media file hidden folder:
 - Media file thumbnail suffix:

Buttons for 'Save' and 'Reset these settings to default' are visible at the top of the settings area. A note states: 'These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.' An 'Export these settings' link is located at the bottom of the settings area.

8.32.6.3 Configuring custom storage for media library

The default location of all libraries of a particular site is `~/<site name>/media`. You can customize the location by entering a path in **Site Manager -> Settings -> Content -> Media -> Custom media libraries folder**.

You can enter the folder location in the following formats:

- **physical path** - e.g. `c:\Libraries`.
- **virtual path** - e.g. `~/Libraries`.
- **UNC path** - e.g. `\\<server name>\Libraries`.

If you enable the **Use site-specific subfolders for custom media libraries folder** option, media library files will be stored in a sub-folder named as the site code name under the custom files folder, i.e. `<custom media libraries folder>/<site code name>`.

Please note

In case that you are running the system on a **web farm** and have **the same UNC root defined** on all servers, it is necessary to add the following key into your `web.config` in order for the files stored in the libraries not to be transferred when synchronizing the web farm content:

```
<add key="CMSWebFarmSynchronizeMediaFiles" value="false" />
```

8.32.6.4 Configuring custom file types

You can allow custom media types by a simple modification to the site's `web.config` and **MediaControl.ascx** inline controls. Any media types can be enabled to be recognized by the system in case that you have the right player for the file type.

The following example shows how to enable `.flv` videos in the system.

1. Add the following keys into the **appSettings** section of your `web.config` file. Add your custom extensions for the particular document types here for the files to be recognized as image/audio/video by the system, as you did with the highlighted **flv** extension.

```
<add key="CMSImageExtensions" value="bmp;gif;ico;png;wmf;jpg;jpeg;tiff;tif" />
<add key="CMSAudioExtensions" value="wav;wma;mp2;mp3;mid;midi;mpga" />
<add key="CMSVideoExtensions" value="avi;mp4;mpg;mpeg;wmv;qt;mov;rm;flv" />
```

2. Add the **flv** extension to the enumeration in **Site Manager -> Settings -> Content -> Media -> Media file allowed extensions**, which will allow upload of these files into media libraries, and click the **Save** button.

You may also want to add the extension to the **Site Manager -> Settings -> System -> Files -> Upload extensions** enumeration, which will allow upload of these files as CMS.File documents and document attachments, and click the **Save** button.

3. Download a player for your media type. In this example, you will use the JW FLV Player available here: <http://www.longtailvideo.com/players/jw-flv-player/>.

4. Extract the **swfobject.js** and **player.swf** files and put them in a folder under your website folder, e.g. **~/FlvPlayer**. This path will be used in the **CreateFlvObject()**, which you will create in step 6.

5. Open the **~/CMSInlineControls/MediaControl.ascx.cs** inline control in Visual Studio and replace the **Page_PreRender** method with the following code. It is the original code of the method with the first condition added. The added code ensures that when the file extension is **.flv**, the **CreateFlvObject()** method is called.

[C#]

```
protected void Page_PreRender(object sender, EventArgs e)
{
    if ((this.Type != null) && (this.Type.TrimStart('.').ToLower() == "flv"))
    {
        CreateFlvObject();
    }
    else if (MediaHelper.IsFlash(this.Type))
    {
        CreateFlash();
    }
    else if (ImageHelper.IsImage(this.Type))
    {
        CreateImage();
    }
    else
    {
        CreateMedia();
    }
}
```

6. Now you need to add the **CreateFlvObject()** private method to the control. In this example, it looks like the code sample below.

The method creates a new DIV tag for the FLV player, with ID generated in the **divID** variable. It also handles the player URL in a special way - the URL must be absolute and must end with *flv*. Support for the Autoplay and Loop properties of the player is also ensured.

[C#]

```
private void CreateFlvObject()
{
    string playerID = Guid.NewGuid().ToString("N");
    string flvUrl = URLHelper.GetAbsoluteUrl(this.Url)
        .Replace("?", "%3F");
}
```

```

        .Replace("=", "%3D")
        .Replace("&", "%26");

string flashVars = "file=" + flvUrl + "&provider=video&";
flashVars += "controlbar=" + (AVControls ? "bottom" : "none") + "&";
flashVars += "autostart=" + (AutoPlay ? "true" : "false") + "&";
flashVars += "repeat=" + (Loop ? "always" : "none");

string player = "";
player += "<object id=\"" + playerId + "\"";
player += "classid=\"clsid:D27CDB6E-AE6D-11cf-96B8-444553540000\"";
player += "codebase=\"http://download.macromedia.com/pub/";
player += "shockwave/cabs/flash/swflash.cab#version=9.0.115\"";
player += "width=\"" + Width + "\" height=\"" + Height + "\">";
player += "<param name=bgcolor value=\"#FFFFFF\">";
player += "<param name=movie value=\"" + ResolveUrl("~/FlvPlayer/player.swf")
+ "\">";
player += "<param name=allowfullscreen value=\"true\">";
player += "<param name=allowscriptaccess value=\"always\">";
player += "<param name=\"flashvars\" value=\"" + flashVars + "\">";
player += "<embed name=\"" + playerId + "\" ";
player += "type=\"application/x-shockwave-flash\" ";
player += "pluginspage=\"http://www.macromedia.com/go/getflashplayer\" ";
player += "width=\"" + Width + "\" height=\"" + Height + "\" ";
player += "bgcolor=\"#FFFFFF\" ";
player += "src=\"" + ResolveUrl("~/FlvPlayer/player.swf") + "\" ";
player += "allowfullscreen=\"true\" ";
player += "allowscriptaccess=\"always\" ";
player += "flashvars=\"" + flashVars + "\">";
player += "</embed>";
player += "</object>";

this.ltlMedia.Text = player;
}

```

7. To make this work also on the live site using media library transformations, you now need to open the `~/CMSModules/MediaLibrary/Controls/LiveControls/MediaFilePreview.ascx.cs` file and replace the following line of code:

```
else if (CMS.GlobalHelper.MediaHelper.IsVideo(mfi.FileExtension))
```

with this piece of code:

```

else if (mfi.FileExtension.TrimStart('.').ToLower() == "flv") {
    this.ltlOutput.Text = CreateFlvObject(url);
}
else if (CMS.GlobalHelper.MediaHelper.IsVideo(mfi.FileExtension))

```

8. Similarly, you will need to add the `CreateFlvObject(string url)` private method to the control. In this example, it looks like the code sample below.

The method creates a new DIV tag for the FLV player, with ID generated in the `divID` variable. It also handles the player URL in a special way - the URL must be absolute and must end with `flv`. Please note that the Autoplay and Loop properties of the player are defined firmly in the code.

```
private string CreateFlvObject(string url)
{
    string playerId = Guid.NewGuid().ToString("N");
    string flvUrl = URLHelper.GetAbsoluteUrl(url)
        .Replace("?", "%3F")
        .Replace("=", "%3D")
        .Replace("&", "%26");

    bool avControls = true;
    bool autoPlay = false;
    bool loop = false;

    string flashVars = "file=" + flvUrl + "&provider=video&";
    flashVars += "controlbar=" + (avControls ? "bottom" : "none") + "&";
    flashVars += "autostart=" + (autoPlay ? "true" : "false") + "&";
    flashVars += "repeat=" + (loop ? "always" : "none");

    string player = "";
    player += "<object id=\"" + playerId + "\"";
    player += "classid=\"clsid:D27CDB6E-AE6D-11cf-96B8-444553540000\"";
    player += "codebase=\"http://download.macromedia.com/pub/";
    player += "shockwave/cabs/flash/swflash.cab#version=9.0.115\"";
    player += "width=\"" + Width + "\" height=\"" + Height + "\">";
    player += "<param name=bgcolor value=\"#FFFFFF\">";
    player += "<param name=movie value=\"" + ResolveUrl("~/FlvPlayer/player.swf")
+ "\">";
    player += "<param name=allowfullscreen value=\"true\">";
    player += "<param name=allowscriptaccess value=\"always\">";
    player += "<param name=\"flashvars\" value=\"" + flashVars + "\">";
    player += "<embed name=\"" + playerId + "\" ";
    player += "type=\"application/x-shockwave-flash\" ";
    player += "pluginspage=\"http://www.macromedia.com/go/getflashplayer\" ";
    player += "width=\"" + Width + "\" height=\"" + Height + "\" ";
    player += "bgcolor=\"#FFFFFF\" ";
    player += "src=\"" + ResolveUrl("~/FlvPlayer/player.swf") + "\" ";
    player += "allowfullscreen=\"true\" ";
    player += "allowscriptaccess=\"always\" ";
    player += "flashvars=\"" + flashVars + "\">";
    player += "</embed>";
    player += "</object>";

    return player;
}
```

If you need to change the behavior of the player, please modify these lines of code of the added method.

```
bool avControls = true;
```

```
bool autoPlay = false;
bool loop = false;
```

9. Now .flv files are recognized as videos by the system. The custom player is used for the files on the live site and also in the **Insert image or media** dialog, as you can see in the screenshot below.

8.32.6.5 Configuring maximum uploaded file size

The default maximum uploaded file size setting on IIS6/7 is 30MB. To enable uploads of larger files, which is essential for the functionality that the media libraries were designed for, you need to add the following keys to your **web.config** file:

IIS 6

All you need to do is to set the value of the following property, which is already present in your **web.config**, to the desired value, while the value is entered in **kiloBytes**:

```
<httpRuntime maxRequestLength="2000000" />
```

IIS 7

You need to do the same setting as described above for IIS 6. Then, you need to add the following highlighted code to the end of your **web.config**. The value of the **maxAllowedContentLength** property is entered in **Bytes**:

```
...

<system.webServer>
  <security>
    <requestFiltering>
      <requestLimits maxAllowedContentLength="2147483648" />
    </requestFiltering>
  </security>
  <validation validateIntegratedModeConfiguration="false" />
  <modules>
    <add name="ScriptModule" preCondition="integratedMode"
type="System.Web.Handlers.ScriptModule, System.Web.Extensions, Version=3.5.0.0,
Culture=neutral, PublicKeyToken=31bf3856ad364e35" />
    <add name="XhtmlModule" type="CMS.CMSOutputFilter.OutputFilterModule,
CMS.OutputFilter" />
  </modules>
  <handlers>
    <remove name="WebServiceHandlerFactory-Integrated" />
    <add name="ScriptHandlerFactory" verb="*" path="*.asmx"
preCondition="integratedMode"
type="System.Web.Script.Services.ScriptHandlerFactory, System.Web.Extensions,
Version=3.5.0.0, Culture=neutral, PublicKeyToken=31bf3856ad364e35" />
    <add name="ScriptHandlerFactoryAppServices" verb="*" path="*_AppService.axd"
preCondition="integratedMode"
type="System.Web.Script.Services.ScriptHandlerFactory, System.Web.Extensions,
Version=3.5.0.0, Culture=neutral, PublicKeyToken=31bf3856ad364e35" />
    <add name="ScriptResource" preCondition="integratedMode" verb="GET,HEAD"
path="ScriptResource.axd" type="System.Web.Handlers.ScriptResourceHandler,
System.Web.Extensions, Version=3.5.0.0, Culture=neutral,
PublicKeyToken=31bf3856ad364e35" />
  </handlers>
</system.webServer>
</configuration>
```

8.32.7 Security

8.32.7.1 Overview

In this subchapter you will learn how to adjust media library security settings.

- If you would like to learn how to deal with secured and non-secured libraries on your site, please refer to the [Secured vs. Non-secured libraries](#) topic.
- If you would like to learn how to set media library permissions, please refer to the [Media library](#)

[permissions](#) topic.

8.32.7.2 Media library permissions

Media library module permissions

The following permissions can be set in **Site Manager -> Administration -> Permissions**, when you choose the **Modules -> Media libraries** permissions matrix:

- **Manage** - allows to create, delete and edit media libraries and manage media library content via the administration interface.
- **Read** - allows seeing media library content and its properties when editing a media library, but does not allow to make any changes to it.
- **Destroy** - allows users to destroy the media library version history.

| Role | Read | Manage | Destroy |
|------------------------------|-------------------------------------|-------------------------------------|--------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Editors | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Readers | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Facebook users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Gold Partners | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| LinkedIn users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Live ID users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Marketing Manager | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Not authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| OpenID users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Silver Partners | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

Media library permissions

On the **Security** tab of each media library, you can assign permissions for particular actions. This can be useful if settings for the Media library module permissions are not sufficient for your needs and you want to restrict users from performing certain actions in certain media libraries. If this is the case, permissions for particular actions can be assigned to:

- **Nobody** - nobody can perform the action.
- **All users** - all users including anonymous site visitors can perform the action.
- **Authenticated users** - only signed-in site members can perform the action.
- **Authorized roles** - only members of roles selected by the check-boxes below can perform the action.

> [Media](#) > Media

Files General Security

| | Create file | Create folder | Delete file | Delete folder | Modify file | Modify folder | See library content |
|---------------------|----------------------------------|----------------------------------|----------------------------------|----------------------------------|----------------------------------|----------------------------------|----------------------------------|
| Nobody | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| All users | <input checked="" type="radio"/> | <input checked="" type="radio"/> | <input checked="" type="radio"/> | <input checked="" type="radio"/> | <input checked="" type="radio"/> | <input checked="" type="radio"/> | <input checked="" type="radio"/> |
| Authenticated users | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Authorized roles | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |

Please select the authorized roles (available only when you select the "Authorized roles" option above):

When editing media library of some group, permissions for particular actions can be assigned to:

- **Nobody** - nobody can perform the action.
- **All users** - all users including anonymous site visitors can perform the action.
- **Authenticated users** - only signed-in site members can perform the action.
- **Group members** - only members of the group can perform the action.
- **Authorized roles** - only members of group roles selected by the check-boxes below can perform the action.

The following table shows which permissions need to be assigned to allow users to perform particular actions. Global administrators can perform all of these actions for all general and group media libraries on the site. Group administrators can perform all of these actions for group media libraries of groups where they are group administrators.

8.32.7.3 Secured vs. Non-secured libraries

Media libraries on your site can be secured or non-secured. To ensure the required functionality, several settings need to be done as described below.

**Please note**

By default, files in media libraries are NOT secured and can be accessed directly by anybody who knows the exact link to the file. If you want to prevent this behavior, please set up your media library as a secured one.

Secured libraries

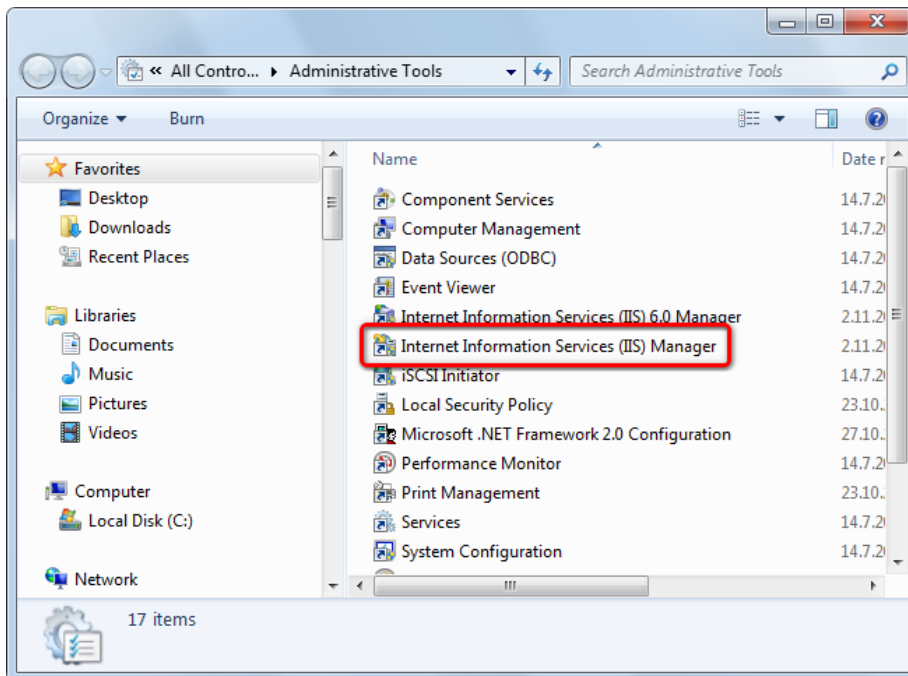

Secured media libraries allow viewing of their content only to members of authorized roles or only to authenticated users, based on the settings made on the library's **Security** tab. Secured libraries are also slower than the non-secured ones as permission checking involves some processing overhead.

To set up a media library to behave as a secured library, you have to take the following steps:

1. IIS setup

You have to **set up your IIS** so that files can't be downloaded directly from the library by typing the link to the file like `<site url>/media/file.jpg` into the browser.

a) Go to **Start -> Control Panel -> Administrative Tools** and start the **Internet Information Services (IIS) Manager**.

b) Locate and select the media library folder in the IIS tree, then click on the **Authentication** icon.

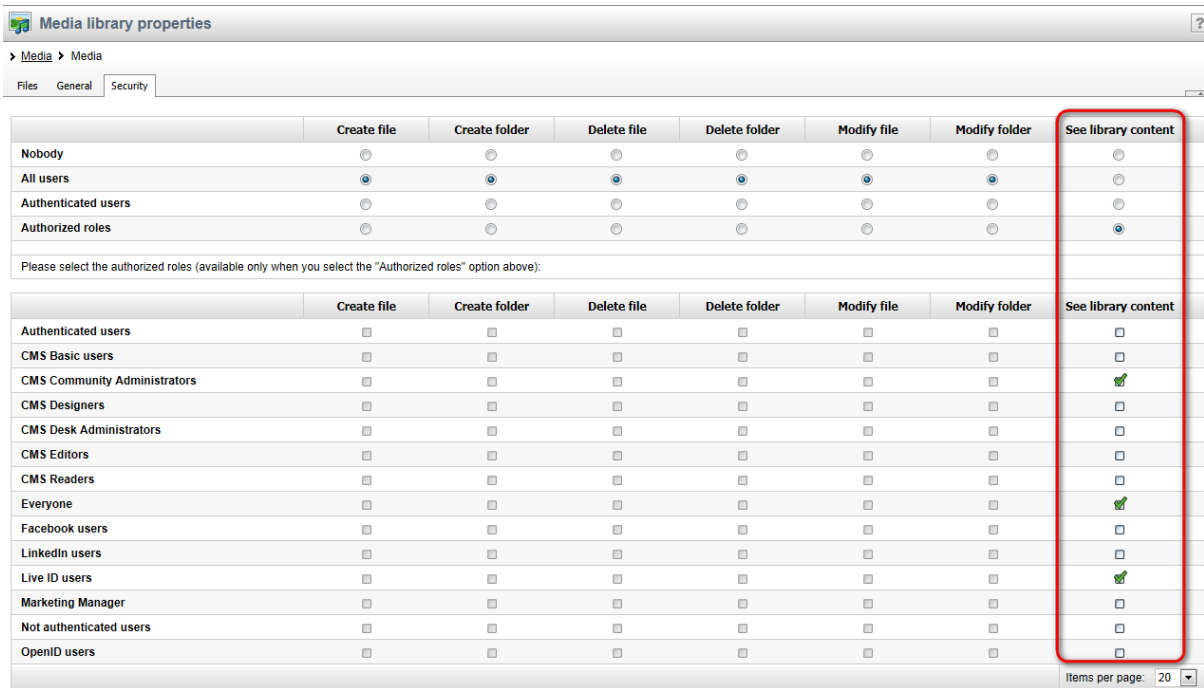

c) Disable the **Anonymous Authentication** by clicking the **Disable** link in the **Actions** list. If enabled, disable also the **Windows Authentication**.

2. Media library security settings

You have to assign the **See library content** permission to the appropriate roles or all authenticated users on the media library's **Security** tab.

You also have to make sure that the **Check files permissions** option is enabled in **Site Manager -> Settings -> Content -> Media**. With this option disabled, permission checks would not be performed.

3. Media gallery web part settings

- a) You need to enable the **Use secure links** web part property.
- b) When writing your transformations for the **Media gallery** web part, you should stick to the following rules:

File previews and **file details** should be displayed using the following control:

```
<ccl:MediaFilePreview ID="filePreview" runat="server" maxsize="117" />
```

Download links should be obtained using the following method:

```
<%# MediaLibraryFunctions.GetMediaFileUrl(Eval("FileLibraryID"), Eval("FilePath"), Eval("FileGUID"), Eval("FileName"), GetDataControlValue<bool>("UseSecureLinks")) %>
```

You can see an example of a real-world use of this web part, including the defined transformations, on the **Community Site** sample website, in the **Media** section.

Non-secured libraries

Content of non-secured media libraries is accessible to all site users or visitors. These libraries are also faster than the secured ones, as no permissions need to be checked.

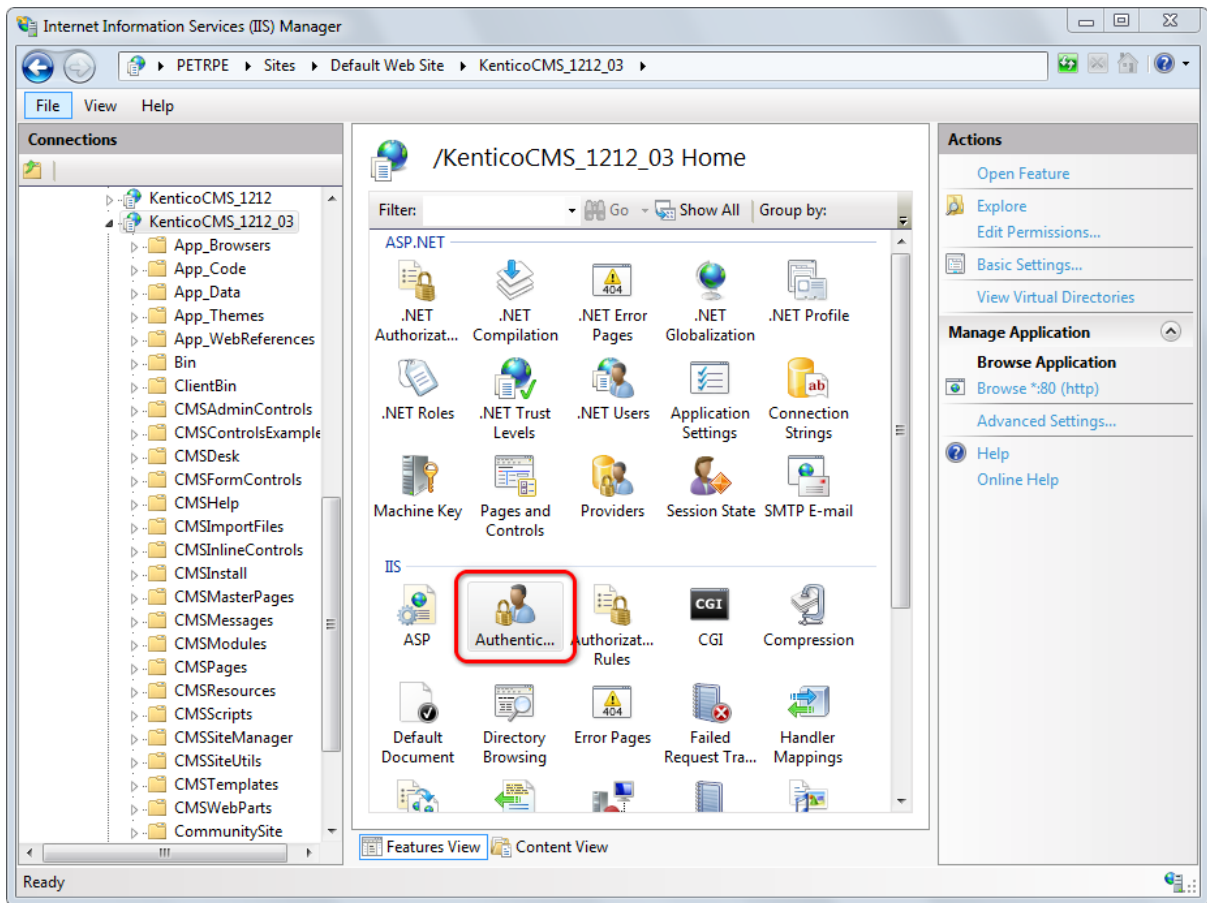

1. IIS setup

You have to **set up your IIS** so that files in the library can be accessed directly by anonymous users.

a) Go to **Start -> Control Panel -> Administrative Tools** and start the **Internet Information Services (IIS) Manager**.

b) Locate and select the media library folder in the IIS tree, then click on the **Authentication** icon.

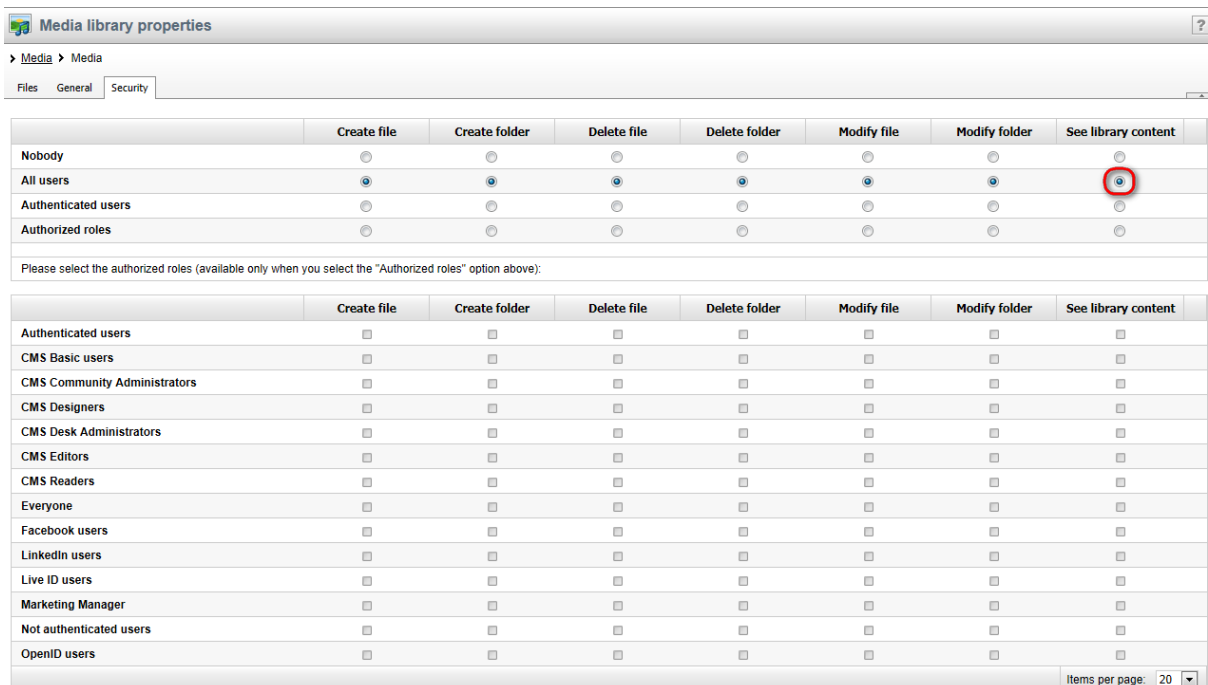

c) Enable the **Anonymous Authentication** by clicking the **Enable** link in the **Actions** list.

2. Media library security settings

You have to assign the **See library content** permission to **All users** on the media library's **Security** tab.

Alternatively, if all media libraries on the site are non-secured, you can disable the **Check files permissions** option in **Site Manager -> Settings -> Content -> Media**. This disables all permission checks for all media libraries on the site, which enables all users to see the libraries' content.

3. Media gallery web part settings

- a) The **Use secured links** web part property should be disabled for the file requesting to be faster.
- b) When writing your transformations for the **Media gallery** web part, you should stick to the following rules:

Image previews and **image details** should be obtained using the following method because they need to be resized:

```
<ccl:MediaFilePreview ID="filePreview" runat="server" maxsize="117" />
```

Other **file types previews** and **details** can be obtained using direct links. **Download links** can be obtained directly too.

8.32.8 Media internals and API

8.32.8.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Media libraries module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this

guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.32.8.2 Database tables

The following database tables are used in the Media libraries module:

- **Media_Library** - contains records representing media libraries.
- **Media_File** - contains records representing media files.
- **Media_LibraryRolePermission** - represents that particular roles have particular permissions in particular media libraries.

8.32.8.3 API classes

If you are not familiar with the database table data management by Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The Media libraries module classes use the **CMS.MediaLibrary** namespace.

Media_Library table API:

- **MediaLibraryInfo** - represents one media library.
- **MediaLibraryInfoProvider** - provides management of media libraries.

Media_File table API:

- **MediaFileInfo** - represents one media file.
- **MediaFileInfoProvider** - provides management of media files.

Media_LibraryRolePermission table API:

- **MediaLibraryRolePermissionInfo** - represents that a particular role has a particular permission in a particular media library.
- **MediaLibraryRolePermissionInfoProvider** - provides management of relationships between media libraries, roles and permissions.

8.32.8.4 API examples

8.32.8.4.1 Overview

Please note

All API examples can be simulated in the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Tools\MediaLibrary\Default.aspx.cs**.

8.33 Message boards

8.33.1 Overview

The Message boards module enables site visitors to comment on the content of a particular page. Each message board is related to a document on which it is placed, and optionally to a user or group. Messages can be moderated by board moderators. Users can subscribe to receiving notifications about new messages and rate the content of the document.

The module thus provides similar functionality like the [Forums](#) module. However, unlike structured forums, message boards are flat and simpler.

- The internals and API of the Message boards module are described in the [Message boards internals and API](#) subchapter.

8.33.2 Using the Message board web part

Message board can be placed on any page (document) on your website. It allows site visitors to send instant comments on the content of the particular page. You can have unlimited number of message boards on one page.

In the following example, you will see the basic process of adding a message board to your site. Our goal will be to add a Message board to the **Your first news** document on the sample **Corporate site**.

1. Log in to CMS Desk as *administrator*. From the content tree, select **News**.
2. Click the **Add web part** (+) icon at the top right corner of **Main zone** web part zone and in the web part selection dialog, choose **Message board -> Message board** and click **OK**.
3. In the web part properties window, you can set a number of properties. As there is quite a lot of them, we will leave default values and set only those listed below. If you want exact explanation of the meanings of each of the properties, please refer to [Kentico CMS Web Parts Reference](#) or click the **Documentation** (🔗) link at the top right corner of the web part properties window.
 - **Message transformation** - transformation used for displaying board messages; you can use *Community.Transformations.MessageBoard*, which is a default predefined transformation for board messages

- **No messages text** - text message that will be displayed to site visitors when there are no messages in the board
- **Display name** - display name of the message board, it will be used in the administration interface to identify the message board, so it is advisable to use some well-descriptive name under that you will recognize the message board; it is useful to use macros, such as `{%SiteName%} - my first message board`

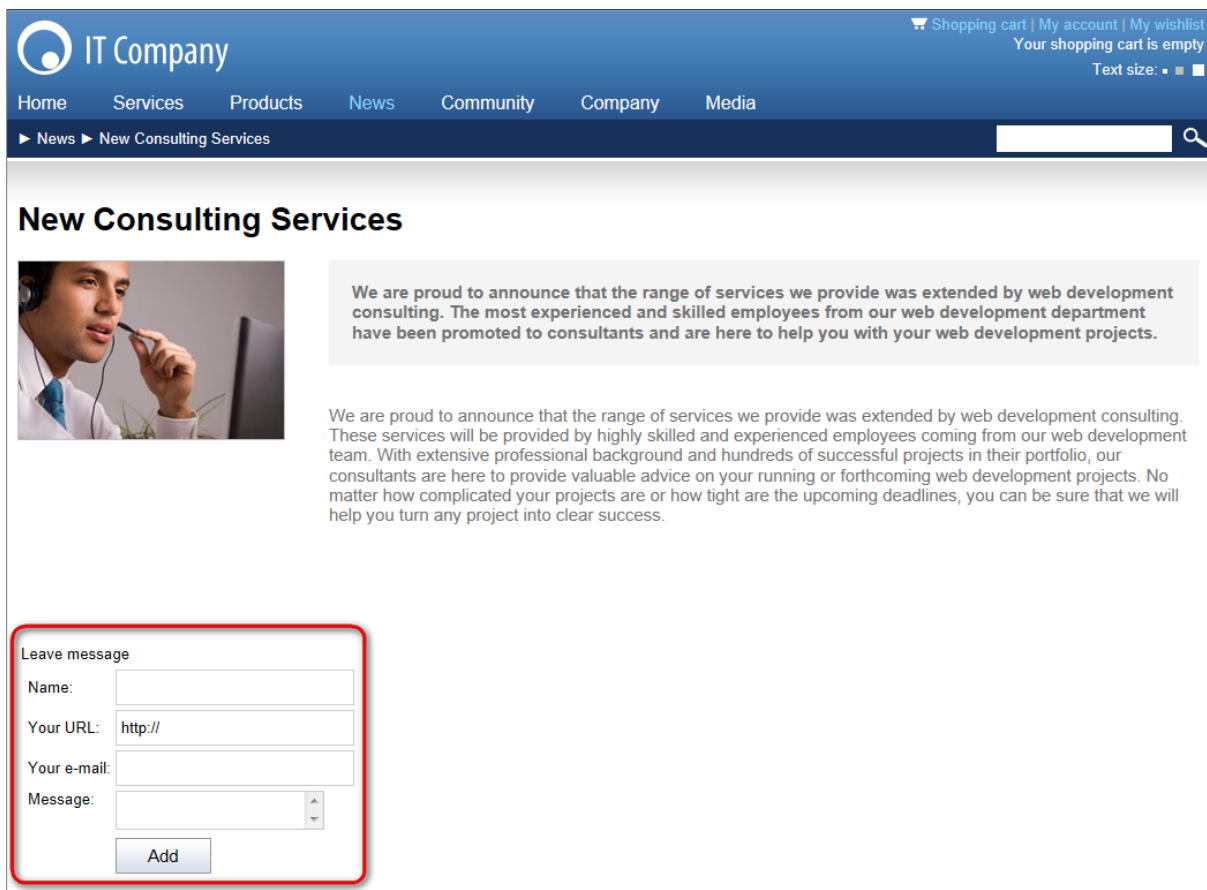

Click **OK** when you are finished entering the values.

Board default settings

Properties in the **New board settings** section will be used when the message board is created (after first message or subscription). Thereafter, changes made to the web part properties will take no effect. To change some of these properties, you will have to edit the message board in **CMS Desk -> Tools -> Message boards -> Boards** tab.

4. If you switch to the **Live Site** mode, you should see the form for entering board messages and the 'No messages text' displayed above it, as you can see in the following screenshot.

The screenshot shows a website for 'IT Company' with a navigation menu (Home, Services, Products, News, Community, Company, Media) and a shopping cart icon. The main content area is titled 'New Consulting Services' and features an image of a man on a headset. Below the image is a text block announcing the extension of services. At the bottom of the page, there is a 'Leave message' form with the following fields: Name, Your URL (pre-filled with 'http://'), Your e-mail, and Message. An 'Add' button is located below the Message field.

5. If you go to the administration interface located in **CMS Desk -> Tools -> Message boards**, you won't see the message board yet as message boards are created in the administration interface section

after first message is added to it, not after adding the web part to the site. Try adding some message now. After doing so, go to **CMS Desk -> Tools -> Message boards**. You should see the new message board in the list as in the following screenshot.

Message boards are document related, you need to place a Message board web part to your page to create a new message board. It will be created automatically after first comment is inserted.

Board name:

[Show](#)

| Actions | Board name ^ | Enabled | Open | Moderated | Posts | Last post | Document |
|---------|---|---------|------|-----------|-------|----------------------|---------------------------------|
| | Community Website Section (/News/Community Website Section) | Yes | Yes | No | 2 | 8/16/2011 2:27:05 PM | /News/Community Website Section |
| | News (/News) | Yes | Yes | No | 1 | 8/16/2011 2:28:10 PM | /News |

Items per page: 25

8.33.3 Administrating message boards

Message boards administration can be performed in **CMS Desk -> Tools -> Message boards**. The section is divided into two tabs.

Messages tab

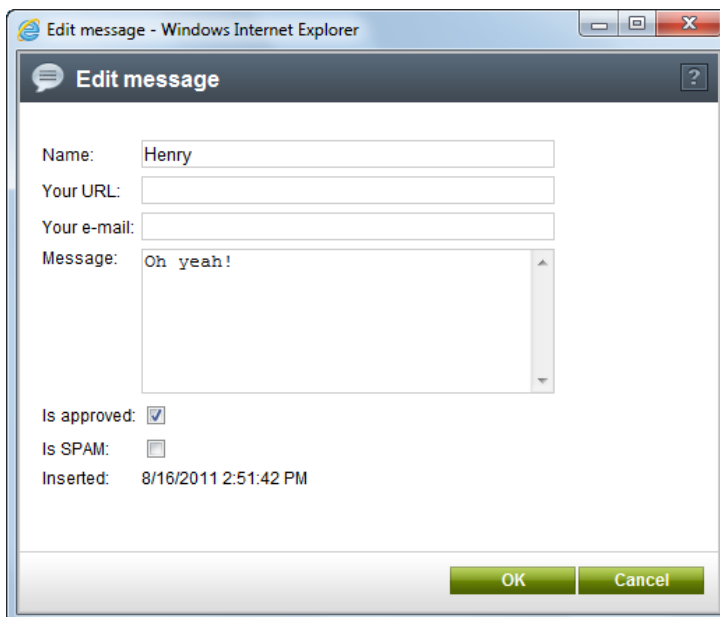

On this tab, moderators can manage board messages. By default, there are only messages requiring approval displayed when you access the page, so that the moderator sees only new messages that need to be approved or rejected. Until the messages are approved, they won't be displayed on the message board. Rejected messages won't be displayed either.

Using the filter above the list, you can determine which messages you want to display. The following filtering parameters are available:

- **Site name** - only messages from the selected site will be displayed
- **Board name** - only messages from the selected message board will be displayed
- **User name** - only messages posted by the user specified here will be displayed; you can also enter only a part of the user name
- **Text** - only messages containing the entered text will be displayed
- **Is approved** - you can choose whether to display only approved or disapproved messages
- **Is SPAM** - you can choose whether to display only messages marked or not marked as SPAM

Messages in the list can be **Approved** (✔), **Rejected** (⊘), **Deleted** (✖) or **Edited** (✎). If you choose to edit a message, the following window pops up, letting you make changes to it. You can also select more messages using the check-boxes and perform one of these actions for all of them using the **Selected items** drop-down list and clicking the **OK** button.

Boards tab

On this tab, you can see a list of all message boards on the current site. Using the **Board name** field above the list, you can filter the displayed message boards. You don't need to enter the exact name, you can enter only a part of it and the list will display all message boards with name containing the entered expression. It is a good idea to give your message boards well-descriptive names so that you can tell one from another and search efficiently.

Message boards can be **Edited** (✎) and **Deleted** (✖) on this tab.

| Actions | Board name ^ | Enabled | Open | Moderated | Posts | Last post | Document |
|---------|---|---------|------|-----------|-------|----------------------|---|
| | Apple iPad 2 In Stock (/News/Apple iPad 2 In Stock) | Yes | Yes | Yes | 1 | 8/16/2011 3:27:34 PM | /News/Apple iPad 2 In Stock |
| | Company Growth Exceeds Expectations (/News/Company Growth Exceeds Expectations) | Yes | Yes | No | 1 | 8/16/2011 3:26:53 PM | /News/Company Growth Exceeds Expectations |
| | News (/News) | Yes | Yes | No | 2 | 8/16/2011 3:26:46 PM | /News |

8.33.4 Editing message boards

You can edit message board properties at **CMS Desk -> Tools -> Message boards**, on the **Boards** tab. If you click the **Edit** () icon next to some message board, its editing interface will be displayed.

The administration interface reflects the **Message board** web part properties. When you add the web part to a page, you can set its properties in the web part properties dialog. When the first message is added to the board, the message board is created in this section of the administration interface. At this point, changes made to the web part properties have no effect and you have to make all changes only in this section!

The administration interface for editing message boards is divided into five tabs:

Messages tab

This tab displays a list of all messages on the message board. Using **New message**, you can add new messages to the board directly from the administration interface. Below is a filter, letting you display only messages matching specified criteria. The following filtering parameters are available:

- **User name** - only messages posted by the user specified here will be displayed; you can also enter only a part of the user name.
- **Text** - only messages containing the entered text will be displayed.
- **Is approved** - you can choose whether to display only approved or disapproved messages.
- **Is SPAM** - you can choose whether to display only messages marked or not marked as SPAM.

Messages can be **Edited** () , **Deleted** () , **Approved** () or **Rejected** () . You can also select more messages using the check-boxes and perform one of these actions for all of them using the **Selected items** drop-down list and clicking the **OK** button.

The screenshot shows the Kentico Message Boards interface. At the top, there are tabs for 'Messages' and 'Boards'. Below that, a breadcrumb trail reads 'Message boards > Apple iPad 2 In Stock (/News/Apple iPad 2 In Stock)'. There are sub-tabs for 'Messages', 'General', 'Subscriptions', 'Moderators', and 'Security'. A 'New message' button is visible. Below this is a form with fields for 'User name', 'Text', 'Is approved:' (dropdown menu set to '(all)'), and 'Is SPAM:' (dropdown menu set to '(all)'). A 'Show' button is below the form. Below the form is a table with columns: 'Actions', 'User name', 'Text', 'Approved', 'Is SPAM', and 'Inserted'. The table contains two rows of messages. At the bottom, there is a 'Selected items:' dropdown and an 'OK' button.

| Actions | User name | Text | Approved | Is SPAM | Inserted |
|---------|-----------|-------------|----------|---------|----------------------|
| | Andy | 1st message | Yes | No | 8/16/2011 3:48:11 PM |
| | Admin | Hello | Yes | No | 8/16/2011 3:27:34 PM |

General tab

On the general tab, you can specify the following properties of the message board:

- **Display name** - name that is displayed in the user interface.
- **Code name** - name that is used in code.
- **Description** - text describing the message board.
- **Enable** - if unchecked, the message board will be hidden from the live site; if checked, the message board will work normally.
- **Open** - if checked, users can add messages to the message board; if unchecked, messages are displayed but cannot be added.
- **Open from / to** - using these fields, you can define the time interval during which users can add new messages.
- **Enable subscriptions** - if checked, users can subscribe to receiving notifications about new messages on the board.
- **Base URL** - URL used as the URL base of links to message boards in notification e-mails; if empty, value from **Site Manager -> Settings -> Community -> Message boards -> Board base URL** will be used; if that setting is also empty, message boards cannot be placed on pages with wildcard URLs.
- **Unsubscription URL** - URL of the page containing the **Message board unsubscription** web part. The web part handles notification unsubscription requests. If the value is not set, the value in **Site Manager -> Settings -> Community -> Message boards -> Board unsubscription URL** will be used.
- **Require e-mail addresses** - if checked, users are required to enter their e-mail address when posting board messages.
- **Enable double opt-in** - indicates if double opt-in should be enabled for message boards. When enabled, users are required to confirm their subscription by clicking a link that is sent to them in an e-mail.
- **Approval page path** - path to the page that contains the **Message board subscription confirmation** web part. The subscription confirmation link that will be sent to users will point to this page.
- **Send double opt-in confirmation** - indicates if an e-mail confirmation should be sent to user after they approve a subscription. If double opt-in is disabled, these confirmation e-mails are always sent.

Messages Boards

> Message boards > Apple iPad 2 In Stock (/News/Apple iPad 2 In Stock)

Messages General Subscriptions Moderators Security

Messages General Subscriptions Moderators Security

| Actions | E-mail | User name |
|---|------------------------|-----------|
|   | andy@localhost.local | - |
|   | gold@localhost.local | gold |
|   | silver@localhost.local | - |

Moderators tab

On this tab, you can make the message board moderated by checking the **Message board is moderated** check-box. In such case, new messages will be displayed only after approval by some of the moderators listed in the **Moderators** list-box below. Moderators can be **Added** or **Removed** using the corresponding buttons.

The screenshot shows a web interface for configuring a message board. At the top, there are tabs for 'Messages' and 'Boards'. Below this, a breadcrumb trail reads '> Message boards > Apple iPad 2 In Stock (/News/Apple iPad 2 In Stock)'. Underneath, there are sub-tabs for 'Messages', 'General', 'Subscriptions', 'Moderators', and 'Security'. The 'Moderators' tab is active. A checkbox labeled 'Message board is moderated' is checked. Below this, the section is titled 'Moderators:'. It contains a table with two rows: the first row has a checkbox and the text 'User'; the second row has a checkbox and the text 'Global Administrator (administrator)'. At the bottom of this section are two buttons: 'Remove selected' and 'Add users' with a dropdown arrow.

Security tab

On this tab, you can set security-related properties of the message board.

If the **Use security code (CAPTCHA)** check-box is checked, users will have to retype the CAPTCHA security code before adding a new message.

The **Allow comments** section can be used to define which users can add new messages to the board. The following options are available:

- **All users** - everyone can add messages to the board
- **Only authenticated users** - only signed-in users can add messages to the board
- **Only authorized roles** - only members of the roles in the list-box below can add messages to the board

The following two options can be set only for group message boards:

- **Only group members** - only members of the group can add messages to the board
- **Only group admin** - only administrators of the group can add messages to the board

8.33.5 Setting Board base URL

Board base URL is the URL which will be used as the URL base for unsubscription links in notification e-mails. It can be set in two ways:

- In **Site Manager -> Settings -> Community -> Message boards -> Board base URL**; from here, it can be inherited by the web parts.
- Directly in **Message board web part properties**.

The following rules should be followed when creating user and group message boards placed on these pages in order for the unsubscription links to work correctly:

1. When you create a **user message board**, which is a message board placed on a user's profile, it is recommended to set the **Board base URL** directly in web part properties, for example like this:

```
~/Members/Profile.aspx
```

You can find a live example of this setting on the Community Site sample website.

2. When you create a **group message board**, which is a board placed on a group's profile, it is recommended to set the **Board base URL** directly in web part properties, for example like this:

```
~/Groups/Profile.aspx
```

3. When you create a public message board, which is a board placed on any document without a wildcard URL, the Board base URL property needn't be set.

8.33.6 Settings

Settings of the **Message boards** module are located in **Site Manager -> Settings -> Community -> Message boards**. Among other community-related settings, the following settings are related to the **Message boards** module:

- **Send message board e-mails from** - e-mail address that will appear in the From field of notification messages about new message board messages.
- **Board base URL** - global board base URL that can be inherited by message boards; it can be used by board notification e-mails and message board viewers.
- **Board unsubscription URL** - URL of the site on which the **Message board unsubscription** web part is placed; this web part handles requests for unsubscription from notifications about new message board messages.
- **Enable double opt-in for message boards** - indicates if double opt-in should be enabled for message boards. When enabled, users are required to confirm their subscription by clicking a link that is sent to them in an e-mail.
- **Double opt-in approval page path** - path to the page that contains the **Message board subscription confirmation** web part. The subscription confirmation link that will be sent to users will point to this page.
- **Double opt-in interval (hours)** - amount of time in hours, during which a user has to confirm their subscription request.
- **Send double opt-in confirmation** - indicates if an e-mail confirmation should be sent to user after they approve a subscription. If double opt-in is disabled, these confirmation e-mails are always sent.

8.33.7 Security

Message board

Based on the **Access** and **Message board owner** properties of the **Message board** web part, you can determine who will be allowed to add new messages to the board.

Changing the values

Remember that once the message board is created (after inserting first message or subscribing), you cannot make changes to these settings in the **New board settings** section of web part properties. You can only modify values of the **Access** property on the **Security** tab when editing the corresponding message board in **CMS Desk -> Tools -> Message boards**.

The following table explains **who can add messages to the board** under particular configurations. The difference between **User** and **Public boards** is that **Public boards** are always related to a document, while **User boards** are always related to a document and a user.

Public boards are typically used when you want multiple users to post messages to it. **User boards**

are typically used on user profiles, as you can see on the **Community starter site** sample website, on the **Members -> Profile** page.

| Message board owner | Access | Anonymous user | Authenticated user | Authorized role | Owner | Owner in authorized role |
|---------------------|---------------------|----------------|--------------------|-----------------|-------|--------------------------|
| Public board | All users | Yes | Yes | Yes | Yes | Yes |
| Public board | Authenticated users | | Yes | Yes | Yes | Yes |
| Public board | Authorized roles | | | Yes | | Yes |
| Public board | Owner | | | | Yes | Yes |
| User | All users | Yes | Yes | Yes | Yes | Yes |
| User | Authenticated users | | Yes | Yes | Yes | Yes |
| User | Authorized roles | | | Yes | | Yes |
| User | Owner | | | | Yes | Yes |

When a board is in the **User x Owner** configuration, the following conditions need to be met in order for the current user to be able to post messages:

- the page must be accessed with *userid* or *username* parameter in querystring
- the current user must be the same as the one whose *userid* or *username* is passed in querystring
- the current user must not be hidden (configured by the *Is hidden* option when editing the user)

This can be typically used on user profiles, where messages to such board can be posted only by the owner of the profile, while other users can only read these messages. An example of such board is the **MessageBoardAnnouncements** board on the **/Members/Profile** page of the sample Community Site.

Group message board

The Group message board is always related to some group, hence only the **Access** property can be set. You can see a typical usage of this web part on the **Community starter site** sample website, on the **Groups -> Profile** page.

| Access | Anonymous user | Authenticated user | Authorized role | Group member | Group member in authorized role | Group admin |
|---------------------|----------------|--------------------|-----------------|--------------|---------------------------------|-------------|
| All users | Yes | Yes | Yes | Yes | Yes | Yes |
| Authenticated users | | Yes | Yes | Yes | Yes | Yes |
| Authorized roles | | | Yes | | Yes | Yes |
| Group members | | | | Yes | Yes | Yes |
| Group admin | | | | | | Yes |

When the **Group members** option is set, the following conditions need to be met in order for the current

user to be able to post messages:

- the page must be accessed with *groupid* parameter in querystring
- the current user must be member of the group whose *groupid* is in the querystring
- the current user must not be hidden (configured by the *Is hidden* option when editing the user)

This can be typically used on group profiles, where messages to such board can be posted only by members of the group, while other users can only read these messages. An example of such board is the **GroupMessageBoard** board on the **/Group-pages/<group name>** page of the sample Community Site.

Permissions

Permissions for access to **Message boards** administration interface can be set in **Site Manager -> Administration -> Permissions**. You have to select the **Modules -> Message boards** permission matrix.

- **Modify** - members of the roles are allowed to edit message board settings, delete the boards and manage message board posts
- **Read** - selected role members are allowed to read the records and configuration of particular message boards, but are not allowed to modify them

| Permissions | | |
|------------------------------|-------------------------------------|--|
| Site: | Corporate site | |
| Permissions for: | Module | Message boards |
| Report for user: | (none) | <input type="checkbox"/> Show only this user's roles |
| Role | Read | Modify |
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Editors | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Readers | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> |
| Facebook users | <input type="checkbox"/> | <input type="checkbox"/> |
| Gold Partners | <input type="checkbox"/> | <input type="checkbox"/> |
| LinkedIn users | <input type="checkbox"/> | <input type="checkbox"/> |
| Live ID users | <input type="checkbox"/> | <input type="checkbox"/> |
| Marketing Manager | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Not authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |

8.33.8 Message board notifications

8.33.8.1 Overview

The Message boards module enables users to subscribe to receiving notifications about messages that have been added to your message board.

- To learn who can receive notifications when a new message is added or during message editing, please refer to the [Who can be notified](#) topic.
- To learn how to let users subscribe to receiving notifications about new messages added to the message board, please refer to the [User subscriptions](#) topic.
- E-mail templates used when sending notifications to subscribers and board moderators are described in the [E-mail templates](#) topic.

8.33.8.2 Who can be notified

When a new message is added or edited, notifications can be sent to:

- **Board moderators**
- **Subscribers**

The following text explains to whom notifications are sent under specific conditions.

New message inserted

1. Message has been added by a board moderator, global administrator, board owner (in case of a user board), user with the **Modify** permission, or group administrator (in case of group boards):

- the message is marked as APPROVED
- the e-mail is sent to subscribers

2. Message has been added by anybody else
a) board is moderated

- the message is marked as NOT APPROVED
- the e-mail is sent to moderators

b) board is not moderated

- the message is marked as APPROVED
- the e-mail is sent to subscribers

Existing message edited

1. the message is switched from NOT APPROVED to APPROVED

- the e-mail is sent to subscribers

2. other message changes

- no e-mail is sent

8.33.8.3 User subscriptions

You can let users subscribe to receiving notifications about new messages added to a message board. This topic describes the different ways in which you can set up and manage message board subscriptions.

Enabling subscriptions

You can enable your site visitors to subscribe to a message board by doing one of the following:

- In case of a new board, i.e. one that hasn't been posted to yet, open the properties of the particular **Message board** web part and set the **Enable subscriptions** property to true.
- In case of an existing board, go to **CMS Desk -> Tools -> Message boards -> Message boards**, edit your board and on the **General** tab, check the **Enable subscription** box, then click **Save**.

Enabling double opt-in

To make users confirm that the e-mail address they're subscribing with really exists and belongs to them, you can enable the double opt-in functionality. With double opt-in enabled, subscribers will be sent an e-mail with a confirmation link. They will have to click the link to create their subscription.

To enable double opt-in globally for all message boards:

1. Go to **Site Manager -> Settings -> Community -> Message boards**.
2. Turn on the **Enable double opt-in for message boards** setting.
3. Specify how long you want the confirmation links to be valid in the **Double opt-in interval** setting.

The following two steps are optional. If you omit them, the system will use the default approval page located in `~/CMSModules/MessageBoards/CMSPages/SubscriptionApproval.aspx`.

4. Place the **Message board subscription confirmation** web part on a new page. Adjust its properties according to your needs.
5. Enter the page's path into the **Double opt-in approval page path** setting.

Double opt-in should now be configured for all message boards. You can override the settings for each existing message board in its properties in **CMS Desk -> Tools -> Message boards**, or for not yet existing message boards in the properties of the respective **Message board** web part.

The functionality uses the **Boards - Subscription request e-mail template**. You can insert the confirmation link into the template using the `{%SubscriptionLink%}` macro.

Subscribing to a board

Users can subscribe in two ways. They can either check the **Subscribe to message board** checkbox, which subscribes them along with adding the message. Or, they can click the **Subscribe to board** link, which displays only one **E-mail** field. After entering their address and clicking the **Subscribe** button, they can subscribe to notifications for this board without leaving any message.

Leave message [Subscribe](#)

Name:

Your URL:

Your e-mail:

Message:

[Subscribe me to this message board](#)

Managing subscriptions

Users can view their subscriptions and potentially **unsubscribe** using the **Delete** (✘) icon at the following two places:

- Users with access to **CMS Desk** can view their subscriptions on the **My Desk -> My profile -> Subscriptions** tab.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Live Site' and 'Site Manager'. The main navigation menu has 'My desk' selected. The 'My profile' page is open, with the 'Subscriptions' tab selected. The 'Message board subscriptions' section is highlighted with a red box and contains the following table:

| Actions | E-mail | Message board | Approved |
|---------|-------------------------------|--|----------|
| ✘ | administrator@localhost.local | CorporateSite - sample message board | Yes |

- On the live site, users can view their subscriptions in the **My account** web part. The **Display my subscriptions** property of the web part must be enabled for this to be possible.

Special Pages User My Account

My Account

On this page, you can view and change the details of your user account. To modify the listed details, just change values of particular user profile fields and click OK.

Personal settings Change password Notifications Messages **Subscriptions**

Newsletter subscriptions

Your e-mail address administrator@localhost.local is currently subscribed to receive the following newsletters:
No newsletters selected.

Blog post subscriptions

You aren't currently subscribed to receive notifications on any blog comments.

Message board subscriptions

You are currently subscribed to receive notifications on new posts added to the following message boards:

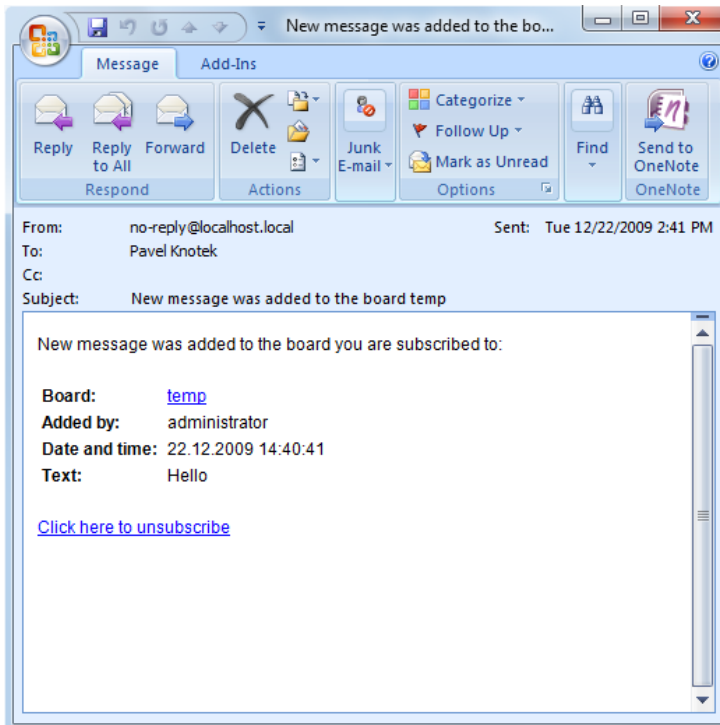

| E-mail | Message board |
|---|------------------------------|
|  administrator@localhost.local | News (/News) |

Items per page: 10

In both these locations, users can  **Delete** the subscription. If double opt-in is enabled and a subscription hasn't been yet confirmed by clicking the link in the e-mail the user received, they can also  **Approve** the subscription.

Unsubscription link configuration

Each message board notification e-mail contains an unsubscription link (when using the default e-mail template). By clicking the link, users can unsubscribe from receiving notifications about new messages.

For the unsubscription links to work, you have to do the following tasks:

1. Place the **Message board unsubscription** web part on a page. It is recommended to create a special page for this purpose, as you can see at **Corporate site -> Special pages -> Unsubscribe -> Board** or **Community site -> Special-pages -> Board unsubscribe**. You can set only one property of the web part - **Confirmation text**. This is the text that will be displayed after successful unsubscription.
2. Set the URL of the page created in step 1 as the **Unsubscription URL** property of the message board. This can be done in three ways:
 - Enter the URL into the **Board unsubscription URL** field in **Site Manager -> Settings -> Community -> Message boards**. This URL will be used by default when no URL is entered in web part properties of the message board.
 - When adding the **Message board** web part, you can set its **Unsubscription URL** property. This setting overrides the option in **Site Manager -> Settings -> Community -> Message boards**.
 - When the message board is created, you can edit the **Unsubscription URL** property on the **CMS Desk -> Tools -> Message boards -> Boards tab -> Edit (✎)** the message board -> **General** tab.

8.33.8.4 E-mail templates

There are two different e-mail templates that can be used when sending notifications to subscribers and board moderators:

- **Subscribers** - e-mails are based on the **Boards - Notification to board subscribers** template.
- **Moderators** - e-mails are based on the **Boards - Notification to board moderators** template.

There is also a template that is used when double opt-in is enabled - **Boards - Subscription request**.

The following macros can be used in the notification e-mails:

Data macros

- **Board.XXX** - where XXX are columns of the *Board_Board* table.
- **Message.XXX** - where XXX are columns of the *Board_Message* table.
- **MessageUser.XXX** - where XXX are columns of the *CMS_User* table.
- **MessageUserSettings.XXX** - where XXX are columns of the *CMS_UserSettings* table.

Source macros

- **DocumentLink** - link to the document where the board is placed.
- **SubscriptionLink** - link used to confirm the subscription when double opt-in is enabled.
- **UnsubscriptionLink** - unsubscription link.

8.33.9 Message boards internals and API

8.33.9.1 Overview

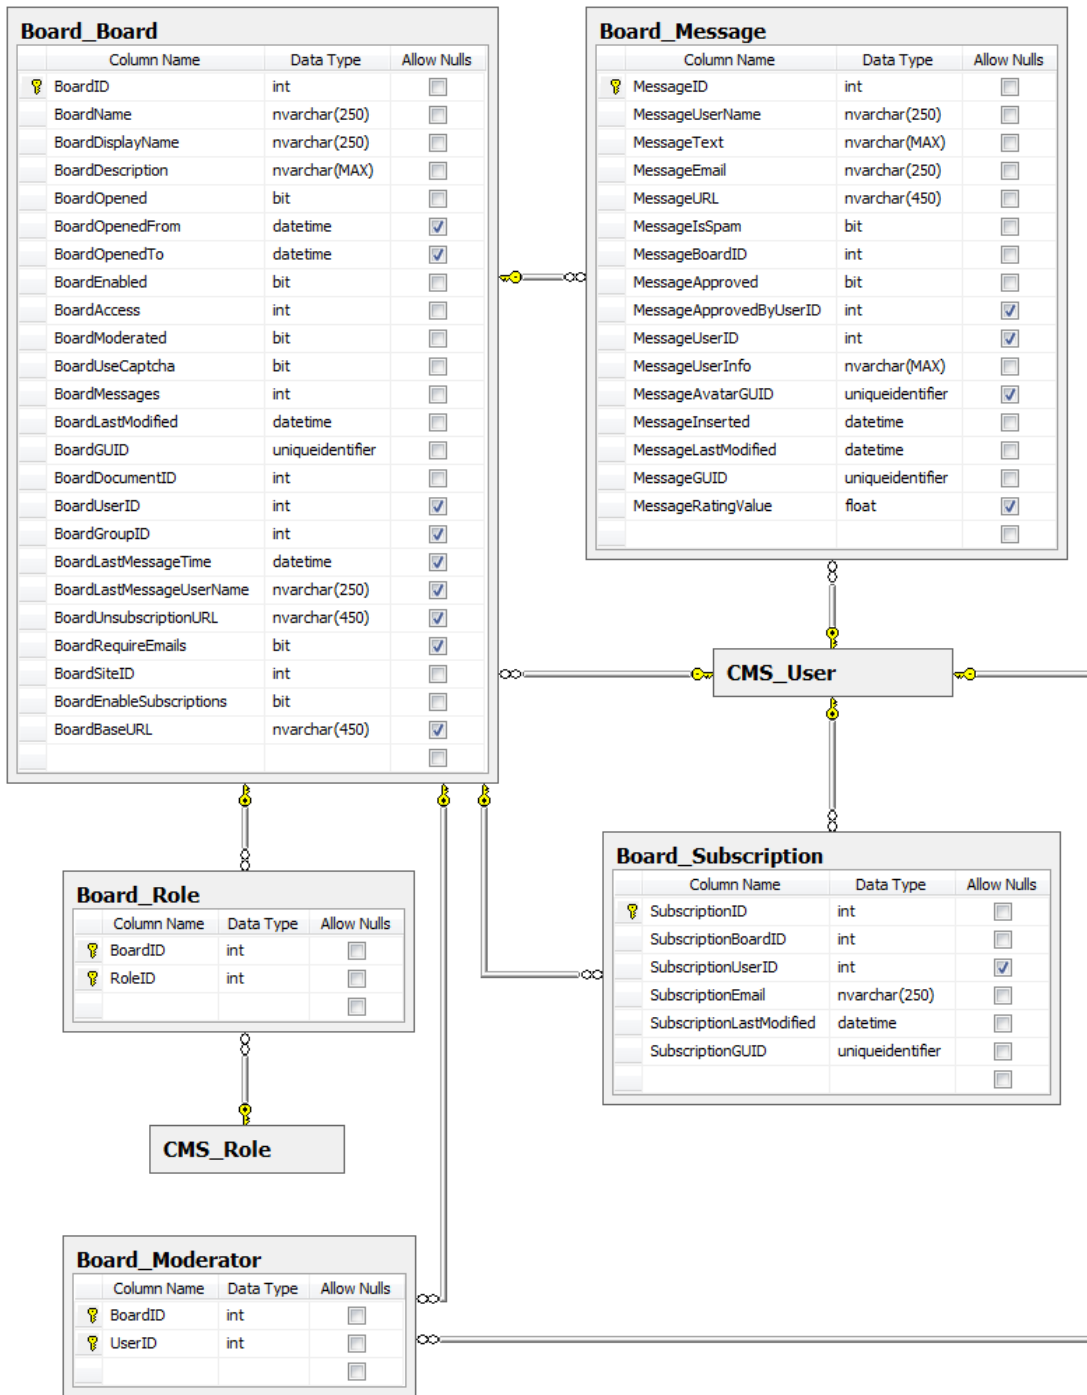

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Message boards module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.33.9.2 Database tables

The following database tables are used in the Message boards module:

- **Board_Board** - contains records representing message boards.
- **Board_Message** - contains records representing messages.
- **Board_Subscription** - contains records representing message board subscriptions.
- **Board_Role** - contains relationships between roles and message boards indicating that particular roles are allowed to add comments to a particular board.
- **Board_Moderator** - contains relationships between users and message boards indicating that a particular user can moderate messages of a particular board.

8.33.9.3 API classes

If you are not familiar with the database table data management by Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

**Please note**

The Message boards module classes use the **CMS.MessageBoard** namespace.

Board_Board table API:

- **BoardInfo** - represents one message board.
- **BoardBoardInfoProvider** - provides management of message boards.

Board_Message table API:

- **BoardMessageInfo** - represents one message.
- **BoardMessageInfoProvider** - provides management of messages.

Board_Subscription table API:

- **BoardSubscriptionInfo** - represents one message board subscription.
- **BoardSubscriptionInfoProvider** - provides management of message board subscriptions.

Board_Role table API:

- **BoardRoleInfo** - represents a relationship between one role and one message board expressing that a particular role is allowed to add comments to a particular board.
- **BoardRoleInfoProvider** - provides management of relationships between roles and message boards.

Board_Moderator table API:

- **BoardModeratorInfo** - represents a relationship between one user and one message board expressing that a particular user can moderate messages of a particular message board.
- **BoardModeratorInfoProvider** - provides management of relationships between moderators and message boards.

8.33.9.4 API examples

8.33.9.4.1 Overview

Please note

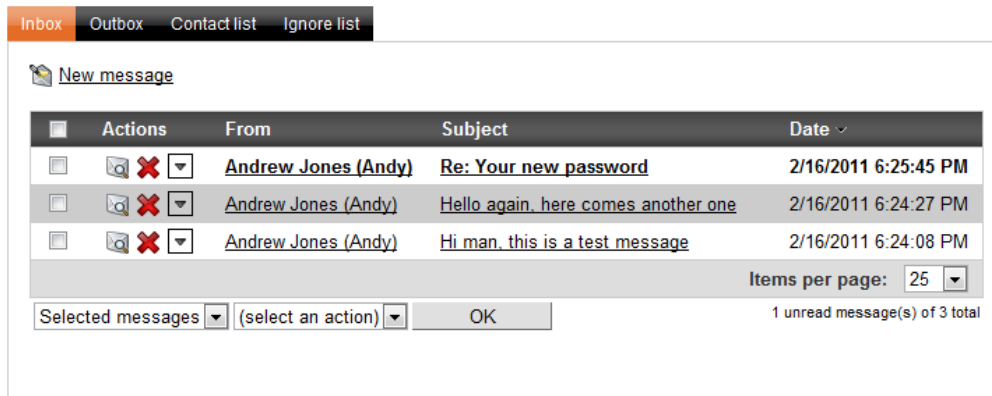

All API examples can be simulated in the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Community\MessageBoards\Default.aspx.cs**.

8.34 Messaging

8.34.1 Overview

The **Messaging** module allows users of your website to communicate via text messages. Its purpose is to provide an internal way of communication with other users of the website, both on the live site and in the user interface.

Users with access to Kentico CMS user interface can send, receive and manage their messages in **CMS Desk -> My desk -> Messages**. Functionality provided by this section of the user interface is described in the [My messages](#) topic. If you want to try to send out a testing message, you may proceed to the [Sending a new message](#) topic. On the live site, identical functionality can be provided by a single **My messages** web part, or separately by other web parts which come with the module. All Messaging module web parts are described in the [Adding the messaging functionality to the live site](#) topic.

It is possible to let Kentico CMS notify users about new messages by means of automatic notification e-mails. Information related to this topic can be found in the [E-mail notifications](#) topic. The [Security](#) topic explains messaging possibilities of unregistered anonymous website visitors.

The [Messaging internals and API](#) sub-chapter provides an overview of database tables and API classes used by the module. It also provides examples of how methods from the classes can be used to handle messaging in your custom code.

There are other ways how you can enable users of your website to communicate with each other. The [Forums](#) module enables you to add standard discussion forums to the live site. The [Message boards](#) modules provides similar functionality as the forums, with the difference that message boards are not structured and are typically used to let users add comments on the content of a particular page.

8.34.2 My messages

The **CMS Desk -> My desk -> Messages** section of the administration interface is divided into the following four tabs:

Inbox

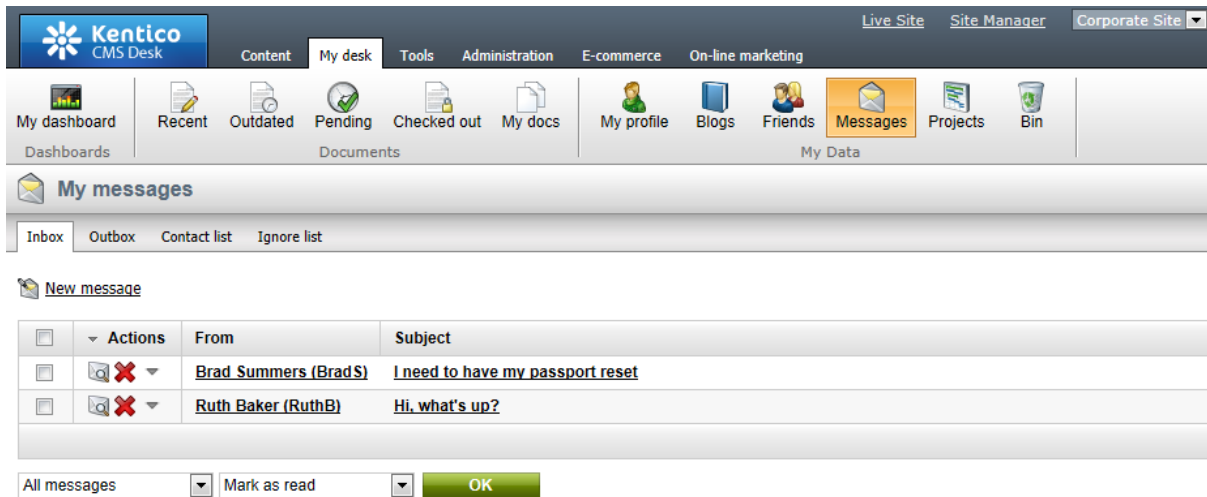

On this tab, the current user can see a list of all their received messages. The following actions are available for each message:

-  **View** - displays the message. Alternatively, you can view a message by clicking its **Subject** or its sender in the **From** column.
-  **Delete** - deletes the message.

Other actions are available if you unfold the drop-down menu by clicking the ▾ icon in a message's row:

-  **Reply** - opens a dialog where a reply to the message can be written and sent out.
-  **Forward** - opens a dialog where you can forward the message to other users.
-  **Mark as read** - marks the message as read (already opened), which is recognizable by a non-bold font in the listing.
-  **Mark as unread** - marks the message as unread (not opened yet), which is recognizable by a bold font in the listing.

Certain actions can be performed to more messages at once, as explained in [Bulk actions for Inbox and Outbox](#) below.

Outbox

This tab lists all messages sent out by the current user. These actions are available for each message on this tab:

-  **View** - displays the message. Alternatively, you can view a message by clicking its **Subject** or its recipient in the **To** column.
-  **Forward** - opens a dialog where you can forward the message to other users.
-  **Delete** - deletes the message.

The Delete action can be performed to more messages at once, as explained in [Bulk actions for Inbox and Outbox](#) below.

Message has been successfully sent.

[New message](#)

| <input type="checkbox"/> | Actions | To | Subject |
|--------------------------|---------|--------------------------------------|---|
| <input type="checkbox"/> | | Brad Summers (BradS) | RE:I need to have my passport reset |
| <input type="checkbox"/> | | Luke Hillman (LukeH) | Please stop posting adverts to our website forums |

Selected messages:

Bulk actions in Inbox and Outbox

In **Inbox** and **Outbox**, you can perform certain actions with multiple messages at once. For this purpose, you need to adjust the two drop-down lists below the listing. In the first one, you can choose from the following options:

- **Selected messages** - the action will only be performed to messages selected by the check-boxes in the respective rows.
- **All messages** - the action will be performed to all listed messages.

After choosing from the first drop-down list, you need to select the action to be taken from the second one and click **OK**. In **Inbox**, the **Delete**, **Mark as read** and **Mark as unread** actions are available. In **Outbox**, you can only use the **Delete** action for multiple files at once.

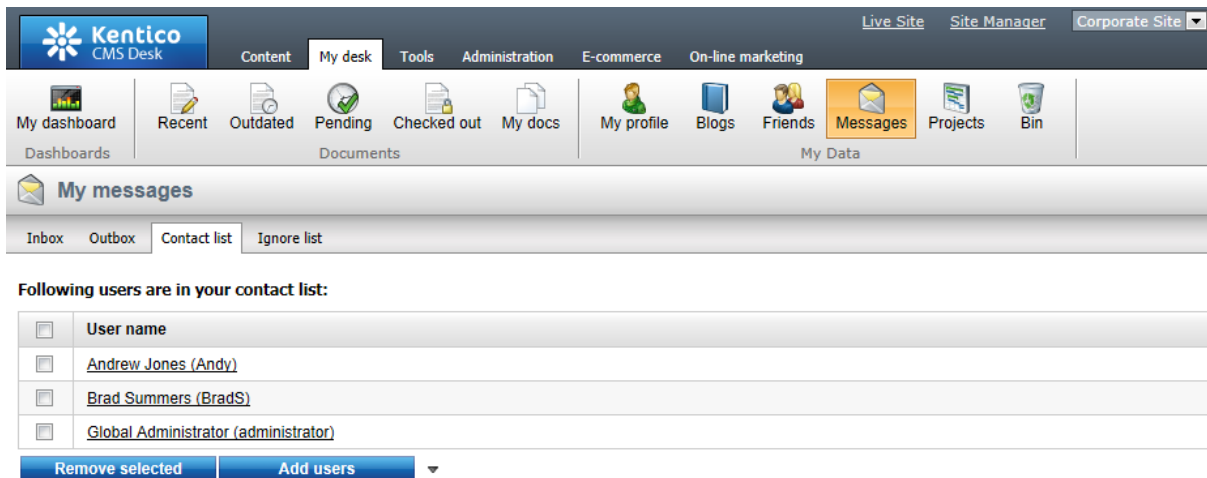

| <input type="checkbox"/> | Actions | From | Subject |
|--------------------------|---------|--------------------------------------|--|
| <input type="checkbox"/> | | Brad Summers (BradS) | I need to have my passport reset |
| <input type="checkbox"/> | | Ruth Baker (RuthB) | Hi, what's up? |

All messages

Contact list

This tab represents the current user's contact list, i.e. a list of users they communicate with. Having a user in the contact list makes it easier to select the user as a recipient when creating a new message.

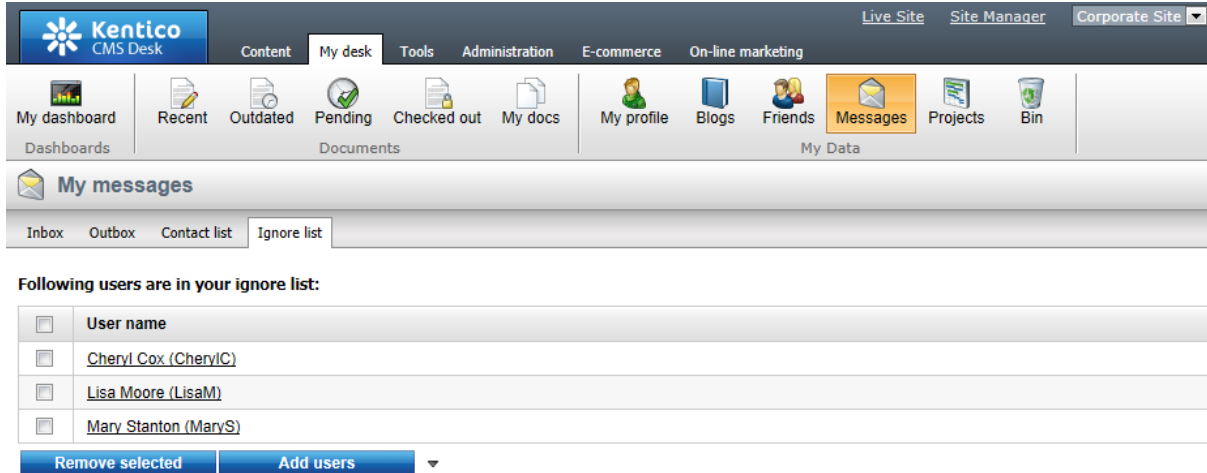

The **Add users** button opens a pop-up dialog where you can select users to be added to the list. The **Remove selected** button removes users selected by the check-boxes from the list.

Ignore list

This tab represents the current user's ignore list, i.e. a list of users from which no messages will be received. If a user who is in your ignore list sends you a message, the message will simply not be delivered.

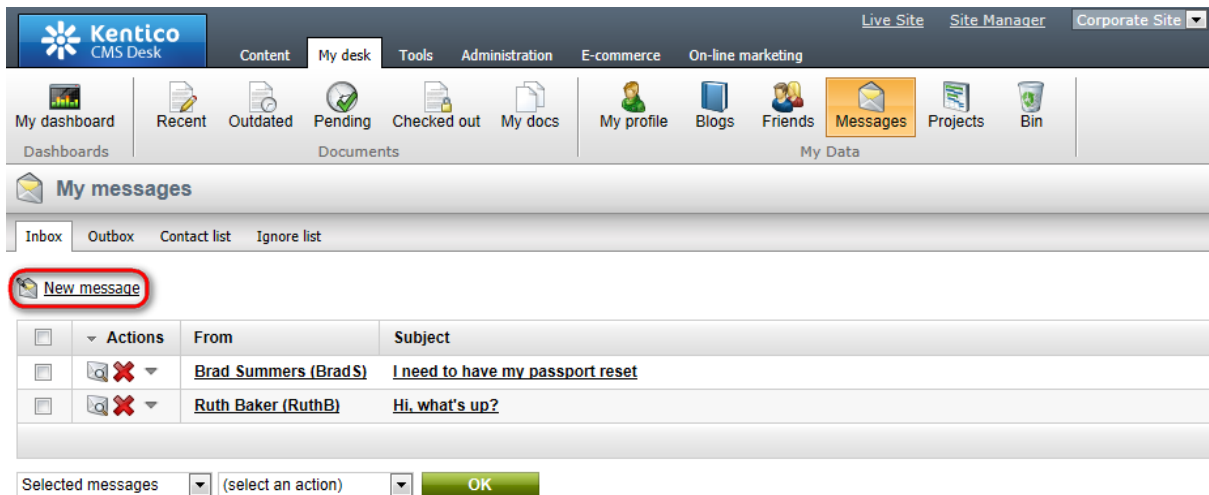

The **Add users** button opens a pop-up dialog where you can select users to be added to the list. The **Remove selected** button removes users selected by the check-boxes from the list.

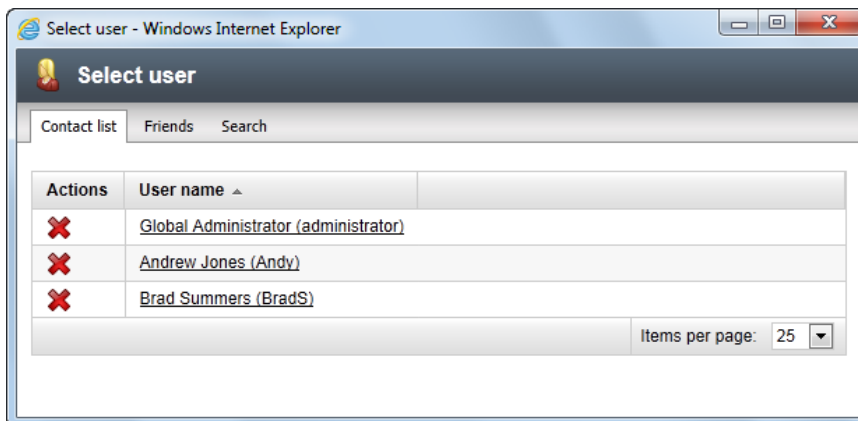

8.34.3 Sending a new message

New messages can be created and sent out in **CMS Desk -> My Desk -> Messages**, on both the **Inbox** and **Outbox** tabs in this part of the UI.

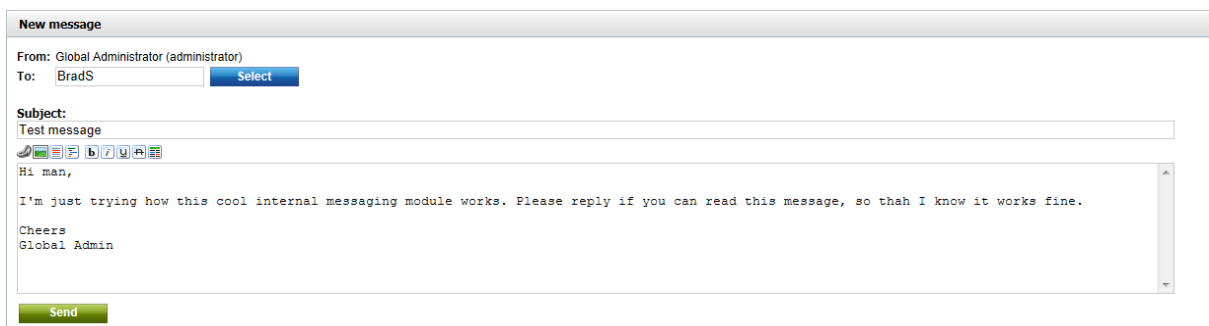

1. On each of these tabs, the first thing to do is to click  **New message** above the messages listing.

2. Clicking the link opens the **New message** dialog where new messages can be created and sent out. When creating a message, you first need to select its recipient. By clicking the **Select** button next to the **To** field, you open a pop-up dialog where the recipient can be selected from the contact list, from the your [friends](#), or searched among all visible website users.

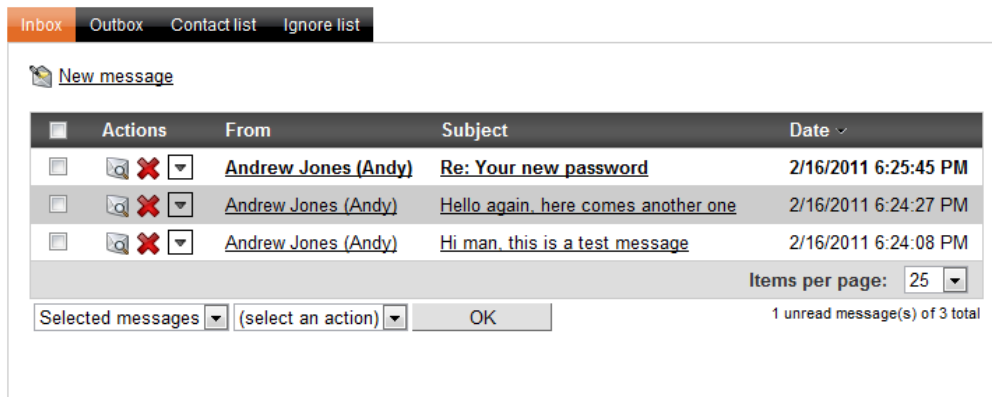

3. Then you need to fill in the **Subject** field and the actual text of the message into the large text area. Entered text can be formatted using BBCode. This is possible either by entering BBCode tags directly, or using the icons above the main text area. Supported BBCode tags are listed and explained in [Modules -> Forums -> BBCode support](#).

4. Finally, the message can be sent out using the **Send** button.

8.34.4 Adding the messaging functionality to the live site

The same functionality that is described in the [My messages](#) topic can be added to the live site as well. It is possible using the web parts stored under the **Messaging** web part category. This page gives just a brief overview of the messaging web parts. Detailed descriptions of each web part and its properties can be found in [Kentico CMS Web Parts Reference](#).

The **My messages** web part, shown in the screenshot above, is an all-in-one messaging web part. It provides exactly the same functionality as the user interface in **CMS Desk -> My Desk -> Messages**. This web part encapsulates the rest of the messaging web parts in one web part. If you need to add just a particular part of the messaging functionality, you can use one of the other messaging web parts:

- **Contact list** - allows users to add other users into their contact list or remove them from the list
- **Ignore list** - allows users to define which users they don't want to receive any messages from
- **Inbox** - shows a list of received messages and allows replying to them and deleting them
- **Messaging info panel** - displays links to inbox, outbox, etc.
- **Outbox** - shows a list of sent messages and allows deleting them
- **Send message** - allows users to send messages

These web parts can be used separately on any page of the website, providing the same functionality as when the **My messages** web part is used. You can also choose which of these web parts will be included in the **My messages** web part. This can be done using its **Display inbox**, **Display outbox**, **Display contact list** and **Display ignore list** properties.

8.34.5 E-mail notifications

Users can be notified about new messages received via the Messaging module by means of notification e-mails. The e-mails are based on the **Messaging - Notification email** e-mail template.

For this to work, the target e-mail address must be filled into a user's **Messaging notification e-mail** field. This can be done several ways:

- On the live site, it can be entered via the **My profile** web part.
- Users with access to the system's user interface can enter it in **CMS Desk -> My desk -> My profile**.
- Global administrators can edit this field of each user in **Site Manager -> Administration -> Users -> edit (✎) a user -> Settings**.

When the e-mail address is entered into the field, a notification e-mail is sent to the address whenever the user receives a new message. This does not apply to messages received from users in the recipient's **Ignore list**.

**Please note**

Your instance of Kentico CMS must be configured to use an SMTP server in order for e-mails to be sent, as described in [Installation and deployment -> Additional configuration tasks -> SMTP server configuration](#).

Macros in messaging e-mail template

In text of the **Messaging - Notification email** template, you can access the following specific objects and their properties (e.g. `{% Sender.UserName %}`) using [context macros](#) to include dynamic values in their text:

- **{% Sender %}** - *UserInfo* object of the message sender.
- **{% Recipient %}** - *UserInfo* object of the message recipient.
- **{% Message %}** - *MessageInfo* object of the message.

Besides these special ones, you can also use all other standard macro expressions in the templates. See the [Development -> Macro expressions](#) chapter of this guide for more information about macro expressions in Kentico CMS.

Related settings

In **Site manager -> Settings -> Community -> Messaging**, you can find the following settings related to the notification e-mails:

- **Messaging sender e-mail** - e-mail address that will be used as the sender address (*From* field) of the notification e-mails.
- **Messaging e-mail subject** - entered text will be used as content of the *Subject* field of notification e-mails.

8.34.6 Security

Even **unregistered anonymous users** can send messages to registered users of your website. This is possible only from the **Send message** web part, the **My messages** web part can be used only by registered users.

To allow this functionality, go to properties of the **Send message** web part and check the **Allow anonymous users** check-box. By checking the **Allow anonymous users to select recipient** check-box below, you can give anonymous users permission to view a list of all registered users and select a user from this list.

8.34.7 Messaging internals and API

8.34.7.1 Overview

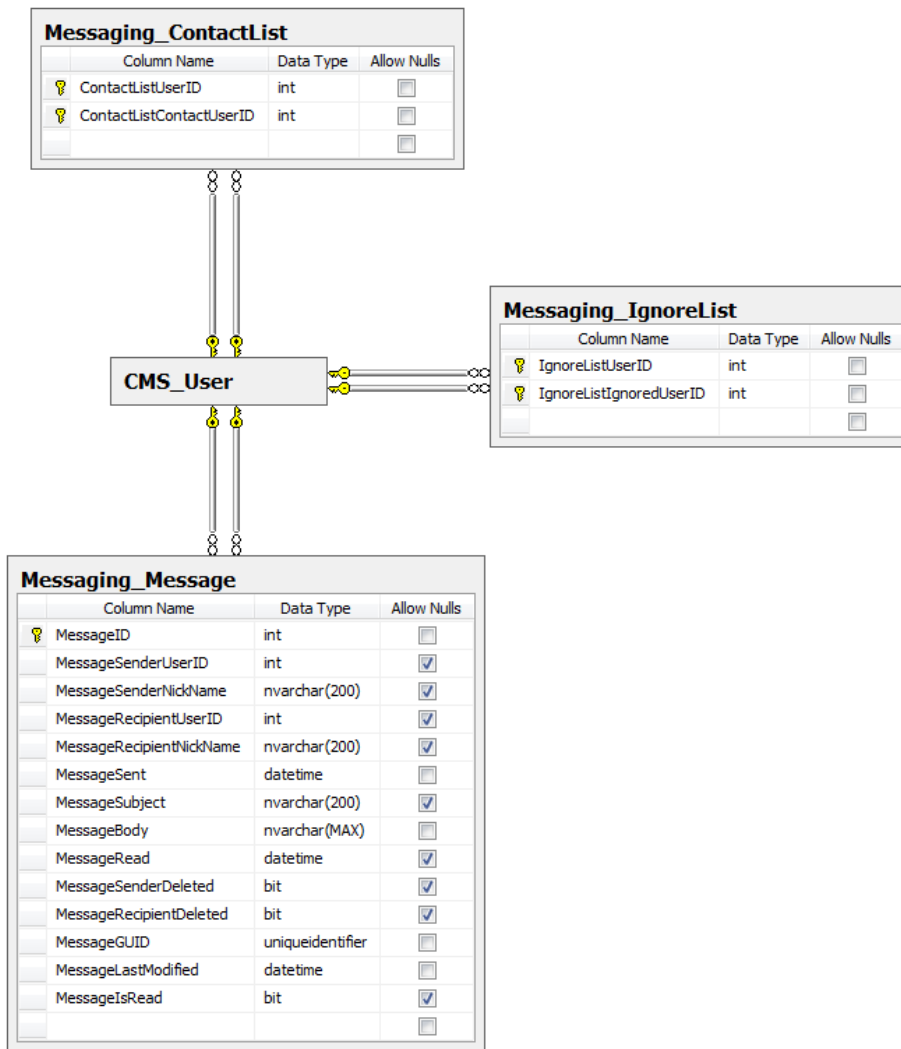

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Messaging module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.34.7.2 Database tables

The Messaging module uses the following database tables:

- **Messaging_Message** - contains records representing messages.
- **Messaging_ContactList** - contains relationships between pairs of users. Each record indicates that the first user has the second user in their contact list.
- **Messaging_IgnoreList** - contains relationships between pairs of users. Each record indicates that the first user has the second user in their ignore list.

8.34.7.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Messaging module can be found in the **CMS.Messaging** namespace.

Messaging_Message table API:

- **MessageInfo** - represents one message object.
- **MessageInfoProvider** - provides management functionality for abuse reports.

Messaging_ContactList table API:

- **ContactListInfo** - represents one contact list object.
- **ContactListInfoProvider** - provides management functionality for contact lists.

Messaging_IgnoreList table API:

- **IgnoreListInfo** - represents one ignore list object.
- **IgnoreListInfoObject** - provides management functionality for ignore lists.

8.34.7.4 API examples

8.34.7.4.1 Overview

These topics show examples of how the API of the Messaging module can be used:

- [Managing messages](#)
- [Managing contact lists](#)
- [Managing ignore lists](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Community\Messaging\Default.aspx.cs**.

The Messaging API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.Messaging;
```

8.34.7.4.2 Managing messages

The following example creates a message.

```
private bool CreateMessage()
{
    // Create new message object
    MessageInfo newMessage = new MessageInfo();
}
```

```
// Set the properties
newMessage.MessageSubject = "API example message";
newMessage.MessageBody = "Hello! This is a sample message created by Kentico
CMS API.";

// Get sender and recipient of the message
UserInfo sender = CMSContext.CurrentUser;
UserInfo recipient = UserInfoProvider.GetUserInfo("administrator");

// Check if both sender and recipient exist
if ((sender != null) && (recipient != null))
{
    newMessage.MessageSenderUserID = sender.UserID;
    newMessage.MessageSenderNickName = sender.UserNickName;
    newMessage.MessageRecipientUserID = recipient.UserID;
    newMessage.MessageRecipientNickName = recipient.UserNickName;
    newMessage.MessageSent = DateTime.Now;

    // Save the message
    MessageInfoProvider.SetMessageInfo(newMessage);

    return true;
}

return false;
}
```

The following example gets and updates the message created by the code example above.

```
private bool GetAndUpdateMessage()
{
    // Prepare the parameters
    string where = "[MessageSubject] = 'API example message'";

    // Get the data
    DataSet messages = MessageInfoProvider.GetMessages(where, null, 1, null);
    if (!DataHelper.DataSourceIsEmpty(messages))
    {
        // Get the message from the DataSet
        MessageInfo modifyMessage = new MessageInfo(messages.Tables[0].Rows[0]);

        // Update the properties
        modifyMessage.MessageBody = modifyMessage.MessageBody.ToUpper();

        // Save the changes
        MessageInfoProvider.SetMessageInfo(modifyMessage);

        return true;
    }

    return false;
}
```

```
}
```

The following example gets and bulk updates multiple messages selected from database based on a WHERE condition.

```
private bool GetAndBulkUpdateMessages()
{
    // Prepare the parameters
    string where = "[MessageSubject] = 'API example message'";

    // Get the data
    DataSet messages = MessageInfoProvider.GetMessages(where, null);
    if (!DataHelper.DataSourceIsEmpty(messages))
    {
        // Loop through the individual items
        foreach (DataRow messageDr in messages.Tables[0].Rows)
        {
            // Create object from DataRow
            MessageInfo modifyMessage = new MessageInfo(messageDr);

            // Update the properties
            modifyMessage.MessageBody = modifyMessage.MessageBody.ToLower();

            // Save the changes
            MessageInfoProvider.SetMessageInfo(modifyMessage);
        }

        return true;
    }

    return false;
}
```

The following example deletes all messages created by the first code example on this page.

```
private bool DeleteMessage()
{
    // Prepare the parameters
    string where = "[MessageSubject] = 'API example message'";

    // Get the message
    DataSet messages = MessageInfoProvider.GetMessages(where, null);

    if (!DataHelper.DataSourceIsEmpty(messages))
    {
        foreach (DataRow messageDr in messages.Tables[0].Rows)
        {
            // Create message object from DataRow
            MessageInfo deleteMessage = new MessageInfo(messageDr);
        }
    }
}
```

```
        // Delete the message
        MessageInfoProvider.DeleteMessageInfo(deleteMessage);
    }

    return true;
}

return false;
}
```

8.34.7.4.3 Managing contact lists

The following example adds the **cmseditor** user to the current user's contact list.

```
private bool AddUserToContactList()
{
    // Gets "cmseditor" UserInfo object
    UserInfo user = UserInfoProvider.GetUserInfo("cmseditor");

    if (!ContactListInfoProvider.IsInContactList(CMSContext.CurrentUser.UserID,
        user.UserID))
    {
        // Adds "cmseditor" to the current user's contact list
        ContactListInfoProvider.AddToContactList(CMSContext.CurrentUser.UserID,
            user.UserID);

        return true;
    }

    return false;
}
```

The following example removes the **cmseditor** user from the current user's contact list.

```
private bool RemoveUserFromContactList()
{
    // Gets "cmseditor" UserInfo object
    UserInfo user = UserInfoProvider.GetUserInfo("cmseditor");

    if (ContactListInfoProvider.IsInContactList(CMSContext.CurrentUser.UserID,
        user.UserID))
    {
        // Removes "cmseditor" from the current user's contact list
        ContactListInfoProvider.RemoveFromContactList
        (CMSContext.CurrentUser.UserID, user.UserID);

        return true;
    }

    return false;
}
```

```
}
```

8.34.7.4.4 Managing ignore lists

The following example adds the **cmseditor** user to the current user's ignore list.

```
private bool AddUserToIgnoreList()
{
    // Gets "cmseditor" UserInfo object
    UserInfo user = UserInfoProvider.GetUserInfo("cmseditor");

    if (!IgnoreListInfoProvider.IsInIgnoreList(CMSContext.CurrentUser.UserID,
        user.UserID))
    {
        // Adds "cmseditor" to the current user's ignore list
        IgnoreListInfoProvider.AddToIgnoreList(CMSContext.CurrentUser.UserID,
            user.UserID);

        return true;
    }

    return false;
}
```

The following example removes the **cmseditor** user from the current user's ignore list.

```
private bool RemoveUserFromIgnoreList()
{
    // Gets "cmseditor" UserInfo object
    UserInfo user = UserInfoProvider.GetUserInfo("cmseditor");

    if (IgnoreListInfoProvider.IsInIgnoreList(CMSContext.CurrentUser.UserID,
        user.UserID))
    {
        // Removes "cmseditor" from the current user's ignore list
        IgnoreListInfoProvider.RemoveFromIgnoreList(CMSContext.CurrentUser.UserID,
            user.UserID);

        return true;
    }

    return false;
}
```

8.35 Multivariate testing

8.35.1 Overview

For information about **Multivariate testing**, please see the [Modules -> Website optimization -> Multivariate testing](#) chapter of this guide.

8.36 Newsletters

8.36.1 Overview

The Newsletters module allows the creation and management of highly configurable newsletters. Newsletters are used to regularly send e-mails about a certain topic to users who agree to receive them by subscribing.

When a newsletter issue is sent, e-mails are created and personalized (if applicable) for every individual subscriber. This procedure is performed by the Newsletter queue and any e-mails lost due to errors are automatically re-sent. This is handled by the **Send queued newsletters scheduled task**. Once this process is complete, the e-mails are sent either directly to the SMTP server or to the [E-mail queue](#) if the given newsletter is configured to do so (later topics in this chapter describe how this can be done). Using the e-mail queue is recommended for newsletters with large amounts of subscribers to ensure that all e-mails are delivered correctly.

The newsletters can be of two types:

- [Static newsletters](#) - every issue is edited and sent manually. The newsletters are based on predefined templates.
- [Dynamic newsletters](#) - issues are sent out to all subscribers automatically at a specified interval. The content is dynamically taken from a specified page, which is usually updated between newsletter issues.

Users can manage their subscriptions and find information about newsletters directly on the pages of a website if it contains the appropriate web parts. Please refer to the [Integrating newsletters into the site](#) topic to see what web parts are available.

Newsletters make use of templates to give all issues and related notification e-mails a unified appearance by utilizing design elements such as a company logo or footer. Templates may also contain various macros that are resolved into data matching individual recipients during the mail merge. For more details, please see the [Newsletter templates](#) topic.

The subscribers of all newsletters are stored in the system and can be monitored and managed as shown in the [Subscriber management](#) topic. The [Subscriber import and export](#) topic describes how tasks affecting large amounts of subscribers can be performed.

Newsletters also offer several tools that help track, monitor and optimize issues, which can be very useful when carrying out e-mail marketing campaigns. More information about this is given in the [On-line marketing](#) chapter.

The [Troubleshooting](#) topic contains a list of solutions that can be used to resolve common problems with newsletter e-mails.

8.36.2 Creating a static newsletter

In this topic, you will learn how to create a static (template-based) newsletter:

1. Go to **CMS Desk -> Tools -> Newsletters** and click  **New newsletter**. Enter the following details:

- **Newsletter display name:** *My newsletter*, this is the name displayed to users.
- **Newsletter name:** leave the (*automatic*) option; this name is used internally as an identifier in web part properties, URLs and the API. The system will generate an appropriate one based on the display name.
- **Subscription confirmation:** Subscription confirmation template
- **Unsubscription confirmation:** Unsubscription confirmation template
- **Sender name:** Enter your full name
- **Sender e-mail:** Enter your e-mail address

Choose the **Template-based newsletter** option and use the *Newsletter issue template*. Click  **Save**. The newsletter will be created and you will be redirected to its **Configuration** tab, where the following additional options can now be set:

- **Base URL** - here you can specify the base URL of your website (protocol, domain name and virtual directory), which is used to convert relative links to absolute URLs in newsletter issues. It may be necessary to set this property in order for the unsubscription links to work properly. It's also useful if you encounter any issues with links in newsletter e-mails, e.g. if you are using a different URL for your editing environment than for the live website.
Example: *https://www.example.com*
- **Unsubscription page URL** - enter *~/SpecialPages/Unsubscribe/Newsletter.aspx*. This page on the sample Corporate site contains a [Newsletter unsubscription](#) web part, which ensures the required functionality.
- **Send draft e-mails to** - the addresses specified here are pre-entered by default when sending draft newsletter issues for testing purposes. Multiple addresses must be separated by semicolons. Draft e-mails are not included in tracking statistics (e-mail opening and link clicking).
- **Send issues via e-mail queue** - if enabled, newsletter issues will be sent to the SMTP server through the [E-mail queue](#). This is recommended for newsletters with a large number of recipients. If disabled, the issues will be sent directly to the SMTP server.
- **Enable resending** - if enabled, it will be possible to edit newsletter issues and manually send them again even after they have been mailed out to subscribers. You can disable this property to ensure that subscribers do not accidentally receive the same content multiple times. Issues that utilize [A/B testing](#) are an exception and can never be re-sent.
- **On-line marketing** - the properties in this section are related to tracking of the newsletter's e-mails and keeping marketing statistics. Please see the [On-line marketing](#) chapter for further details.
- **Double opt-in** - the properties in this section are related to double opt-in subscription. Please refer to the [Double opt-in](#) topic for more information.

Newsletters

> Newsletters > My newsletter

Issues Configuration Subscribers Templates

Approval page URL:

Send double opt-in confirmation:

Click  **Save** again.

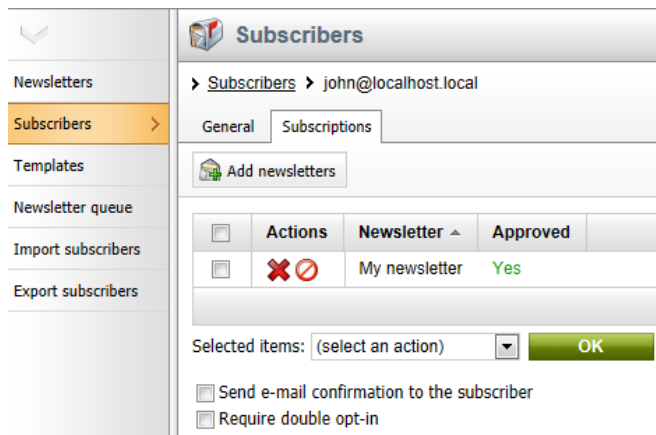

2. Now we will create a new subscriber. Select the main **Subscribers** tab in the left menu and click the  **New subscriber** button. Enter the following details:

- **E-mail** - subscriber's e-mail address. If you wish to check the newsletter e-mail once it is sent, enter a valid address that you can access.
- **First name** - subscriber's first name.
- **Last name** - subscriber's last name.

Click **Save** to add the subscriber.

3. Now we will assign this subscriber to our previously created newsletter. Switch to the **Subscriptions** tab, click the **Add newsletters** button, check the box next to **My newsletter** in the selection dialog and click **OK**.

If you check the **Send e-mail confirmation to the subscriber** box before adding a newsletter to a subscriber, an e-mail informing about the subscription will be sent to them. If you check the **Require double opt-in** box, subscriptions to newsletters that have double opt-in enabled will be inactive (rejected) until the user confirms them or the **Approve** (✔) action is manually selected in the list of subscriptions.

4. Your newsletter is configured. You can now create new issues as is described in the [Authoring static newsletter issues](#) topic.

8.36.3 Authoring static newsletter issues

Now that you have created a static newsletter with a subscriber as described in the [Creating a static newsletter](#) topic, it is possible to write and send individual issues. The following steps describe how this can be done:

1. Go to the **Newsletters** tab in the left menu and edit (✎) **My newsletter**. Click **Create new issue** on the **Issues** tab. A wizard will guide you through the process of creating a new newsletter issue.
2. In Step 1, start by entering the following **Subject**: *Welcome to issue #1 of My newsletter*
3. Then copy the following text into the **content** editable region:

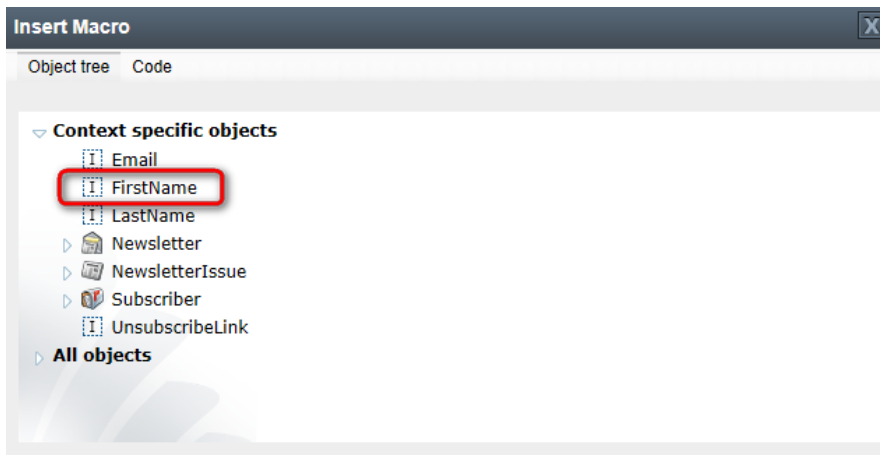

Dear ,

welcome to the first issue.

Yours,

Me

Place the cursor after the word *Dear* and click the **Insert macro** (⌘) button on the toolbar of the WYSIWYG editor. In the displayed dialog, choose the **FirstName** option under the **Context specific objects** section.

The `{% FirstName %}` macro expression will be placed into the text. This macro will automatically be replaced by the e-mail recipient's first name during the mail merge. The issue should now look like this:

Newsletter templates

The overall structure of this issue is defined by the *Newsletter issue template*, which can be edited under the **Templates** section of the left menu. Templates are described in the [Newsletter templates](#) topic.

Some newsletters may have multiple issue templates assigned. In this case, there will be an additional step in the wizard where you can choose the template that you wish to use for the new issue.

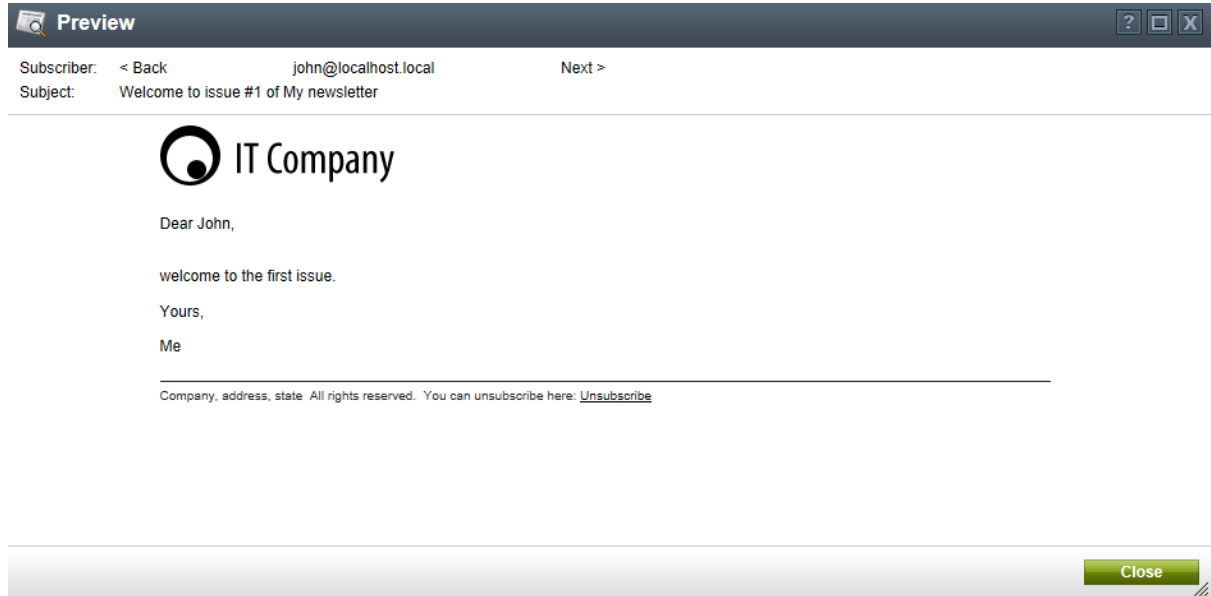

It is also possible to change the template by clicking **Show advanced properties** next to the **Subject** field and selecting a different option through the **Template** selector.

4. Click the **Save** button at the top. Once the issue is saved, you can manage it using the actions described below:

- **Send draft** - allows you to send a test draft of the newsletter issue to any e-mail address. Draft e-mails do not correctly resolve newsletter macros (such as unsubscription links), since the recipients are not linked to subscribers in the system.
- **Preview** - opens a dialog window where you can view how the issue will appear to specific subscribers.
- **Attachments** - allows you to attach files to the issue, such as images, an event agenda, white papers, etc. The attachments will be included in the issue e-mails when they are sent out. Please note that other attachments may already be included in the newsletter template on which the issue is based.
- **Create A/B test** - may be used to prepare an A/B test for the issue. This allows you to create

several different versions of the issue, evaluate them on a test group of subscribers and then send out the most successful one. Clicking this button adds the first testing variant of the issue. Please see the [On-line marketing -> A/B testing](#) topic to learn more.

Try clicking the  **Preview** button. This will open a dialog where you can see how the content of the issue will appear for each subscriber.

Close the preview dialog.

5. Now click **Next**. This automatically saves the content of the issue and moves you to the final step of the wizard. Here you can choose when the newsletter issue should be sent out:

- **Send now to all subscribers** - the newsletter issue is sent out immediately to all subscribers.
- **Schedule newsletter mail-out** - the issue will be sent out on the specified date and time.
- **Send the newsletter manually later** - the issue will not be sent for now and you can decide on the mail-out time later.

Step 2
New Issue
Send

Send now to all subscribers

Schedule newsletter mail-out to all subscribers
Date and time: Now

Send the newsletter manually later

Back
Finish

Select **Send now to all subscribers** and click **Finish**. On the **Issues** tab, you can review the statistics and details of the newsletter's issues.

Newsletters ?

» [Newsletters](#) » My newsletter

[Issues](#) [Configuration](#) [Subscribers](#) [Templates](#)

Create new issue

| Actions | Issue subject | Send on | Sent e-mails | Opened e-mails | Unsubscribed | A/B test | Status |
|---------|--------------------------------------|----------------------|--------------|----------------|--------------|----------|----------|
| | Welcome to issue #1 of My newsletter | 5/15/2012 2:53:43 PM | 1 | 0 | 0 | No | Finished |

Items per page: 25

Issues that are scheduled to be sent out in the future can be modified by clicking the **Edit** () action. This allows you to work with their content and other settings.

6. If you experience problems receiving the newsletter issue e-mail, please follow the instructions in the [Troubleshooting](#) topic.

8.36.4 Creating a dynamic newsletter

Dynamic newsletters are based the content of a specified page and they are sent out automatically on a regular basis using the built-in scheduling system. When the mailout of a dynamic newsletter is scheduled, a new [scheduled task](#) called *Send dynamic newsletter: <newsletter name>* is created for the current site, which reads the content of the given source page and ensures that the issues are sent out according to the set time interval.

The following steps will guide you through the creation of a dynamic newsletter:

1. Go to **CMS Desk -> Tools -> Newsletters** and click  **New newsletter**. Enter the following details:

- **Newsletter display name:** My dynamic newsletter
- **Newsletter name:** leave the *(automatic)* option; the system will generate an appropriate one based on the display name.
- **Subscription confirmation:** Subscription confirmation template
- **Unsubscription confirmation:** Unsubscription confirmation template
- **Sender name:** Enter your full name
- **Sender e-mail:** Enter your e-mail address

Choose **Dynamic newsletter** and enter the following details:

- **Source page URL:** *http://www.kentico.com/*; this is the URL of the page from which the newsletter will take its content.
- **Schedule mail-outs:** Enabled
 - **Period:** Minute
 - **Start time:** Use the date-time picker to select the current date and time (click **Now**)
 - **Every:** 1 minute
 - **Between:** 00:00 and 23:59
 - **Days:** Check all days

Click **Save**. The newsletter will be created and you will be redirected to its **Configuration** tab, where the following additional options can now be set:

- **Base URL** - here you can specify the base URL of your website (protocol, domain name and virtual directory), which is used to convert relative links to absolute URLs in newsletter issues. It may be necessary to set this property in order for the unsubscription links to work properly. It's also useful if you encounter any issues with links in newsletter e-mails, e.g. if you are using a different URL for your editing environment than for the live website.
Example: *https://www.example.com*
- **Unsubscription page URL** - enter *~/SpecialPages/Unsubscribe/Newsletter.aspx*. This page on the sample Corporate site contains a [Newsletter unsubscription](#) web part, which ensures the required functionality.
- **Send draft e-mails to** - the addresses specified here are pre-entered by default when sending draft newsletter issues for testing purposes. Multiple addresses must be separated by semicolons. Draft e-mails are not included in tracking statistics (e-mail opening and link clicking).
- **Send issues via e-mail queue** - if enabled, newsletter issues will be sent to the SMTP server through the [E-mail queue](#). This is recommended for newsletters with a large number of recipients. If disabled, the issues will be sent directly to the SMTP server.
- **Enable resending** - if enabled, it will be possible to manually send the newsletter's issues again even after they have been mailed out to subscribers. You can disable this property to ensure that subscribers do not accidentally receive the same content multiple times.

- **Subject** - sets the subject of the dynamic newsletter e-mails. It can either use the page title of the content, or be entered manually by selecting *Use the following subject*.
- **On-line marketing** - the properties in this section are related to tracking of the newsletter's e-mails and keeping marketing statistics. Please see the [On-line marketing](#) chapter for further details.
- **Double opt-in** - the properties in this section are related to double opt-in subscription. Please refer to the [Double opt-in](#) topic for more information.

| <input type="checkbox"/> | Actions | Subscriber name | E-mail | Approved |
|--------------------------|---|-----------------|----------------------|----------|
| <input type="checkbox"/> |   | John Smith | john@localhost.local | Yes |

Selected items: (select an action)

Send e-mail confirmation to the subscriber

Require double opt-in

If you add a subscriber with the **Send e-mail confirmation to the subscriber** box checked, a notification e-mail will be sent to the selected users, informing them about the changes in their subscriptions. If you check the **Require double opt-in** box (only available if the newsletter has double opt-in enabled), the added subscriptions will be inactive (rejected) until the users confirm them or the **Approve**  action is manually selected in the list of subscriptions.

3. Go to the **Issues** tab. Here, you will see a list of sent issues. You may need to wait up to 2 minutes until the first issue is sent out. You can refresh the list by clicking the **Issues** tab again.

| Actions | Issue subject | Sent on | Sent e-mails | Opened e-mails | Unsubscribed | A/B test | Status |
|---------|--|----------------------|--------------|----------------|--------------|----------|----------|
| | .NET Web Content Management System Kentico CMS for ASP.NET | 5/15/2012 4:06:48 PM | 1 | 0 | 0 | No | Finished |
| | .NET Web Content Management System Kentico CMS for ASP.NET | 5/15/2012 4:03:37 PM | 1 | 0 | 0 | No | Finished |

Items per page: 25

4. Check your mail box, you should receive the content of the given page by e-mail:

This way, you can send out any page from your website. You can create a new page specifically for the purposes of a dynamic newsletter that will display e.g. new articles added to your website during the last month. Please note that some e-mail clients may not be able to process and display pages exactly like a standard browser. It may be necessary to simplify the source page's content or adjust its CSS stylesheet.

Dynamic newsletter unsubscription

Because the content of a dynamic newsletter is loaded from a web page, it may be difficult to include a standard unsubscription link. To allow users to easily cancel their

subscription, you can instead add the [Unsubscription request](#) web part onto the newsletter's source page.

Subscribers will then be able to enter their address and receive a special e-mail with an appropriate unsubscription link.

Blocking dynamic newsletter mail-out

If you want to block the mail-out of the page (e.g. if there are no new articles), you can either disable the **Schedule mail-outs** property of the dynamic newsletter on its **Configuration** tab or you can set the title of the source page to `##DONOTSEND##` and the newsletter will not be sent. The title of a page can easily be changed by selecting the corresponding document from the content tree in **CMS Desk -> Content -> Edit** and editing the **Page title** field on the **Properties -> Metadata** tab.

8.36.5 Double opt-in

Double opt-in functionality, also referred to as confirmed opt-in, provides an additional security layer to newsletter subscription. It confirms that the entered e-mail address actually exists and prevents users from being unknowingly subscribed to a newsletter by someone else, either intentionally or by mistake.

When double opt-in is disabled for a newsletter, anyone may simply submit an e-mail address for subscription, without any steps being taken to ensure that the address actually belongs to that user. With double opt-in, new subscribers are not immediately activated and do not receive newsletter issues. Instead, an automatic e-mail is sent to them, containing an activation link. Upon clicking the link, users are redirected to a special page and their subscription is confirmed.

Enabling double opt-in

To configure a newsletter to use double opt-in, open the **CMS Desk -> Tools -> Newsletters** interface, edit (✎) the appropriate newsletter and switch to its **Configuration** tab. Now check the **Enable double opt-in** option in the bottom section of properties and set the remaining ones below it:

- **Double opt-in template** - selects the template used for the subscription activation e-mails that are sent to users. Only templates of the *Double opt-in* type may be selected. Please see the [Newsletter templates](#) topic to learn about creating templates.
- **Approval page URL** - sets the URL of the page where users can confirm their subscription to the newsletter. The *Subscription approval* web part must be placed on the specified page to ensure the required functionality. This URL is used by the *Activation link* field, which is typically inserted into the Double opt-in template. If left empty, the value of the *Site Manager -> Settings -> On-line marketing -> Newsletters -> Newsletter double opt-in approval page URL* field is used. If this setting is empty as well, the default system page is used.
- **Send double opt-in confirmation** - if checked, a confirmation e-mail will be sent to users after they successfully activate their subscription.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Live Site', 'Site Manager', 'Corporate Site', and 'Global Administration'. The main menu has categories like 'Content', 'Community', 'Collaboration', and 'Marketing & Reports'. The left sidebar lists 'Newsletters', 'Subscribers', 'Templates', 'Newsletter queue', 'Import subscribers', and 'Export subscribers'. The main content area is titled 'Newsletters' and 'My newsletter', with tabs for 'Issues', 'Configuration', 'Subscribers', and 'Templates'. A 'Save' button is visible. The configuration is divided into sections: 'General' (with fields for display name, name, confirmation templates, sender name, and e-mail), 'Template-based newsletter configuration' (with a dropdown for the newsletter template), 'On-line marketing' (with checkboxes for tracking and logging), and 'Double opt-in' (highlighted with a red box, containing fields for enabling double opt-in, selecting a template, approval page URL, and confirmation checkbox).

Click the **Save** button to confirm any changes. Now any users who subscribe to the newsletter will receive an e-mail similar to the following (depending on the used double opt-in template):

You have been registered to a newsletter

Thank you for registering for a newsletter. In order to receive the newsletter, you need to confirm your subscription here:

[Confirm the subscription](#)

Company, address, state All rights reserved. You can unsubscribe here: [Unsubscribe](#)

When a user clicks the **Confirm the subscription** link, they will be redirected to the default `~/CMSModules/Newsletters/CMSPages/SubscriptionApproval.aspx` page, where their subscription will be activated and a basic confirmation message will be displayed. The identifier of the exact subscription is passed to the page as a parameter in the query string of the URL in the activation link.

Approval will only be possible for a limited amount of time after the initial subscription (12 hours by default). You can set the length of this time interval for all newsletters through the **Site Manager -> Settings -> On-line marketing -> Newsletters -> Double-opt in interval** setting. If a user does not

activate their subscription within the specified number of hours, the link in the confirmation e-mail will expire, and the user will have to subscribe again.

If you wish to use a custom activation page, simply create a new page on your website according to the specific requirements and place the [Subscription approval](#) web part on it. Remember to enter the URL of this page into the **Approval page URL** property of individual newsletters, or in the **Newsletter double opt-in approval page URL** field of the website settings in **Site Manager -> Settings -> On-line marketing -> Newsletters** to assign the page to all newsletters that do not have an approval page specified.

Alternatively, newsletter administrators may also activate subscriptions manually using the **Approve** (✓) action or **Reject** (✗) existing ones.

| | Actions | Subscriber name | E-mail | Approved |
|--------------------------|---------|-----------------|-------------------------------|----------|
| <input type="checkbox"/> | ✗ ✓ | Frank Maguire | frank.maguire@localhost.local | No |
| <input type="checkbox"/> | ✗ ✓ | John Smith | john@localhost.local | Yes |
| <input type="checkbox"/> | ✗ ✓ | Mary Jones | mary.jones@localhost.local | No |

The [Subscriber management](#) topic provides more information about this subject.

8.36.6 Integrating newsletters into the site

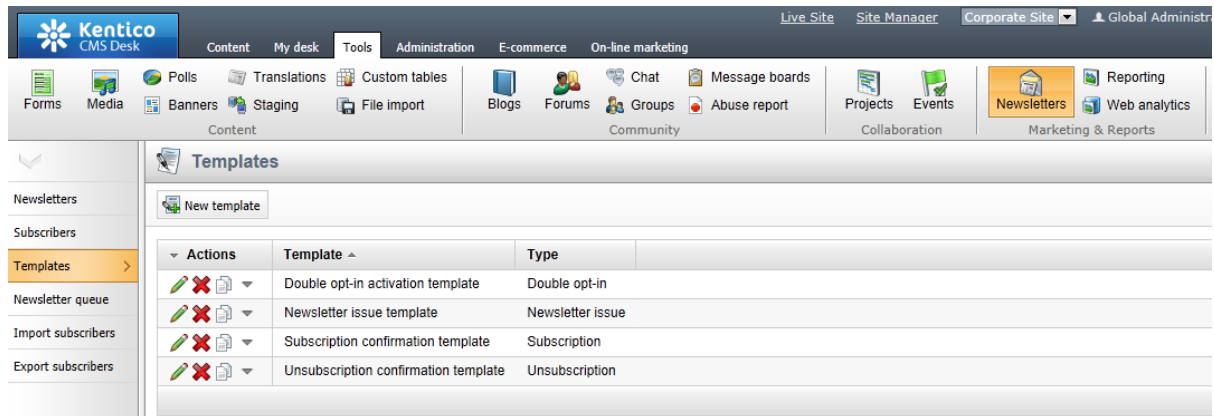

You can integrate newsletters into your website using the following web parts:

- [Newsletter subscription](#) - displays a dialog that may be used by the website's users to subscribe to newsletters.
- [Custom subscription form](#) - provides a newsletter subscription form like the *Newsletter subscription* web part, but with the option of using a different layout and appearance. The customized subscription form must be defined as an [alternative form](#) of the *Newsletter - Subscriber* system table, which can be edited in *Site Manager -> Development -> System tables*.
- [Newsletter unsubscription](#) - unsubscribes users from a newsletter and displays a confirmation message. Users are typically directed to the page containing this web part through the "Unsubscribe" link in newsletter issues. Identifiers of the exact newsletter and subscriber are read from parameters passed in the query string of the URL.
- [Newsletter archive](#) - displays archived issues of a specified newsletter.
- [Unsubscription request](#) - this web part allows newsletter subscribers to request an unsubscription e-mail (based on the *Newsletters - Unsubscription request* e-mail template, which can be edited in *Site Manager/CMS Desk -> Administration -> E-mail templates*) by submitting their e-mail address. The unsubscription link in the sent e-mail will only be valid for the amount of hours specified in the *Site Manager -> Settings -> On-line marketing -> Newsletters -> Double-opt in interval* setting.

- [My subscriptions](#) - this web part can be used by users to add or remove their newsletter subscriptions.
- [My account](#) - if configured to display newsletter subscriptions, this web part can be used by users to add or remove their subscriptions.
- [Subscription approval](#) - approves subscriptions to newsletters with double opt-in enabled and displays a confirmation message. Subscribers are typically directed to the page containing this web part through a link in the double opt-in activation e-mail. An identifier of the exact subscription is read from a parameter passed in the query string of the URL.

8.36.7 Newsletter templates

The e-mails sent by the Newsletter module are defined by templates (with the exception of dynamic newsletter issues). These templates can be managed in **CMS Desk -> Tools -> Newsletters -> Templates**.

There are four types of templates:

- **Double opt-in** - template for e-mail messages sent to users to confirm their subscription to a newsletter that has double opt-in enabled.
- **Newsletter issue** - this is a template that defines the layout and design of static newsletter issues. Templates of this type typically contain editable regions where newsletter authors can enter the content of individual issues.
- **Subscription** - template for the confirmation e-mail message sent when a user subscribes to the newsletter.
- **Unsubscription** - template for the e-mail message sent when a user unsubscribes.

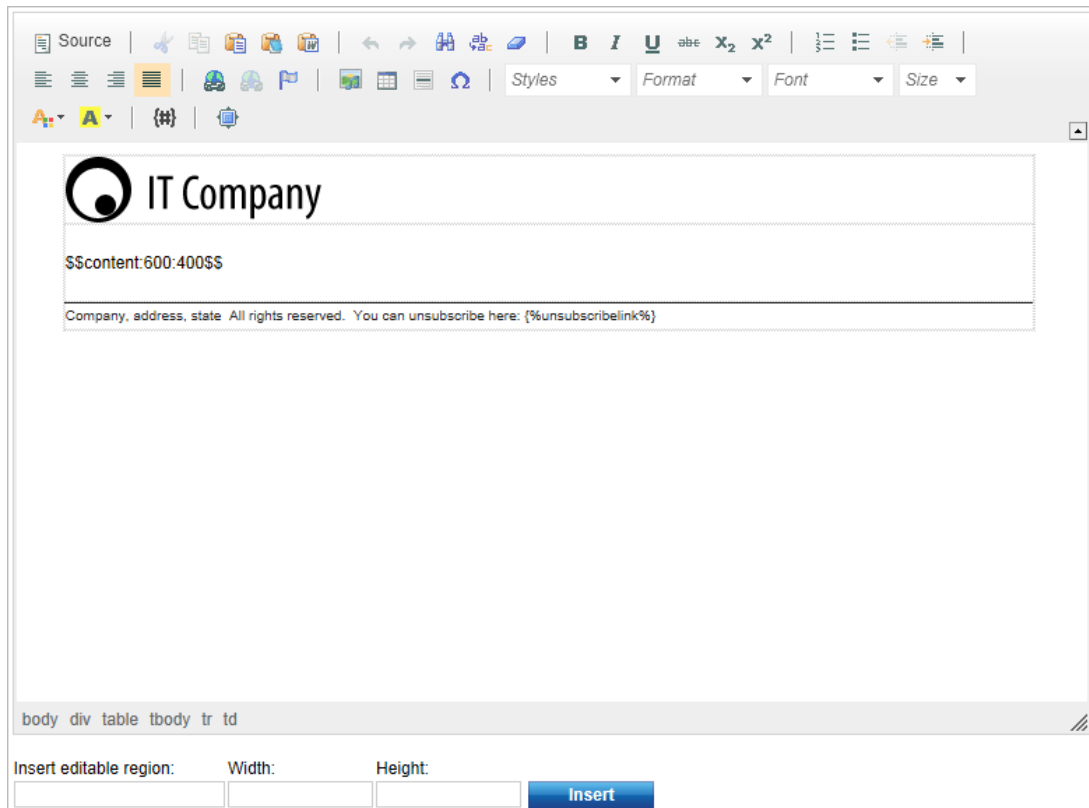

Editing templates

When editing a template, the following configuration can be made on the **General** tab:

- **Display name** - sets the name of the template that is displayed in the newsletter interface.
- **Code name** - sets the name of the template that is used as an identifier, for example in URLs or the API.
- **Thumbnail** - allows you to upload an image that will be displayed as a representation of the template in the selection dialog (when creating new newsletter issues). Only available for *Newsletter issue* templates.
- **Subject** - can be used to set the subject of the e-mails based on this template. This field is not available for *Newsletter issue* templates, since the e-mail subject is entered locally when writing

individual issues.

- **Header (HTML)** - the opening HTML code of the e-mail message, including the <html> element.
- **Body** - defines the main layout of the e-mails that use this template. Here you can enter static text, use the WYSIWYG editor and insert macros or newsletter fields. *Newsletter issue* templates may also contain editable regions where editors can enter the content of individual newsletter issues. These can be inserted using the *Insert editable region* section below the editing area. Regions are inserted as expressions in format: `$$regionName:width:height$$`

- **Footer (HTML)** - the closing HTML code.
- **CSS stylesheet** - may be used to define CSS classes that will be applied to the e-mails based on this template.

You can insert the following newsletter fields anywhere inside the body of the template:

- **{%ActivationLink%}** - only available for *Double opt-in* templates. It is resolved into a link to the subscription approval page, as defined by the *Approval page URL* property of the given newsletter.
- **{%Email%}** - resolves into the e-mail address of the e-mail recipient.
- **{%FirstName%}** - resolves into the first name of the recipient.
- **{%LastName%}** - resolves into the last name of the recipient.
- **{%UnsubscribeLink%}** - resolves into a link to the unsubscription page, as defined by the *Unsubscription page URL* property of the given newsletter.

To easily add these expressions into the body, click the **Insert macro** (##) button on the WYSIWYG editor toolbar and select the appropriate option under the **Context specific objects** section.

Note: The newsletter field expressions only work in e-mails sent to actual subscribers. The macros do not resolve correctly when sending draft e-mails for newsletter issues, since the recipients are not linked

to subscribers in the system.

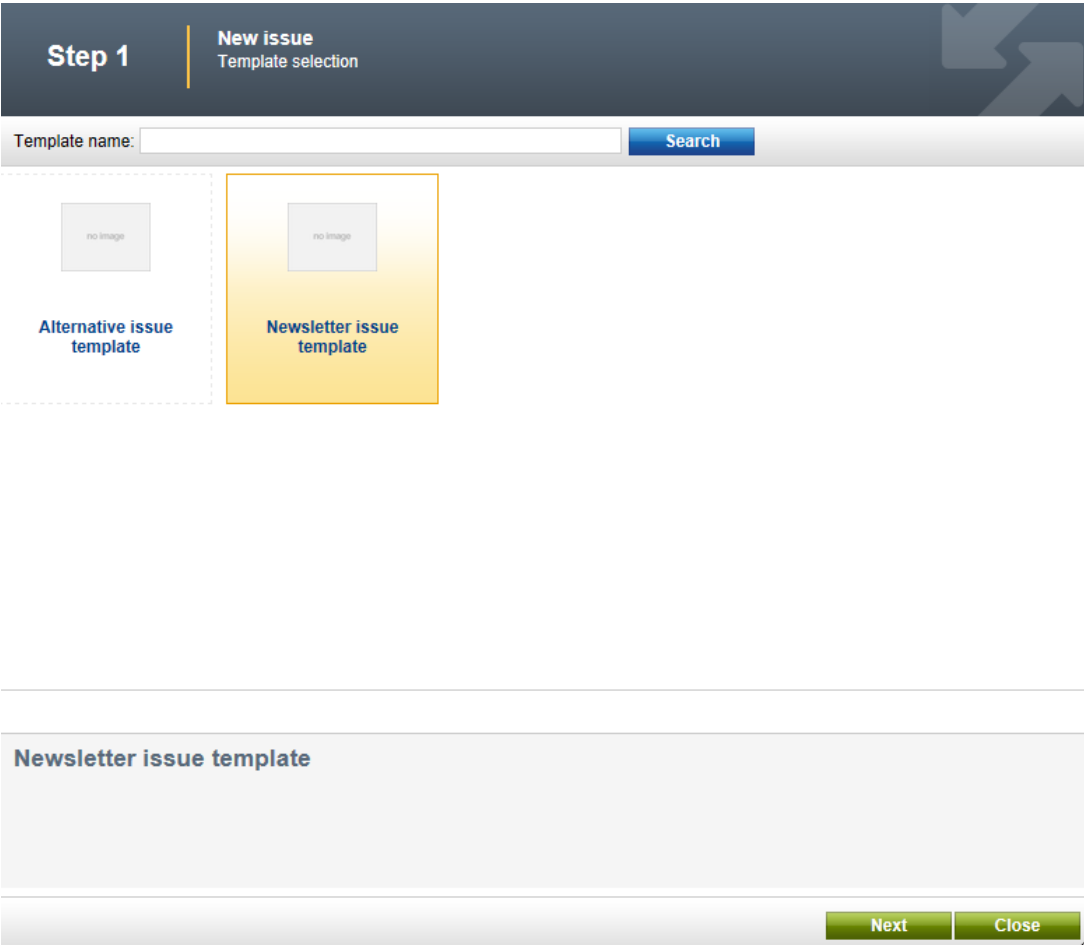

Newsletter templates also support all other types of [macro expressions](#).

You can attach files to newsletter templates and manage them as needed by clicking the  **Attachments** button in the header of the editing page. When e-mails based on the given template are sent out, the attachments will be included. For example, if you wish to display a logo image somewhere in the template layout and have it stored directly in the e-mails, you can upload it as an attachment and then insert it into the body content. In the case of newsletter issue templates, further attachments may also be added when creating specific issues.

Assigning issue templates to newsletters

In addition to the main template configured for a static newsletter, it is also possible to add any number of alternative templates that may be selected for specific issues. When editing a *Newsletter issue* type template, you can assign it to individual newsletters on the **Newsletters** tab. Alternatively, newsletter-template bindings can be configured from the opposite side of the relationship by editing a static newsletter on its **Templates** tab.

Once a newsletter has multiple templates allowed, authors of issues can choose which one they wish to use in the first step of the [New issue wizard](#).

Step 1 | **New issue**
Template selection

Template name:

Alternative issue template

Newsletter issue template

Newsletter issue template

The template of an existing issue may also be changed through the **Template** selector available among the *advanced options* when editing the given issue on the **Content** tab.

8.36.8 Subscriber management

You can manage subscribers at **CMS Desk -> Tools -> Newsletters -> Subscribers**.

The screenshot shows the 'Subscribers' management page. On the left is a navigation menu with 'Subscribers' selected. The main area has a 'New subscriber' button and a table of subscribers. Each row has an 'Actions' column with icons for edit (pencil), delete (red X), and add (plus).

| Actions | Subscriber name | E-mail |
|---------|--------------------------------|-------------------------------|
| | Contact group 'Male customers' | |
| | David Scott | david.scott@example.com |
| | Frank Maguire | frank.maguire@localhost.local |
| | John Smith | john@localhost.local |
| | Mary Jones | mary.jones@localhost.local |
| | Role 'Facebook users' | |
| | User 'Andrew Jones' | andy@localhost.local |

On this page, you can see a list of all subscribers belonging to the website's newsletters. You can filter these according to their name or e-mail by entering the desired value into the appropriate filter field and clicking the **Show** button.

By clicking the **Delete** () action icon next to a subscriber record, you can remove the subscriber from the list and consequently from all newsletters to which they are subscribed.

Through the **Edit** () icon, you can modify a subscriber's details and manage their newsletter subscriptions. On the **General** tab, you have the same options as when creating a new subscriber.

The screenshot shows the 'Subscribers' management page with the 'Subscriptions' tab selected. The breadcrumb trail is 'Subscribers > john@localhost.local'. There are 'General' and 'Subscriptions' tabs, and a 'Save' button. The form fields are:

E-mail:

First name:

Last name:

Customizing subscriber fields

If you wish to store additional data for newsletter subscribers, you can add your own custom fields. To do this, go to **Site Manager -> Development -> System** tables and edit the **Newsletter - Subscriber** table. Then you can define any required fields on the **Fields** tab.

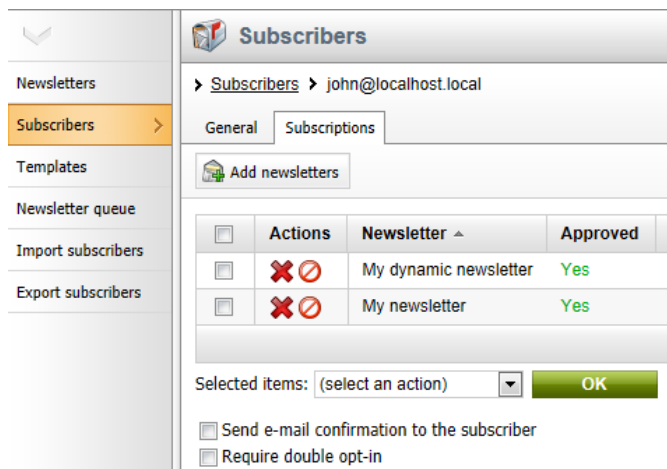

Please note that the default fields must remain unchanged to ensure that the module continues to work correctly.

The values of custom fields may be entered manually on the **General** tab, filled in by users who subscribe through an appropriately configured [Custom subscription form](#) web part, or populated via the API.

On the **Subscriptions** tab, you can see a list of newsletters to which the edited subscriber is subscribed. Additional ones can be added by using the  **Add newsletters** button. Individual newsletter subscriptions may be managed via the following actions:

-  **Remove** - unsubscribes the subscriber from the selected newsletter.
-  **Approve** - manually approves the subscription to the selected newsletter, causing issues to be sent.
-  **Reject** - rejected subscriptions remain in the list, but issues of the selected newsletter are not sent. Users who subscribe to newsletters with double opt-in enabled are rejected by default until they confirm their subscription.

To apply these actions to multiple newsletters, mark them using the boxes on the left choose an action from the drop-down list below and click **OK**.

If you check the **Send e-mail confirmation to the subscriber** box before performing an action, a notification e-mail will be sent to the edited subscriber, informing about the changes in their subscription. If you check the **Require double opt-in** box before adding newsletters, subscriptions to newsletters that have double opt-in enabled will be inactive (rejected) until the user confirms them or the **Approve** () action is manually selected in the list of newsletters.

Subscribers of individual newsletters

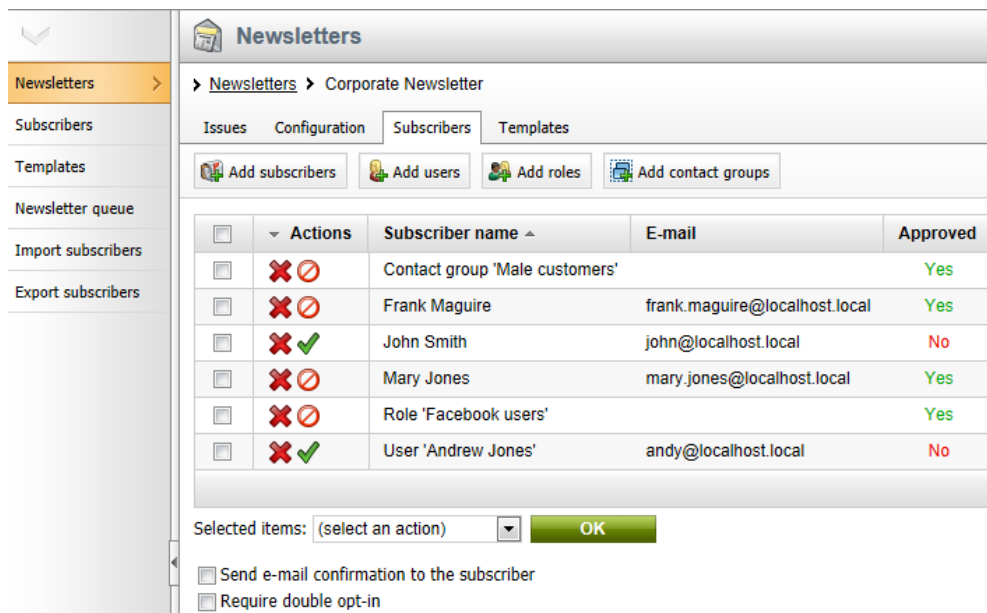

Alternatively, subscribers of individual newsletters can be managed by selecting **Newsletters** in the left menu and editing () the given newsletter on the **Subscribers** tab. Here you can find a list similar to the one on the main Subscribers tab, but it only contains subscribers of the current newsletter. If necessary, subscribers in the list can be filtered by their e-mail, name or approval status. Subscribers can be added by using the following buttons:

-  **Add subscribers** - allows selection from a list of all subscribers in the system.
-  **Add users** - allows selection from the registered users of the current site.
-  **Add roles** - allows selection from the roles of the current site (newsletter issues will be sent to all members of the selected roles).
-  **Add contact group** - allows selection from all on-line marketing contact groups defined for the current site (all contacts that belong to the selected groups will be added as subscribers).

Individual subscriptions can be managed via the following actions:

-  **Remove** - unsubscribes the address, user, role or contact group from the edited newsletter.
-  **Approve** - manually approves the given subscription, causing it to receive newsletter issues.
-  **Reject** - rejected subscriptions remain in the list, but they do not receive newsletter issues. Users who subscribe to newsletters with double opt-in enabled are rejected by default until they confirm their subscription.

To apply these actions to multiple subscriptions, mark them using the boxes on the left choose an action from the drop-down list below and click **OK**.

| <input type="checkbox"/> | Actions | Subscriber name ^ | E-mail | Approved |
|--------------------------|---|--------------------------------|-------------------------------|----------|
| <input type="checkbox"/> |   | Contact group 'Male customers' | | Yes |
| <input type="checkbox"/> |   | Frank Maguire | frank.maguire@localhost.local | Yes |
| <input type="checkbox"/> |   | John Smith | john@localhost.local | No |
| <input type="checkbox"/> |   | Mary Jones | mary.jones@localhost.local | Yes |
| <input type="checkbox"/> |   | Role 'Facebook users' | | Yes |
| <input type="checkbox"/> |   | User 'Andrew Jones' | andy@localhost.local | No |

Selected items: (select an action)

Send e-mail confirmation to the subscriber
 Require double opt-in

If you check the **Send e-mail confirmation to the subscriber** box before performing an action, a notification e-mail will be sent to the affected users, informing them about the changes in their subscriptions. If you check the **Require double opt-in** box (only available if the newsletter has double opt-in enabled), added subscriptions will be inactive (rejected) until the users confirm them or the **Approve** () action is manually selected in the list of subscriptions.

Duplicate subscriber addresses

Even though all regular newsletter subscribers need to have a unique e-mail address, it is still possible to have a single address subscribed to a newsletter multiple times through users, roles or contact groups.

In these cases, the duplicate addresses are filtered out from the newsletter queue, so that each e-mail address only receives the newsletter's issues once.

If you need to add or modify a large amount of subscribers, the **Import subscribers** tab described in the [Subscriber import and export](#) topic provides an easier way.

8.36.9 Subscriber import and export

When handling a large amount of subscribers, creating or modifying them one by one would be very slow and inefficient. The import and export functionality provides a way to perform mass actions or get subscriber data using specially formatted text.

Importing subscribers

You can import or modify large amounts of subscribers using the **CMS Desk -> Tools -> Newsletters -> Import subscribers** dialog.

The screenshot displays the 'Import subscribers' dialog in the Kentico CMS Desk. The top navigation bar includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The 'Tools' menu is expanded, showing various options like 'Forms', 'Media', 'Polls', 'Translations', 'Custom tables', 'Blogs', 'Forums', 'Groups', 'Chat', 'Message boards', 'Projects', 'Events', 'Newsletters', and 'Web analytics'. The 'Newsletters' menu item is selected, leading to the 'Import subscribers' dialog. The dialog features a sidebar with 'Import subscribers' highlighted. The main content area is titled 'Import subscribers' and contains the following elements:

- Available actions:**
 - Subscribe imported users to selected newsletters
 - Do not subscribe existing users to selected newsletters
 - Unsubscribe the users from selected newsletters
 - Delete the subscribers
- List of subscribers to be processed:** A large, empty text area for pasting subscriber data.
- Please note:** Please enter one subscriber per line in format e-mail;firstname;lastname (firstname and lastname may be omitted). It's recommended that you do not import more than 1000 subscribers at once.
- List of newsletters:**
 - Newsletter
 - Corporate Newsletter
- Buttons:** 'Remove selected', 'Add newsletters', and a large green 'Import' button.

You need to prepare a list of subscribers in the following format:

- **email;firstname;lastname**

Copy the list into the **List of subscribers to be processed** text area.

- Each record must be on a new line.
- The name sections are optional.

The following examples are all valid:

```
david.scott@localhost.local;David;Scott  
mary.jones@example.com;;Jones  
frank.maguire@localhost.local;Frank  
monica@localhost.local
```

Note

Importing more than 1000 subscribers at once is not recommended.

If you need to import more subscribers in a single operation, apply [hotfix 7.0.28](#) or newer. With the hotfix, the system performs the import process asynchronously, allowing you to import any number of subscribers.

Select one of the following actions using the radio-buttons above the text area:

- **Subscribe imported users to the selected newsletters** - the imported users will be subscribed to the selected newsletters.
 - **Do not subscribe existing users to selected newsletters** - if checked, the import only updates the names of existing subscribers with matching e-mail addresses (does not add the subscribers to the selected newsletters).
- **Unsubscribe the users from selected newsletters** - removes the imported users from the selected newsletters.
- **Delete the subscribers** - deletes subscribers matching the imported data from the system.

Click **Add newsletters** to select the target newsletters for the subscribe or unsubscribe actions.

If you check **Send e-mail confirmation to the subscriber** before performing the import, a notification e-mail will be sent to the entered addresses, informing them about the changes in their subscriptions. If you check **Require double opt-in**, subscriptions to newsletters that have double opt-in enabled will be inactive (rejected) until the users confirms them.

Clicking **Import** takes the subscribers from the list and performs the selected action. If one of the lines contains an invalid entry, the import is not processed for any of the records and an error is displayed.

Exporting subscribers

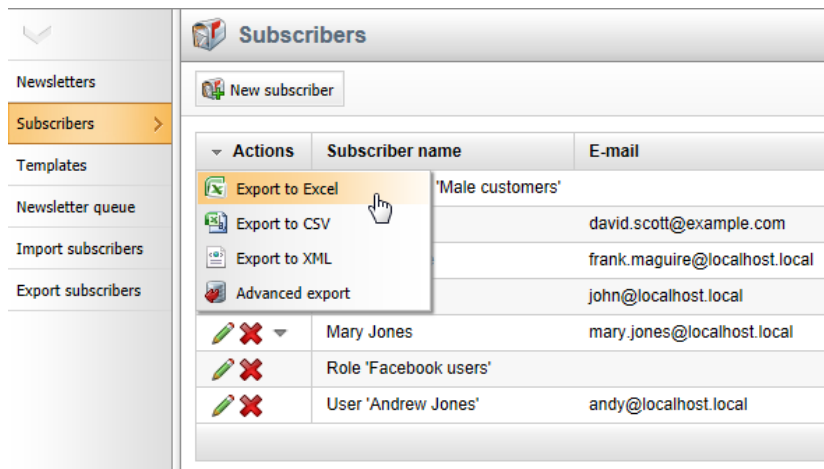

If you need to export a list of subscribers to some other application, you can do so using the **CMS Desk -> Tools -> Newsletters -> Export subscribers** dialog.

You can choose if you want to export all subscribers (do not set any newsletters) or only subscribers of the newsletters specified using the **Add newsletters** button. The subscribers are exported in format:

- **email;firstname;lastname**

The **Export subscribers** radio buttons allow the output to be limited according to the approval status of the subscriptions. Clicking **Export** generates the output, which can be copied from the textbox to your application.

Alternatively, you can also export subscriber data into other file formats (XLSX, CSV, XML) using the general export feature, which is available for all lists of data in Kentico CMS. This can be done by clicking the  icon in the **Actions** column header of the list on the **Subscribers** tab, either in the main menu of the Newsletters module or when editing a specific newsletter. For more details, please refer to the [Modules -> UI data export](#) chapter of this guide.

8.36.10 On-line marketing

8.36.10.1 Overview

When using newsletters for e-mail marketing campaigns, it is important to determine their overall effectiveness and optimize issues according to the results. This can be achieved by tracking e-mails and monitoring the reactions of recipients. Kentico CMS offers several features that provide feedback and statistics about how successful your newsletters are and which actions subscribers take when reading issues, including the following:

- [E-mail tracking](#) - measures how many newsletter issues were actually opened by subscribers and the clickthrough rate of any links placed into the content of the e-mails.
- [Bounced e-mail monitoring](#) - allows you to identify and block subscribers with invalid e-mail addresses to which newsletter issues cannot be delivered.
- [A/B testing](#) - provides a way to create several different versions of each newsletter issue and evaluate them based on the e-mail tracking statistics measured for a test group of subscribers. This allows you to send the most successful variant to the remainder of the subscribers.

Please note that these features are only available if the **Enable on-line marketing** setting is enabled in **Site Manager -> Settings -> On-line marketing**.

8.36.10.2 E-mail tracking

Two types of tracking can be used for the e-mails that deliver newsletter issues to subscribers. This functionality may be enabled for individual newsletters through the **CMS Desk -> Tools -> Newsletters** interface by editing the selected newsletter on the **Configuration** tab:

- **Track opened e-mails** - if enabled, the e-mails used to send out the issues of the newsletter will be tracked and statistics will be kept about the amount of e-mails that are opened by subscribers.
- **Track clicked links** - if enabled, statistics will be kept about the amount of clicks subscribers perform on hyperlinks placed in the e-mail issues of the newsletter.

The screenshot shows the 'Newsletters' configuration page for 'My newsletter'. The 'Configuration' tab is active. The 'General' section includes fields for 'Newsletter display name' (My newsletter), 'Newsletter name' (My_newsletter), 'Subscription confirmation' (Subscription confirmation template), 'Unsubscription confirmation' (Unsubscription confirmation template), 'Sender name' (Company Name), and 'Sender e-mail' (sender@localhost.local). The 'Template-based newsletter configuration' section shows 'Newsletter template' set to 'Newsletter issue template'. The 'On-line marketing' section, highlighted with a red box, contains three checked options: 'Track opened e-mails', 'Track clicked links', and 'Log on-line marketing activities'.

Please note that tracking cannot be done retroactively for e-mails that have already been sent before the appropriate settings were enabled. Also, since draft e-mails are intended only for testing purposes, they are not included in tracking statistics (only the e-mails sent to actual subscribers are measured).

Logging newsletter actions as activities

You can also decide if you want the actions related to a specific newsletter to be included in the site's on-line marketing activity statistics. This is done by setting the **Log newsletter actions as on-line marketing activities** property on the **Configuration** tab.

Activities include the following types of events: Subscription, Unsubscription, E-mail opening, Link clickthrough.

You can then keep track of the logged activities in the **CMS Desk -> On-line marketing -> Activities** interface.

Opened e-mails

This feature allows you to monitor how many newsletter e-mails are actually opened by subscribers. Open rate is one of the key metrics for judging an e-mail campaign's success.

Tracking of this type is achieved by embedding a small, invisible image into the content of e-mails. When this image is requested from the server for the first time, the system marks the e-mail as received and opened for the given subscriber. As a result, mails will only be counted as opened if the e-mail client of the subscriber allows the loading of images. Alternatively, if the recipient clicks on a link contained in the e-mail and **Track clicked links** is enabled for the newsletter, the e-mail will be recognized as opened even if images are blocked. Because of these factors, the indicated number of opened e-mails may be slightly lower than the actual amount.

If tracking is enabled, the statistics of newsletter issues can be viewed when editing a specific newsletter on the **Issues** tab. The amount of e-mails that were received and opened by subscribers can be compared side by side with the total number of sent e-mails.

| Actions | Issue subject | Send on | Sent e-mails | Opened e-mails | Unsubscribed | A/B test | Status |
|---------|---------------|----------------------|--------------|----------------|--------------|----------|----------|
| | Second issue | 5/16/2012 9:06:30 AM | 15 | 4 | 0 | No | Finished |
| | First issue | 5/15/2012 9:04:15 AM | 8 | 4 | 0 | No | Finished |

If the number is greater than zero, it can be clicked to display a dialog containing a detailed list of all subscribers who opened the e-mail.

Issue opened by

Subscriber name: LIKE

E-mail: LIKE

Opened between: Now and Now

[Show](#)

| Subscriber name | E-mail | Opened when |
|---------------------|-------------------------------|----------------------|
| John Smith | john@localhost.local | 5/16/2012 9:10:03 AM |
| Frank Maguire | frank.maguire@localhost.local | 5/16/2012 9:09:09 AM |
| User 'Andrew Jones' | andy@localhost.local | 5/16/2012 9:09:05 AM |
| Mary Jones | mary.jones@localhost.local | 5/16/2012 9:07:51 AM |

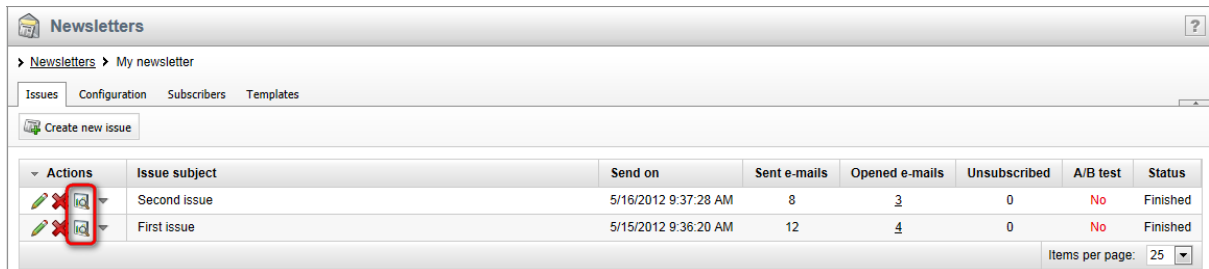

[Close](#)

The subscribers can be filtered according to their name, e-mail address or the time interval during which they opened the e-mail.

Clicked links

Another way to measure the effectiveness of an e-mail campaign is to track which links are clicked by the recipients and how many times, also known as the *clickthrough rate*. If this type of tracking is enabled, all links in newsletter issues are converted to tracking links when they are sent out and the information is stored. This applies to both template-based and dynamic newsletters.

Link statistics of individual newsletter issues can be viewed when editing a specific newsletter on the **Issues** tab. The **View tracking statistics** (📊) action is available for all issues that contain tracked hyperlinks.

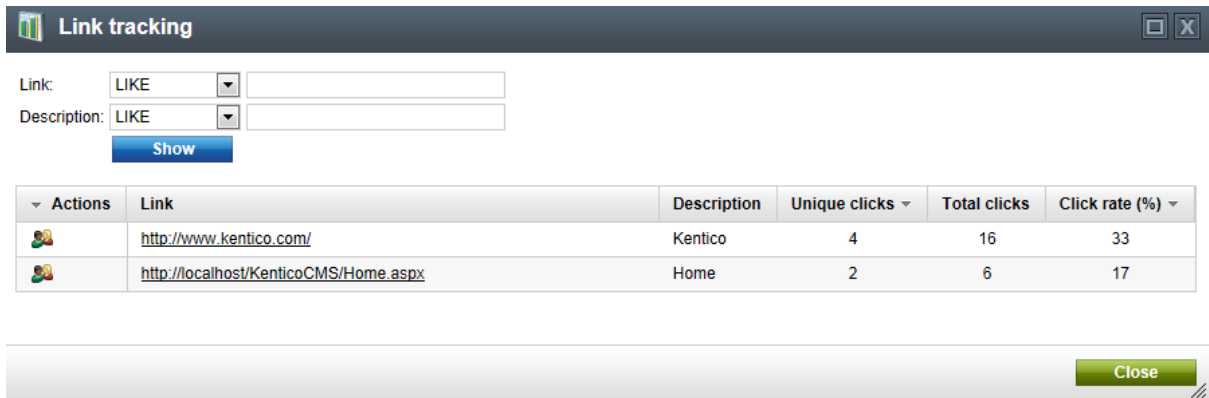

The screenshot shows the 'Newsletters' management interface. A table lists newsletter issues with columns for 'Issue subject', 'Send on', 'Sent e-mails', 'Opened e-mails', 'Unsubscribed', 'A/B test', and 'Status'. The 'Second issue' row has a red box around the 'View tracking statistics' icon (📊) in the 'Actions' column.

| Actions | Issue subject | Send on | Sent e-mails | Opened e-mails | Unsubscribed | A/B test | Status |
|---------|---------------|----------------------|--------------|----------------|--------------|----------|----------|
| | Second issue | 5/16/2012 9:37:28 AM | 8 | 3 | 0 | No | Finished |
| | First issue | 5/15/2012 9:36:20 AM | 12 | 4 | 0 | No | Finished |

When clicked, this action opens a modal dialog that lists all links in the given issue and displays the following information about them:

- **Unique clicks** - shows how many different subscribers clicked on the link.
- **Total clicks** - indicates how many times the link was clicked, including multiple clicks from the same user.
- **Click rate (%)** - displays the clickthrough rate of the link as a percentage. Calculated as the number of unique clicks divided by the total amount of sent e-mails.

The screenshot shows the 'Link tracking' modal dialog. It has input fields for 'Link' and 'Description', both with a dropdown menu set to 'LIKE'. A 'Show' button is below the input fields. Below the button is a table with columns for 'Actions', 'Link', 'Description', 'Unique clicks', 'Total clicks', and 'Click rate (%)'.

| Actions | Link | Description | Unique clicks | Total clicks | Click rate (%) |
|---------|---|-------------|---------------|--------------|----------------|
| | http://www.kentico.com/ | Kentico | 4 | 16 | 33 |
| | http://localhost/KenticoCMS/Home.aspx | Home | 2 | 6 | 17 |

A 'Close' button is located at the bottom right of the dialog.

Further details can be displayed for each link by using the **View participating subscribers** (👤) action. This opens another dialog containing the names and addresses of the subscribers that used the given link and their respective click count.

Participating subscribers
□ X

Subscriber name: LIKE

E-mail: LIKE

Show

| Subscriber name | E-mail | Clicks |
|---------------------|-------------------------------|--------|
| User 'Andrew Jones' | andy@localhost.local | 5 |
| Frank Maguire | frank.maguire@localhost.local | 4 |
| Mary Jones | mary.jones@localhost.local | 4 |
| John Smith | john@localhost.local | 3 |

Close

Excluding links from tracking

The newsletter unsubscribe links generated by the `{%UnsubscribeLink %}` expression are not tracked. Links to local anchors within the content of the e-mail are also excluded.

The tracking of any link in a newsletter issue may be manually disabled by editing the source and inserting the **tracking="false"** attribute into the `<a>` tag of the given hyperlink, for example:

```
<a href="http://www.kentico.com/home.aspx" tracking="false">Kentico CMS</a>
```

When editing the content of a newsletter issue, you can easily switch to its source using the **Source** button on the toolbar of the WYSIWYG editor.

8.36.10.3 Bounced e-mail monitoring

When an e-mail cannot be delivered successfully for some reason, an automatic reply informing about the problem is returned (bounced) back to the sender. Tracking bounced e-mails allows the system to identify addresses that do not correctly receive newsletter issues. Removing invalid addresses from your mailing lists saves bandwidth and improves the accuracy of your subscription statistics.

To enable this feature, go to **Site Manager -> Settings -> On-line marketing -> Newsletters** and check the **Monitor bounced e-mails** box. It is also necessary to properly fill in the remaining settings in the **Bounced e-mails** and **POP3 settings** categories (more information about individual fields is given in the [Settings](#) topic).

Once this is done, the **Check bounced e-mails** [scheduled task](#) periodically checks the specified mailbox for newsletter e-mail bounces, analyzes them and increases the bounce counter of subscribers as necessary. Once a bounced e-mail is processed, it is deleted from the mailbox. By default, this task is executed once per hour. Some mail servers may be configured to store e-mails even after they are downloaded, which causes bounces to be counted multiple times (every time the scheduled task is executed), so please adjust the settings of the e-mail server if you experience issues of this type.

If the amount of bounces from a subscriber reaches the **Bounced e-mail limit**, the system will automatically block the address from receiving any further newsletter issues.

Bounce statistics can be viewed in various parts of the **CMS Desk -> Tools -> Newsletters** interface. On the **Subscribers** tab, the amount of bounces associated with individual subscribers is displayed.

| Actions | Subscriber name | E-mail | Blocked | Bounces |
|---------|--------------------------------|-------------------------------|---------|---------|
| | Contact group 'Male customers' | | | |
| | David Scott | david.scott@example.com | Yes | |
| | Frank Maguire | frank.maguire@localhost.local | No | |
| | John Smith | john@localhost.local | No | 2 |
| | Mary Jones | mary.jones@localhost.local | No | |
| | Role 'Facebook users' | | | |
| | User 'Andrew Jones' | andy@localhost.local | No | |

The **Blocked** filter may be used to display only blocked or active subscribers. The **Block** () or **Unblock** () actions may be used to manually change the status of subscribers. When a subscriber is unblocked, their bounce counter is reset to zero. To perform these actions for individual subscribers assigned through a role or contact group, edit () the given role or contact group and switch to the **Users** or **Contacts** tab respectively.

The same options are also available when viewing the subscribers of a specific newsletter in **Newsletters -> edit** () **newsletter -> Subscribers**. The bounce count of a subscriber is shared for all newsletters on the given site.

On the **Issues** tab of a newsletter, the total amount of bounces per issue is tracked. The amount of sent e-mails can be viewed and compared with the number of bounces.

| Actions | Issue subject | Send on | Sent e-mails | Opened e-mails | Unsubscribed | Bounced e-mails | A/B test | Status |
|---------|---------------|----------------------|--------------|----------------|--------------|-----------------|----------|----------|
| | Second issue | 5/16/2012 8:37:07 AM | 115 | 100 | 0 | 3 | No | Finished |
| | First issue | 5/15/2012 8:32:35 AM | 120 | 99 | 0 | 8 | No | Finished |

Monitoring bounced e-mails under medium trust

If your application is running in a medium trust environment, the bounced e-mails feature will not be functional by default.

For more details and a possible solution, please refer to [Configuration for Medium Trust environment](#).

8.36.10.4 A/B testing

When preparing a newsletter issue, it can be difficult to predict exactly how subscribers will react to various important elements, such as the e-mail subject or the primary call to action. In some cases, you may also wish to find out which option out of several alternatives will have the most positive effect. Optimizing your newsletter issues via A/B testing provides a possible solution to these problems.

It allows you to create multiple different versions of each issue referred to as *variants*. These variants are then mailed out to a *test group* of subscribers, typically a relatively small percentage of the newsletter's full mailing list. This way, the best version of the issue can be identified based on the tracking statistics measured for the test group, and then sent to the remainder of the subscribers. The winning variant can either be selected automatically by the system according to specified criteria or manually after evaluating the results of the test.

Please note that A/B testing works best for newsletters that have a large number of subscribers. With a small testing group, the results may be heavily affected by random factors and will not be statistically significant.

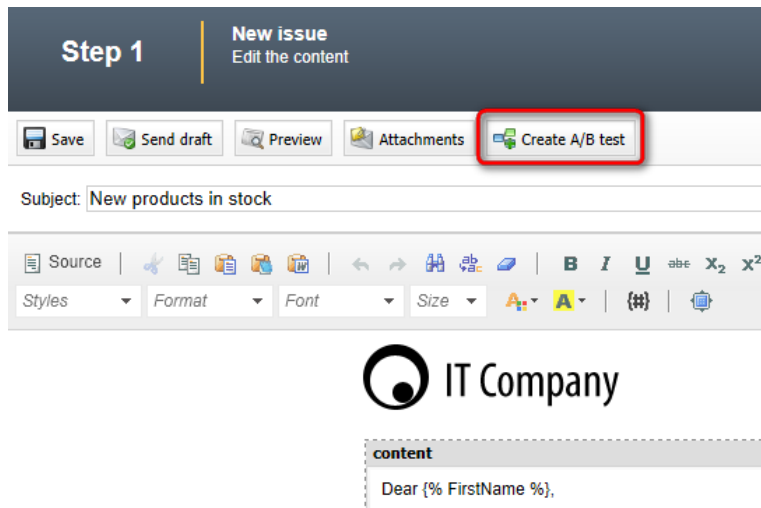

Prerequisites

A/B testing variants of newsletter issues are evaluated based on the actions performed by recipients, so both types of [E-mail tracking](#) need to be enabled for the given newsletter on its **Configuration** tab (**Track opened e-mails** and **Track clicked links**). This also requires the **Enable on-line marketing** setting to be enabled in **Site Manager -> Settings -> On-line marketing**.

Additionally, A/B testing is only supported for [template-based \(static\)](#) newsletters.

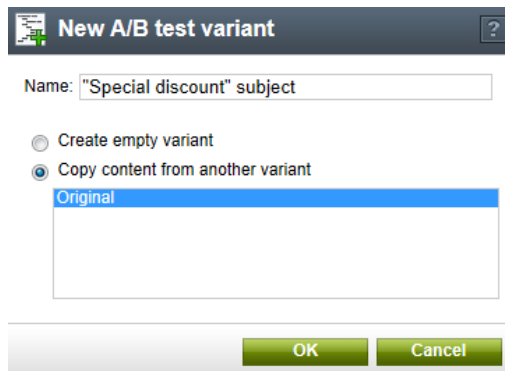

Creating A/B tests for newsletter issues

If the conditions described in the section above are met, A/B tests can be defined through the **CMS Desk -> Tools -> Newsletters** interface either directly when creating a new newsletter issue via the [wizard](#), or when editing an existing issue on the **Content** tab. In the case of new issues, it is necessary to  **Save** the content before the advanced actions become available. To add the first testing variant for the issue, click the  **Create A/B test** button offered among the header actions.

This opens a dialog where the new variant can be defined. Start by filling in the **Name**, which will be used to identify the variant while working with the A/B test. You can then choose one of two possible options that determine the initial content of the variant:

- **Create empty variant** - select this option if you wish to create the issue variant from scratch. The variant will use the main template set for the newsletter on the *Configuration* tab and the content of its editable regions will be empty.
- **Copy content from another variant** - if selected, the content of an existing variant (or the original issue) will be used as a starting point that you can modify as required. Choose the source from the list of issue variants in the list below. The variant will use the same template as the source issue and all editable region content will also be copied. This option makes it easy to create variants for testing small changes, such as a different e-mail subject or text headline.

Now that the issue has an A/B testing variant defined, a slider will be displayed at the top of the content editing page. You can use it to switch between individual variants, including the original issue. The name of the currently selected variant is shown next to the slider. You may manage the A/B test variants using the following buttons:

- **Add variant** - creates another variant of the issue. You can add any number of variants.
- **Remove variant** - deletes the variant currently selected through the slider.
- **Edit properties** - allows you to change the name of the currently selected variant. If required, you may also rename the *original* issue.

The settings and content of the currently selected variant can be modified just like when editing a standard issue. Each variant may have a different subject, issue template, editable region content etc. This allows you to test any variables that you need.

The screenshot displays the 'New issue' editor interface. At the top, it indicates 'Step 1' and 'New issue Edit the content'. A red box highlights the 'A/B test variant' slider, which is set to 2/3, and the subject field containing '"Special discount" subject'. Below this are buttons for 'Save', 'Send draft', 'Preview', and 'Attachments'. The main content area shows a subject field with 'Special discount on new products' and a rich text editor with various formatting options. The email content preview shows a header for 'IT Company' and a body with a personalized greeting and promotional text.

Sending A/B test issues

When all of the issue's variants are defined as required, the next step is to configure and schedule how the test should be sent out and evaluated. This can be done either in the send step of the new issue wizard or when editing an existing issue on the **Send** tab.

The size of the subscriber test group can be defined using the slider in the upper part of the page. By moving the slider's handle, you can increase or decrease the number of subscribers that will receive the variants of the newsletter during the testing phase. The test group is automatically balanced so that each variant is sent to the same amount of subscribers. Because of this, the overall test group size will always be a multiple of the total number of variants created for the issue.

The remaining subscribers who are not part of the test group will receive the variant that achieves the best results (i.e. the winner) after the testing process is complete.

Step 2
New Issue
Send

Size of test group:

Test group 30% (15 subscribers) Remainder 70% (35 subscribers)

Schedule mail-out

| <input type="checkbox"/> | Variant name | Send on |
|--------------------------|----------------------------|--|

Change mail-out time of (all) ▾ variants to [Now](#) [OK](#)

Winner selection

Select a winner according to:

Number of opened e-mails
 Total unique clicks
 Manually

Select a winner after: Day(s) ▾

Winner will be sent on 6/9/2012 8:27:39 AM.

[Back](#) [Save without sending](#) [Send and close](#)

Using a full test group

It is even possible to set up a scenario where the test group includes 100% of all subscribers. In this case, the A/B test simply provides a way to evenly distribute different versions of the issue between the subscribers and the selection of the winner is only done for statistical purposes.

In the **Schedule mail-out** section below the slider, you can specify when individual issue variants should be sent to the subscribers from the corresponding portion of the test group. To schedule the mail-out, enter the required date and time into the field below the list (you may use the **Calendar** selector or the **Now** link) and then click **OK**. This can either be done for a specific variant, *all* variants or only those selected through the checkboxes in the list. If the mail-out time is the same for multiple variants, they will be sent in sequence with approximately 1 minute intervals between individual variants.

The configuration made in the **Winner selection** section determines how the winning variant of the A/B test will be chosen. You can select one of the following options:

- **Number of opened e-mails** - the system will automatically choose the variant with the highest number of opened e-mails as the winner. This type of testing focuses on optimizing the first impression of the newsletter, i.e. the subject of the e-mails and the sender name or address, not the actual content.
- **Total unique clicks** - the winner will be chosen automatically according to the amount of link clicks measured for each variant. Each link placed in the issue's content will only be counted once per subscriber, even when clicked multiple times. This option is recommended if the primary goal of your newsletter is to encourage subscribers to follow the links provided in the issues.

- **Manually** - the winner of the A/B test will not be selected automatically. Instead, the author of the issue (or other authorized users) can monitor the results of the test and choose the winning variant manually at any time.

When using an automatic selection option (one of the first two), it is also necessary to enter the duration of the testing period through the **Select a winner after** settings below. This way, you can specify how long the system should wait after the last variant is sent out before it chooses a winner and mails it to the remaining subscribers.

Once everything is configured as required, you can confirm that the variants should be sent according to their mail-out scheduling time by clicking the  **Send** button (or **Send and close** in the new issue wizard). If you only wish to save the configuration of the A/B test without actually starting the mail-out, use the  **Save (Save without sending)** button instead.

Evaluating A/B tests

The testing phase begins after the first variant is sent out. If you need to make any changes to the configuration of the A/B test or the content of its variants, you can do so by editing the issue.

On the **Content** tab, you may modify the variants that have not yet been mailed, but the slider actions will be disabled. This means that it is no longer possible to add, remove or rename variants.

If you switch to the **Send** tab, the test group slider will now be locked. However, you can view the e-mail tracking data measured for individual variants in the **Test results** section. The current tracking statistics are shown for each variant, specifically the number of *opened e-mails* and amount of *unique link clicks* performed by subscribers. By clicking on these numbers, you can open a dialog with the details of the corresponding statistic for the given variant. It is also possible to reschedule the sending of variants that have not been mailed yet using the selector and date-time field below the list.

The  **Select as winner** action allows you to manually choose a winner (even when using automatic selection). It opens a confirmation dialog where you can schedule when the winning issue variant should be sent to the remaining subscribers. If you specify a date in the future, you will still have the option of choosing a different winner during the interval before the mail-out.

The winner selection criteria may also be changed at any point while the testing is still in progress.

Winner selection

Select a winner according to:

Number of opened e-mails

Total unique clicks

Manually

Select a winner after: 2 Day(s)

Winner will be sent on 6/9/2012 8:52:19 AM.

Special cases with tied results

If a draw occurs at the end of the testing phase (i.e. the top value in the tested statistic is achieved by multiple issue variants), the selection of the winner will be postponed and evaluated again after one hour.

In certain situations, you may need to choose the winner manually even when using automatic selection, e.g. if you are testing the number of opened e-mails and all subscribers in the test group view the received issue.

Once the test is concluded and the winner is decided, the given variant is highlighted by a green background. At this point, the winning issue is mailed out to the remaining subscribers who were not included in the test group and no further actions are possible except for viewing the statistics of the variants.

Below you can check results of testing variants.

Test results

| Variant name | Send on | Opened e-mails | Unique clicks | Status |
|-------------------------------------|---------------------|----------------|---------------|----------|
| Original | 6/7/2012 8:47:32 AM | 4 | 2 | Finished |
| Last name in salutation | 6/7/2012 8:51:39 AM | 4 | 1 | Finished |
| "Special discount" subject (winner) | 6/7/2012 8:48:33 AM | 5 | 3 | Finished |

Items per page: 25

The overall statistics of the A/B tested issue, including the e-mails used to deliver the winning variant to the subscribers outside of the test group, can be monitored in the usual way on the **Issues** tab of the newsletter. When viewing the opened e-mail or clickthrough data in the detail dialogs, you may use the additional **Variants** filter to display either the total (*all*) values for the entire issue, or only those of

specific variants. The statistics of the winning variant include both the corresponding portion of the test group and the remainder of the subscribers who received it after the completion of the testing phase.

8.36.11 Security

You can control access to the Newsletters module from **CMS Site Manager (or CMS Desk) -> Administration -> Permissions**, after selecting the **Module -> Newsletters** permission matrix. The Newsletters module has the following permissions:

- **Read** - members of the selected roles are allowed to view all data in the *CMS Desk -> Tools -> Newsletters* interface.
- **Destroy** - allows members of the roles to delete the version history of newsletter objects.
- **Configure newsletters** - members of the selected roles are allowed to configure newsletter settings.
- **Author newsletter issues** - members of the selected roles are allowed to create and edit newsletter issues.
- **Manage subscribers** - members of the selected roles are allowed to add and remove newsletter subscribers.
- **Manage templates** - members of the selected roles are allowed to create, edit and delete newsletter templates.

| Permissions | | | | | | | |
|------------------------------|-------------------------------------|--|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| Site: | Corporate site | | | | | | |

8.36.12 Settings

Site-level or global newsletter settings can be configured at **Site Manager -> Settings -> On-line marketing -> Newsletters**. The following options are available:

General

- **Newsletter unsubscription page URL** - sets the URL of the page where users can unsubscribe from a newsletter. The *Newsletter unsubscription* web part must be placed on the specified page to ensure the required functionality. The value of this setting is inherited by individual

newsletters if their *Unsubscription page URL* property is not set. If empty, the `~/CMSPages/Unsubscribe.aspx` default system page is used.

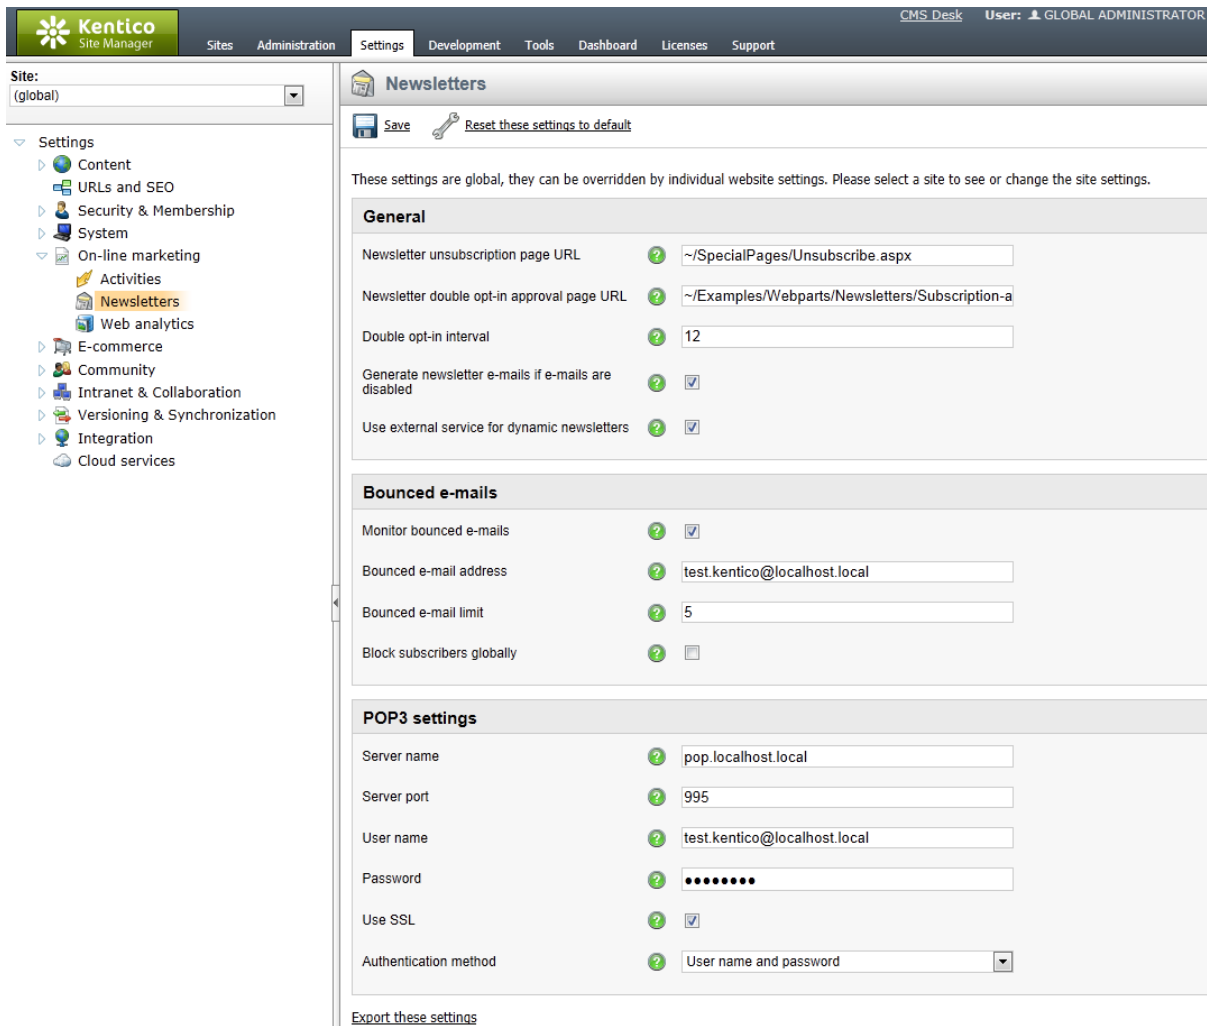

- **Newsletter double opt-in approval page URL** - sets the URL of the page where users can confirm their subscription to a newsletter with double opt-in enabled. The *Subscription approval* web part must be placed on the specified page to ensure the required functionality. The value of this setting is inherited by individual newsletters if their *Approval page URL* property is not set. If empty, the `~/CMSModules/Newsletters/CMSPages/SubscriptionApproval.aspx` default system page is used.
- **Double opt-in interval** - sets the length (in hours) of the time interval during which users will be allowed to confirm their subscription to a newsletter that uses double opt-in. If a user does not activate their subscription within the specified number of hours, the link in their confirmation e-mail will expire and become invalid. The same time limit is also applied to unsubscription requests submitted through the *Unsubscription request* web part.
- **Generate newsletter e-mails if e-mails are disabled** - if enabled, newsletter e-mails will be generated and saved into the [E-mail queue](#) even if the sending of e-mails is disabled in *Site Manager -> Settings -> System -> E-mails*.
- **Use external service for dynamic newsletters** - if enabled, the [scheduled tasks](#) that are created to ensure the mail-out of new dynamic newsletters will be set to be processed by the external scheduling service by default. Please note that this does not change the settings of existing dynamic newsletter tasks. If you wish to configure these to use the external scheduler Windows service, you will have to enable their *Use external service* property manually in the *Site Manager -> Administration -> Scheduled tasks* interface (remember to select the appropriate site, these tasks are not global).

Bounced e-mails

- **Monitor bounced e-mails** - indicates if bounced e-mails should be tracked for newsletter subscribers. Bounced e-mails are received whenever there is a problem with the delivery of a newsletter issue to a subscriber.
- **Bounced e-mail address** - sets the address to which bounced e-mails are sent when the delivery of a newsletter issue to a subscriber fails. If set, this address is used in the *From* field of newsletter issue e-mails.
- **Bounced e-mail limit** - sets the amount of bounced e-mails that can be counted for a subscriber before the system blocks them from receiving further newsletter issues. This limit is set for all newsletters under the selected site. If *0* is entered, subscribers will never be blocked automatically, but their bounced e-mail count will still be tracked and displayed in the *CMS Desk -> Tools -> Newsletters* interface.
- **Block subscribers globally** - if checked, bounces will be added to all subscribers that have the same e-mail address. This is applied across all sites in the system. Please note that this setting does not ensure consistency between the bounce counts of all subscribers with a shared address, only that new bounces will be added to all of them.

POP3 settings

- **Server name** - sets the domain name or IP address of the mail server where the bounced e-mails are stored. POP3 is used to check the server and monitor bounced e-mails.
- **Server port** - specifies the number of the port used to connect to the mail server.
- **User name** - sets the user name used for authentication against the mail server.
- **Password** - sets the password used for authentication against the mail server.
- **Use SSL** - indicates whether the connection to the mail server should be secured using SSL.
- **Authentication method** - allows the selection of the authentication method used for the connection to the mail server. Options include basic user name and password authentication and several challenge-response mechanisms. The *Auto* option uses APOP if the server supports it and plain text user name and password authentication otherwise.

8.36.13 Troubleshooting

Problems with sending e-mails

If you are not correctly receiving newsletter e-mails, please check the following:

1. The newsletter issues are sent out using a [scheduled task](#) that is executed every 1 minute by default. You may need to wait for up to 2 minutes before you receive newsletter issue e-mail. The scheduled task status can be checked at **CMS Desk -> Administration -> Scheduled tasks**.
2. Go to **CMS Desk -> Tools -> Newsletter -> Newsletter queue**. If some e-mail failed, you will find the error message here. After you resolve the technical issue, you can resend all failed e-mails by clicking  **Resend all failed**.
3. If your newsletters are configured to use the e-mail queue, go to **CMS Site Manager -> Administration -> E-mail queue**. Any e-mails lost due to errors can be monitored and re-sent here.
4. Make sure you are using the correct e-mail addresses.

5. Make sure the newsletter issues aren't being blocked by some anti-spam software.
6. Go to **Site Manager -> Settings -> System -> E-mails** or **Administration -> SMTP servers** and make sure your SMTP servers are configured correctly. You can find additional details on SMTP server configuration in the [SMTP server configuration](#) topic. You can try sending a test e-mail in **Site Manager -> Administration -> System -> E-mail**.
7. Newsletter e-mail debugging might be helpful when solving problems with newsletter e-mails. To enable newsletter debugging, add the following keys to the `/configuration/appSettings` section of your project's `web.config` file:

```
<add key="CMSLogEmails" value="true"/>
<add key="CMSDebugEmails" value="true"/>
```

The first key enables you to log all the sent e-mails. You can find the logged e-mails in `<web root>/AppData/logemails.log`. The log contains each e-mail's recipient and subject.

The second key enables you to log all the sent e-mails into event log without actually sending them to the recipients. This is helpful when you need to test the functionality but do not want the testing e-mails to actually reach the recipient. You can view the event log in **Administration -> Event log** section of both **CMS Desk** and **Site Manager**. The e-mails are logged as an **Information** type of event.

Additionally, with the second key enabled, a *Sending failed for <recipient's e-mail address>* error is generated at random to simulate an error when sending an e-mail.

Problems with unsubscription links

If your unsubscription links are not resolving correctly, check that the **Base URL** property of the given newsletter is set correctly according to the domain name of your website. To configure this property:

1. Go to **CMS Desk -> Tools -> Newsletters**.
2. **Edit** (✎) the newsletter and switch to its **Configuration** tab.

Note: Newsletters only generate valid unsubscription links when sending issues to actual subscribers. Unsubscription links do not work in draft e-mails, since the recipients are not linked to subscribers in the system.

Problems with role or contact group subscribers

If you have a user role set as a subscriber for your newsletter, it is highly recommended to send the newsletter issues via the [e-mail queue](#) in order for the issues to be successfully sent to all members of the role. To set the newsletter to use the newsletter queue:

1. Go to **CMS Desk -> Tools -> Newsletter**.
2. **Edit** (✎) your newsletter and switch to the **Configuration** tab.
3. Enable the **Send issues via e-mail queue** property.
4. Click **Save**.

Problems with event log spam [This option is only available after applying [hotfix 7.0.18](#) or newer]

By default, the system logs an [event log](#) entry for every sent newsletter issue. When mailing out issues to a very large number of subscribers, this may lead to a cluttered event log or even website performance problems.

You can disable logging of newsletter issue changes (including send events) by adding the following key to the `/configuration/appSettings` section of your project's `web.config` file:

```
<add key="CMSLogNewsletterIssueEvents" value="false" />
```

8.36.14 Newsletters internals and API

8.36.14.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used by the Newsletters module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.36.14.2 Database tables

The following database tables are used for the newsletters module:

- **Newsletter_Newsletter** - contains records representing newsletters and their configuration.
- **Newsletter_NewsletterIssue** - used to store individual newsletter issues, including their content.
- **Newsletter_Subscriber** - contains records representing newsletter subscribers.
- **Newsletter_SubscriberNewsletter** - stores relationships between subscribers and newsletters. This table also contains data that determines whether the subscriber is approved for the given newsletter.
- **Newsletter_EmailTemplate** - used to store the templates on which newsletter issues and notification messages are based (all types).
- **Newsletter_EmailTemplateNewsletter** - stores relationships between newsletter issue templates and static newsletters. Each record indicates that a certain template may be used for the issues of a specific newsletter.
- **Newsletter_Emails** - this table stores newsletter e-mails that could not be sent out successfully (i.e. the newsletter queue). This allows them to be re-sent at a later time.
- **Newsletter_OpenedEmail** - stores relationships between subscribers and newsletter issues. Each record indicates that a subscriber has opened a specific issue.
- **Newsletter_Link** - contains records representing links inside the content of newsletter issues.
- **Newsletter_SubscriberLink** - stores relationships between subscribers and newsletter links. Each record indicates that a subscriber has clicked on a specific link.
- **Newsletter_ABTest** - stores records that contain the A/B testing configuration of newsletter issues. Individual A/B test variants of issues are saved as separate items in the `Newsletter_NewsletterIssue` table.

8.36.14.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the newsletters module can be found in the **CMS.Newsletter** namespace.

Newsletter_Newsletter table API:

- **NewsletterInfo** - represents one newsletter object.
- **NewsletterInfoProvider** - provides management functionality for newsletters.

Newsletter_NewsletterIssue table API:

- **IssueInfo** - represents one newsletter issue.
- **IssueInfoProvider** - provides management functionality for newsletter issues.

Newsletter_Subscriber table API:

- **SubscriberInfo** - represents one newsletter subscriber.
- **SubscriberInfoProvider** - provides management functionality for subscribers.

Newsletter_SubscriberNewsletter table API:

- **SubscriberNewsletterInfo** - represents a relationship between a subscriber and a newsletter.
- **SubscriberNewsletterInfoProvider** - provides management functionality for subscriber-newsletter relationships.

Newsletter_EmailTemplate table API:

- **EmailTemplateInfo** - represents one newsletter e-mail template.
- **EmailTemplateInfoProvider** - provides management functionality for newsletter templates.

Newsletter_EmailTemplateNewsletter table API:

- **EmailTemplateNewsletterInfo** - represents a relationship between a newsletter and an issue template.
- **EmailTemplateNewsletterInfoProvider** - provides management functionality for newsletter-template relationships.

Newsletter_Emails table API:

- **EmailQueueItem** - represents an issue e-mail in the newsletter e-mail queue.
- **EmailQueueManager** - provides management functionality for the newsletter queue.

Newsletter_OpenedEmail table API:

- **OpenedEmailInfo** - represents a relationship which indicates that a subscriber has opened a newsletter issue.
- **OpenedEmailInfoProvider** - provides management functionality for subscriber-issue relationships.

Newsletter_Link table API:

- **LinkInfo** - represents a link in a newsletter.
- **LinkInfoProvider** - provides management functionality for newsletter links.

Newsletter_SubscriberLink table API:

- **SubscriberLinkInfo** - represents a relationship between a subscriber and a newsletter link (i.e. the amount of clicks that the given subscriber performed, if any).
- **SubscriberLinkInfoProvider** - provides management functionality for subscriber-link relationships.

Newsletter_ABTest table API:

- **ABTestInfo** - represents the A/B test configuration of a newsletter issue.
- **ABTestInfoProvider** - provides management functionality for newsletter issue A/B tests.

8.36.14.4 API examples

8.36.14.4.1 Overview

These topics show examples of how the Newsletters module API can be used:

- [Managing email templates](#)
- [Managing newsletters](#)
- [Managing subscribers](#)
- [Managing issues](#)

**Please note**

All API examples can be simulated in the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\OnlineMarketing\Newsletters\Default.aspx.cs**.

The Newsletters module API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
```

```
using CMS.CMSHelper;  
using CMS.SiteProvider;  
using CMS.Newsletter;
```

8.36.14.4.2 Managing email templates

The following example creates a subscription template.

```
private void CreateSubscriptionTemplate()  
{  
    // Creates a new subscription template object  
    EmailTemplateInfo newTemplate = new EmailTemplateInfo();  
  
    // Sets the properties  
    newTemplate.TemplateDisplayName = "My new subscription template";  
    newTemplate.TemplateName = "MyNewSubscriptionTemplate";  
    newTemplate.TemplateType = EmailTemplateType.Subscription;  
    newTemplate.TemplateBody = "My new subscription template body";  
    newTemplate.TemplateHeader = "<html xmlns=\"http://www.w3.org/1999/  
xhtml\"><head><title>Newsletter</title><meta http-equiv=\"content-type\"  
content=\"text/html; charset=UTF-8\" /></head><body>";  
    newTemplate.TemplateFooter = "</body></html>";  
    newTemplate.TemplateSiteID = CMSContext.CurrentSiteID;  
  
    // Saves the subscription template  
    EmailTemplateInfoProvider.SetEmailTemplateInfo(newTemplate);  
}
```

The following example creates an unsubscription template.

```
private void CreateUnsubscriptionTemplate()  
{  
    // Creates a new unsubscription template object  
    EmailTemplateInfo newTemplate = new EmailTemplateInfo();  
  
    // Sets the properties  
    newTemplate.TemplateDisplayName = "My new unsubscription template";  
    newTemplate.TemplateName = "MyNewUnsubscriptionTemplate";  
    newTemplate.TemplateType = EmailTemplateType.Unsubscription;  
    newTemplate.TemplateBody = "My new unsubscription template body";  
    newTemplate.TemplateHeader = "<html xmlns=\"http://www.w3.org/1999/  
xhtml\"><head><title>Newsletter</title><meta http-equiv=\"content-type\"  
content=\"text/html; charset=UTF-8\" /></head><body>";  
    newTemplate.TemplateFooter = "</body></html>";  
    newTemplate.TemplateSiteID = CMSContext.CurrentSiteID;  
  
    // Saves the unsubscription template  
    EmailTemplateInfoProvider.SetEmailTemplateInfo(newTemplate);  
}
```

The following example creates an issue template.

```
private void CreateIssueTemplate()
{
    // Creates a new issue template object
    EmailTemplateInfo newTemplate = new EmailTemplateInfo();

    // Sets the properties
    newTemplate.TemplateDisplayName = "My new issue template";
    newTemplate.TemplateName = "MyNewIssueTemplate";
    newTemplate.TemplateType = EmailTemplateType.Issue;
    newTemplate.TemplateBody = "<p>My new issue template body</p>";
    newTemplate.TemplateHeader = "<html xmlns=\"http://www.w3.org/1999/xhtml\"><head><title>Newsletter< title><meta http-equiv=\"content-type\" content=\"text/html; charset=UTF-8\" /></head><body>";
    newTemplate.TemplateFooter = "</body></html>";
    newTemplate.TemplateSiteID = CMSContext.CurrentSiteID;

    // Saves the issue template
    EmailTemplateInfoProvider.SetEmailTemplateInfo(newTemplate);
}
```

The following example gets and updates an issue template.

```
private bool GetAndUpdateIssueTemplate()
{
    // Gets the issue template
    EmailTemplateInfo updateTemplate =
    EmailTemplateInfoProvider.GetEmailTemplateInfo("MyNewIssueTemplate",
    CMSContext.CurrentSiteID);
    if (updateTemplate != null)
    {
        // Updates the properties
        updateTemplate.TemplateDisplayName =
        updateTemplate.TemplateDisplayName.ToLower();

        // Saves the changes
        EmailTemplateInfoProvider.SetEmailTemplateInfo(updateTemplate);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates issue templates.

```
private bool GetAndBulkUpdateIssueTemplates()
{
```

```
// Prepares the parameters
string where = "TemplateName LIKE N'MyNewIssueTemplate%'";

// Gets the data
DataSet templates = EmailTemplateInfoProvider.GetEmailTemplates(where, null);
if (!DataHelper.DataSourceIsEmpty(templates))
{
    // Loops through individual items
    foreach (DataRow templateDr in templates.Tables[0].Rows)
    {
        // Creates an object from the DataRow
        EmailTemplateInfo modifyTemplate = new EmailTemplateInfo(templateDr);

        // Updates the properties
        modifyTemplate.TemplateDisplayName =
modifyTemplate.TemplateDisplayName.ToUpper();

        // Saves the changes
        EmailTemplateInfoProvider.SetEmailTemplateInfo(modifyTemplate);
    }

    return true;
}

return false;
}
```

The following example deletes a subscription template.

```
private bool DeleteSubscriptionTemplate()
{
    // Gets the subscription template
    EmailTemplateInfo deleteTemplate =
EmailTemplateInfoProvider.GetEmailTemplateInfo("MyNewSubscriptionTemplate",
CMSContext.CurrentSiteID);

    // Deletes the subscription template
    EmailTemplateInfoProvider.DeleteEmailTemplateInfo(deleteTemplate);

    return (deleteTemplate != null);
}
```

The following example deletes an unsubscription template.

```
private bool DeleteUnsubscriptionTemplate()
{
    // Gets the unsubscription template
    EmailTemplateInfo deleteTemplate =
EmailTemplateInfoProvider.GetEmailTemplateInfo("MyNewUnsubscriptionTemplate",
CMSContext.CurrentSiteID);
}
```

```
// Deletes the unsubscription template
EmailTemplateInfoProvider.DeleteEmailTemplateInfo(deleteTemplate);

return (deleteTemplate != null);
}
```

The following example deletes an issue template.

```
private bool DeleteIssueTemplate()
{
    // Gets the issue template
    EmailTemplateInfo deleteTemplate =
    EmailTemplateInfoProvider.GetEmailTemplateInfo("MyNewIssueTemplate",
    CMSContext.CurrentSiteID);

    // Deletes the issue template
    EmailTemplateInfoProvider.DeleteEmailTemplateInfo(deleteTemplate);

    return (deleteTemplate != null);
}
```

8.36.14.4.3 Managing new sletters

The following example creates a static newsletter.

```
private bool CreateStaticNewsletter()
{
    EmailTemplateInfo subscriptionTemplate =
    EmailTemplateInfoProvider.GetEmailTemplateInfo("MyNewSubscriptionTemplate",
    CMSContext.CurrentSiteID);
    EmailTemplateInfo unsubscriptionTemplate =
    EmailTemplateInfoProvider.GetEmailTemplateInfo("MyNewUnsubscriptionTemplate",
    CMSContext.CurrentSiteID);
    EmailTemplateInfo myNewIssueTemplate =
    EmailTemplateInfoProvider.GetEmailTemplateInfo("MyNewIssueTemplate",
    CMSContext.CurrentSiteID);

    if ((subscriptionTemplate != null) && (unsubscriptionTemplate != null) &&
    (myNewIssueTemplate != null))
    {
        // Creates a new static newsletter object
        NewsletterInfo newNewsletter = new NewsletterInfo();

        // Sets the properties
        newNewsletter.NewsletterDisplayName = "My new static newsletter";
        newNewsletter.NewsletterName = "MyNewStaticNewsletter";
        newNewsletter.NewsletterType = NewsletterType.TemplateBased;
        newNewsletter.NewsletterSubscriptionTemplateID =
        subscriptionTemplate.TemplateID;
    }
}
```

```
        newNewsletter.NewsletterUnsubscriptionTemplateID =
unsubscribeTemplate.TemplateID;
        newNewsletter.NewsletterTemplateID = myNewIssueTemplate.TemplateID;
        newNewsletter.NewsletterSenderName = "Sender name";
        newNewsletter.NewsletterSenderEmail = "sender@localhost.local";
        newNewsletter.NewsletterSiteID = CMSContext.CurrentSiteID;

        // Saves the static newsletter
        NewsletterInfoProvider.SetNewsletterInfo(newNewsletter);

        return true;
    }

    return false;
}
```

The following example gets and updates a static newsletter.

```
private bool GetAndUpdateStaticNewsletter()
{
    // Gets the static newsletter
    NewsletterInfo updateNewsletter = NewsletterInfoProvider.GetNewsletterInfo
("MyNewStaticNewsletter", CMSContext.CurrentSiteID);
    if (updateNewsletter != null)
    {
        // Updates the properties
        updateNewsletter.NewsletterDisplayName =
updateNewsletter.NewsletterDisplayName.ToLower();

        // Saves the changes
        NewsletterInfoProvider.SetNewsletterInfo(updateNewsletter);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates static newsletters.

```
private bool GetAndBulkUpdateStaticNewsletters()
{
    // Prepares the parameters
    string where = "NewsletterName LIKE N'MyNewStaticNewsletter%'";

    // Gets the data
    DataSet newsletters = NewsletterInfoProvider.GetNewsletters(where, null, 0,
null);
    if (!DataHelper.DataSourceIsEmpty(newsletters))
    {
```

```
// Loops through the items
foreach (DataRow newsletterDr in newsletters.Tables[0].Rows)
{
    // Creates an object from the DataRow
    NewsletterInfo modifyNewsletter = new NewsletterInfo(newsletterDr);

    // Updates the properties
    modifyNewsletter.NewsletterDisplayName =
modifyNewsletter.NewsletterDisplayName.ToUpper();

    // Saves the changes
    NewsletterInfoProvider.SetNewsletterInfo(modifyNewsletter);
}

return true;
}

return false;
}
```

The following example creates a dynamic newsletter.

```
private bool CreateDynamicNewsletter()
{
    EmailTemplateInfo subscriptionTemplate =
EmailTemplateInfoProvider.GetEmailTemplateInfo("MyNewSubscriptionTemplate",
CMSContext.CurrentSiteID);
    EmailTemplateInfo unsubscriptionTemplate =
EmailTemplateInfoProvider.GetEmailTemplateInfo("MyNewUnsubscriptionTemplate",
CMSContext.CurrentSiteID);

    if ((subscriptionTemplate != null) && (unsubscriptionTemplate != null))
    {
        // Creates a new dynamic newsletter object
        NewsletterInfo newNewsletter = new NewsletterInfo();

        // Sets the properties
        newNewsletter.NewsletterDisplayName = "My new dynamic newsletter";
        newNewsletter.NewsletterName = "MyNewDynamicNewsletter";
        newNewsletter.NewsletterType = NewsletterType.Dynamic;
        newNewsletter.NewsletterSubscriptionTemplateID =
subscriptionTemplate.TemplateID;
        newNewsletter.NewsletterUnsubscriptionTemplateID =
unsubscriptionTemplate.TemplateID;
        newNewsletter.NewsletterSenderName = "Sender name";
        newNewsletter.NewsletterSenderEmail = "sender@localhost.local";
        newNewsletter.NewsletterDynamicURL = "http://www.google.com";
        newNewsletter.NewsletterDynamicSubject = "My new dynamic issue";
        newNewsletter.NewsletterSiteID = CMSContext.CurrentSiteID;

        // Saves the dynamic newsletter
        NewsletterInfoProvider.SetNewsletterInfo(newNewsletter);
    }
}
```

```
        return true;
    }

    return false;
}
```

The following example gets and updates a dynamic newsletter.

```
private bool GetAndUpdateDynamicNewsletter()
{
    // Gets the dynamic newsletter
    NewsletterInfo updateNewsletter = NewsletterInfoProvider.GetNewsletterInfo
("MyNewDynamicNewsletter", CMSContext.CurrentSiteID);
    if (updateNewsletter != null)
    {
        // Updates the properties
        updateNewsletter.NewsletterDisplayName =
updateNewsletter.NewsletterDisplayName.ToLower();

        // Saves the changes
        NewsletterInfoProvider.SetNewsletterInfo(updateNewsletter);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates dynamic newsletters.

```
private bool GetAndBulkUpdateDynamicNewsletters()
{
    // Prepares the parameters
    string where = "NewsletterName LIKE N'MyNewDynamicNewsletter%'";

    // Gets the data
    DataSet newsletters = NewsletterInfoProvider.GetNewsletters(where, null, 0,
null);
    if (!DataHelper.DataSourceIsEmpty(newsletters))
    {
        // Loops through the items
        foreach (DataRow newsletterDr in newsletters.Tables[0].Rows)
        {
            // Creates an object from the DataRow
            NewsletterInfo modifyNewsletter = new NewsletterInfo(newsletterDr);

            // Updates the properties
            modifyNewsletter.NewsletterDisplayName =
modifyNewsletter.NewsletterDisplayName.ToUpper();
        }
    }
}
```

```
        // Saves the changes
        NewsletterInfoProvider.SetNewsletterInfo(modifyNewsletter);
    }

    return true;
}

return false;
}
```

The following example deletes a dynamic newsletter.

```
private bool DeleteDynamicNewsletter()
{
    // Gets the dynamic newsletter
    NewsletterInfo deleteNewsletter = NewsletterInfoProvider.GetNewsletterInfo
("MyNewDynamicNewsletter", CMSContext.CurrentSiteID);

    // Deletes the dynamic newsletter
    NewsletterInfoProvider.DeleteNewsletterInfo(deleteNewsletter);

    return (deleteNewsletter != null);
}
```

The following example deletes a static newsletter.

```
private bool DeleteStaticNewsletter()
{
    // Gets the static newsletter
    NewsletterInfo deleteNewsletter = NewsletterInfoProvider.GetNewsletterInfo
("MyNewStaticNewsletter", CMSContext.CurrentSiteID);

    // Deletes the static newsletter
    NewsletterInfoProvider.DeleteNewsletterInfo(deleteNewsletter);

    return (deleteNewsletter != null);
}
```

8.36.14.4.4 Managing subscribers

The following example creates a subscriber.

```
private bool CreateSubscriber()
{
    // Creates a new subscriber object
    SubscriberInfo newSubscriber = new SubscriberInfo();
}
```

```
// Sets the properties
newSubscriber.SubscriberFirstName = "Name";
newSubscriber.SubscriberLastName = "Surname";
newSubscriber.SubscriberFullName = "Name Surname";
newSubscriber.SubscriberEmail = "subscriber@localhost.local";
newSubscriber.SubscriberSiteID = CMSContext.CurrentSiteID;

// Saves the subscriber
SubscriberInfoProvider.SetSubscriberInfo(newSubscriber);

return true;
}
```

The following example gets and updates a subscriber.

```
private bool GetAndUpdateSubscriber()
{
    // Gets the subscriber
    SubscriberInfo updateSubscriber = SubscriberInfoProvider.GetSubscriberInfo
("subscriber@localhost.local", CMSContext.CurrentSiteID);
    if (updateSubscriber != null)
    {
        // Updates the properties
        updateSubscriber.SubscriberFullName =
updateSubscriber.SubscriberFullName.ToLower();

        // Saves the changes
        SubscriberInfoProvider.SetSubscriberInfo(updateSubscriber);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates subscribers.

```
private bool GetAndBulkUpdateSubscribers()
{
    // Prepares the parameters
    string where = "SubscriberEmail LIKE N'subscriber@localhost.local%";

    // Gets the data
    DataSet subscribers = SubscriberInfoProvider.GetSubscribers(where, null);
    if (!DataHelper.DataSourceIsEmpty(subscribers))
    {
        // Loops through the items
        foreach (DataRow subscriberDr in subscribers.Tables[0].Rows)
        {
            // Creates an object from the DataRow
            SubscriberInfo modifySubscriber = new SubscriberInfo(subscriberDr);
        }
    }
}
```

```
        // Updates the properties
        modifySubscriber.SubscriberFullName =
modifySubscriber.SubscriberFullName.ToUpper();

        // Saves the changes
        SubscriberInfoProvider.SetSubscriberInfo(modifySubscriber);
    }

    return true;
}

return false;
}
```

The following example subscribes a subscriber to newsletter.

```
private bool SubscribeToNewsletter()
{
    // Gets the subscriber and newsletter
    SubscriberInfo subscriber = SubscriberInfoProvider.GetSubscriberInfo
("subscriber@localhost.local", CMSContext.CurrentSiteID);
    NewsletterInfo newsletter = NewsletterInfoProvider.GetNewsletterInfo
("MyNewStaticNewsletter", CMSContext.CurrentSiteID);

    if ((subscriber != null) && (newsletter != null))
    {
        // Subscribes to 'My new static newsletter'
        SubscriberInfoProvider.Subscribe(subscriber.SubscriberID,
newsletter.NewsletterID, DateTime.Now);

        return true;
    }

    return false;
}
```

The following example unsubscribes a subscriber from newsletter.

```
private bool UnsubscribeFromNewsletter()
{
    // Gets the subscriber and newsletter
    SubscriberInfo subscriber = SubscriberInfoProvider.GetSubscriberInfo
("subscriber@localhost.local", CMSContext.CurrentSiteID);
    NewsletterInfo newsletter = NewsletterInfoProvider.GetNewsletterInfo
("MyNewStaticNewsletter", CMSContext.CurrentSiteID);

    if ((subscriber != null) && (newsletter != null))
    {
        // Unsubscribes from 'My new static newsletter'
```

```
        SubscriberInfoProvider.Unsubscribe(subscriber.SubscriberID,
newsletter.NewsletterID);

        return true;
    }

    return false;
}
```

The following example deletes a subscriber.

```
private bool DeleteSubscriber()
{
    // Gets the subscriber
    SubscriberInfo deleteSubscriber = SubscriberInfoProvider.GetSubscriberInfo
("subscriber@localhost.local", CMSContext.CurrentSiteID);

    // Deletes the subscriber
    SubscriberInfoProvider.DeleteSubscriberInfo(deleteSubscriber);

    return (deleteSubscriber != null);
}
```

8.36.14.4.5 Managing issues

The following example creates a static issue.

```
private bool CreateStaticIssue()
{
    // Gets the newsletter
    NewsletterInfo newsletter = NewsletterInfoProvider.GetNewsletterInfo
("MyNewStaticNewsletter", CMSContext.CurrentSiteID);

    if (newsletter != null)
    {
        // Creates a new static issue object
        IssueInfo newIssue = new IssueInfo();

        // Sets the properties
        newIssue.IssueSubject = "My new static issue";
        newIssue.IssueNewsletterID = newsletter.NewsletterID;
        newIssue.IssueSiteID = CMSContext.CurrentSiteID;
        newIssue.IssueText = "<?xml version=\"1.0\" encoding=\"utf-16\"?
><content><region id=\"content\">Issue text</region></content>";
        newIssue.IssueUnsubscribed = 0;
        newIssue.IssueSentEmails = 0;
        newIssue.IssueTemplateID = newsletter.NewsletterTemplateID;
        newIssue.IssueShowInNewsletterArchive = false;

        // Saves the static issue
    }
}
```

```
        IssueInfoProvider.SetIssueInfo(newIssue);

        return true;
    }

    return false;
}
```

The following example gets and updates a static issue.

```
private bool GetAndUpdateStaticIssue()
{
    // Gets the newsletter
    NewsletterInfo newsletter = NewsletterInfoProvider.GetNewsletterInfo
("MyNewStaticNewsletter", CMSContext.CurrentSiteID);

    if (newsletter != null)
    {
        // Prepares the parameters
        string where = "IssueNewsletterID = " + newsletter.NewsletterID;

        // Gets the data
        DataSet issues = IssueInfoProvider.GetIssues(where, null);

        if (!DataHelper.DataSourceIsEmpty(issues))
        {
            // Creates an object from the DataRow
            IssueInfo updateIssue = new IssueInfo(issues.Tables[0].Rows[0]);

            if (updateIssue != null)
            {
                // Updates the properties
                updateIssue.IssueSubject = updateIssue.IssueSubject.ToLower();

                // Saves the changes
                IssueInfoProvider.SetIssueInfo(updateIssue);

                return true;
            }
        }
    }
    return false;
}
```

The following example gets and bulk updates static issues.

```
private bool GetAndBulkUpdateStaticIssues()
{
    // Gets the newsletter
    NewsletterInfo newsletter = NewsletterInfoProvider.GetNewsletterInfo
```

```
("MyNewStaticNewsletter", CMSContext.CurrentSiteID);

    if (newsletter != null)
    {
        // Prepares the parameters
        string where = "IssueNewsletterID = " + newsletter.NewsletterID;

        // Gets the data
        DataSet issues = IssueInfoProvider.GetIssues(where, null);
        if (!DataHelper.DataSourceIsEmpty(issues))
        {
            // Loops through the items
            foreach (DataRow issueDr in issues.Tables[0].Rows)
            {
                // Creates object from the DataRow
                IssueInfo modifyIssue = new IssueInfo(issueDr);

                // Updates the properties
                modifyIssue.IssueSubject = modifyIssue.IssueSubject.ToUpper();

                // Saves the changes
                IssueInfoProvider.SetIssueInfo(modifyIssue);
            }

            return true;
        }
    }

    return false;
}
```

The following example creates a dynamic issue.

```
private bool CreateDynamicIssue()
{
    // Gets the newsletter
    NewsletterInfo newsletter = NewsletterInfoProvider.GetNewsletterInfo
("MyNewDynamicNewsletter", CMSContext.CurrentSiteID);

    if (newsletter != null)
    {
        // Generates a dynamic issue
        EmailQueueManager.GenerateDynamicIssue(newsletter.NewsletterID);

        return true;
    }

    return false;
}
```

The following example gets and updates a dynamic issue.

```
private bool GetAndUpdateDynamicIssue()
{
    // Gets the newsletter
    NewsletterInfo newsletter = NewsletterInfoProvider.GetNewsletterInfo
("MyNewDynamicNewsletter", CMSContext.CurrentSiteID);

    if (newsletter != null)
    {
        // Prepares the parameters
        string where = "IssueNewsletterID = " + newsletter.NewsletterID;

        // Gets the data
        DataSet issues = IssueInfoProvider.GetIssues(where, null);

        if (!DataHelper.DataSourceIsEmpty(issues))
        {
            // Creates an object from the DataRow
            IssueInfo updateIssue = new IssueInfo(issues.Tables[0].Rows[0]);

            if (updateIssue != null)
            {
                // Updates the properties
                updateIssue.IssueSubject = updateIssue.IssueSubject.ToLower();

                // Saves the changes
                IssueInfoProvider.SetIssueInfo(updateIssue);

                return true;
            }
        }
    }
    return false;
}
```

The following example gets and bulk updates dynamic issues.

```
private bool GetAndBulkUpdateDynamicIssues()
{
    // Gets the newsletter
    NewsletterInfo newsletter = NewsletterInfoProvider.GetNewsletterInfo
("MyNewDynamicNewsletter", CMSContext.CurrentSiteID);

    if (newsletter != null)
    {
        // Prepares the parameters
        string where = "IssueNewsletterID = " + newsletter.NewsletterID;

        // Gets the data
        DataSet issues = IssueInfoProvider.GetIssues(where, null);
        if (!DataHelper.DataSourceIsEmpty(issues))
        {
            // Loops through the individual items
        }
    }
}
```

```
        foreach (DataRow issueDr in issues.Tables[0].Rows)
        {
            // Creates an object from the DataRow
            IssueInfo modifyIssue = new IssueInfo(issueDr);

            // Updates the properties
            modifyIssue.IssueSubject = modifyIssue.IssueSubject.ToUpper();

            // Saves the changes
            IssueInfoProvider.SetIssueInfo(modifyIssue);
        }

        return true;
    }
}
return false;
}
```

The following example deletes a dynamic issue.

```
private bool DeleteDynamicIssue()
{
    // Gets the newsletter
    NewsletterInfo newsletter = NewsletterInfoProvider.GetNewsletterInfo
("MyNewDynamicNewsletter", CMSContext.CurrentSiteID);

    if (newsletter != null)
    {
        // Prepares the parameters
        string where = "IssueNewsletterID = " + newsletter.NewsletterID;

        // Gets the data
        DataSet issues = IssueInfoProvider.GetIssues(where, null);

        if (!DataHelper.DataSourceIsEmpty(issues))
        {
            // Creates an object from the DataRow
            IssueInfo deleteIssue = new IssueInfo(issues.Tables[0].Rows[0]);

            // Deletes the dynamic issue
            IssueInfoProvider.DeleteIssueInfo(deleteIssue);

            return (deleteIssue != null);
        }
    }
    return false;
}
```

The following example deletes a static issue.

```
private bool DeleteStaticIssue()
```

```
{
    // Gets the newsletter
    NewsletterInfo newsletter = NewsletterInfoProvider.GetNewsletterInfo
("MyNewStaticNewsletter", CMSContext.CurrentSiteID);

    if (newsletter != null)
    {
        // Prepares the parameters
        string where = "IssueNewsletterID = " + newsletter.NewsletterID;

        // Gets the data
        DataSet issues = IssueInfoProvider.GetIssues(where, null);

        if (!DataHelper.DataSourceIsEmpty(issues))
        {
            // Creates an object from the DataRow
            IssueInfo deleteIssue = new IssueInfo(issues.Tables[0].Rows[0]);

            // Deletes the static issue
            IssueInfoProvider.DeleteIssueInfo(deleteIssue);

            return (deleteIssue != null);
        }
    }
    return false;
}
```

8.37 Notifications

8.37.1 Overview

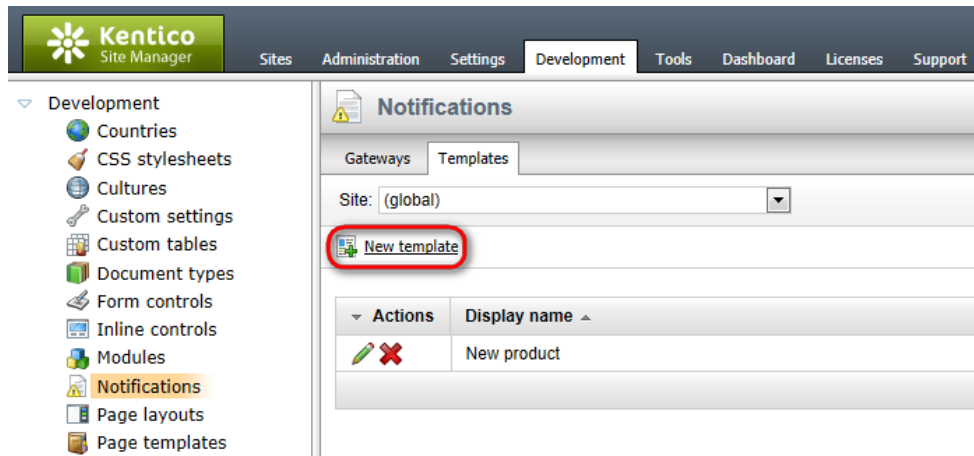

The Notifications module enables sending of notification messages using notification providers. Kentico CMS comes with a built-in e-mail notification gateway. However, you can create your custom gateways, such as an SMS or ICQ provider.

Please note that for one event, users can obtain notification messages from multiple providers. There are three built-in events (document created, document updated, document deleted). However, you can create and use your custom ones.

- To learn how to create notification message templates, please refer to the [Creating a notification message template](#) topic.
- To learn how to allow site visitors or CMS Desk administrators to subscribe to receiving notifications, please refer to the [Subscribing users to content changes notifications](#) topic.
- To learn how to manage users' notifications and choose providers from which the users will receive their notification messages, please refer to the [Managing users' notifications](#) topic.
- To learn how to create your own notification gateway, please refer to the [Custom notification gateway](#) subchapter.
- Module settings are described in the [Settings](#) topic.
- Module security is described in the [Security](#) topic.
- The internals and API of the Notifications module are described in the [Notifications internals and API](#) subchapter.

8.37.2 Creating a notification message template

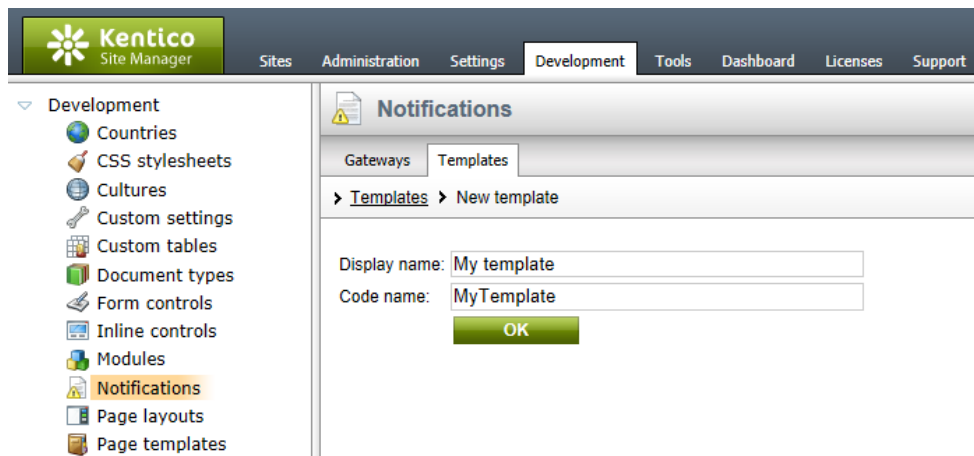

1. Go to **Site Manager -> Development -> Notifications** and switch to the **Templates** tab. Using the **Sites** drop-down list, you can select which site will be the template used by. If you choose **(global)**, the template will be available for all sites. When selected, click  **New template**. You will be redirected to the **New template** form.

2. On the **New template** form, enter the following details:

- **Display name** - display name of the template
- **Code name** - code name of the template

Click **OK**. The template will be created.

3. Now you should see the same form that you've just filled, but in the **General** tab, while another tab called **Text** is also available. Switch to the **Text** tab.

On this tab, the text of the notification message can be defined. You should see **sections for each of the defined gateways**. Texts can be set separately for each gateway, so that for one event, you can have different texts sent via e-mail and via SMS. Each of the sections contains the gateway name and some of the following three fields, depending on the gateway settings:

- **Subject** - message subject text

- **HTML text** - text of the message in HTML format
- **Plain text** - text of the message in plain text format

The following macros can be used in your notification templates:

- **{%notificationsubscription.SubscriptionID%}** - displays the value of specified data column from the *Notification_Subscription* table; this represents subscription information
- **{%notificationgateway.GatewayID%}** - displays the value of the specified data column from the *Notification_Gateway* table; this represents the notification gateway which performs the sending of the notification message
- **{%notificationuser.UserID%}** - displays the value of the specified user data column from the *CMS_Usertable* table; this represents the user the notification message is being sent to
- **{%notificationcustomdata.XXX%}** - displays the value of the specified data column from a custom data source. You can use the Document, Tree and SKU columns from *View_CMS_Tree_Joined* and also the document type's table (e.g. *CONTENT_article* for *CMS.article* document type).
- **{%documentlink%}** - displays the link to the document (for content event notifications only)

The screenshot shows the Kentico CMS 7.0 Developer's Guide interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The 'Development' tab is active. The left sidebar lists various development tools, with 'Notifications' highlighted. The main content area is titled 'Notifications' and has tabs for 'Gateways' and 'Templates'. The 'Templates' tab is active, showing a configuration for a 'New product' notification. The 'Text' sub-tab is selected, and the 'Save' button is visible. The 'HTML text' field contains a rich text editor with the following content: 'Hi there, New product in '{%notificationsubscription.subscriptioneventdata1%}' section has been added. This is automatically generated notification. Please do not reply to this e-mail.' The 'Plain text' field contains the same content in plain text format.

When you have entered appropriate text for each available gateway, click **Save**.

8.37.3 Subscribing users to content changes notifications

The **Content subscription** web part is a pre-configured version of the **Notification subscription** web part. It can be conveniently used to let site visitors subscribe to notifications about the following three events:

- **Document has been created**
- **Document has been updated**
- **Document has been deleted**

Subscribe for new product notification:

E-mail:

In the following example, you will learn how to add the **Content subscription** web part to your site and set it up. We will use the Corporate site sample website as the starting point. Let's presume that we want to enable site visitors to receive an e-mail whenever a new product is added.

Please note

In order for you to see the full functionality, it is necessary to have a SMTP server configured correctly. For more information on how to do this, please refer to the [SMTP server configuration](#) chapter.

1. Sign in to **CMS Desk** as the global administrator (login *administrator* with blank password by default). From the content tree on the left, select the **Products** title page and switch to the **Design** tab.
2. Add the **Content subscription** web part to the **Left zone** web part zone, below the **CSS list menu**. In the **Web part properties** dialog, set the following properties:

- **Site name** - (current site)
- **Path** - /Products/%
- **Document type** - CMS.Product
- **Event description** - Enter your e-mail address to receive notifications about new products:

- **Gateway names** - CMS.EmailGateway
- **Notification preferred format** - HTML

- **Create event enabled** - true
- **Create event display name** - New product notification
- **Create event template name** - MyTemplate

and click **OK**.

Please note

It is important that the template you have recently created according to the *Creating a notification message template* topic is global or assigned to the current site.

Create event display name: New product notification

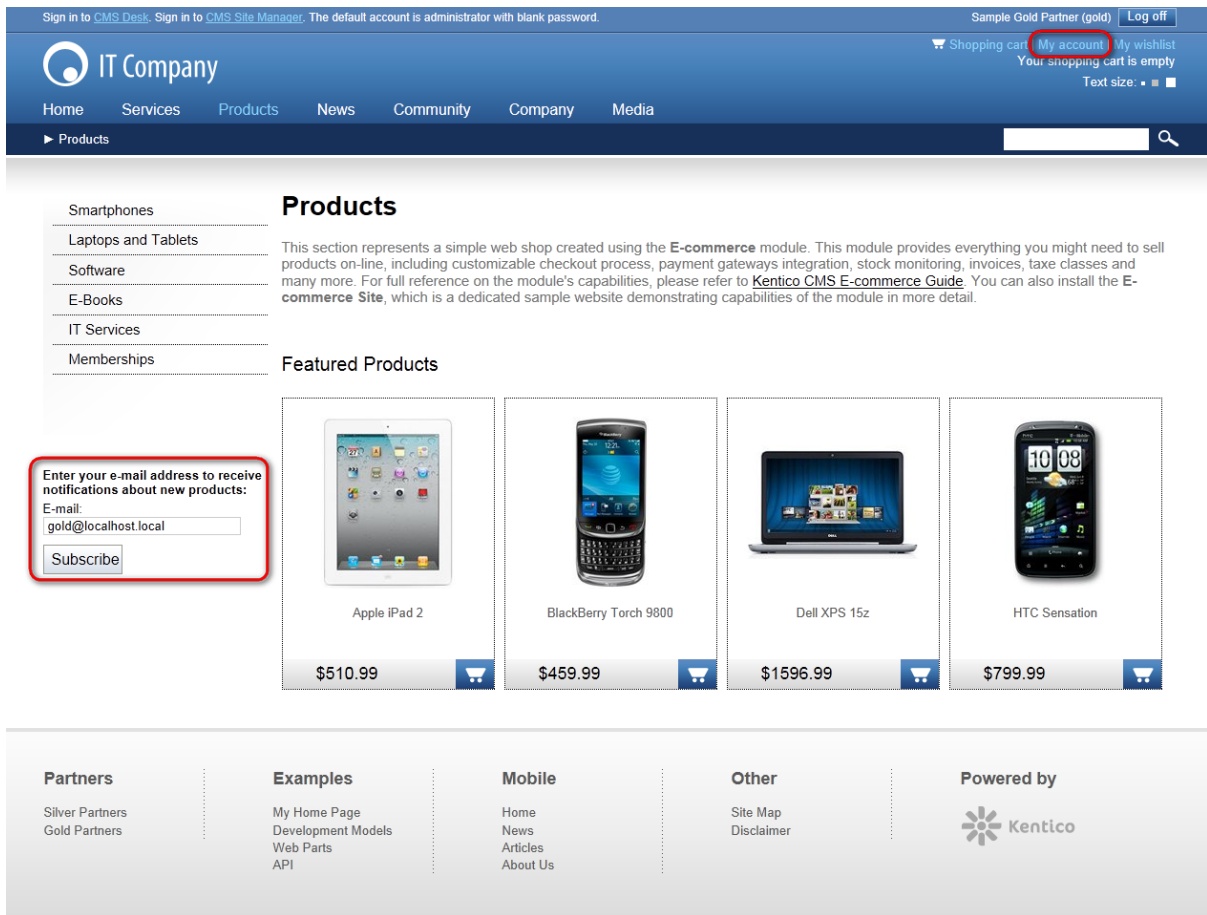

Create event template name: NewProduct Select Clear

Refresh content OK Cancel Apply

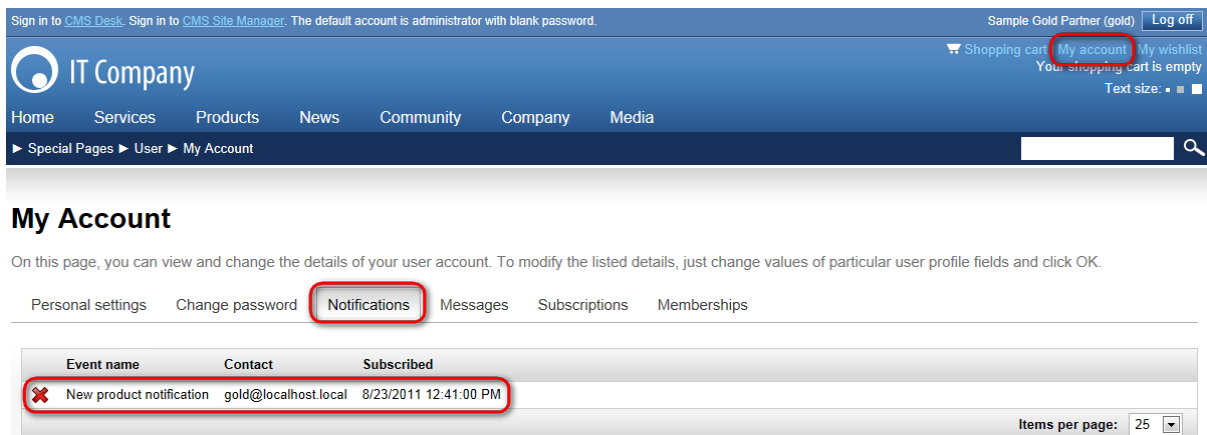

3. Let's switch to the **site visitor's** perspective now. Sign out of **CMS Desk**.

As notifications are available only for registered users, the web part is not visible unless you log in. Use the **My account** link at the top of the page to display a logon form and sign in; use e.g. user name *Gold* with blank password. Once signed in, switch to the **Products** page. You should see the **Content subscription** web part underneath the tree menu as highlighted in the screenshot below.

If you want to receive notifications about new products on this page, you can just type in your e-mail address into the **E-mail** field and click **Subscribe**. In case that you want to verify the functionality later on, enter your own e-mail address so that you can check your inbox for notification e-mails.

4. You can immediately verify your subscription by going to the **My account** section again. If you switch to the **Notifications** section of the **My account** web part, you should see the notification subscription present.

5. Now you can verify that the whole setup works. Log in to **CMS Desk** as the *administrator* again. From the content tree, select **Products** and click the **New** icon above the content tree. Choose to create some new product, e.g. a Cell phone, enter some sample data about the cell phone and click **Save**. Check your e-mail inbox in a few minutes. You should have received a new notification message about the newly added product.

8.37.4 Managing users' notifications

Site administrators can manage subscriptions of particular users in **Site Manager -> Administrator -> Users**. If you choose to **Edit** (✎) a user and switch to the **Notifications** tab, you will see all notifications that the current user is subscribed to. You can unsubscribe the user from a notification by clicking the **Delete** (✖) icon next to it.

The screenshot shows the Kentico Site Manager Administration interface. The left sidebar contains a navigation menu with 'Users' highlighted. The main content area shows the 'Users' section for the 'administrator' user. The 'Notifications' tab is selected, displaying a table of notifications.

| Event name | Contact | Subscribed ^ |
|----------------------------|-------------------------------|----------------------|
| ✖ New product notification | administrator@localhost.local | 8/23/2011 1:24:47 PM |

CMS Desk users can manage their own subscriptions the same way in **CMS Desk -> My Desk -> Account -> Notifications**.

The screenshot shows the Kentico CMS Desk 'My Desk' interface. The 'My profile' section is active, and the 'Notifications' tab is selected. A table of notifications is displayed below.

| Event name | Contact | Subscribed ^ |
|----------------------------|-------------------------------|----------------------|
| ✖ New product notification | administrator@localhost.local | 8/23/2011 1:24:47 PM |

Site visitors registered to the site can manage their subscriptions the same way using the **My account** web part, on its **Notifications** tab.

My Account

On this page, you can view and change the details of your user account. To modify the listed details, just change values of particular user profile fields and click OK.

Personal settings Change password **Notifications** Messages Subscriptions Memberships

| Event name | Contact | Subscribed |
|----------------------------|-------------------------------|----------------------|
| ✘ New product notification | administrator@localhost.local | 8/23/2011 1:24:47 PM |

8.37.5 Custom notification gateway

8.37.5.1 Overview

In this chapter, you will get familiar with the process of creating a custom notification gateway and using it on your site. The general description is supplied by code examples of a sample e-mail notification gateway.

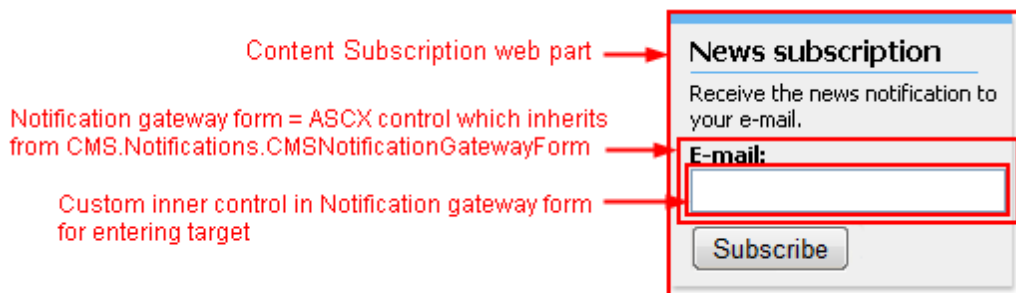

General steps

Here is a general overview of the steps that need to be taken when implementing a custom notification gateway:

1. [Create a custom notification gateway form](#) with your custom inner control(s) for entering the target where the notification messages should be sent.
2. [Create a custom notification gateway class](#) which handles loading of correct notification gateway form and sending notification messages.
3. [Register the custom notification gateway](#) in **Site Manager -> Development -> Notifications** and [create a template](#) for notification messages.
4. [Use the gateway](#) with the **Content subscription** web part on the live site.

8.37.5.2 Custom notification gateway form

In the picture below, you can see how the default **E-mail notification gateway form** is contained within the **Content subscription** web part.

The following steps need to be taken to create a custom notification gateway form:

1. Create a new web user control (*.ascx) and place it into your site folder which is located in the root of your web project. You can place it anywhere in your web project, but since the control is located in the site folder, it will be included in your site's export packages.
2. Set the control's class to inherit from the **CMS.Notifications.CMSNotificationGatewayForm** class.

3. There are two methods and one property you will need to override to reach the required functionality:
 - **object Value** - gets or sets the value from the custom inner control (e.g. gets or sets the text of the inner TextBox in the picture above)
 - **string Validate()** – validates the inner control's value and returns an error message if the value doesn't meet the requirements of the notification gateway (e.g. the TextBox value is validated for e-mail address format for the **E-mail notification gateway**)
 - **void ClearForm()** – your custom code inside this method should set the inner control to the default state; example: text of the TextBox should be cleared (set to the empty string)

Example - E-mail notification gateway form

The following code samples show how a custom e-mail notification gateway form can be implemented:

EmailNotificationForm.ascx

Please note: If you installed the Kentico CMS project as a web application, you need to rename the *CodeFile* property on the first line to *Codebehind* for the code example to be functional.

```
<%@ Control Language="C#" AutoEventWireup="true" CodeFile="EmailNotificationForm.ascx"
    Inherits="CMSModules_Notifications_Controls_NotificationSubscription_EmailNotifi
    <asp:Label ID="lblEmail" runat="server" />
    <asp:TextBox ID="txtEmail" runat="server" CssClass="EmailNotificationForm" EnableVie
```

EmailNotificationForm.ascx.cs

[C#]

```
using System;
using System.Data;
using System.Configuration;
using System.Collections;
using System.Web;
using System.Web.Security;
using System.Web.UI;
using System.Web.UI.WebControls;
using System.Web.UI.WebControls.WebParts;
using System.Web.UI.HtmlControls;

using CMS.Notifications;
using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.EventLog;

public partial class
CMSModules_Notifications_Controls_NotificationSubscription_EmailNotificationForm :
CMSNotificationGatewayForm
{
    #region "Variables"

    private bool mEnableMultipleEmails = false;
```

```
#endregion

#region "Properties"

/// <summary>
/// Gets or sets the e-mail(s) from/to textbox.
/// </summary>
public override object Value
{
    get
    {
        return this.txtEmail.Text.Trim();
    }
    set
    {
        this.txtEmail.Text = ValidationHelper.GetString(value, "");
    }
}

/// <summary>
/// Gets or sets the value which determines whether to allow multiple e-mails
separated with semicolon.
/// </summary>
public bool EnableMultipleEmails
{
    get
    {
        return this.mEnableMultipleEmails;
    }
    set
    {
        this.mEnableMultipleEmails = value;
    }
}

#endregion

protected void Page_Load(object sender, EventArgs e)
{
    this.lblEmail.Text = (this.EnableMultipleEmails ? ResHelper.GetString(
("general.emails") : ResHelper.GetString("general.email")) + ResHelper.Colon;

    // Fill in the default e-mail
    if ((!RequestHelper.IsPostBack()) && (CMSContext.CurrentUser != null) &&
(!String.IsNullOrEmpty(CMSContext.CurrentUser.Email)))
    {
        this.txtEmail.Text = CMSContext.CurrentUser.Email;
    }
}
}
```

```
#region "Public methods"

/// <summary>
/// Checks whether the input is correct e-mail address (or multiple e-mail
addresses).
/// </summary>
public override string Validate()
{
    if (this.EnableMultipleEmails)
    {
        if (!ValidationHelper.AreEmails(this.txtEmail.Text.Trim()))
        {
            return ResHelper.GetString("notifications.emailgateway.formats");
        }
    }
    else
    {
        if (!ValidationHelper.IsEmail(this.txtEmail.Text.Trim()))
        {
            return ResHelper.GetString("notifications.emailgateway.format");
        }
    }

    return String.Empty;
}

/// <summary>
/// Clears the e-mail textbox field.
/// </summary>
public override void ClearForm()
{
    this.txtEmail.Text = "";
}

#endregion
}
```

8.37.5.3 Custom notification gateway class

The following steps need to be taken to create a custom notification gateway class:

1. Create a new library (assembly) as a part of your solution and a new class inside this library.
2. Set your class to inherit from the **CMS.Notifications.CMSNotificationGateway** abstract class.
3. There are two methods you will need to override to reach the required functionality:
 - **void SendNotification()** – sends a single notification; it is automatically called after the specified event is raised
 - **CMSNotificationGatewayForm GetNotificationGatewayForm()** – loads and returns notification gateway form for the notification gateway
4. Compile the library.
5. Ensure the library file (*.dll) is included in the **/Bin** directory.

Example - E-mail notification gateway class

The following code sample shows how a custom e-mail notification gateway class can be implemented:

EmailNotificationGateway.cs

[C#]

```
using System;
using System.Collections.Generic;
using System.Text;
using System.Web.UI;

using CMS.EventLog;
using CMS.EmailEngine;
using CMS.GlobalHelper;
using CMS.SiteProvider;
using CMS.SettingsProvider;
using CMS.Notifications;

namespace EmailNotification
{
    /// <summary>
    /// Base class for e-mail notification gateway.
    /// </summary>
    public class EmailNotificationGateway : CMSNotificationGateway
    {
        /// <summary>
        /// Returns the e-mail gateway form.
        /// </summary>
        public override CMSNotificationGatewayForm GetNotificationGatewayForm()
        {
            try
            {
                Control ctrl =
                this.NotificationSubscriptionControl.Page.LoadControl("~/CMSModules/Notifications/
                Controls/NotificationSubscription/EmailNotificationForm.ascx");
                ctrl.ID = ValidationHelper.GetIdentificator("notif" +
                this.NotificationGatewayObj.GatewayName);

                return (CMSNotificationGatewayForm)ctrl;
            }
            catch (Exception ex)
            {
                try
                {
                    // Log the event
                    EventLogProvider eventLog = new EventLogProvider();
                    eventLog.LogEvent("EmailGateway", "EXCEPTION", ex);
                }
                catch
                {
                    // Unable to log the event
                }
            }
        }
    }
}
```

```
    }
    }
    return null;
}

/// <summary>
/// Sends the notification via e-mail.
/// </summary>
public override void SendNotification()
{
    try
    {
        if (this.NotificationSubscriptionObj != null)
        {
            // Get template text
            NotificationTemplateTextInfo templateText =
            NotificationTemplateTextInfoProvider.GetNotificationTemplateTextInfo
            (this.NotificationGatewayObj.GatewayID,
            this.NotificationSubscriptionObj.SubscriptionTemplateID);
            if (templateText != null)
            {
                // Get the site name
                string siteName = null;
                SiteInfo si = SiteInfoProvider.GetSiteInfo
                (this.NotificationSubscriptionObj.SubscriptionSiteID);
                if (si != null)
                {
                    siteName = si.SiteName;
                }

                // Create message object
                EmailMessage message = new EmailMessage();

                // Get sender from settings
                message.From = SettingsKeyProvider.GetStringValue(siteName
                + ".CMSSendEmailNotificationsFrom");

                // Do not send the e-mail if there is no sender specified
                if (message.From != "")
                {
                    // Initialize message
                    message.Recipients =
                    this.NotificationSubscriptionObj.SubscriptionTarget;

                    // Body
                    if
                    ((this.NotificationSubscriptionObj.SubscriptionUseHTML) &&
                    (this.NotificationGatewayObj.GatewaySupportsHTMLText) &&
                    (templateText.TemplateHTMLText != ""))
                    {
                        // HTML format, set Body property, resolve macros
                        if possible
                    }
                }
            }
        }
    }
}
```

```

    }
  }
}
// Unable to log the event

```

8.37.5.4 Registering a custom gateway

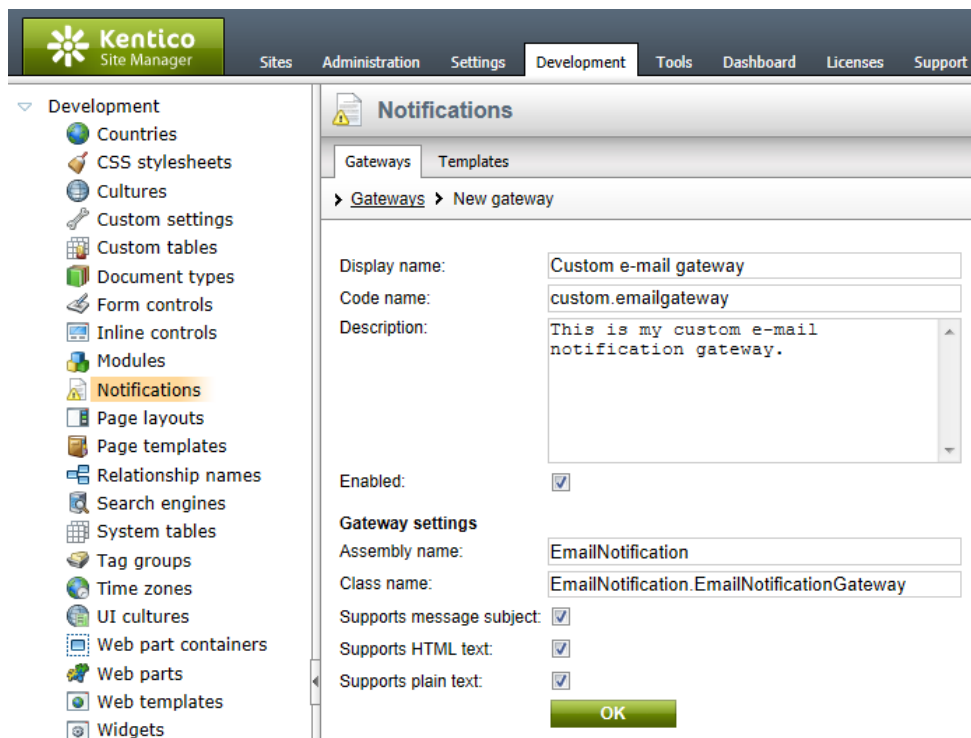

When you have developed a custom notification gateway, you need to take the following steps to register your gateway in the system:

1. Go to **Site Manager -> Development -> Notifications**. At the top of the **Gateways** tab, click  **New gateway**. The **New gateway** form will be displayed.

2. Enter the following details into the **New gateway** form:

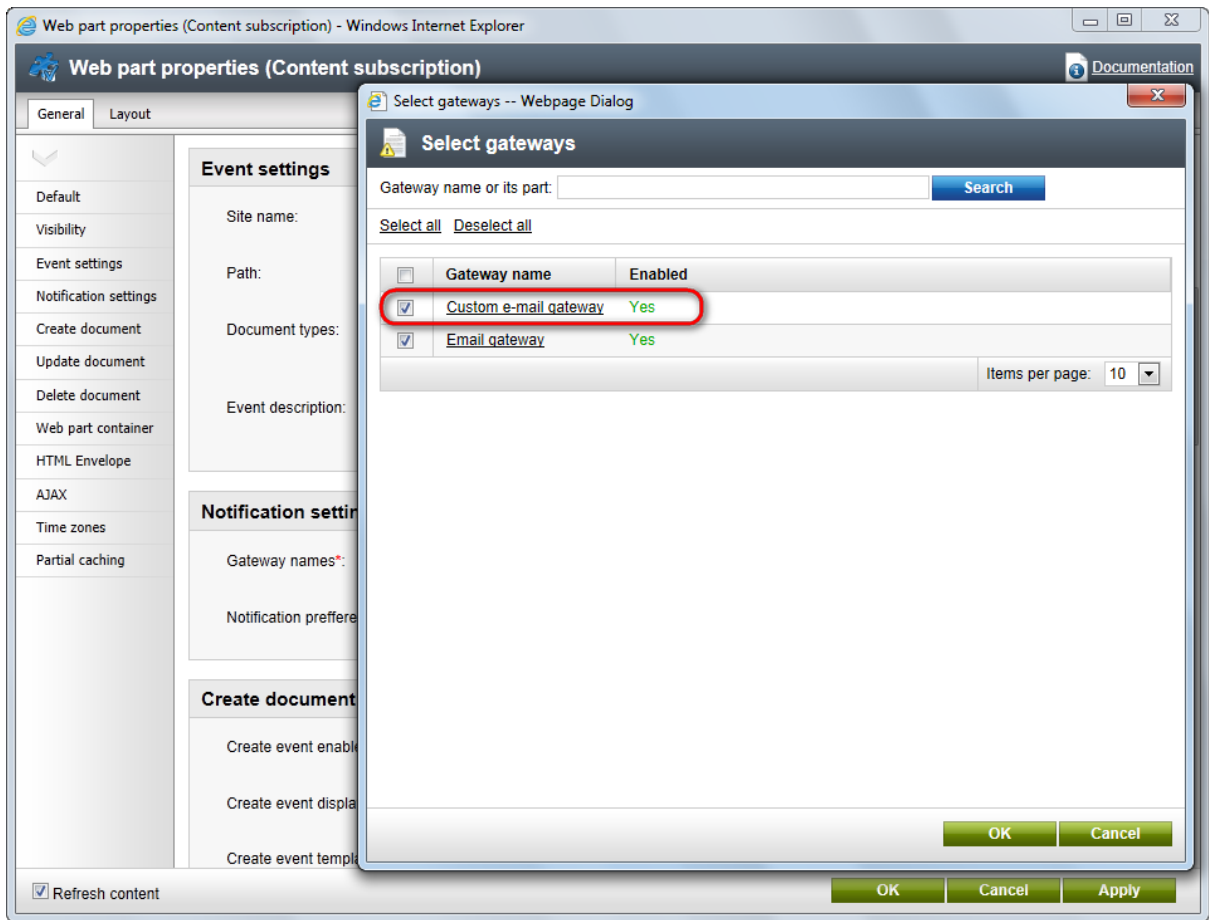

- **Display name** - display name of the notification gateway
- **Code name** - code name of the gateway
- **Description** - text describing the gateway
- **Enabled** - if unchecked, the notification gateway is not functional - this can be useful if you want to temporarily disable the gateway so that no messages will be sent, e.g. when you are performing some administration tasks; if checked, the gateway works normally
- **Assembly name** - name of the assembly in that the gateway code is stored
- **Class name** - name of the class containing the gateway code; must be entered including the assembly name, as you can see in the screenshot below
- **Supports message subject** - enable if the gateway's message format supports message subjects
- **Supports HTML text** - enable if the gateway supports messages in HTML format (e.g. for e-mails)
- **Supports plain text** - enable if the gateway supports plain text format (e.g. for SMS)

3. After entering all the details, click **OK** to confirm the changes you have made.

8.37.5.5 Using the gateway on your site

On the live site, you can enable users to subscribe using the **Content subscription** web part, just as described [here](#). You only need to enable your gateway in the **Gateway names** property of the web part.

On the live site, the web part displays a check-box for each gateway when multiple gateways are selected. If you enable a particular check-box, the gateway's form is displayed, as you can see in the screenshot below.

The screenshot shows the 'IT Company' e-commerce website. The top navigation bar includes links for Home, Services, Products, News, Community, Company, and Media. A shopping cart icon indicates 'Your shopping cart is empty'. Below the navigation is a search bar and a 'Products' dropdown menu.

The main content area is titled 'Products'. It contains a paragraph explaining that the section represents a simple web shop created using the E-commerce module, listing capabilities like customizable checkout, payment gateway integration, and stock monitoring. It also mentions the 'Kentico CMS E-commerce Guide' and the 'E-commerce Site'.

Below the text is a 'Featured Products' section with four product cards:

- Apple iPhone 4**: Price \$759.99
- Apple MacBook Pro MC723LL/A**: Price \$2199.00
- BlackBerry Torch 9800**: Price \$459.99
- Motorola Atrix 4G**: Price \$529.98

Each product card includes an image, the product name, the price, and a blue shopping cart icon.

On the left side of the product grid, there is a red-bordered box containing a notification subscription form:

Receive notifications about new products via:

- Email gateway
- Custom e-mail gateway

Subscribe

8.37.6 Settings

The **Notifications** module has only one setting to be done in **Site Manager -> Settings -> System**:

- **Send e-mail notifications from** - sets the e-mail address that will be used as the sender address (the **From** field) of notification e-mails

The screenshot displays the Kentico CMS 7.0 Administration interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The 'Settings' tab is active, and the 'System' option in the left-hand navigation menu is highlighted with a red circle. The main content area shows the 'System' settings page, which is divided into several sections: General, E-mails, Scheduler, Time zones, and User interface. In the 'E-mails' section, the 'Send e-mail notifications from' field is circled in red, showing the value 'no-reply@localhost.local'. Other settings include Event log size (1000), Log metadata changes (checked), Default user ID (53), DB object schema (dbo), Application scheduler interval (60), Use external service (unchecked), Service scheduler interval (30), Enable time zones (unchecked), Server time zone ((GMT-06:00) Central America), Site time zone (none), Show splash screen (checked), Hide unavailable user interface (unchecked), and Max UI tree nodes (100). A 'Save' button and a 'Reset these settings to default' link are visible at the top of the settings area.

8.37.7 Security

The **Notifications** module has no permissions to be set in **CMS Desk/Site Manager -> Administration -> Permissions**.

Subscription to notifications is **allowed only for registered users**. This is why the **Content subscription** and **Notification subscription** web parts are **hidden to public anonymous users** by default.

8.37.8 Notifications internals and API

8.37.8.1 Overview

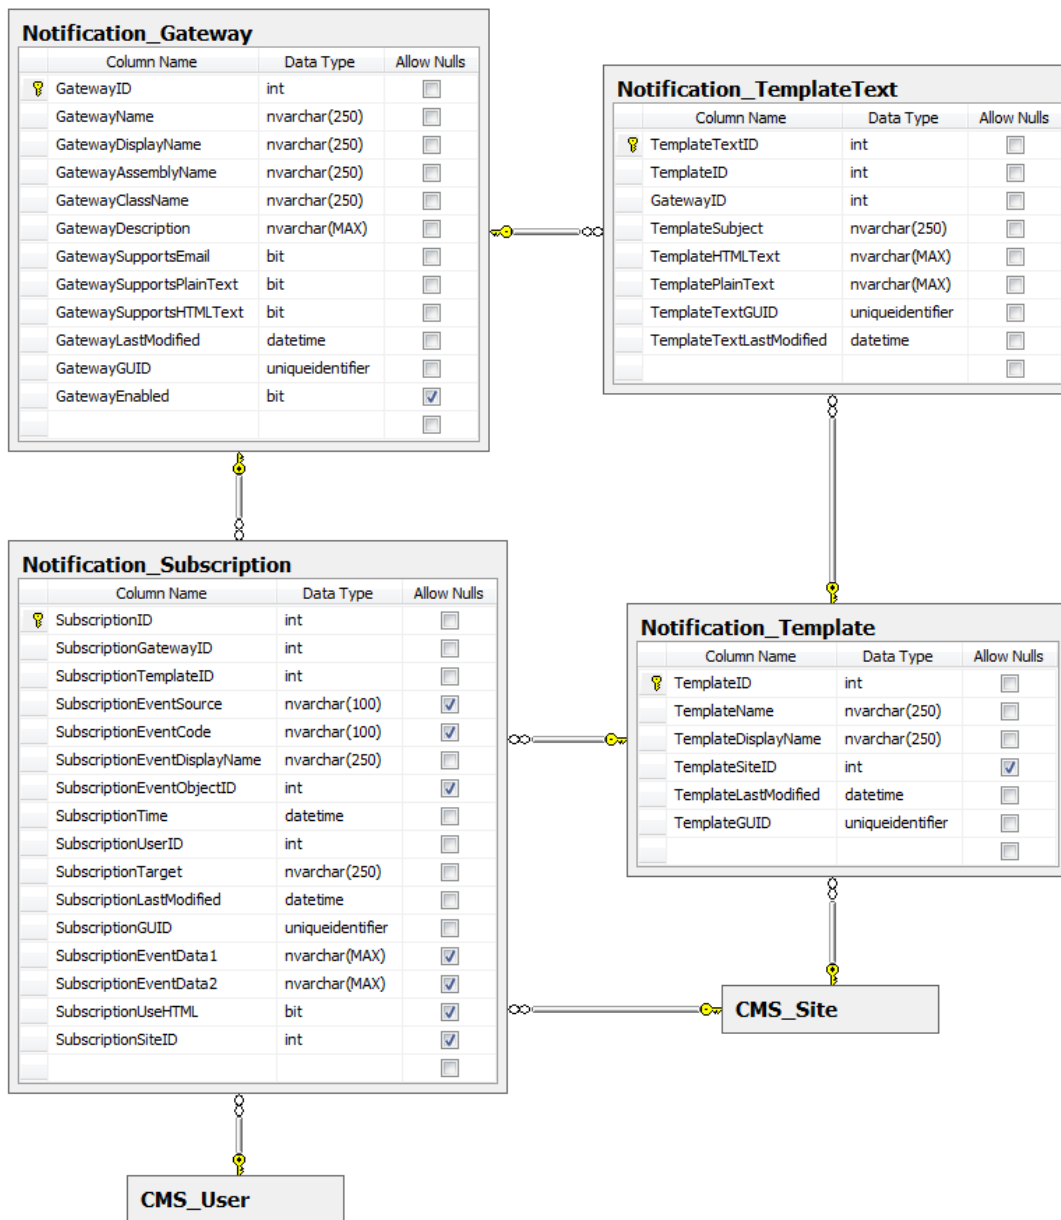

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Notifications module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.37.8.2 Database tables

The following database tables are used in the Notifications module:

- **Notification_Gateway** - contains records representing notification gateways.
- **Notification_Template** - contains records representing notification templates.
- **Notification_TemplateText** - contains records representing notification template texts.
- **Notification_Subscription** - contains records representing notification subscriptions.

8.37.8.3 API classes

If you are not familiar with the database table data management by Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The Notifications module classes use the **CMS.Notifications** namespace.

Notification_Gateway table API:

- **NotificationGatewayInfo** - represents one notification gateway.
- **NotificationGatewayInfoProvider** - provides management of notification gateways.

Notification_Template table API:

- **NotificationTemplateInfo** - represents one notification template.
- **NotificationTemplateInfoProvider** - provides management of notification templates.

Notification_TemplateText table API:

- **NotificationTemplateTextInfo** - represents one notification template text.
- **NotificationTemplateTextInfoProvider** - provides management of notification template texts.

Notification_Subscription table API:

- **NotificationSubscriptionInfo** - represents one notification subscription.
- **NotificationSubscriptionInfoProvider** - provides management of notification subscriptions.

Other classes:

- **NotificationSender** - used for asynchronous sending of notification messages.
- **CMSNotificationGateway** - the base class for notification gateways. All [custom notification gateways](#) need to inherit from this class.
- **CMSEmailNotificationGateway** - a built-in e-mail notification gateway.

8.37.8.4 API examples

8.37.8.4.1 Overview

These topics show examples of how the Notifications module API can be used:

- [Managing notification templates](#)

Please note

All API examples can be simulated in the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Development\Notifications\Default.aspx.cs**.

The Notifications module API examples use the following namespaces:

```
using System;
```

```
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.Notifications;
```

8.37.8.4.2 Managing notification templates

The following example creates a notification template.

```
private bool CreateNotificationTemplate()
{
    // Create new notification template object
    NotificationTemplateInfo newTemplate = new NotificationTemplateInfo();

    // Set the properties
    newTemplate.TemplateDisplayName = "My new template";
    newTemplate.TemplateName = "MyNewTemplate";
    newTemplate.TemplateSiteID = CMSContext.CurrentSiteID;

    // Create the notification template
    NotificationTemplateInfoProvider.SetNotificationTemplateInfo(newTemplate);

    return true;
}
```

The following example gets and updates a notification template.

```
private bool GetAndUpdateNotificationTemplate()
{
    // Get the notification template
    NotificationTemplateInfo updateTemplate =
    NotificationTemplateInfoProvider.GetNotificationTemplateInfo("MyNewTemplate",
    CMSContext.CurrentSiteID);
    if (updateTemplate != null)
    {
        // Update the property
        updateTemplate.TemplateDisplayName =
        updateTemplate.TemplateDisplayName.ToLower();

        // Update the notification template
        NotificationTemplateInfoProvider.SetNotificationTemplateInfo
        (updateTemplate);

        return true;
    }

    return false;
}
```

```
}
```

The following example gets and bulk updates notification templates.

```
private bool GetAndBulkUpdateNotificationTemplates()
{
    // Prepare the parameters
    string where = "TemplateName LIKE N'MyNewTemplate%'";
    where = SqlHelperClass.AddWhereCondition(where, "TemplateSiteID = " +
    CMSContext.CurrentSiteID, "AND");

    // Get the data
    DataSet templates = NotificationTemplateInfoProvider.GetTemplates(where,
    null);
    if (!DataHelper.DataSourceIsEmpty(templates))
    {
        // Loop through the individual items
        foreach (DataRow templateDr in templates.Tables[0].Rows)
        {
            // Create object from DataRow
            NotificationTemplateInfo modifyTemplate = new NotificationTemplateInfo
            (templateDr);

            // Update the property
            modifyTemplate.TemplateDisplayName =
            modifyTemplate.TemplateDisplayName.ToUpper();

            // Update the notification template
            NotificationTemplateInfoProvider.SetNotificationTemplateInfo
            (modifyTemplate);
        }

        return true;
    }

    return false;
}
```

The following example deletes a notification template.

```
private bool DeleteNotificationTemplate()
{
    // Get the notification template
    NotificationTemplateInfo deleteTemplate =
    NotificationTemplateInfoProvider.GetNotificationTemplateInfo("MyNewTemplate",
    CMSContext.CurrentSiteID);

    // Delete the notification template
    NotificationTemplateInfoProvider.DeleteNotificationTemplateInfo
    (deleteTemplate);
}
```

```
return (deleteTemplate != null);
}
```

8.38 On-line users

8.38.1 Overview

The On-line users module allows you to monitor users currently connected to the website. This can be useful for various site administration purposes. In addition to providing information, the module also provides a way to temporarily kick a specific user off the website.

The screenshot shows the 'Users' module interface. It has tabs for 'Users', 'Mass e-mail', 'On-line users', and 'Kicked users'. The 'On-line users' tab is active. Below the tabs is a 'Refresh' button and a navigation bar with letters A through Z. A search bar with 'Search' and 'Reset' buttons is present. Below the search bar is a 'Display advanced filter' dropdown. The main area contains a table with the following data:

| Actions | Full name ^ | E-mail | User name | Nickname | Created | Last activity | Location | Site |
|---------|----------------------|-------------------------------|---------------|----------|----------------------|-----------------------|-----------|----------------|
| | Andrew Jones | andy@localhost.local | Andy | | 6/21/2012 8:08:31 AM | 6/23/2012 11:01:35 AM | /Products | Corporate Site |
| | Global Administrator | administrator@localhost.local | administrator | | | 6/23/2012 11:01:18 AM | /Home | Corporate Site |

At the bottom of the table, it says '2 user(s) on-line: 2 logged in and 0 guest(s)'. There is also an 'Items per page: 25' dropdown menu.

The module identifies a new user when a new session between a client browser and the server is started. The user is considered off-line if the session expires or when the user logs off. This means that a user is still considered on-line for some time when they close their web browser without signing off.

To utilize the module on your site, you need to perform the following simple steps:

1. Enable and configure on-line user monitoring in the system. Learn how in the [Enabling the On-line users module](#) topic.
2. Keep track of users on the [On-line users tab](#) or display information about them on your website using the [On-line users web part](#).

The [On-line users internals and API](#) sub-chapter provides information about the database tables and classes used by the module and examples of how on-line users can be managed using the API.

For more general information about users and site membership, please refer to the [Development -> Membership, permissions and security](#) chapter of this guide.

8.38.2 Enabling the On-line users module

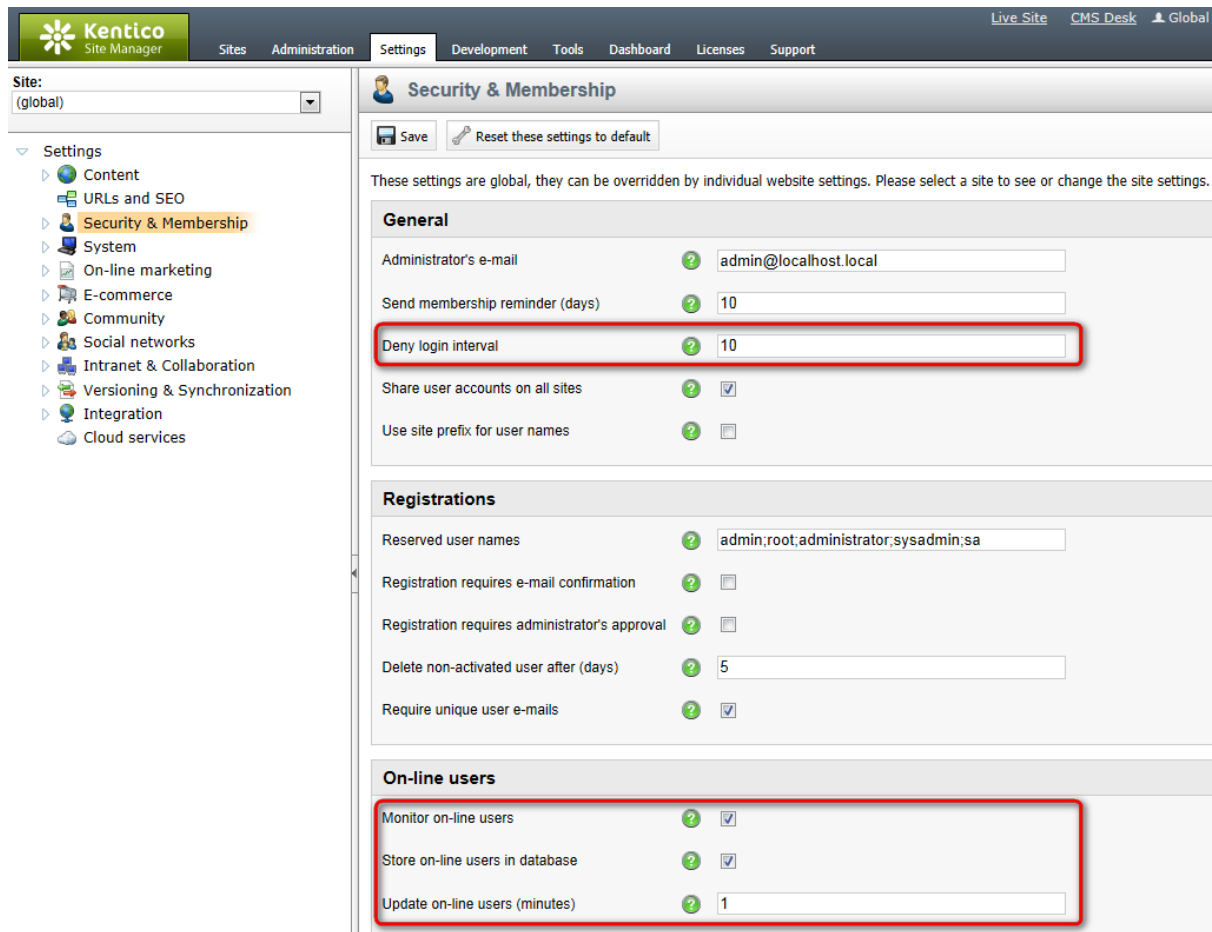

The On-line users module can be enabled in **Site Manager -> Settings -> Security & Membership** by checking the **Monitor on-line users** check-box.

If you are running the system on a [web farm](#), you also have to check the **Store on-line users in**

database check-box. This causes information about on-line users to be saved in the database and also allows the system to provide more detailed information about guests (anonymous users).

The **Deny login interval** property determines how long users will not be able to log-in after they are kicked. The value is entered in minutes.

Finally, the **Update on-line users (minutes)** property defines how often information about users accessing the site is reloaded. The value is entered in minutes. When running the system on a web farm, you need to enter the same value which is set for the **Remove expired sessions** scheduled task (you can read the value in **Site Manager -> Administration -> Scheduled tasks -> edit (✎) Remove expired sessions -> Task interval -> Every: X minute**).

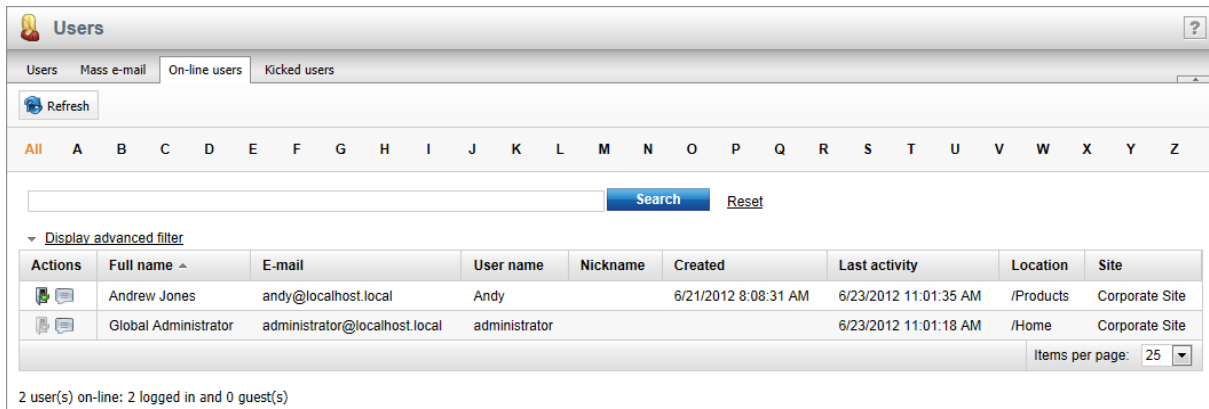

8.38.3 On-line users tab

If you go to **Site Manager/CMS Desk -> Administration -> Users** and switch to the **On-line users** tab, you can see a list of all users that are currently accessing the website. By clicking one of the letters at the top of the page, you can view only those users whose user names begin with the selected letter.

Below the letters, you can find a filter. This filter can further limit displayed users according to the specified criteria. The filter can work in two modes between which you can switch by clicking the **Display advanced filter** or **Display simplified filter** links respectively.

Simplified filter

This option offers only one field. Enter an expression into the field to find users according to their **User Name**, **Full Name**, **E-mail Address** or **Nickname**.

The screenshot shows the 'Users' management interface. At the top, there are tabs for 'Users', 'Mass e-mail', 'On-line users', and 'Kicked users'. Below the tabs is a 'Refresh' button and a search bar with 'Search' and 'Reset' buttons. A navigation bar shows letters A through Z. Below the search bar is a 'Display advanced filter' dropdown. The main area contains a table with the following data:

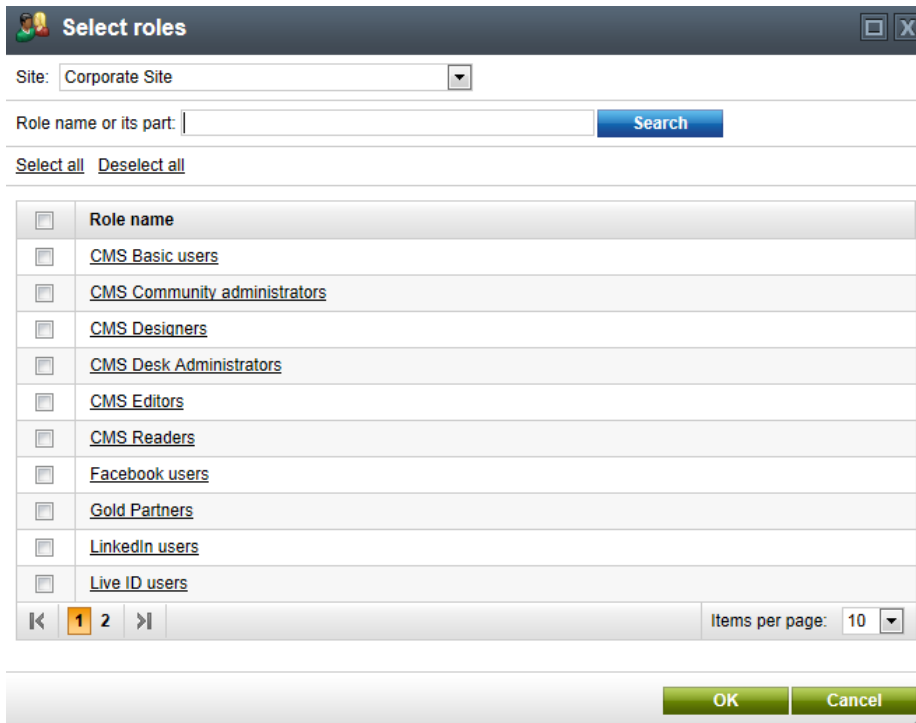

| Actions | Full name ^ | E-mail | User name | Nickname | Created | Last activity | Location | Site |
|---------|----------------------|-------------------------------|---------------|----------|----------------------|-----------------------|-----------|----------------|
| | Andrew Jones | andy@localhost.local | Andy | | 6/21/2012 8:08:31 AM | 6/23/2012 11:01:35 AM | /Products | Corporate Site |
| | Global Administrator | administrator@localhost.local | administrator | | | 6/23/2012 11:01:18 AM | /Home | Corporate Site |

At the bottom right of the table, there is an 'Items per page' dropdown set to 25. Below the table, it says '2 user(s) on-line: 2 logged in and 0 guest(s)'.

Advanced filter

The advanced filter offers searching for users based on specific **User Name**, **Full Name**, **E-mail Address** or **Nickname** values.

You can also filter on-line users by the roles to which they belong. To specify roles into either the **In roles** or **Not in roles** fields, use the **Add roles** button to open the role selection dialog. Click **OK** to confirm the selection.

The screenshot shows the 'Select roles' dialog box. At the top, there is a 'Site' dropdown menu set to 'Corporate Site'. Below it is a text input field for 'Role name or its part:' and a 'Search' button. Below the search field are links for 'Select all' and 'Deselect all'. The main area is a list of roles with checkboxes:

- Role name
- CMS Basic users
- CMS Community administrators
- CMS Designers
- CMS Desk Administrators
- CMS Editors
- CMS Readers
- Facebook users
- Gold Partners
- LinkedIn users
- Live ID users

At the bottom left, there is a pagination control showing '1' selected out of 2 items. At the bottom right, there is an 'Items per page' dropdown set to 10. At the very bottom, there are 'OK' and 'Cancel' buttons.

If you have selected more than one user role, you can also select if the displayed users should (not) be members of **All** or **Any** of the selected roles.

The **Display guests** option indicates whether individual visitors who are not logged in should be displayed. This is only possible if the on-line user data is stored in the database. If [Contact management](#) is being used on the website, the system also provides the names and e-mail addresses of guests based on the available contact data.

The **Show hidden users** checkbox determines whether the list should include users who are flagged as hidden (e.g. administrators or other internal user accounts).

When you have entered all filtering data, click the **Show** button. Only those users that match the specified criteria are listed.

Items per page: 25

3 user(s) on-line: 2 logged in and 1 guest(s)

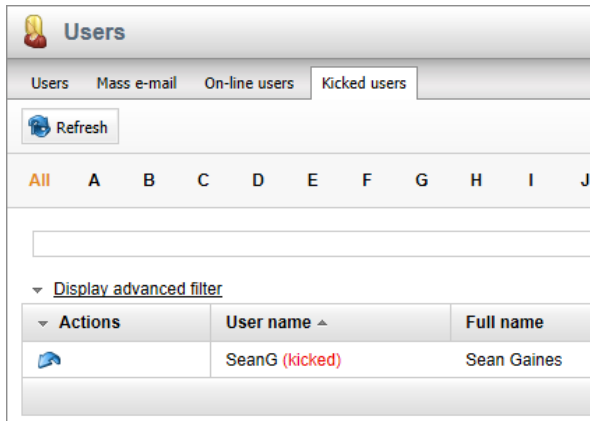

Kicking a user

You can kick users off the website by clicking the **Kick** (🚫) action next to one of the listed users. This means that the user is logged out of the website and will not be able to log back in for the duration specified in the **Site Manager -> Settings -> Security & Membership -> Deny login interval** setting.

| Actions | Full name ^ |
|---------|----------------------|
| [icon] | Andrew Jones |
| [icon] | Global Administrator |
| [icon] | Sean Gaines |

After doing so, a (**kicked**) label is added in red letters after the given user's name. When the on-line user data is being stored in the database, you can view all users who are currently kicked on the **Kicked users** tab. Otherwise the kicked users are included in the main list of on-line users.

To revoke a kick, click the **Take back** (🔄) action.

If the reason for kicking a user is serious enough, you may want to consider using the [Banned IPs](#) module to permanently block the user from accessing the website.

Chatting with on-line users

Clicking the **Initiate chat** action next to an on-line user allows you to directly communicate with the given person through a chat window. To work correctly, support chat must be enabled for the website and the page that the user is currently viewing needs to contain the the [Initiated chat](#) web part. Please see the [Modules -> Chat -> Support chat](#) chapter for more information.

8.38.4 On-line users web part

The module comes with the [On-line users](#) web part. In the web part selection dialog, you can find the web part in the **Membership -> Users** category. The image below displays the output of the web part enclosed in the **Orange box** web part container.

The web part displays a summary defined by the **Additional info text** property, followed by a list of users that are currently on-line. Users are displayed based on the transformation specified in the **Transformation name** property.

The web part has the following related properties:

| | |
|---------------------|--|
| Transformation name | Sets the transformation used to display the on-line users.

You can use the default CMS.Root.OnLineUsers transformation, which displays user names separated by spaces. |
| Path | If you enter an alias path here, only users that are accessing pages found under the specified path will be displayed. |
| Select top N | Sets the maximum number of users that can be selected and displayed. |

| | |
|-----------------------|--|
| Additional info text | <p>Sets the text which will be displayed above the list of on-line users.</p> <p>You can use the following formatting macros that will be resolved into the appropriate number:</p> <p>{0} - number of all connected users
 {2} - number of connected registered users
 {1} - number of connected anonymous users</p> |
| No users on-line text | Sets the text that will be displayed if no users are currently on-line. |
| Columns | <p>Lists which columns should be loaded from the CMS_User or CMS_UserSettings tables along with user records. Column names need to be separated by commas (,). Specifying a list without unnecessary columns may significantly improve performance.</p> <p>These columns may be used in the code of the specified transformation to display data related to the on-line users.</p> |

8.38.5 On-line users internals and API

8.38.5.1 Overview

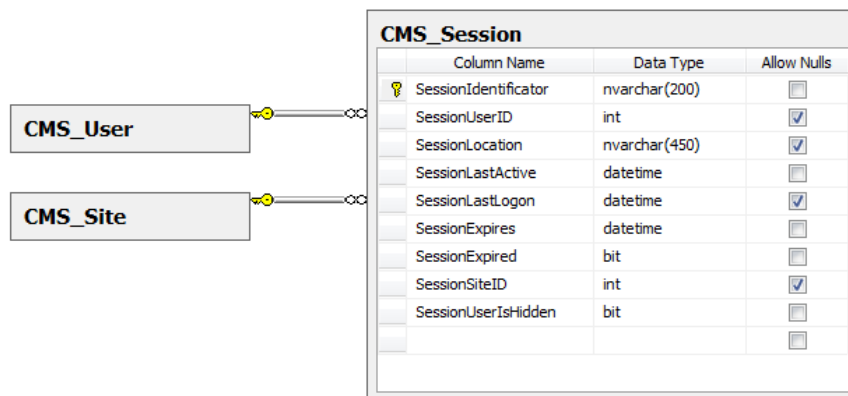

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the On-line users module. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the module's classes, please refer to [Kentico CMS API Reference](#).

8.38.5.2 Database tables

The following database table is used to store information about on-line users:

- **CMS_Session** - contains records representing users that are currently connected to a website. On-line users are only stored in the database if the *Site Manager -> Settings -> Security & Membership -> Store on-line users in database* setting is enabled. This is necessary when running the system on a web farm.

8.38.5.3 API classes

The functionality for managing sessions, which includes the monitoring of on-line users, is provided by the **SessionManager** class found in the **CMS.CMSHelper** namespace.

User and site objects can be handled via the corresponding Info and Provider classes from the **CMS.SiteProvider** namespace. If you are not familiar with this type of database table management, we strongly recommend that you refer to the [Database table API](#) topic first.

CMS_User table API:

- **UserInfo** - represents one user object.
- **UserInfoProvider** - provides management functionality for users.

CMS_Site table API:

- **SiteInfo** - represents one site object.
- **SiteInfoProvider** - provides management functionality for sites.

8.38.5.4 API examples

8.38.5.4.1 Overview

The following topic shows examples of how the API of the On-line users module can be used:

- [Managing on-line users](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Administration\Membership\Default.aspx.cs**.

The on-line user API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.SiteProvider;
```

8.38.5.4.2 Managing on-line users

The following example gets a dataset of on-line users and updates their properties.

```
private bool GetOnlineUsers()
{
    string where = "";
    int topN = 10;
    string orderBy = "";
    string location = "";
    string siteName = CMSContext.CurrentSiteName;
    bool includeHidden = true;
    bool includeKicked = false;

    // Get DataSet of on-line users
    DataSet users = SessionManager.GetOnlineUsers(where, orderBy, topN, location,
siteName, includeHidden, includeKicked);
    if (!DataHelper.DataSourceIsEmpty(users))
    {
        foreach (DataRow userDr in users.Tables[0].Rows)
        {
            // Create object from DataRow
            UserInfo modifyUser = new UserInfo(userDr);

            // Update the properties
            modifyUser.FullName = modifyUser.FullName.ToUpper();

            // Save the changes
            UserInfoProvider.SetUserInfo(modifyUser);
        }

        return true;
    }

    return false;
}
```

The following example checks if a specified user is currently on-line.

```
private bool IsUserOnline()
{
    bool includeHidden = true;

    // Get user and site objects
    UserInfo user = UserInfoProvider.GetUserInfo("MyNewUser");
    SiteInfo site = SiteInfoProvider.GetSiteInfo
(CMSContext.CurrentSiteName);

    if ((user != null) && (site != null))
    {
        // Check if user is online
        return SessionManager.IsUserOnline(site.SiteName, user.UserID,
includeHidden);
    }

    return false;
}
```

```
}
```

The following example kicks a user from a site.

```
private bool KickUser()
{
    // Get the user
    UserInfo kickedUser = UserInfoProvider.GetUserInfo
(CMSContext.CurrentUser.UserID);

    if (kickedUser != null)
    {
        // Kick the user
        SessionManager.KickUser(kickedUser.UserID);

        return true;
    }

    return false;
}
```

8.39 Polls

8.39.1 Overview

The Polls module allows you to create, edit and publish polls on your websites created with Kentico CMS. There are two types of poll in Kentico CMS:

- **Global poll** - the poll is shared across more websites.
- **Site poll** - the poll has a relationship with a particular site. Such poll is not accessible from other sites.

The module can display voting statistics in the form of graph, which represents either the absolute number of votes or percentage. Besides, the module enables you to control whether single or multiple answers will be allowed on the page and you have the possibility to deny multiple votes for one site visitor.

By placing polls on the pages of your website, you give site visitors the chance to vote for certain options. These options can be related directly to the current page, to the contents of the whole website or simply to anything on which you would like visitors of your web pages to express their opinion. Polls in Kentico CMS are customizable and the module supports integration with the built-in [WYSIWYG editor](#).

- To learn how to perform administrative tasks related to polls, please refer to the [Managing polls](#) topic.
- To learn how to make your polls available from your web pages, please refer to the [Publishing polls](#) topic.
- If you would like to see an example of how to integrate polls on your site, please refer to the [Adding a poll to your site](#) topic.
- To learn how to make your polls in more than one cultural version, please refer to the [Multilingual support](#) topic.
- If you would like to learn about the security possibilities of the Polls module, please refer to the [Security](#) topic.

A practical example of the use of the Polls module can be found in Kentico CMS Personal Site Guide. You can see a step-by-step tutorial on how to add a poll to your personal website in [Personal Site Guide -> Adding web parts -> Adding a poll](#).

You will need to have the Personal Site sample website installed to follow the Personal Site Guide.

Several more practical examples of the use of the Polls module are available in Kentico CMS Community Site Guide; please note that these examples do not concern the whole functionality of the module but focus on its use in a broader context of the Community Site sample website:

- See e.g. [Part 2 -> Pre-development tasks -> Creating a sample poll](#) in this guide: You will learn how to create a sample poll that you will publish on the Home page of your website later on.
- See also e.g. [Creating the Home page](#) in the same section of the guide: Here you will learn how to

publish the previously created sample poll on the Home page your website.

You will need to have the Community Site sample website installed to follow the Community Site Guide.

8.39.2 Managing polls

In this topic, you will learn how to [create](#) a new poll, [edit](#) poll properties, define poll [answers](#), define [who can vote](#) and you will also learn how to [share a global poll](#) between sites, and how to [preview](#) a poll.

By default, both global and site polls are allowed in Kentico CMS; to learn how to customize these settings, please refer to the [Security](#) topic. Both types of polls can be managed in **CMS Desk -> Tools -> Polls**.

Creating a new poll

First, you need to choose whether the new poll will be site-based or global. This can be done using the **Site** drop-down list:

| | |
|------------------------|---|
| (global and this site) | Both global and current site polls are listed in the poll list. The option does not allow to create a new poll. |
| (global) | Only global polls are listed in the poll list. The option allows to create a new global poll. |
| current site | Only current site polls are listed in the poll list. The option allows to create a new site poll. |

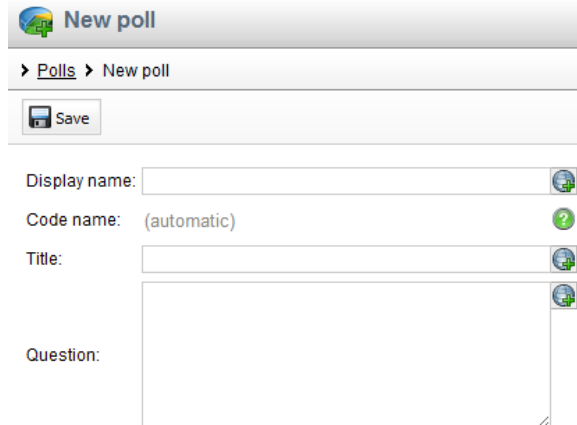

Please note

The **Site** drop-down list may be disabled for a particular user due to security reasons. For more details, please refer to [this](#) topic.

Now click  **New poll** and enter the following values:

| | |
|--------------|---|
| Display name | The name of the poll displayed to poll administrators. |
| Code name | The name of the poll used in the code. |
| Title | The title of the poll displayed in the poll view; optional field. |
| Question | The poll question displayed in the poll view. |

New poll

› Polls › New poll

Save

Display name:

Code name: (automatic) 

Title:

Question:

After entering the required values,  **Save** the changes you have made.

Editing poll properties

On the **General** tab, you can define more poll details by entering the following values:

| | |
|------------------------|---|
| Display name | The name of the poll displayed to poll administrators. |
| Code name | The name of the poll used in the code. |
| Title | The title of the poll displayed in the poll view; optional field. |
| Question | The poll question displayed in the poll view; optional field. |
| Open from | Indicates when the voting is opened; optional field. |
| Open to | Indicates when the voting is closed; optional field. |
| Message after vote | The message displayed after vote; optional field. |
| Allow multiple choices | Indicates if a visitor can select more than one option. |

Poll properties

› Polls › Continents

 Save

Display name: 

Code name: 

Title:

Question:

Open from:  Now

Open to:  Now

Message after vote:

Allow multiple choices:

 **Save** the changes you have made to the poll.

Defining answers

Then you can define a list of available answers on the **Answers** tab. To create a new answer, click  **New answer** and enter the answer text. Your poll answers can be **Edited** () , **Deleted** () , **Moved Up** () and **Moved down** () .

Poll properties

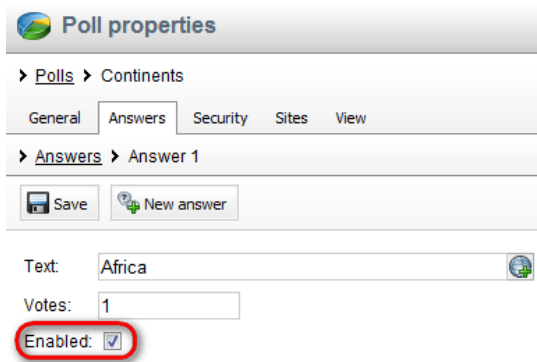

› Polls › Continents

General **Answers** Security Sites View

 New answer  Reset answers

| Actions | Text | Count | Enabled |
|---|-----------|-------|---------|
|     | Africa | 1 | Yes |
|     | Asia | 2 | Yes |
|     | Europe | 4 | Yes |
|     | America | 3 | Yes |
|     | Australia | 2 | Yes |

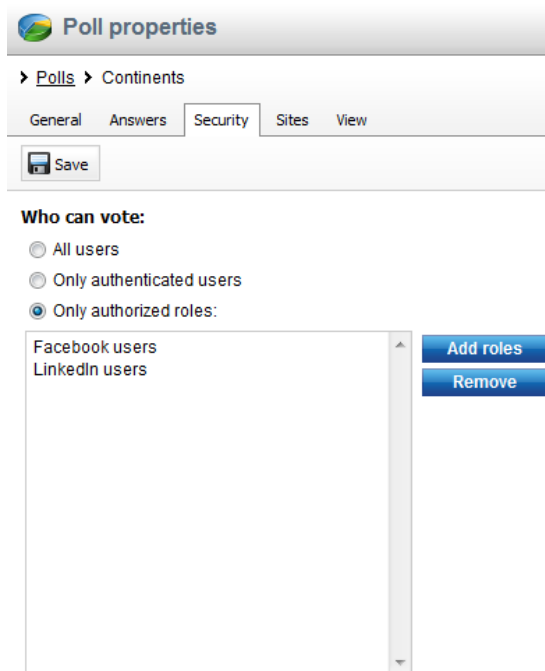

You can choose if the given answer should be enabled, i.e. displayed in the list of options. This is useful if you need to remove an answer from the poll while keeping the number of votes in the history. The disabled option is then not calculated into the displayed results.

You can also reset answers in your poll by clicking  **Reset answers**.

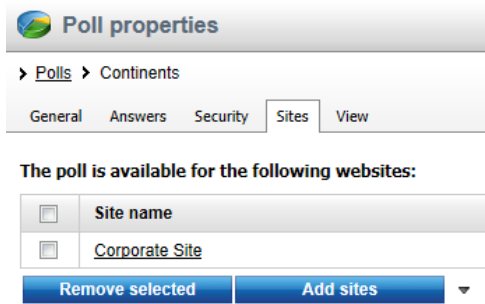

Defining who can vote

On the **Security** tab, you can choose which users can vote in your poll. For more details on who is authorized to vote in your poll, please refer to the [Security](#) topic:

Sharing a global poll between sites

On the **Sites** tab, you can choose on which sites a particular global poll will be available. It will be offered to content editors and developers of the selected websites so that they can put it into the text. By default, the site where you created the poll is added.

Poll properties

> Polls > Continents

General Answers Security **Sites** View

The poll is available for the following websites:

| <input type="checkbox"/> | Site name |
|-------------------------------------|----------------|
| <input checked="" type="checkbox"/> | Corporate Site |

Remove selected Add sites

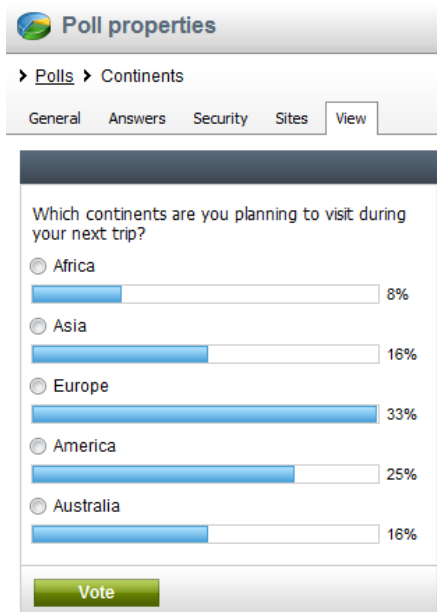

Please note

The **Sites** tab is visible only in global poll management.

Previewing the poll

You can preview the poll on the **View** tab. The actual poll on your website may use a different design depending on the design of this website. It may also behave differently depending on the web part settings (in case you publish it using a web part).

Vote

8.39.3 Publishing polls

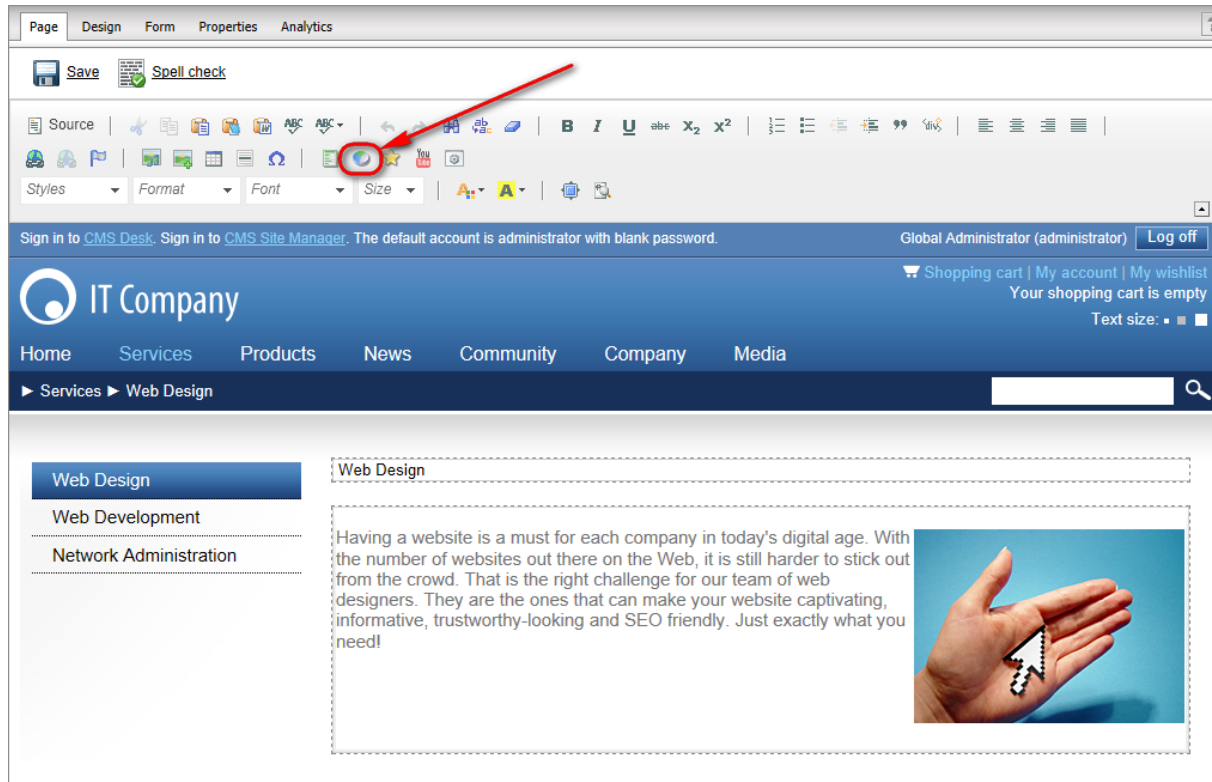

There are two ways how you can publish a poll on your website:

- [Content editors](#) can place a poll into editable regions of a page using the **Insert Poll** button on the WYSIWYG editor toolbar.
- [Developers](#) can place a poll on the page using the **Polls -> Poll** web part.

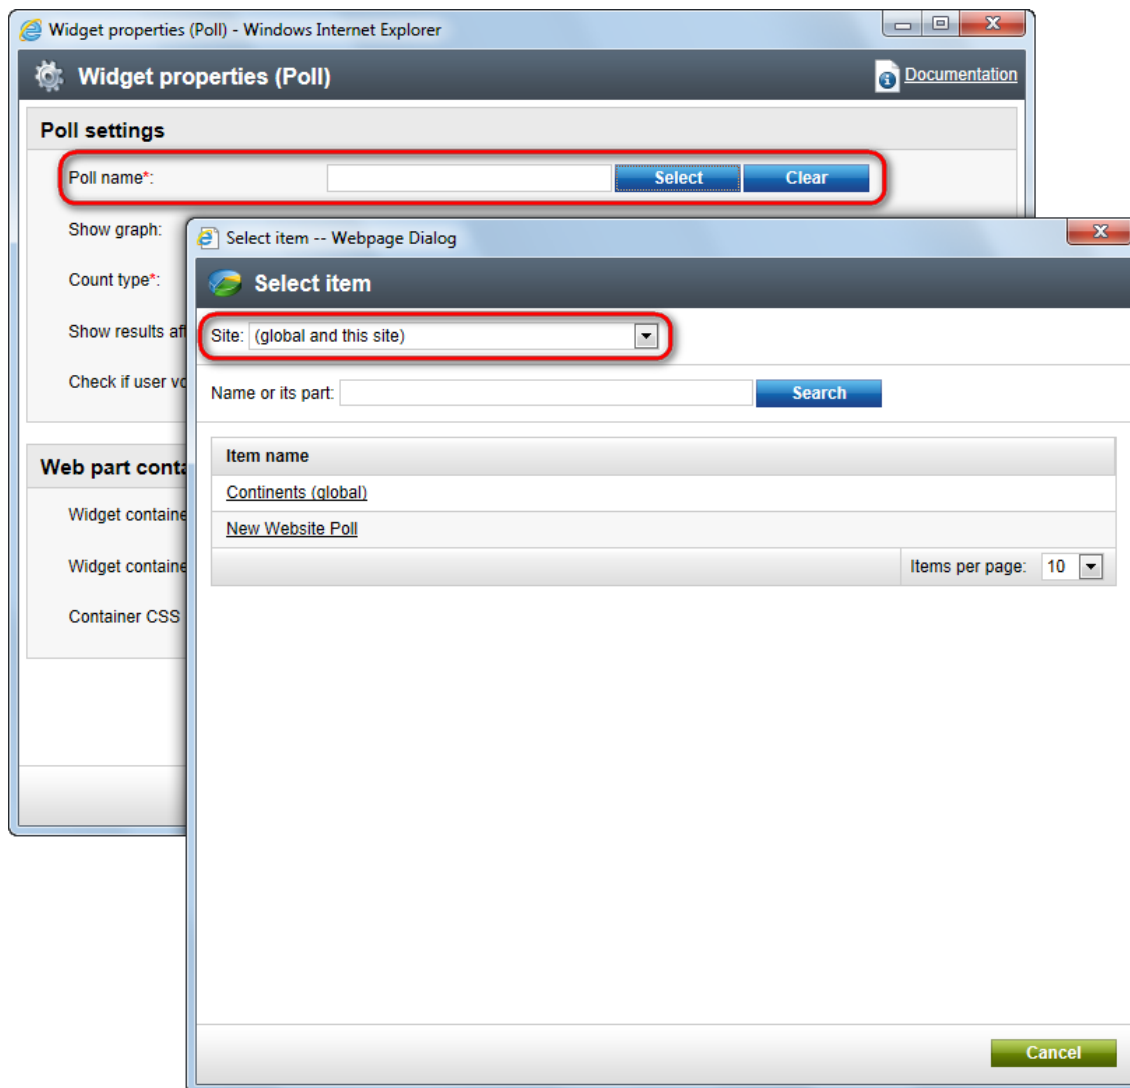

- Users with appropriate permissions can insert a poll into a widget zone of a page using the **Forms & Surveys -> Poll** widget.

Publishing polls for content editors

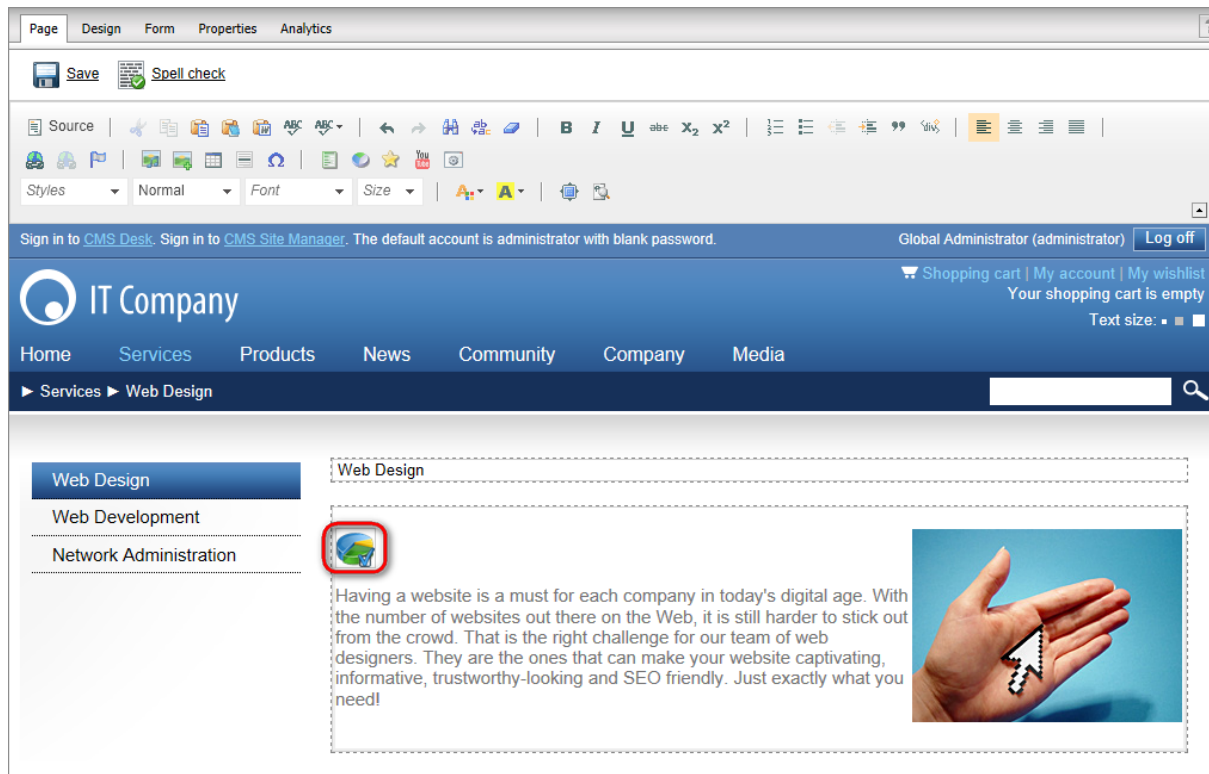

After defining your poll, you need to go to **CMS Desk -> Content** and navigate to the page where you want to have the poll displayed. Switch to the **Edit -> Page** tab and edit the page content using the built-in WYSIWYG editor. You will insert the poll by clicking the **Insert Poll** (🗳️) button on the WYSIWYG editor toolbar.

The poll will be inserted as an [Inline widget](#). First, the Poll widget's configuration dialog will be displayed, where you can set its properties. Most importantly, the poll that should be displayed must be selected via the **Poll name** property. To do this, click the **Select** button and open the **Select item** dialog window. Here you may first need to set the **Site** property [if available](#), and then select one of the available polls.

Once configured, the poll will be placed on the page, represented by a placeholder image in the editable text region. The properties of the poll widget can be edited at any time by double-clicking the placeholder image.

The placeholder image will be replaced by the actual poll on the live site.

Publishing polls for developers

If you are a developer, you can go to **CMS Desk -> Content -> Edit** and from the content tree choose the page where you want to put the poll. Switch to the **Design** tab and add the **Polls -> Poll** web part into a zone on the page.

You need to enter the code name of the poll. Then you can configure some additional settings of the poll that are described in more detail in the [Kentico CMS Web Parts](#) reference.

If you are using **ASPX page templates**, you need to drag-and-drop the `~/CMSWebParts/Polls/Poll.ascx` user control (web part) onto your ASPX page.

Please note

If both global and site poll have the same code name, the value of the **Poll name** property will be returned in the `.<pollname>` format when selecting the global poll from the **Select item** dialog.

When entering the value manually, to put the global poll on the page you need to enter the value in the same format.

Tip: Global polls not showing up in the list

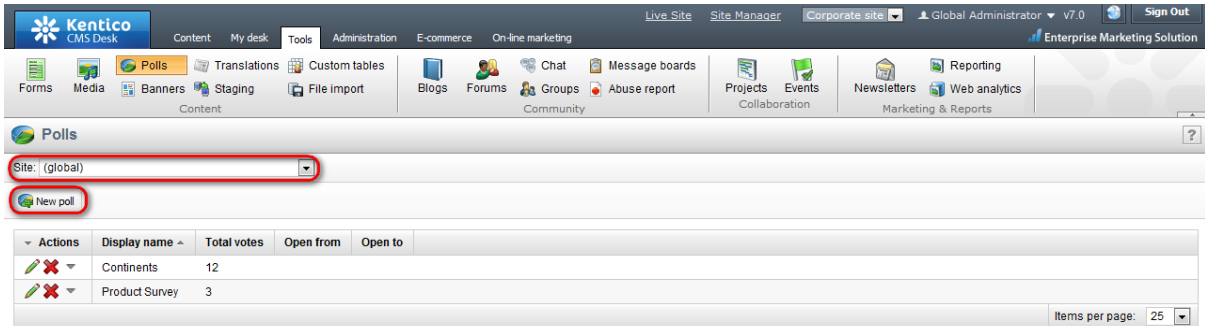

If global polls are not showing up in the list of polls, you may need to enable them in **Site Manager -> Settings -> Content -> Polls**; more details can be found in the [Security](#) topic.

You may also need to enable the particular poll for the given website. This can be done in **CMS Desk -> Tools -> Polls**; more details can be found in the [Managing polls](#) topic.

8.39.4 Adding a poll to your site

Here you will learn how to create a new poll and publish it on a page of your website. Please note that in this example, we will be creating a global poll. However, you would proceed analogically if you needed to create a site poll.

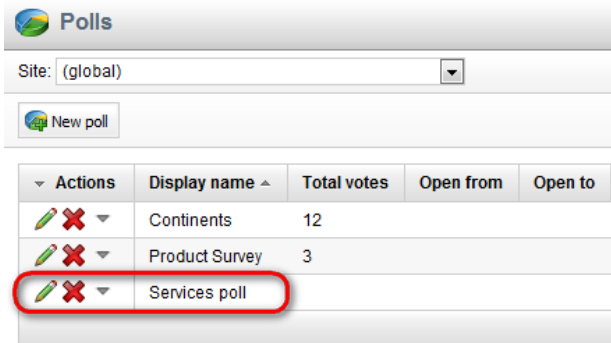

1. First go to **CMS Desk -> Tools -> Polls**, set the **Site** property to (*global*) and click **New poll**.

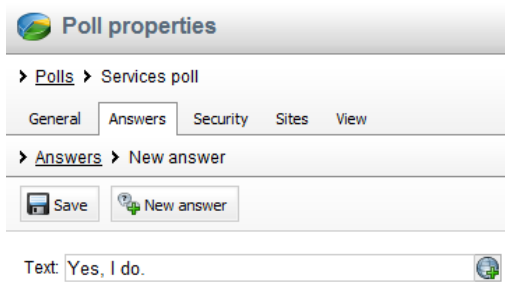

2. Enter the following information for the new poll.

- **Display name:** *Services poll*
- **Code name:** *ServicesPoll*
- **Title:** *Services poll*
- **Question:** *Do you like our services?*

Click **OK** to save the changes. If you switch back to the **CMS Desk -> Tools -> Polls** tab, the poll you have just created will be displayed in the list.

3. Now you need to define some answers for your new poll. Choose to **Edit** () the poll, in the **Poll properties** dialog switch to the **Answers** tab and click **New answer**. Enter *Yes, I do.* into the **Text** text box and click **Save**.

Poll properties

> **Polls** > Services poll

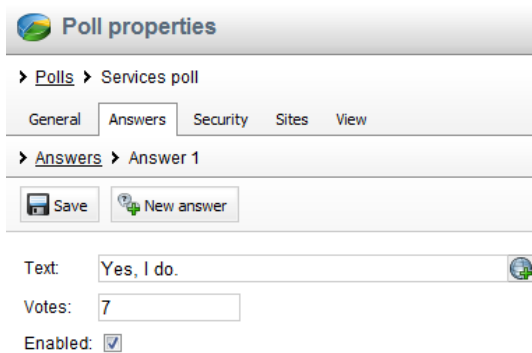

General **Answers** Security Sites View

> **Answers** > New answer

 Save  New answer

Text: 

To make the answer available on the live site, check the **Enabled** check box. Besides, you can also enter the initial value for votes. For the purpose of this example, enter 7 and  **Save** the changes.

Poll properties

> **Polls** > Services poll

General **Answers** Security Sites View

> **Answers** > Answer 1

 Save 

Text: 

Votes:

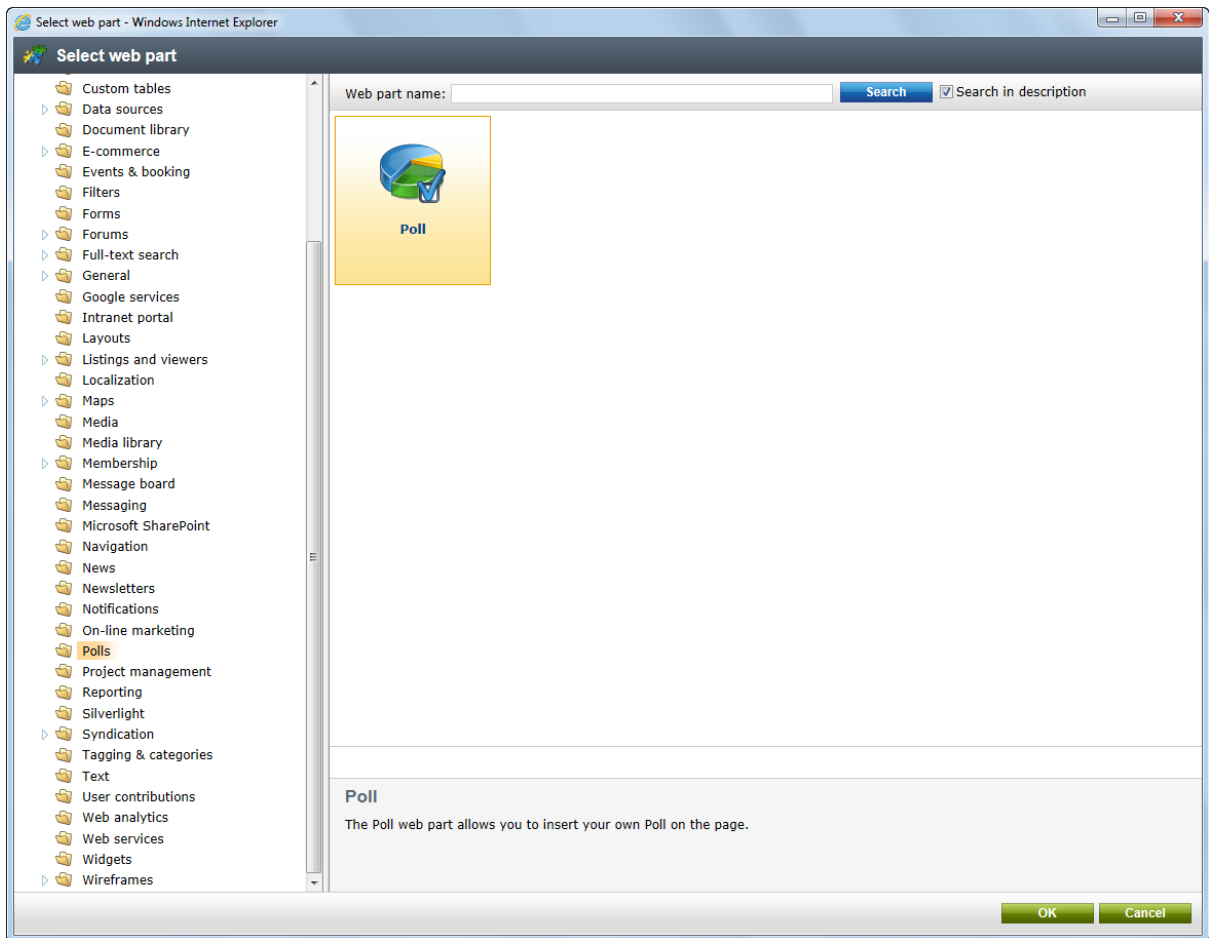

Enabled:

Repeat this step entering *No, I don't.* as an alternative answer and 3 as its initial value for votes. Optionally you can define more answers for your poll.

4. Now you are ready to publish your new poll on the website. Go to **CMS Desk -> Content**, navigate to the page where you want to add your poll and switch to the **Design** tab. Click **Add web part (+)** in one of the available web part zones

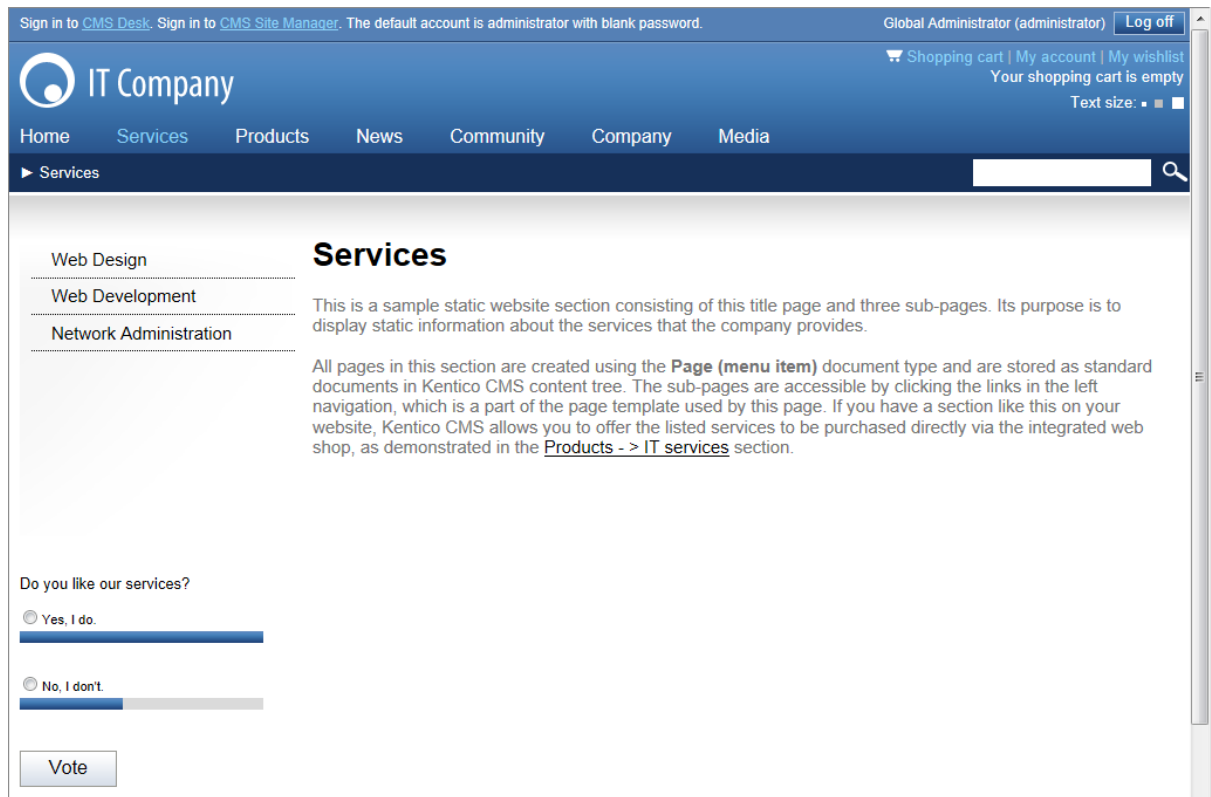

and in the **Select web part** dialog choose the **Polls** -> **Poll** web part.

5. In the **Web part properties (Poll)** dialog, make sure *.ServicesPoll* is selected as **Poll name** and click **OK**. Please note that in this dialog you can configure also some additional settings of the poll; this is described in more detail in the [Kentico CMS Web Parts](#) reference.

If you now switch to the live site, you will see that the page you have just finished editing contains your poll.

Sign in to [CMS Desk](#). Sign in to [CMS Site Manager](#). The default account is administrator with blank password. Global Administrator (administrator) [Log off](#)

Web Design

Web Development

Network Administration

This is a sample static website section consisting of this title page and three sub-pages. Its purpose is to display static information about the services that the company provides.

All pages in this section are created using the **Page (menu item)** document type and are stored as standard documents in Kentico CMS content tree. The sub-pages are accessible by clicking the links in the left navigation, which is a part of the page template used by this page. If you have a section like this on your website, Kentico CMS allows you to offer the listed services to be purchased directly via the integrated web shop, as demonstrated in the [Products - > IT services](#) section.

Do you like our services?

Yes, I do.

No, I don't.

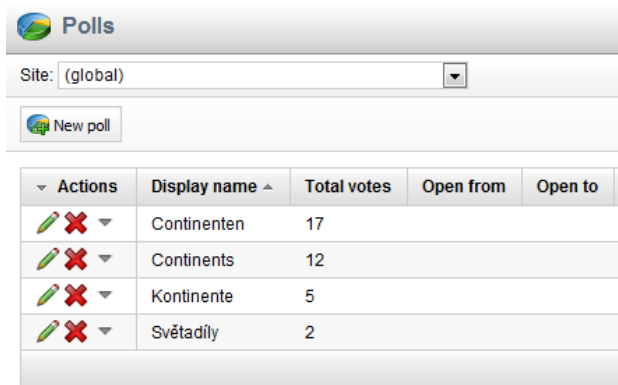

Please note

You can also add a poll to your web page using the built-in WYSIWYG editor as described in more detail in the [Publishing polls](#) topic. However, this option gives you fewer possibilities of further adjustment of your poll.

8.39.5 Multilingual support

When you use the Polls module on a multilingual website, you can choose from two options:

- You can create a **new poll for every language** - this is useful if you wish to track votes for different cultures/countries of your website.

| Actions | Display name ^ | Total votes | Open from | Open to |
|---------|----------------|-------------|-----------|---------|
| ▾ | Continenten | 17 | | |
| ▾ | Continents | 12 | | |
| ▾ | Kontinente | 5 | | |
| ▾ | Světadíly | 2 | | |

or

- You can create a **single poll for all languages** using in-place localization expressions - in this case, all votes are tracked together. In order to learn how to localize strings of the poll, please refer to the [Localization Expressions](#) topic. More detailed information on these expressions can be found in [Development -> Macro expressions](#).

If you want to create a single localized poll (or adjust an existing one to create a single localized poll), you will need to take steps similar to those described in the [Managing polls](#) topic. The main difference consists in entering localization expressions into the corresponding text fields. For example, if you would like to have your poll both in the website default language and in Czech, the macro must be entered in the `{$=Default string|cs-cz=Czech string}` format.

On the **General** tab of the **Poll properties** dialog, use localization expressions for the following fields:

- **Display name**
- **Question**
- **Message after vote**

When you have entered the new value, click  **Save** again.

Please note

To culturally localize your polls, you can also use basic localization macros. These are entered in the `{%=string.key%}` format. The system uses the `ResHelper.GetString` (“string.key”) method and replaces the macros with the appropriate resource strings. To learn more about this type of localization, please refer to the [Configuring multilingual and RTL UI](#) topic.

8.39.6 Security

Here you will learn how to configure your CMS to enable users to [access](#) the Polls module, to allow [global polls](#) and you will also learn how to configure which users are authorized to [vote](#) in the poll.

Access to the Polls module

Access to the Polls module can be configured in **CMS Desk -> Administration -> Permissions**. To view the Polls module permissions matrix, you now need to select *Module* and *Polls* from the **Permissions for:** drop-down lists.

The following [permissions](#) can be assigned to particular roles:

- **Read global** - members of the given role can view global polls and their configuration, but are not allowed to make any changes to them.
- **Modify global** - members of the given role can create, edit and delete global polls.
- **Read** - members of the given role can view site polls and their configuration, but are not allowed to make any changes to them.
- **Modify** - members of the given role can create, edit and delete site polls.

The screenshot shows the Kentico CMS Administration interface. The 'Permissions' module is selected, and the configuration is set for 'Module' and 'Polls'. The 'Report for user' is set to '(none)'. Below the configuration, a table displays the permissions matrix for various roles.

| Role | Read global | Modify global | Read | Modify |
|------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Editors | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Readers | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Facebook users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Gold Partners | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| LinkedIn users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Live ID users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Marketing Manager | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Not authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

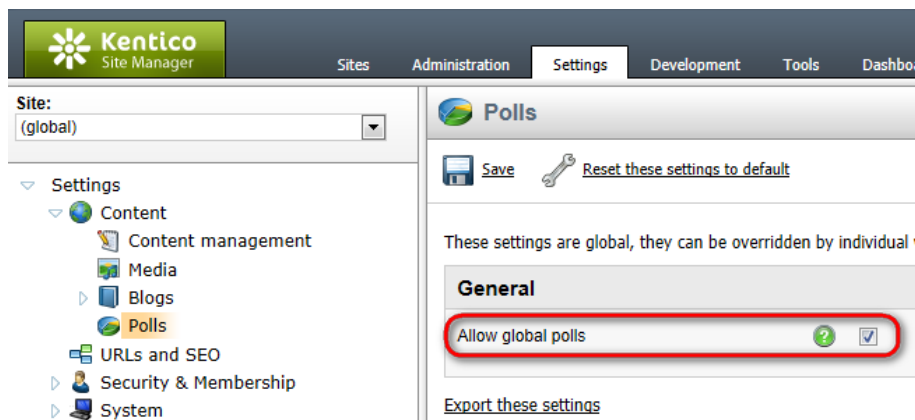

Please note

You can configure access to the Polls module also in **Site Manager -> Administration -> Permissions**. However, as this is a global interface, here you will need to select also the site for which your Polls module permissions assignment applies.

Access to global polls

By default, both global and site polls are allowed in Kentico CMS. However, if you need to restrict access to global polls on a particular website, you can disallow these polls in **Site Manager -> Settings -> Content -> Polls**.

For detailed information on how to configure these settings, please refer to the [Website settings](#) topic.

Access to voting

You can configure the poll and specify which users are authorized to vote on the **Security** tab of the **Poll properties** dialog. Here you can choose one of the following options:

- **All users** - any visitor can vote.
- **Only authenticated users** - only site members who sign in can vote.
- **Only authorized roles** - only authenticated members of chosen roles can vote.

 **Poll properties**

> Polls > Continents

General Answers **Security** Sites View

 Save

Who can vote:

All users

Only authenticated users

Only authorized roles:

Facebook users 

LinkedIn users 

Please note

To ensure that the same visitor (using the same browser) cannot vote twice in the same poll, the Polls module uses cookies.

Other security settings

Developers can customize the behavior of the **Polls** web part using the following web part properties:

- **Check permissions** - indicates if permissions for voting specified for the given poll should be checked.
- **Hide to unauthorized users** - hides the web part if the user is not authorized to vote.

8.39.7 Polls internals and API

8.39.7.1 Overview

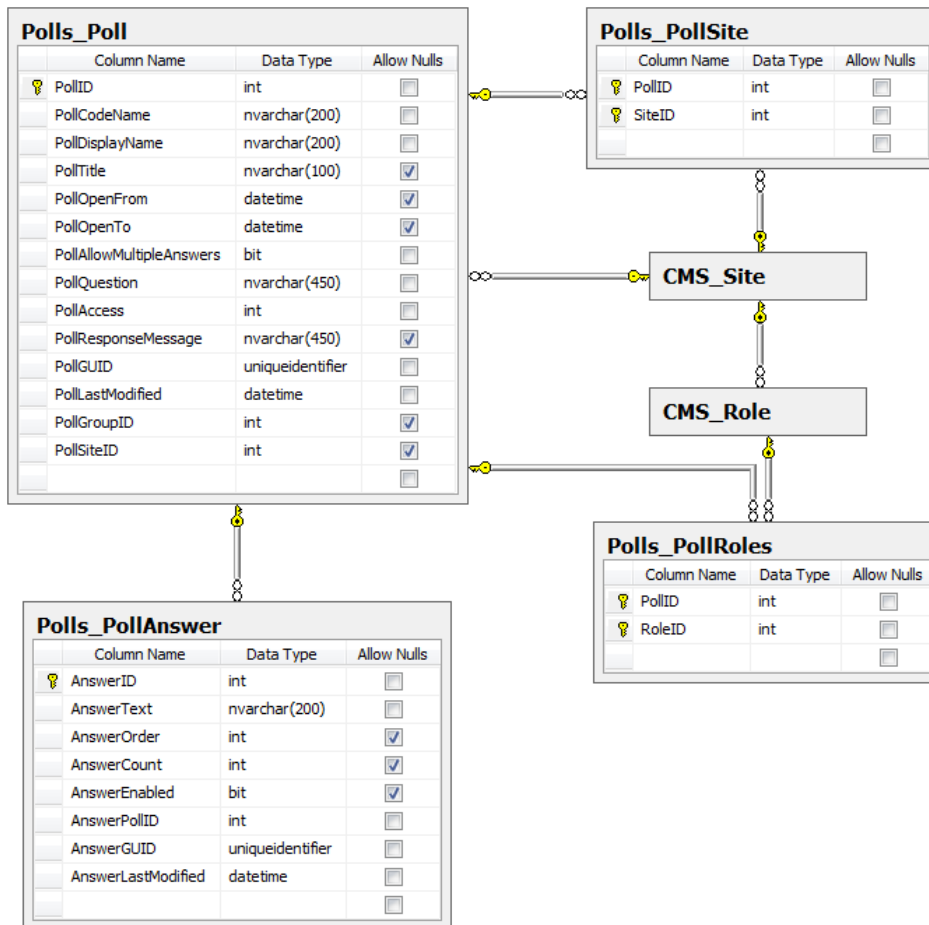

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Polls module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.39.7.2 Database tables

The following database tables are used in the Polls module:

- **Polls_Poll** - contains records representing polls.
- **Polls_PollSite** - contains records representing sites where the poll can be used (M:N).
- **Polls_PollAnswer** - contains records representing poll answers (1:N).
- **Polls_PollRoles** - contains records representing roles authorized to vote (M:N).

8.39.7.3 API classes

If you are not familiar with the database table data management by Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The Polls module classes use the **CMS.Polls** namespace.

Polls_Poll table API:

- **PollInfo** - represents one poll.
- **PollInfoProvider** - provides management of polls.

Polls_PollSite table API:

- **PollSiteInfo** - represents one site where the poll can be used.
- **PollSiteInfoProvider** - provides management of sites where the poll can be used.

Polls_PollAnswer table API:

- **PollAnswerInfo** - represents one poll answer.
- **PollAnswerInfoProvider** - provides management of poll answers.

Polls_PollRoles table API:

- **PollRolesInfo** - represents one role authorized to vote.
- **PollRolesInfoProvider** - provides management of roles authorized to vote.

8.39.7.4 API examples

8.39.7.4.1 Overview

These topics show examples of how the Polls module API can be used:

- [Managing polls](#)
- [Managing answers](#)

Please note

All API examples can be simulated in the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<your web project folder>\CMSAPIExamples\Code\Tools\Polls\Default.aspx.cs**.

The Polls module API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.Polls;
```

8.39.7.4.2 Managing polls

The following example creates a poll.

```
private bool CreatePoll()
{
    // Create new poll object
    PollInfo newPoll = new PollInfo();

    // Set the properties
    newPoll.PollDisplayName = "My new poll";
    newPoll.PollCodeName = "MyNewPoll";
    newPoll.PollTitle = "My title";
    newPoll.PollQuestion = "My question";
    newPoll.PollResponseMessage = "My response message.";
    newPoll.PollAllowMultipleAnswers = false;
    newPoll.PollAccess = 0;

    // Save the poll
    PollInfoProvider.SetPollInfo(newPoll);

    return true;
}
```

The following example gets and updates a poll.

```
private bool GetAndUpdatePoll()
{
    // Get the poll
    PollInfo updatePoll = PollInfoProvider.GetPollInfo("MyNewPoll");

    if (updatePoll != null)
    {
        // Update the properties
        updatePoll.PollDisplayName = updatePoll.PollDisplayName.ToLower();

        // Save the changes
        PollInfoProvider.SetPollInfo(updatePoll);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates polls.

```
private bool GetAndBulkUpdatePolls()
{

```

```
// Prepare the parameters
string where = "PollCodeName LIKE N'MyNewPoll%'";

// Get the data
DataSet polls = PollInfoProvider.GetPolls(where, null);

if (!DataHelper.DataSourceIsEmpty(polls))
{
    // Loop through the individual items
    foreach (DataRow pollDr in polls.Tables[0].Rows)
    {
        // Create object from DataRow
        PollInfo modifyPoll = new PollInfo(pollDr);

        // Update the properties
        modifyPoll.PollDisplayName = modifyPoll.PollDisplayName.ToUpper();

        // Save the changes
        PollInfoProvider.SetPollInfo(modifyPoll);
    }

    return true;
}

return false;
}
```

The following example adds a poll to site.

```
private bool AddPollToSite()
{
    // Get the poll
    PollInfo poll = PollInfoProvider.GetPollInfo("MyNewPoll");

    if (poll != null)
    {
        int pollId = poll.PollID;
        int siteId = CMSContext.CurrentSiteID;

        // Save the binding
        PollSiteInfoProvider.AddPollToSite(pollId, siteId);

        return true;
    }

    return false;
}
```

The following example removes a poll from site.

```
private bool RemovePollFromSite()
```

```
{
    // Get the poll
    PollInfo removePoll = PollInfoProvider.GetPollInfo("MyNewPoll");

    if (removePoll != null)
    {
        // Remove poll from site
        PollSiteInfoProvider.RemovePollFromSite(removePoll.PollID,
        CMSContext.CurrentSiteID);

        return true;
    }

    return false;
}
```

The following example deletes a poll.

```
private bool DeletePoll()
{
    // Get the poll
    PollInfo deletePoll = PollInfoProvider.GetPollInfo("MyNewPoll");

    // Delete the poll
    PollInfoProvider.DeletePollInfo(deletePoll);

    return (deletePoll != null);
}
```

8.39.7.4.3 Managing answers

The following example creates an answer.

```
private bool CreateAnswer()
{
    // Get the poll
    PollInfo poll = PollInfoProvider.GetPollInfo("MyNewPoll");

    if (poll != null)
    {
        // Create new answer object
        PollAnswerInfo newAnswer = new PollAnswerInfo();

        // Set the properties
        newAnswer.AnswerPollID = poll.PollID;
        newAnswer.AnswerText = "My new answer";
        newAnswer.AnswerEnabled = true;
        newAnswer.AnswerCount = 0;

        // Save the answer
    }
}
```

```
        PollAnswerInfoProvider.SetPollAnswerInfo(newAnswer);

        return true;
    }

    return false;
}
```

The following example gets and updates an answer.

```
private bool GetAndUpdateAnswer()
{
    // Get the answer
    PollInfo updatePoll = PollInfoProvider.GetPollInfo("MyNewPoll");

    if (updatePoll != null)
    {
        DataSet answers = PollAnswerInfoProvider.GetAnswers(updatePoll.PollID, 1,
null);

        if (!DataHelper.DataSourceIsEmpty(answers))
        {
            PollAnswerInfo updateAnswer = new PollAnswerInfo(answers.Tables[0]
.Rows[0]);

            // Update the properties
            updateAnswer.AnswerText = updateAnswer.AnswerText.ToLower();

            // Save the changes
            PollAnswerInfoProvider.SetPollAnswerInfo(updateAnswer);

            return true;
        }
    }

    return false;
}
```

The following example gets and bulk updates answers.

```
private bool GetAndBulkUpdateAnswers()
{
    PollInfo updatePoll = PollInfoProvider.GetPollInfo("MyNewPoll");

    if (updatePoll != null)
    {
        // Get the data
        DataSet answers = PollAnswerInfoProvider.GetAnswers(updatePoll.PollID);
        if (!DataHelper.DataSourceIsEmpty(answers))
        {
```

```
// Loop through the individual items
foreach (DataRow answerDr in answers.Tables[0].Rows)
{
    // Create object from DataRow
    PollAnswerInfo modifyAnswer = new PollAnswerInfo(answerDr);

    // Update the properties
    modifyAnswer.AnswerText = modifyAnswer.AnswerText.ToUpper();

    // Save the changes
    PollAnswerInfoProvider.SetPollAnswerInfo(modifyAnswer);
}

return true;
}

return false;
}
```

The following example deletes an answer.

```
private bool DeleteAnswer()
{
    // Get the poll
    PollInfo updatePoll = PollInfoProvider.GetPollInfo("MyNewPoll");

    if (updatePoll != null)
    {
        // Get the answer
        DataSet answers = PollAnswerInfoProvider.GetAnswers(updatePoll.PollID, 1,
null);

        if (!DataHelper.DataSourceIsEmpty(answers))
        {
            PollAnswerInfo deleteAnswer = new PollAnswerInfo(answers.Tables[0]
.Rows[0]);

            // Delete the answer
            PollAnswerInfoProvider.DeletePollAnswerInfo(deleteAnswer);

            return (deleteAnswer != null);
        }
    }

    return false;
}
```

8.40 Project management

8.40.1 Overview

Project management is a module that provides a system that helps organize work and keep track of its progress. This is achieved by creating objects within the Kentico CMS system called **projects**, that represent a certain segment of work with a specific goal, time frame, set of conditions or various other properties. Individual assignments called **tasks**, which are usually (but not necessarily) categorized under a certain project, can be given to users within the system.

Microsoft Office Upgrade

Project goal: Upgrade Microsoft Office on all our network computers to version 2010.

Deadline: 11/30/2010 7:41:33 PM

Progress: 52%

Project status: On track

Owner: Brad Summers (BradS)

Created by: Brad Summers (BradS)

[New task](#)

| Actions | Title | Assigned to | Progress | Estimate (hours) | Owner | Priority | Status | | | | |
|---------|-------|-------------|----------|------------------|---------------------------------------|-------------------------|--|----|----------------------|--------|--|
| | | | | | Verify installed Office versions | Ruth Baker (RuthB) | <div style="display: inline-block; width: 50px; height: 10px; background-color: #008000; margin-right: 5px;"></div> 68% | 4 | Brad Summers (BradS) | Normal | |
| | | | | | Consult budget limit with Mr. Hillman | Collin Douglas (ColinD) | <div style="display: inline-block; width: 50px; height: 10px; background-color: #008000; margin-right: 5px;"></div> 100% | 2 | Brad Summers (BradS) | High | |

Items per page: 25

Projects can be created, monitored and managed on any page (document) in the site content tree that contains the appropriate project management web parts. The document where a project is created is important, as the project is bound to that page and can only be viewed or edited on that specific page. This functionality can be used to categorize projects by having several different pages with project management web parts, which can then be individually configured.

All projects and their tasks can be administered at **CMS Desk -> Tools -> Project Management**, regardless of the document where they were created. Here, administrators can also implement custom priority and status options to be used by projects and tasks. More detailed information about administering and using projects and tasks is given in the [Managing projects and tasks](#) topic.

Project management is also integrated into the [groups](#) module. Group projects function just as described above, but they belong to a certain group in addition to being bound to the specific group page where they were created. Group projects only operate within the scope of their group, which means that tasks can only be assigned to group members, project security settings can be configured for group roles instead of site-related roles etc. This can be used to create groups for handling certain types of projects. Projects associated with a group are not displayed in the **CMS Desk -> Tools -> Project Management** interface. They can instead be managed by group or global administrators under the **Projects** tab when editing a group.

Users can manage tasks that they own or those that are assigned to them on pages containing specific project management web parts or widgets. Tasks are displayed without regard to the project they belong under or the page or group where they were created, the only thing that matters is that they are relevant to the current user (and that any permission requirements are fulfilled). If the displaying web part/widget is configured to do so, even tasks from other sites can be viewed. These web parts and widgets also allow users to create new personal tasks that aren't categorized under any group or project.

To ensure that users are aware of task assignments or any changes in tasks related to them, project management uses a system of notification e-mails based on templates, that are automatically sent when required.

An overview of the web parts and widgets that allow users to interact with the project management module on the live site can be found in the [Project management web parts and widgets](#) topic.

Permissions for project/task management are determined by many factors. Please refer to the [Security](#) topic for more information.

8.40.2 Managing projects and tasks

There are several ways how projects and their tasks can be used and managed:

Using the main project management interface

All projects that do not belong to a group can be managed by users with sufficient permissions at **CMS Desk -> Tools -> Project management -> Projects**.

| Actions | Name | Deadline | Owner | Status | Progress |
|---------|-----------------|----------|----------------------|--------|--|
| | Network Upgrade | | Brad Summers (BradS) | | <div style="width: 38%;"><div style="width: 38%;"></div></div> 38% |

Here, existing projects are displayed in a list where they may be **Edited** () or **Deleted** ()

Create a new project using **New project** and fill in the following properties:

- **Display name** - name of the project that is displayed on the live site and in the user interface.
- **Code name** - code name of the project.
- **Project goal** - text description of the purpose of the project.
- **Start date** - specifies the date and time when work on the project should start.
- **Deadline** - specifies the date and time before which the project should be complete.
- **Owner** - allows the selection of the user who will be set as the project owner. The owner is usually the user who ensures that the project is completed successfully. By default, the user who created the project is entered.
- **Status** - allows one of the predefined project statuses to be selected. Statuses are used to indicate which life cycle step the project is currently in and can be managed on the *Configuration* tab of this interface.
- **Project page** - allows the selection of a document from the current site to which the project will be bound.
- **Allow task ordering** - if enabled, the order of tasks under the project can be changed using arrow

buttons.

The screenshot shows the 'Projects' application interface. At the top, there are tabs for 'Projects', 'Tasks', and 'Configuration'. Below the tabs, the breadcrumb path is 'Projects > New project'. The form contains the following fields and controls:

- Display name:** Text input field containing 'Sample project'.
- Code name:** Text input field containing 'SampleProject'.
- Project goal:** Text area containing 'This i a project example.'.
- Start date:** Date and time picker showing '8/19/2011 12:28:49 PM' with a 'Now' button.
- Deadline:** Date and time picker with a 'Now' button.
- Owner:** Text input field containing 'Global Administrator (administrato)' with 'Select' and 'Clear' buttons.
- Status:** Dropdown menu showing 'Not started'.
- Project page:** Text input field containing '/Departments/IT/Projects' with 'Select' and 'Clear' buttons.
- Allow task ordering:** Checked checkbox.
- OK button:** A green button at the bottom of the form.

Click the **OK** button.

This will open the editing interface of the new project, where three tabs are available. The **General** tab allows the properties that were set when the project was created to be modified and the **Security** tab is where permissions for the project can be configured (learn more in the [Security](#) topic).

The **Tasks** tab contains a list of all tasks under the project, which will currently be empty.

The screenshot shows the 'Projects' application interface for editing a project. At the top, there are tabs for 'Projects', 'Tasks', and 'Configuration'. Below the tabs, the breadcrumb path is 'Projects > Sample project'. Underneath, there are sub-tabs for 'Tasks', 'General', and 'Security'. A '+ New task' button is visible. Below the sub-tabs, the message 'No tasks found.' is displayed.

Click **+ New task** and enter the following properties:

- **Title** - name of the task that is displayed on the live site and in the user interface.
- **Owner** - allows the selection of the user who will be set as the task owner. The owner is usually the user who checks that the task was completed correctly. By default, the user who created the task is entered.
- **Progress** - a percentage representing the amount of progress that has been made on the task.
- **Estimate** - is used to set an approximate amount of hours that the completion of the task should take.
- **Deadline** - specifies the date and time before which the task should be complete.
- **Status** - allows one of the predefined task statuses to be selected. Statuses are used to indicate which life cycle step the task is currently in.

- **Priority** - allows one of the predefined task priorities to be selected.
- **Is private** - if enabled, the task will only be displayed to its owner, the user to whom it is assigned and to users who have permissions to manage the project that the task belongs under (if applicable).
- **Assigned to** - allows the selection of the user who should complete this task. A notification e-mail is automatically sent to the specified user when the task is created or modified.
- **Description** - text containing the goal of the task and any other relevant information.

Click **OK**.

You can manage existing tasks using the appropriate action buttons on the left side: **Edit** () or **Delete** (). The **Send reminder** () button allows an e-mail to be sent to the user to whom the task is assigned, reminding them about the task. If the **Allow task ordering** property of the edited project is enabled, the **Move up** () and **Move down** () buttons can be used to change the order of the tasks.

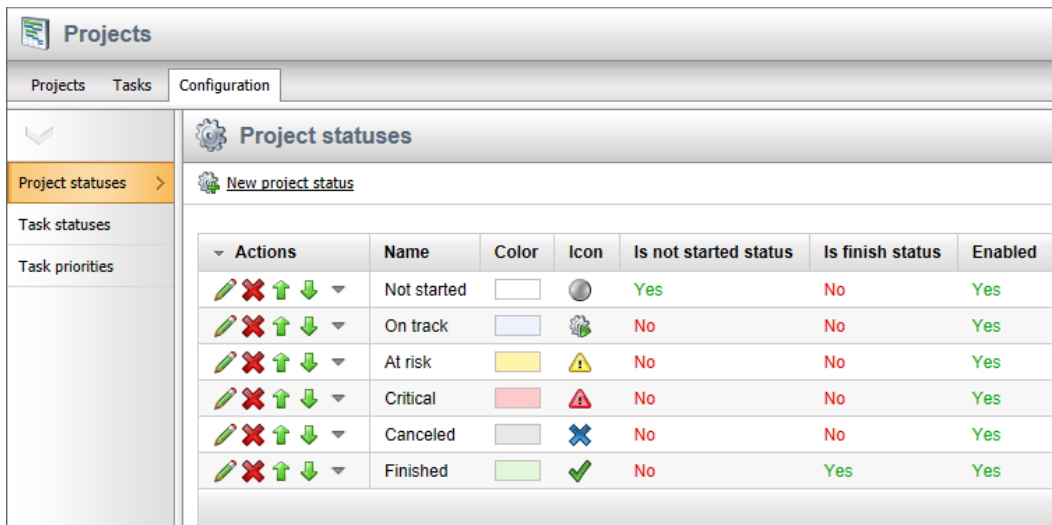

The **Tasks** tab on the top level of the project management interface is very similar to the list of tasks shown when editing a project, except that all tasks are displayed regardless of the project they belong under, including personal tasks without any project.

The screenshot shows the 'Projects' interface with the 'Tasks' tab selected. A table displays a list of tasks:

| Actions | Title | Assigned to | Progress | Estimate (hours) | Owner | Deadline | Project | Priority | Status |
|---------|---------------------------|------------------------|-----------------------------------|------------------|--------------------------------------|----------|-----------------|----------|--------|
| | Implementation of changes | Sharon Evans (SharonE) | <input type="text" value="0%"/> | 0 | Brad Summers (BradS) | | Network Upgrade | Normal | |
| | New Network Design | Ruth Baker (RuthB) | <input type="text" value="100%"/> | 0 | Brad Summers (BradS) | | Network Upgrade | Normal | |
| | Review of network design | Sharon Evans (SharonE) | <input type="text" value="30%"/> | 0 | Brad Summers (BradS) | | Network Upgrade | Normal | |
| | RFP preparation | Brad Summers (BradS) | <input type="text" value="50%"/> | 0 | Brad Summers (BradS) | | Network Upgrade | Normal | |
| | Sample task | Brad Summers (BradS) | <input type="text" value="0%"/> | 2 | Global Administrator (administrator) | | Sample project | Normal | |
| | Vendor Selection | Brad Summers (BradS) | <input type="text" value="10%"/> | 0 | Brad Summers (BradS) | | Network Upgrade | Normal | |

Items per page: 25

The **Configuration** tab is where the statuses and priorities that can be set for projects or tasks may be defined. It may only be accessed by users belonging to roles with the **Manage configuration** permission for the project management module (more information can be found in the [Security](#) topic). All the usual actions such as **Edit** () and **Delete** () are available.

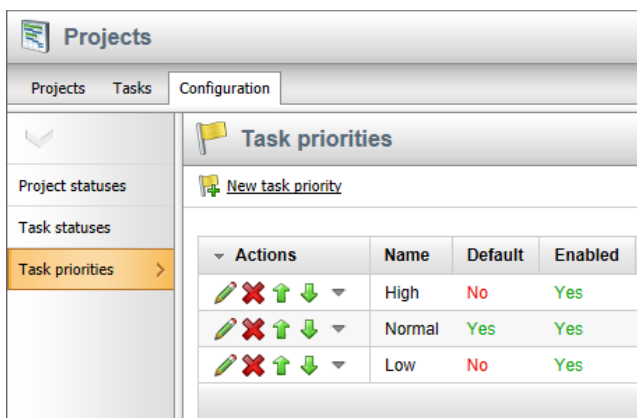

When creating or editing a **status**, the following properties can be set:

- **Display name** - name of the status that is used in the status selection list.
- **Code name** - code name of the status.
- **Status color** - determines the color of projects/tasks that have this status selected. The color selector can be used here.
- **Status icon** - contains the path to an image used as the icon of the status.
- **Is not started status** - if enabled, projects/tasks with this status are marked as not yet started.
- **Is finish status** - if enabled, projects/tasks with this status are marked as finished. A status cannot be both *not started* and *finished*.
- **Enabled** - if enabled, the status can be selected for projects.

The *not started* or *finished* flag given to a project or task by its status can have an effect on whether it is displayed by certain project management web parts or widgets, depending on their configuration.

The **Task priorities** tab is where priorities, which can be selected to determine how urgent a task is, may be managed.

The following properties are available for task priorities:

- **Display name** - name of the priority that is used in the task priority selection list.
- **Code name** - code name of the task priority.

- **Default** - if enabled, the priority is selected by default when a new task is created. Only one priority can be set as default.
- **Enabled** - if enabled, the priority can be selected for tasks.

E-mail notifications

As mentioned above, there are several types of notification e-mails that are sent to users informing them about events related to tasks that they are involved in. These e-mails are sent from the address specified in the value of the **Site Manager -> Settings -> Intranet & Collaboration -> Projects -> Send project management e-mails from** setting and their format can be customized at **Site Manager -> Administration -> E-mail templates**. The [e-mail templates](#) listed below are available:

- **Project Management - New task** - sent when a new task is assigned to the user.
- **Project Management - Changed task** - sent when an assigned or owned task is in some way modified.
- **Project Management - Overdue task** - sent when an assigned task reaches its deadline before it is finished.
- **Project Management - Task reminder** - sent when the **Send reminder** () button is used for an assigned task.

You can use the following specific [context macros](#) in project management notification templates:

- **{% TaskURL %}** - URL of the page where the given task can be edited.
- **{% ProjectTaskDescriptionPlain %}** - resolves into a plain text version of the task's description (all HTML tags are removed or converted to text equivalents).
- **{% ReminderMessage %}** - text of the message entered by the user who sent the reminder.
- **{% ReminderMessagePlain %}** - plain text version of the reminder message.

You can also access the following related objects and their properties (e.g. *{% Project.ProjectDeadline %}*, *{% Owner.FullName %}* etc.):

- **{% Project %}** - *ProjectInfo* object of the project under which the given task belongs.
- **{% ProjectTask %}** - *ProjectTaskInfo* object representing the task to which the notification is related.
- **{% ProjectTaskStatus %}** - *ProjectTaskStatusInfo* object of the task's current status.
- **{% Owner %}** - *UserInfo* object representing the task's owner.
- **{% Assignee %}** - *UserInfo* object of the user to whom the task is assigned.

Besides these special ones, you can also use all other standard macro expressions in the templates. See the [Development -> Macro expressions](#) chapter of this guide for more information about macro expressions in Kentico CMS.

Using the Group management interface

Group projects can be administered by users, who have permissions to manage a given group, by editing the group on its **Projects** tab either at **CMS Desk -> Tools -> Groups** or on-site using the **Group profile** web part. Exactly the same options are available as when using the **Projects** tab of the main project management interface described above, except that the context of the current group is used e.g. for selecting users to whom a task should be assigned.

Using CMS Desk -> My Desk

Users with access to **CMS Desk** can use the **My Desk -> Projects** interface to manage projects and

tasks that they are involved in.

| Actions | Title | Progress | Estimate (hours) | Owner | Deadline | Project | Priority | Status |
|---------|------------------|---|------------------|----------------------|----------|-----------------|----------|--------|
| | RFP preparation | <div style="width: 50%;"><div style="background-color: green; width: 50%;"></div></div> 50% | 0 | Brad Summers (BradS) | | Network Upgrade | Normal | |
| | Vendor Selection | <div style="width: 10%;"><div style="background-color: green; width: 10%;"></div></div> 10% | 0 | Brad Summers (BradS) | | Network Upgrade | Normal | |

The current user can see a list of all tasks assigned to them on the **My tasks** tab, all the projects that they have permissions to access on the **My projects** tab and all tasks that they own on the **Tasks owned by me** tab. Projects and tasks can be managed using the actions described above.

8.40.3 Project management web parts and widgets

The [web parts](#) described in this topic can be placed on pages to create an interface that allows users to work with projects and tasks directly on the live site. They can all be found in the **Project management** web part category. Additional information about using these web parts on the live site is given in the [Using project management on the live site](#) topic.

Project list

The Project list web part displays all projects that are bound to the document it is placed on and allows new ones to be created. If the document is owned by a group, only projects that belong under that group are shown.

Specific properties:

- **Show finished projects** - if enabled, projects that have a status designating a finished project are also displayed.
- **Project can be managed by** - can be used to set the *Create*, *Modify* and *Delete* permissions for the displayed projects. The selection made here overrides the security settings of individual projects. The following options can be selected:
 - *Module administrators* - each displayed project uses its individual security settings.
 - *All users* - all site users receive permissions for the displayed projects.
 - *Authenticated users* - only signed-in users receive permissions for the displayed projects.
 - *Group members* - only members of the group that the current document belongs to receive permissions for the displayed projects.
 - *Authorized roles* - only members of the roles selected in the *Authorized roles* property receive permissions for the displayed projects.
- **Authorized roles** - can be used to select the roles that should have permissions for the displayed projects if *Authorized roles* is selected in the *Project can be managed by* property.

Projects

 [New project](#)

| Actions | Name | Deadline | Owner | Status | Progress |
|---|-----------------|----------|----------------------|---|--|
|   | Network Upgrade | | Brad Summers (BradS) |  | <div style="width: 38%;"><div style="width: 38%;"></div></div> 38% |

Users with the appropriate permissions can manage the displayed projects and their tasks directly on the live site using this web part.

Items per page: 25 ▼

My projects

This web part displays a list of all projects that the current user has access permissions for. Only projects that are bound to an existing document are shown, since the projects in the list also serve as links to that document. Documents that have projects bound to them usually also contain the **Project list** web part and if this is the case, the editing interface of the linked project is automatically opened.

Specific properties:

- **Show finished projects** - if enabled, projects that have a status designating a finished project are also displayed.

MY PROJECTS

| Progress | Name | Deadline | Owner | Status |
|--|--|-----------------------|----------------------|---|
| <div style="width: 52%;"><div style="width: 52%;"></div></div> 52% | Microsoft Office Upgrade | 11/30/2010 7:41:33 PM | Brad Summers (BradS) |  |
| <div style="width: 38%;"><div style="width: 38%;"></div></div> 38% | Network Upgrade | | Brad Summers (BradS) |  |

The **My projects** [widget](#) based on this web part is included in the project management module by default.

Project tasks

This web part displays a list of tasks from a selected set of projects. Users can only view tasks from

those projects that they have access permissions for. Depending on the security settings of the selected projects, tasks can also be edited directly by clicking on their title.

Specific properties:

- **Projects** - allows the projects whose tasks should be displayed to be selected. All projects from the current site that do not belong under any group are available.
- **Show overdue tasks** - if enabled, tasks that have passed their deadline are displayed.
- **Show on time tasks** - if enabled, tasks that haven't yet reached their deadline are displayed.
- **Show private tasks** - if enabled, private tasks are displayed. They are only visible by those users who are allowed to see them.
- **Show finished tasks** - if enabled, tasks that have a status designating a finished task are displayed.
- **Show status as** - allows the way that task statuses are displayed to be selected. Possible options are *Icon*, *Text* and *Icon & Text*.
- **All task actions** - if enabled, users with the appropriate permissions are allowed to delete the displayed tasks.

| PROJECT TASKS | | | | | |
|---------------|---|----------|-----------------|----------|--------|
| Actions | Title | Deadline | Project | Priority | Status |
| ✘ | New Network Design | | Network Upgrade | Normal | ✓ |
| ✘ | Review of network design | | Network Upgrade | Normal | 🕒 |
| ✘ | RFP preparation | | Network Upgrade | Normal | 🕒 |
| ✘ | Vendor Selection | | Network Upgrade | Normal | 🕒 |
| ✘ | Implementation of changes | | Network Upgrade | Normal | 🕒 |

Tasks owned by me / Tasks assigned to me

These two web parts display a list of tasks that are either owned by or assigned to the current user. Personal tasks (those not belonging to a project) are always displayed, but project tasks are only shown if the user has permissions to access the given project. The tasks in the list can be edited directly by clicking their title.

Specific properties:

- **Show overdue tasks, Show on time tasks, Show private tasks, Show finished tasks, Show status as** - are the same as for the *Project tasks* web part described above.
- **All task actions** - if enabled, the displayed tasks can be deleted and new personal tasks (not categorized under any project) can be created using the web part.
- **Site** - can be used to select if tasks should be displayed from (*all sites*), or only the (*current site*).

| TASKS ASSIGNED TO ME | | | | | | |
|---|----------------------------------|----------|----------------------|-----------------|----------|---|
|  New personal task | | | | | | |
| Actions | Title | Deadline | Owner | Project | Priority | Status |

|---|--|------------------------|--------------------------|----------|---|---|
|  New personal task | | | | | | |
| Actions | Title | Deadline | Project | Priority | Status | |
|  | Verify installed Office versions | 11/15/2010 10:00:00 AM | Microsoft Office Upgrade | Normal |  |  |
|  | Send out the New Office Guide | 11/12/2010 5:00:00 PM | Microsoft Office Upgrade | Normal |  | |
|  | New Network Design | | Network Upgrade | Normal |  | |
|  | Review of network design | | Network Upgrade | Normal |  | |
|  | RFP preparation | | Network Upgrade | Normal |  | |
|  | Vendor Selection | | Network Upgrade | Normal |  | |
|  | Implementation of changes | | Network Upgrade | Normal |  | |

The **Tasks owned by me** and **Tasks assigned to me** [widgets](#) based on these two web parts are included in the project management module by default.

Task info panel

The Task info panel can be used to display a message containing task related information, usually showing the amount of tasks that are assigned to the current user serving as a link to a document where the details of the tasks can be viewed.

Specific properties:

- **Task detail page URL** - contains the URL of the document that is linked when the displayed message is clicked. If left empty, the value is taken from the *Site Manager* -> *Settings* -> *Intranet & Collaboration* -> *Projects* -> *Task detail page* field. In the case that neither of these locations contain a value, the message will not work as a link.
- **Info text** - contains the text of the displayed message. It may contain the `{0}` formatting macro expression, which will be resolved into the number of tasks assigned to the current user. Sample value: `{0} active task(s)`
- **Include not started tasks** - if enabled, tasks that have a status designating a task that has not been started yet are counted by the web part.
- **Include finished tasks** - if enabled, tasks that have a status designating a finished task are counted by the web part.

8.40.4 Using project management on the live site

Users can work with projects and tasks on the live site through [Project management web parts and widgets](#). The actions that are available to users depend on project security settings and the configuration of specific web parts or widgets.

The **Project list** web part allows projects, that are bound to the document it is placed on, to be managed in a similar fashion as in the administration interface, which is described in the [Managing projects and](#)

[tasks](#) topic.

Projects

New project

Description:

[Rich text editor toolbar and content area]

Task URL:

In addition to the task properties described in the [Managing projects and tasks](#) topic, the **Task URL** is shown, which can be used to link to the edited task.

Certain other web parts and widgets, such as **Tasks assigned to me**, may be used to edit displayed tasks in the same way.

8.40.5 Security

Permissions for administering the project management module can be set by going to **CMS Site Manager** (or **CMS Desk**) -> **Administration** -> **Permissions** and selecting *Module* and then *Project Management* through the **Permissions for** drop-down lists.

Permissions

Site:

Permissions for:

Report for user: Show only this user's roles

| Role | Manage | Manage configuration | Read |
|------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Editors | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Readers | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

The following permissions can be assigned to members of the selected roles:

- **Manage** - members of the selected roles are allowed to create, modify and delete data in the project management interface, except for the *Configuration* tab.
- **Manage configuration** - members of the selected roles are allowed to view and modify data, such as statuses and priorities, on the *Configuration* tab of the project management interface.
- **Read** - members of the selected roles are allowed to view all data in the project management interface, except for the *Configuration* tab.

To access and use the management interface for group projects, users must either have the **Read** and **Manage** permissions from the *Groups Permission matrix*, or belong to a group role that can manage the given group.

Project permissions

Permissions for individual projects can be configured on the **Security** tab when editing a project. This affects which users can view and manage the project and its tasks using project management web parts.

Projects

Projects Tasks Configuration

> Projects > Network Upgrade

Tasks General Security

| | Access to project | Create | Modify | Delete |
|---------------------|----------------------------------|----------------------------------|----------------------------------|----------------------------------|
| Nobody | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| All users | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Authenticated users | <input checked="" type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Authorized roles | <input type="radio"/> | <input checked="" type="radio"/> | <input checked="" type="radio"/> | <input checked="" type="radio"/> |

Please select the authorized roles (available only when you select the "Authorized roles" option above):

| | Access to project | Create | Modify | Delete |
|--|--------------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| <input type="text"/> <input type="button" value="Search"/> | | | | |
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CEO | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CFO | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CIO | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

The following permissions are available:

- **Access to project** - users with this permission can view and access the project.
- **Create** - users with this permission can create new tasks under the project.
- **Modify** - users with this permission can modify the tasks under the project.
- **Delete** - users with this permission can delete the tasks under the project.

These permissions can be assigned to:

- **Nobody** - nobody can perform the action.
- **All users** - all users can perform the action.
- **Authenticated users** - only signed-in users can perform the action, i.e. anonymous public users cannot perform it.
- **Group members** - only members of the group can perform the action; this option is only available for projects that belong under a group.
- **Authorized roles** - only members that are assigned to the roles selected below can perform the action; for group projects, only the roles defined for the given group can be selected.

Project security exceptions

1. The user who is set as the owner of a project automatically has full permissions for that project.
2. A task can be modified by users that it is assigned to or owned by regardless of the security settings of the project that the task belongs under.

3. Users who belong to roles that have the **Manage** permission for the project management module have full permissions for all projects that do not belong to a group.
4. Users who belong to roles that can manage a group have full permissions for all projects under the given group.
5. The **Project list** web part has its own security properties that can be used to override the permissions set for the projects that it displays.

8.40.6 Settings

Additional settings of the project management module are located in **Site Manager -> Settings -> Intranet & Collaboration -> Projects**. The following can be configured:

- **Task detail page** - URL of a page that displays detailed information about the tasks assigned to users. This page should contain the *Tasks assigned to me* web part. The value of this setting is used for generating links to personal tasks in project management e-mail notifications and as the URL that is linked to by the *Task info panel* web part if its *Task detail page URL* property is empty. Sample value: `~/Employees/Management/My-Projects-and-tasks.aspx`
- **Send project management e-mails from** - sets the e-mail address from which automatic project management notification e-mails are sent when tasks are created or modified.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The 'Settings' section is expanded, showing a tree view of settings categories: Content, URLs and SEO, Security & Membership, System, On-line marketing, E-commerce, Community, Intranet & Collaboration (selected), Events, Projects (highlighted), Versioning & synchronization, Integration, and Cloud services. The 'Projects' settings page is displayed, showing a 'Save' button and a 'Reset these settings to default' link. The settings are for the 'global' site. The 'General' section contains two settings: 'Task detail page' with a value of '~Employees/Management/My-Projects-and-tasks' and 'Send project management emails from' with a value of 'no-reply@localhost.local'. There is also an 'Export these settings' link.

8.40.7 Project management internals and API

8.40.7.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used by the Project management module. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the module's classes, please refer to [Kentico CMS API Reference](#).

8.40.7.2 Database tables

The following database tables are used to store project management data:

- **PM_Project** - contains records representing projects.
- **PM_ProjectStatus** - stores possible project statuses.
- **PM_ProjectRolePermission** - stores relationships between projects and roles as well as a permission type. Each entry in this table indicates that users belonging to the given role have the specified permission for a project.
- **PM_ProjectTask** - contains records representing project management tasks.
- **PM_ProjectTaskPriority** - stores task priorities.
- **PM_ProjectTaskStatus** - stores possible task statuses.

8.40.7.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Project management module can be found in the **CMS.ProjectManagement** namespace.

PM_Project table API:

- **ProjectInfo** - represents one project.
- **ProjectInfoProvider** - provides management functionality for projects.

PM_ProjectStatus table API:

- **ProjectStatusInfo** - represents one project status.
- **ProjectStatusInfoProvider** - provides management functionality for project statuses.

PM_ProjectRolePermission table API:

- **ProjectRolePermissionInfo** - represents a relationship between a project, role and permission.
- **ProjectRolePermissionInfoProvider** - provides management functionality for project-role relationships.

PM_ProjectTask table API:

- **ProjectTaskInfo** - represents one task.
- **ProjectTaskInfoProvider** - provides management functionality for tasks.

PM_ProjectTaskPriority table API:

- **ProjectTaskPriorityInfo** - represents a task priority.
- **ProjectTaskPriorityInfoProvider** - provides management functionality for task priorities.

PM_ProjectTaskStatus table API:

- **ProjectTaskStatusInfo** - represents a task status.
- **ProjectTaskStatusInfoProvider** - provides management functionality for task statuses.

Other classes:

- **Reminder** - this class is used to send project management e-mail reminders.

8.40.7.4 API examples

8.40.7.4.1 Overview

These topics show examples of how the API of the Project management module can be used:

- [Managing projects](#)
- [Managing tasks](#)
- [Managing project security](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Tools\ProjectManagement\Default.aspx.cs**.

The project management API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.ProjectManagement;
using CMS.SiteProvider;
```

8.40.7.4.2 Managing projects

The following example creates a project.

```
private void CreateProject()
{
    ProjectStatusInfo status = ProjectStatusInfoProvider.GetProjectStatusInfo
("NotStarted");

    if (status != null)
    {
        int currentUserID = CMSContext.CurrentUser.UserID;

        // Create new project object
        ProjectInfo newProject = new ProjectInfo();

        // Set the properties
        newProject.ProjectDisplayName = "My new project";
        newProject.ProjectName = "MyNewProject";
        newProject.ProjectStatusID = status.StatusID;
        newProject.ProjectSiteID = CMSContext.CurrentSiteID;
```

```
newProject.ProjectOwner = currentUserID;
newProject.ProjectCreatedByID = currentUserID;

// Save the project
ProjectInfoProvider.SetProjectInfo(newProject);
}
}
```

The following example gets and updates a project.

```
private bool GetAndUpdateProject()
{
    // Get the project
    ProjectInfo updateProject = ProjectInfoProvider.GetProjectInfo("MyNewProject",
CMSContext.CurrentSiteID, 0);
    if (updateProject != null)
    {
        // Update the properties
        updateProject.ProjectDisplayName =
updateProject.ProjectDisplayName.ToLower();

        // Save the changes
        ProjectInfoProvider.SetProjectInfo(updateProject);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates projects.

```
private bool GetAndBulkUpdateProjects()
{
    // Prepare the parameters
    string where = "ProjectName LIKE N'MyNewProject%'";
    string orderBy = "";
    int topN = 0;
    string columns = "";

    // Get the data
    DataSet projects = ProjectInfoProvider.GetProjects(where, orderBy, topN,
columns);
    if (!DataHelper.DataSourceIsEmpty(projects))
    {
        // Loop through the individual items
        foreach (DataRow projectDr in projects.Tables[0].Rows)
        {
            // Create object from DataRow
            ProjectInfo modifyProject = new ProjectInfo(projectDr);
        }
    }
}
```

```
        // Update the properties
        modifyProject.ProjectDisplayName =
modifyProject.ProjectDisplayName.ToUpper();

        // Save the changes
        ProjectInfoProvider.SetProjectInfo(modifyProject);
    }

    return true;
}

return false;
}
```

The following example deletes a project.

```
private bool DeleteProject()
{
    // Get the project
    ProjectInfo deleteProject = ProjectInfoProvider.GetProjectInfo("MyNewProject",
CMSContext.CurrentSiteID, 0);

    // Delete the project
    ProjectInfoProvider.DeleteProjectInfo(deleteProject);

    return (deleteProject != null);
}
```

8.40.7.4.3 Managing tasks

The following example creates a project management task.

```
private bool CreateProjectTask()
{
    ProjectInfo project = ProjectInfoProvider.GetProjectInfo("MyNewProject",
CMSContext.CurrentSiteID, 0);
    ProjectTaskStatusInfo status =
ProjectTaskStatusInfoProvider.GetProjectTaskStatusInfo("NotStarted");
    ProjectTaskPriorityInfo priority =
ProjectTaskPriorityInfoProvider.GetProjectTaskPriorityInfo("Normal");

    if ((project != null) && (status != null) && (priority != null))
    {
        // Create new project task object
        ProjectTaskInfo newTask = new ProjectTaskInfo();

        int currentUserID = CMSContext.CurrentUser.UserID;

        // Set the properties
        newTask.ProjectTaskDisplayName = "My new task";
    }
}
```

```
newTask.ProjectTaskCreatedByID = currentUserID;
newTask.ProjectTaskOwnerID = currentUserID;
newTask.ProjectTaskAssignedToUserID = currentUserID;
newTask.ProjectTaskStatusID = status.TaskStatusID;
newTask.ProjectTaskPriorityID = priority.TaskPriorityID;
newTask.ProjectTaskProjectID = project.ProjectID;

// Save the project task
ProjectTaskInfoProvider.SetProjectTaskInfo(newTask);

return true;
}

return false;
}
```

The following example gets and updates a task.

```
private bool GetAndUpdateProjectTask()
{
    // Prepare the parameters
    string where = "ProjectTaskDisplayName LIKE N'My new task%'";
    string orderBy = "";
    int topN = 0;
    string columns = "";

    // Get the data
    DataSet tasks = ProjectTaskInfoProvider.GetProjectTasks(where, orderBy, topN,
columns);
    if (!DataHelper.DataSourceIsEmpty(tasks))
    {
        // Get the project task
        ProjectTaskInfo updateTask = new ProjectTaskInfo(tasks.Tables[0].Rows[0]);
        if (updateTask != null)
        {
            // Update the properties
            updateTask.ProjectTaskDisplayName =
updateTask.ProjectTaskDisplayName.ToLower();

            // Save the changes
            ProjectTaskInfoProvider.SetProjectTaskInfo(updateTask);

            return true;
        }
    }

    return false;
}
```

The following example gets and bulk updates tasks.

```
private bool GetAndBulkUpdateProjectTasks()
```

```
{
    // Prepare the parameters
    string where = "ProjectTaskDisplayName LIKE N'My new task%'";
    string orderBy = "";
    int topN = 0;
    string columns = "";

    // Get the data
    DataSet tasks = ProjectTaskInfoProvider.GetProjectTasks(where, orderBy, topN,
columns);
    if (!DataHelper.DataSourceIsEmpty(tasks))
    {
        // Loop through the individual items
        foreach (DataRow taskDr in tasks.Tables[0].Rows)
        {
            // Create object from DataRow
            ProjectTaskInfo modifyTask = new ProjectTaskInfo(taskDr);

            // Update the properties
            modifyTask.ProjectTaskDisplayName =
modifyTask.ProjectTaskDisplayName.ToUpper();

            // Save the changes
            ProjectTaskInfoProvider.SetProjectTaskInfo(modifyTask);
        }

        return true;
    }

    return false;
}
```

The following example deletes a task.

```
private bool DeleteProjectTask()
{
    // Prepare the parameters
    string where = "ProjectTaskDisplayName LIKE N'My new task%'";
    string orderBy = "";
    int topN = 0;
    string columns = "";

    // Get the data
    DataSet tasks = ProjectTaskInfoProvider.GetProjectTasks(where, orderBy, topN,
columns);
    if (!DataHelper.DataSourceIsEmpty(tasks))
    {
        // Get the project task
        ProjectTaskInfo deleteTask = new ProjectTaskInfo(tasks.Tables[0].Rows[0]);

        // Delete the project task
        ProjectTaskInfoProvider.DeleteProjectTaskInfo(deleteTask);
    }
}
```

```
        return (deleteTask != null);
    }

    return false;
}
```

8.40.7.4.4 Managing project security

The following example configures the security settings of a project.

```
private bool SetSecurity()
{
    // Get the project
    ProjectInfo project = ProjectInfoProvider.GetProjectInfo("MyNewProject",
        CMSContext.CurrentSiteID, 0);

    if (project != null)
    {
        // Set properties
        project.AllowCreate = SecurityAccessEnum.AllUsers;
        project.AllowDelete = SecurityAccessEnum.Owner;
        project.AllowRead = SecurityAccessEnum.AuthorizedRoles;

        ProjectInfoProvider.SetProjectInfo(project);

        return true;
    }

    return false;
}
```

The following example assigns a project permission to a role.

```
private bool AddAuthorizedRole()
{
    // Get the project
    ProjectInfo project = ProjectInfoProvider.GetProjectInfo("MyNewProject",
        CMSContext.CurrentSiteID, 0);
    RoleInfo role = RoleInfoProvider.GetRoleInfo("CMSDeskAdmin",
        CMSContext.CurrentSiteID);
    PermissionNameInfo permission =
        PermissionNameInfoProvider.GetPermissionNameInfo
        ("AccessToProject", "ProjectManagement", null);

    if ((project != null) && (role != null) && (permission != null))
    {
        // Add relationship
        ProjectRolePermissionInfoProvider.AddRelationship(project.ProjectID,
            role.RoleID, permission.PermissionId);
    }
}
```

```
        return true;
    }

    return false;
}
```

The following example removes a project permission from a role.

```
private bool RemoveAuthorizedRole()
{
    // Get the project
    ProjectInfo project = ProjectInfoProvider.GetProjectInfo("MyNewProject",
CMSContext.CurrentSiteID, 0);
    RoleInfo role = RoleInfoProvider.GetRoleInfo("CMSDeskAdmin",
CMSContext.CurrentSiteID);
    PermissionNameInfo permission =
PermissionNameInfoProvider.GetPermissionNameInfo("AccessToProject",
"ProjectManagement", null);

    if ((project != null) && (role != null) && (permission != null))
    {
        // Remove relationship
        ProjectRolePermissionInfoProvider.RemoveRelationship(project.ProjectID,
role.RoleID, permission.PermissionId);

        return true;
    }

    return false;
}
```

8.41 Reporting

8.41.1 Overview

The Reporting module allows you to create internal reports to watch the activity in the Kentico CMS system and on the website, such as recently created documents, expired documents, website visits, user registration etc. The data the module uses is gathered from the database by using SQL queries and can be displayed in highly customizable reports including tables and graphs.

Report categories are used to group related reports together. See the [Managing report categories](#) topic for more details.

The following topics provide more details and examples on how reports can be created and used:

- [Creating new reports](#)
- [Defining report parameters](#)
- [Saving reports](#)
- [Displaying reports on the website](#)
- [Report subscriptions](#)

The [Security](#) topic describes how permissions can be set up for the reporting module.

The [Reporting internals and API](#) sub-chapter provides information about the database tables and classes used by the module and examples of how reports can be accessed using the API.

Reports are also used by the Web analytics module to display measured data, which you can learn more about in [Modules -> Web analytics](#).

Reports can be managed in **CMS Desk -> Tools -> Reporting**.

Important!

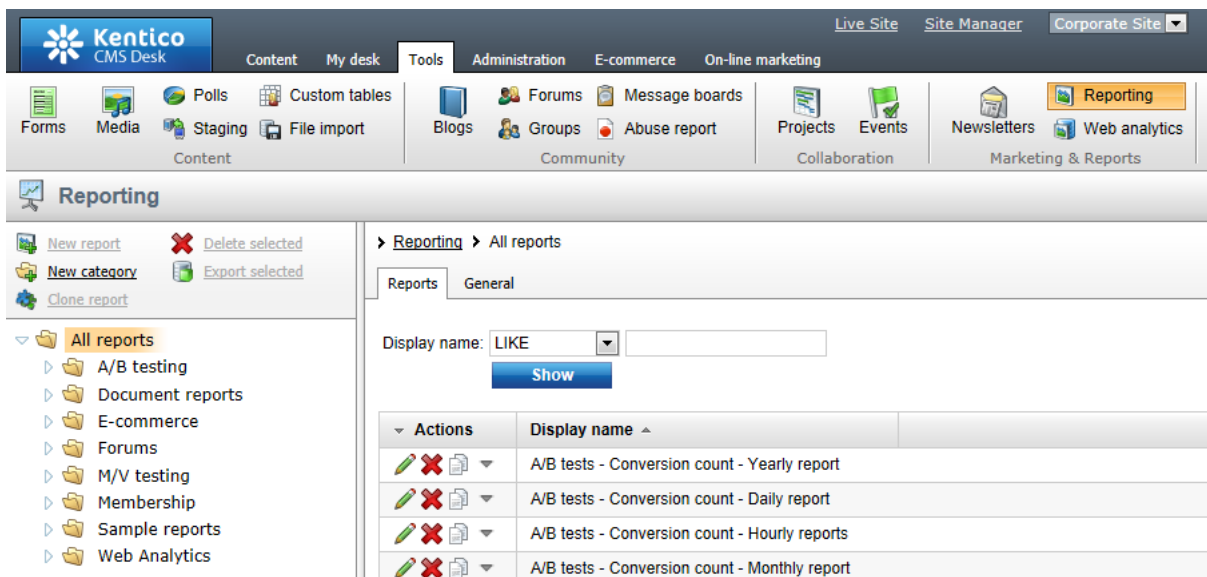

The graphs provided by the module are based on MS Charting Controls for ASP.NET.

If your application uses the 3.5 SP1 version of the .NET Framework and you plan to host it in a medium trust environment, it is necessary to ensure that the MS Chart package is installed on the server. The installation executable can be downloaded from the Microsoft website: <http://www.microsoft.com/download/en/details.aspx?id=14422>

The required assemblies are already included in .NET Framework 4.0, so the installation is not necessary if your application uses this version.

8.41.2 Managing report categories

All reports are organized into categories in a hierarchical tree. It is recommended to keep reports that monitor related actions in one category. You can manage the categories in **CMS Desk -> Tools -> Reporting**.

| Actions | Display name ^ |
|---------|---|
| | A/B tests - Conversion count - Yearly report |
| | A/B tests - Conversion count - Daily report |
| | A/B tests - Conversion count - Hourly reports |
| | A/B tests - Conversion count - Monthly report |

Example

The following steps describe how to create a sample report and how to display it on your website:

To start, you need to create a report category. Go to **CMS Desk -> Tools -> Reporting**, select the root of the reporting tree (the **All reports** category by default) click  **New category** and enter *User reports* as the **Category display name**. You can leave the code name as (*automatic*). Then click **OK**.

The tutorial is continued in the example section of the [Creating new reports](#) topic.

8.41.3 Creating new reports

8.41.3.1 Creating new reports

To create new reports, select a report category from the tree in **CMS Desk -> Tools -> Reporting** and click  **New report**. Existing reports can also be deleted () , cloned () or exported () .

When editing a report on its **General** tab, you can configure the following properties:

| | |
|---------------------------------------|---|
| Report display name | Sets the name of the report displayed in the administration interface. |
| Report code name | A unique name that serves as an identifier of the report, for example in the API or URLs. |
| Report category | Shows the category under which the report belongs. You can move the report to a different category by selecting one from the drop-down. |
| Allow public users to see this report | Indicates if the report should be visible by public users if it is published on the website using a reporting web part. |
| Connection string | <p>Sets the database connection string used by the report's components (graphs, tables and values) when loading data. You can override this value for individual components by editing their details.</p> <p>Only users who have the Set connection string permission for the <i>Reporting</i> module are allowed to change this property's value.</p> <p>The system retrieves the list of connection strings from the <code><connectionStrings></code> section of the application's web.config file. The (<i>default</i>) option represents the <i>CMSConnectionString</i> added by the application's initial database installer.</p> <p>You can check the Inherit box to load the value from the Default report connection string setting configured in Site Manager -> Settings -> Security & Membership.</p> <p>You can use reporting connection strings for the following scenarios:</p> <ul style="list-style-type: none"> Retrieving data from a Separated on-line marketing database Restricting the database-level permissions of reporting queries via a connection string with a limited database user |
| Enable subscription | <p>If enabled, users with the <i>Subscribe</i> permission for the <i>Reporting</i> module are allowed to subscribe to the report and its components (graphs, tables or values).</p> <p>This setting is also available when configuring the details of individual</p> |

components. Subscribing to specific components is only possible if both settings are enabled.

Enter the layout of the report using the built-in [WYSIWYG editor](#). To retrieve and display information from the CMS database, add the following objects into the report's layout:

- [Tables](#)
- [Graphs](#)
- [HTML graphs](#)
- [Values](#)

Additionally, macro expressions as described in [Development -> Macro expressions](#) are supported in the report layout.

You can view the output of the report on the **View** tab.

Localizing strings in reports

If you need to create a single report in multiple languages, follow the instructions given in the [Localization Expressions](#) topic.

Example

1. Click  **New report** and enter the following values:

- **Report display name:** Pages by page template
- **Report code name:** PagesByPageTemplate

Click **OK**. Now you can edit the layout of the report and insert tables, graphs and values.

2. The **General** tab of the report editing interface opens. Enter the following text into the **Layout** text area: *Pages by page template*. Select the text and use the WYSIWYG editor to set its **Format** to *Heading 1*.

Reporting > User reports > Pages by page template

View | General | Parameters | Saved reports | Subscriptions | Versions

Save

Report display name: Pages by page template

Report code name: PagesByPageTemplate

Report category: User reports

Connection string: (default)

Inherit

Allow public users to see this report:

Enable subscription:

Layout:

Source | Styles | Heading 1 | Font | Size | A | (#) | [Icons]

Pages by page template

body h1

Graphs: (please select chart) [Insert] [New] [Icons]

HTML graphs: (please select chart) [Insert] [New] [Icons]

Tables: (please select table) [Insert] [New] [Icons]

Values: (please select value) [Insert] [New] [Icons]

Click  **Save**.

Continued in the example section of the [Creating new tables](#) topic.

8.41.3.2 Creating new tables

Tables allow you to retrieve data from the Kentico CMS database using an SQL query. You can display the data by placing the table into the layout of a report.

The following properties can be used to configure tables:

| Default | |
|---------------|--|
| Display name | The name of the table shown in the user interface. |
| Code name | Name used in your code. |
| Enable export | If enabled, users who view the table are able to export the displayed data to external files using the Microsoft Excel |

| | |
|---------------------|---|
| | (XLSX), CSV or XML format. The data export feature may be accessed by right-clicking the table in the report, which opens a context menu with possible export actions. |
| Enable subscription | If enabled, users will be able to subscribe to the currently edited report table. To allow subscriptions, it is also necessary to have the Enable subscription box checked on the General tab of the given report. |
| Query | |
| Query | Here you can add the SQL query used to retrieve data to be displayed by the table. |
| Is stored procedure | Indicates if the query is a stored procedure or not. |
| Connection string | <p>Sets the database connection string used by the table's query.</p> <p>Only users who have the Set connection string permission for the <i>Reporting</i> module are allowed to change this value.</p> <p>The system loads the list of connection strings from the <code><connectionStrings></code> section of the application's web.config file. The <i>(default)</i> option represents the <i>CMSConnectionString</i> added by the application's initial database installer.</p> <p>You can check the Inherit box to load the Connection string value set for the parent report.</p> |
| No record text | Text to be displayed if the query doesn't return any data. |
| Skin | |
| Skin ID | ID of the .NET skin (stored in the .skin files in <code>~/AppThemes/<theme name></code>) which will be used for the table. |
| Paging | |
| Enable paging | If enabled, paging will be enabled when the report table is displayed. The paging can be configured by the two properties below. |
| Page size | Number of table rows per page. |
| Paging mode | <p>Type of paging controls displayed below the table. The following options are available:</p> <ul style="list-style-type: none"> • Previous-next buttons - displays buttons leading to the previous and next page • Page numbers - displays page numbers leading to the corresponding pages • Previous-next-first-last buttons - displays buttons leading to the first, last, previous and next page • Page numbers-first-last buttons - displays page numbers leading to the corresponding pages and buttons leading to the first and last page |

Tables are entered into the report layout editor as an expression in the following format:

```
%%control:ReportTable?<report code name>.<table code name>%%
```

This is done automatically when the **Insert** button is used.

Writing queries for tables

The queries you write for tables are standard SQL queries that pull data from the Kentico CMS database. You can find the description of Kentico CMS database tables and views in **Kentico CMS Database Reference** that is a part of the standard installation.

For information about documents, you can use the *View_CMS_Tree_Joined* table that returns published versions of all documents.

Table column names

The table column names use the same names as the column names from the returned data set. If you need to use user friendly names, you can use the following syntax in the query:

```
SELECT PageTemplateName AS [Template Name], ...
```

Example

1. Click **New** in the **Tables** section below the layout editor. Enter the following values:

- **Display name:** Pages by Page Template
- **Code name:** PagesByPageTemplate
- **Query:**

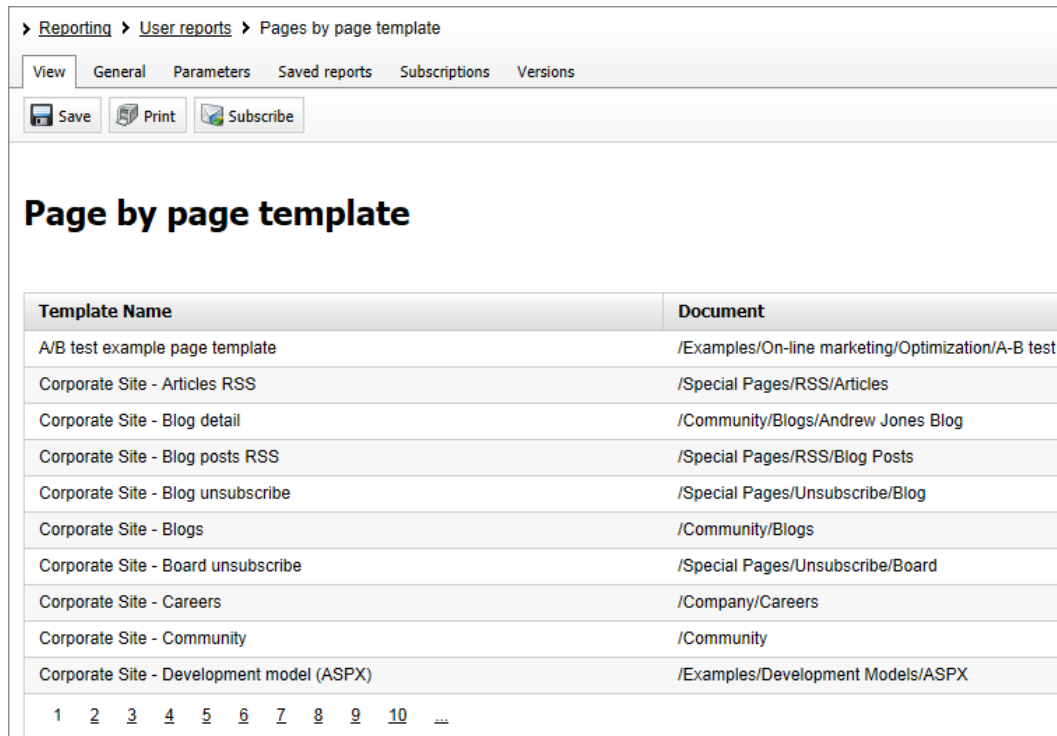

```
SELECT PageTemplateName AS [Template Name], DocumentNamePath AS [Document]
FROM View_CMS_Tree_Joined
LEFT JOIN CMS_PageTemplate
ON CMS_PageTemplate.PageTemplateID = View_CMS_Tree_Joined.DocumentPageTemplateID
WHERE PageTemplateName IS NOT NULL AND PageTemplateIsReusable = 1
ORDER BY PageTemplateName
```

- **Is stored procedure:** no
- **SkinID:** leave empty
- **Enable paging:** enabled
- **Page size:** 10
- **Page mode:** Page numbers

Click **OK**.

2. Place the cursor in the layout editor on a new line under the title, select the table from the drop-down list in the **Tables** section and click **Insert**. A string like `%%control:ReportTable?PagesByPageTemplate.PagesByPageTemplate%%` is added to the text area.

Click  **Save** and switch to the **View** tab. You will see a report like this:

The screenshot shows a web interface for a report. At the top, there is a breadcrumb trail: Reporting > User reports > Pages by page template. Below this are tabs for View, General, Parameters, Saved reports, Subscriptions, and Versions. Under the View tab, there are buttons for Save, Print, and Subscribe. The main content area has the title "Page by page template" and a table with two columns: "Template Name" and "Document". The table lists various templates and their corresponding document paths. At the bottom of the table, there is a pagination control showing numbers 1 through 10 and an ellipsis.

| Template Name | Document |
|---|---|
| A/B test example page template | /Examples/On-line marketing/Optimization/A-B test |
| Corporate Site - Articles RSS | /Special Pages/RSS/Articles |
| Corporate Site - Blog detail | /Community/Blogs/Andrew Jones Blog |
| Corporate Site - Blog posts RSS | /Special Pages/RSS/Blog Posts |
| Corporate Site - Blog unsubscribe | /Special Pages/Unsubscribe/Blog |
| Corporate Site - Blogs | /Community/Blogs |
| Corporate Site - Board unsubscribe | /Special Pages/Unsubscribe/Board |
| Corporate Site - Careers | /Company/Careers |
| Corporate Site - Community | /Community |
| Corporate Site - Development model (ASPX) | /Examples/Development Models/ASPX |

Continued in the example section of the [Creating new graphs](#) topic.

8.41.3.3 Creating new graphs

Graphs can be placed into the layout of a report. They allow you to retrieve data from the Kentico CMS database and display it in various types of visual formats.

The following properties can be used to configure graphs:

Default:

| | |
|---------------|---|
| Display name | Display name of the graph shown in the user interface. |
| Code name | Code name of the graph. |
| Enable export | If enabled, users who view the graph are able to export the displayed data to external files using the Microsoft Excel (XLSX), CSV or XML format. The data export feature may be accessed by right-clicking the graph in the report, which opens a context menu with possible export actions. |

| | |
|---------------------|--|
| Enable subscription | If enabled, users will be able to subscribe to the currently edited report graph. To allow subscriptions, it is also necessary to have the Enable subscription box checked on the General tab of the given report. |
|---------------------|--|

Query:

| | |
|---------------------|--|
| Query | Database query that extracts the data that will be displayed in the graph. It must return at least two columns: first one for categories, the other columns are used for values. |
| Is stored procedure | Indicates if the specified query is a stored procedure. |
| Connection string | <p>Sets the database connection string used by the graph's query.</p> <p>Only users who have the Set connection string permission for the <i>Reporting</i> module are allowed to change this value.</p> <p>The system loads the list of connection strings from the <code><connectionStrings></code> section of the application's web.config file. The <i>(default)</i> option represents the <i>CMSConnectionString</i> added by the application's initial database installer.</p> <p>You can check the Inherit box to load the Connection string value set for the parent report.</p> |
| No record text | Text to be displayed if the query doesn't return any data. |

Chart type:

| | |
|---------------|--|
| Graph type | <p>The following graph types are available:</p> <p>Bar chart - bar graph, accepts multiple values and displays them next to each other.</p> <p>Bar stacked chart - bar graph, accepts multiple values and displays them on top of each other.</p> <p>Pie chart - pie graph, accepts only one column for values.</p> <p>Line chart - line graph, accepts multiple values and displays them as separate lines.</p> |
| Drawing style | <p>The following chart styles are available:</p> <p>Bar chart:</p> <ul style="list-style-type: none"> • Bar - uses rectangular column bars |

- **Cylinder** - uses cylinders

Bar stacked chart:

- **Bar** - uses rectangular bars

- **Cylinder** - uses cylinders

- **Area** - uses a line chart with the space under the lines filled with the respective color

Pie Chart:

- **Pie** - uses a standard circular chart divided into sectors

- **Doughnut** - uses a circular chart with a blank center

Line chart:

- **Line** - uses straight lines to connect values

- **SpLine** - uses smooth curved lines

| | |
|--------------------|---|
| |  |
| Overlay | If enabled, charts with multiple values display them behind each other with the lower values in the front. Only available for Bar charts displayed in 3D. |
| 100% stacked | If enabled, values are displayed as a percentage of their category's column. Only available for Bar stacked charts . |
| Orientation | Determines if bars are displayed horizontally or vertically. Only available for Bar and Bar stacked charts with the Bar drawing style. |
| Drawing design | Determines the aesthetic design of Pie charts . |
| Label style | Determines the style of 'pie piece' descriptions for Pie charts . |
| Doughnut radius | Determines the width of Doughnut style Pie charts . Larger numbers decrease the size of the center. Only available for Pie charts with the Doughnut drawing style. |
| Collect pie slices | Items that represent a smaller percentage of the Pie chart than the value entered here will be added together and displayed as a single item labeled <i>Others</i> . This ensures that pie charts remain legible, even if there are many items with very small values. |
| Show as 3D | If enabled, charts are displayed in 3D. |
| Rotate X | Rotates the chart around its X axis. Accepts values from -90 to 90. Only available if Show as 3D is enabled. |
| Rotate Y | Rotates the chart around its Y axis. Accepts values from -180 to 180. Only available if Show as 3D is enabled. |
| Width | Determines the width of the chart image. |
| Height | Determines the height of the chart image. |
| Show Grid | Shows a thin dotted line grid in the graph chart, Not available for Pie charts . |

Title:

| | |
|-------------|---|
| Title | Title of the chart. |
| Title font | Determines font properties of the chart title. |
| Title color | Determines the color of the chart title. Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. |

| | |
|----------------|---|
| Title position | Determines the position of the chart title. |
|----------------|---|

Legend:

| | |
|------------------|---|
| Background color | Determines the background color of the legend. Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. |
| Border color | Determines the border color of the legend. Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. |
| Border size | Determines the size of the legend border. |
| Border style | Determines the style of the legend border. |
| Position | Determines the position of the legend in the chart. |
| Legend inside | If enabled, the legend is displayed inside the chart area. |
| Fixed legend | <p>Allows a custom description to be set for the value in the legend that will be used instead of the name of the source column. This field is only usable for charts that display one type of series, i.e. each item has a single value. It also cannot be used for Pie charts.</p> <p>It is possible to enter static text or use a macro that resolves into the currently selected value of a report parameter in format {%<parameter name>%}.</p> <p>For example, if the report has a parameter named <i>CampaignName</i> that allows users to display the statistics of a selected marketing campaign, {%CampaignName%} could be entered into this field, and the legend value description would automatically contain the name of the currently displayed campaign.</p> |
| Legend title | Sets the text caption of the legend. |

X-axis:

| | |
|---------------|--|
| X axis title | Title of the horizontal axis in the chart. |
| Title color | Determines the color of the X axis title. Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. |
| X axis angle | Determines the declination angle of X axis descriptions. Setting this parameter to 90 causes upright descriptions. Accepts values from -90 to 90. |
| X axis format | <p>Can be used to specify the format of item descriptions on the X axis that are in numerical or date-time format.</p> <p>Numeric formatting:</p> |

| | |
|--------------------|---|
| | <p>Numbers can be formatted using .NET Custom numeric format strings enclosed in curly brackets.</p> <p>Examples:</p> <p><i>{Item #}</i> - X axis descriptions will be displayed as <i>Item 1, Item 2</i> etc.
 <i>{0.00}</i> - numeric X axis descriptions will be displayed with precision of two decimal places.</p> <p>Date and time formatting:</p> <p>The format can be set using single-letter .NET Standard date and time format specifiers without quotes.</p> <p>In addition, any custom formatting can be defined using expressions enclosed in curly brackets. For example, <i>{yyyy - MM - dd - hh:mm}</i> would specify a date and time format like:
 2010 - 08 - 19 - 12:30</p> |
| Title font | Determines font properties of the X axis title. |
| Position | Determines the position of the X axis title. |
| Axis label font | Determines font properties of X axis descriptions. |
| X axis interval | Sets the interval between X axis descriptions. |
| Use X axis sorting | If enabled, values are connected in the order they appear in on the X axis, otherwise they are connected in the order they have in the returned dataset. Only used by Line charts and Bar Stacked charts with the Area drawing style. |

Y-axis:

| | |
|---------------------|--|
| Y axis title | Title of the vertical axis in the chart. |
| Title color | Determines the color of the Y axis title. Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. |
| Y axis angle | Determines the declination angle of Y axis descriptions. Setting this parameter to 90 causes upright descriptions. Accepts values from -90 to 90. |
| Y axis format | Can be used to specify the format of value descriptions on the Y axis that are in numerical or date-time format. The same formatting options can be used as in the X axis format field described above. |
| Use X axis settings | If enabled, X axis settings are used for the Title font , Position and Axis label font properties. |
| Title font | Determines font properties of the Y axis title. |
| Position | Determines the position of the Y axis title. |
| Axis label font | Determines font properties of Y axis descriptions. |

Series:

| | |
|----------------------------|--|
| Primary background color | Determines the primary color of series items in the chart. Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. Not available for Line charts . |
| Secondary background color | Determines the secondary color of series items in the chart. Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. Not available for Line charts . |
| Gradient | Gradient of the colors of the series items in the chart. Transitions from Primary to Secondary background colors . Not used when displayed in 3D. Not available for Line charts . |
| Border color | Determines the border color for series items in the chart. Not available for Line charts . |
| Border size | Determines the border size for series items in the chart. Not available for Line charts . |
| Border style | Determines the border style for series items in the chart. Not available for Line charts . |
| Display item value | If enabled, values are displayed above series items. |
| Item value format | <p>Sets the format of the text displaying the values of series items in the chart. This overrides the Display item value property.</p> <p>Standard MS chart keywords can be placed into this field, such as for example:</p> <ul style="list-style-type: none"> • #VALX - displays the current value of the X axis. • #VALY - displays the current value of the Y axis. • #AXISLABEL - displays the current X axis label. • #INDEX - displays a number determined by the order of the series item on the X axis, starting from 0. • #SER - displays the name of the current series, i.e. the type of the value. <p>If the current value is numerical, the displayed format can be modified by adding the following parameters after the keyword:</p> <ul style="list-style-type: none"> • {P} - displays the number as a percentage. • {C} - displays the number as a monetary amount in the currency of the current language culture. specified in the browser; please be aware that this does not convert the value, it only influences the format. • {F} - displays the number with a floating point, this is the default parameter. • {E} - displays the number in exponential format. <p>The number of digits after the decimal point can be specified within the curly brackets.</p> |

| | |
|-------------------|--|
| | For example #VALY{F2} displays Y axis values with a floating point and a precision of 2 decimal places. |
| Line color | Determines the line color used in Line charts . Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. |
| Line size | Determines the line size used in Line charts . |
| Line style | Determines the style used in Line charts . Not used when displayed in 3D. |
| Symbols | Determines the symbols used for values in Line charts . |
| Item tooltip | Determines the content and format of the tooltip that is displayed when hovering over a series item in the chart. This field supports both Kentico CMS macro expressions and standard MS chart keywords as described in the Item value format property. |
| Item link | Causes the series items in the chart to serve as links to the specified URL when clicked. The same macro expressions and keywords as described in the Item tooltip property can be used here as well. |
| Values as percent | <p>If checked, graphs with multiple types of series (several values per item) will convert item values into a percentage out of the sum of all values for that item.</p> <p>For example, if an item has two values, 3 and 9, they would be converted to 25 and 75 respectively.</p> <p>When using this setting, it is necessary to set the Chart Area -> Scale max property to at least 100 to ensure that all types of data are displayed correctly.</p> <p>Not available for Pie charts, since these already display one type of value as a percentage.</p> |

Chart area:

| | |
|----------------------------|---|
| Primary background color | Determines the primary background color of the chart area. Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. |
| Secondary background color | Determines the secondary background color of the chart area. Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. |
| Gradient | Gradient of the chart area background colors. Transitions from Primary to Secondary background colors . |
| Border color | Determines the border color of the chart area. Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. |

| | |
|-------------------|---|
| Border size | Determines the size of the chart area border. |
| Border style | Determines the style of the chart area border. |
| Scale min | Sets the minimum Y axis value that is required for an X axis category to be displayed. Not used by Pie charts . |
| Scale max | Sets the maximum value that is displayed on the Y axis. Not used by Pie charts . |
| Ten powers | If large values are present in the chart, they are divided by appropriate ten powers and the division ratio is displayed with the y-axis title. Not used by Pie charts . |
| Reverse Y axis | If enabled, the vertical axis is reversed. Not used by Pie charts . |
| Border skin style | Determines the skin of the chart area border. |

Plot area:

| | |
|----------------------------|--|
| Primary background color | Determines the primary background color of the plot area. Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. |
| Secondary background color | Determines the secondary background color of the plot area. Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. |
| Gradient | Gradient of the plot area background colors. Transitions from Primary to Secondary background colors . |
| Border color | Determines the border color of the plot area. Accepts standard HTML color names and hexadecimal color codes or the color selector can be used. |
| Border size | Determines the size of the plot area border. |
| Border style | Determines the style of the plot area border. |

Graphs are entered into the report layout editor as an expression in the following format:

```
%%control:ReportGraph?<report code name>.<graph code name>%%
```

This is done automatically when the **Insert** button is used.

Writing queries for pie charts

The queries for pie chart graphs must return two columns: the item categories and their values. The graph automatically calculates the displayed size of the given category.

Writing queries for bar graphs

The queries for bar chart graphs must return at least two columns: the item categories

and their values. If you specify more than two columns, the additional columns will be displayed side-by-side (**Bar charts**), in front of each other (**Bar charts with the Overlay** setting enabled), on top of each other (**Bar stacked charts**) or they will divide one column by percentage (**Bar stacked charts with the 100% stacked** setting enabled).

Writing queries for line charts

The queries for line chart graphs must return at least two columns: the item categories and their values. If you specify more than two columns, the additional columns will be displayed as separate lines.

Example

1. Switch back to the **General** tab. Click the **New** button in the **Graphs** section below the layout editor. Enter the following values:

- **Display name:** Favorite Page Templates
- **Code name:** FavoritePageTemplates
- **Query:**

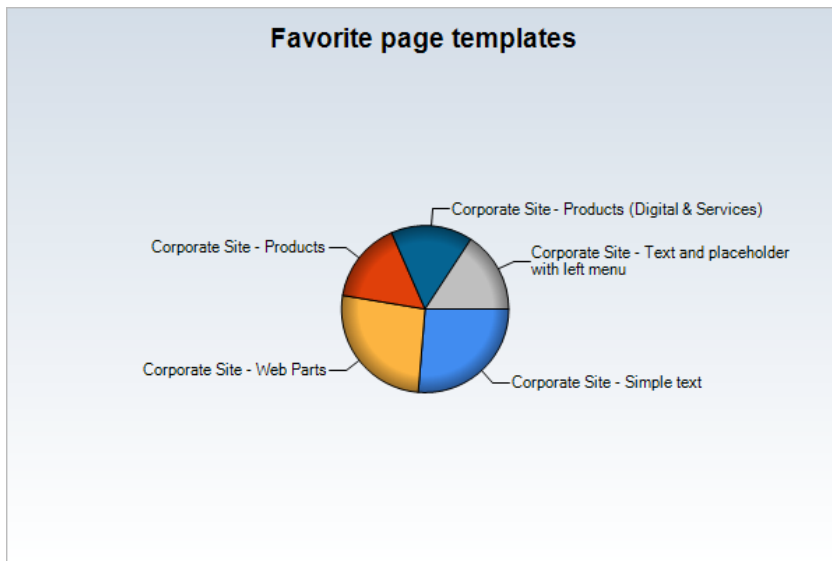

```
SELECT TOP 5 PageTemplateDisplayName AS [Template Name], COUNT
(PageTemplateDisplayName) AS [Usage]
FROM View_CMS_Tree_Joined
LEFT JOIN CMS_PageTemplate
ON CMS_PageTemplate.PageTemplateID = View_CMS_Tree_Joined.DocumentPageTemplateID
WHERE PageTemplateDisplayName IS NOT NULL AND PageTemplateIsReusable = 1
GROUP BY PageTemplateDisplayName
ORDER BY COUNT(PageTemplateDisplayName) DESC
```

- **Graph type:** Pie chart
- **Title:** Favorite page templates
- **Series -> Display item value:** Disabled (unchecked)

Click **OK**.

2. Now place the cursor in the layout editor on a new line under the table, select the graph from the drop-down list in the **Graphs** section and click **Insert**. A string like `%%control:ReportGraph?PagesByPageTemplate.MostFavoritePageTemplates%%` is added to the text area.

Click  **Save** to save the changes and switch to the **View** tab. You will see a graph similar to this in the report:

Continued in the example section of the [Creating new values](#) topic.

8.41.3.4 HTML graphs

In addition to the [image-based graphs](#) described in the previous topic, data can be visually represented in HTML graphs. Graphs of this type are composed purely out of HTML code (table and DIV elements). As a result, they can be dynamically scaled according to the amount of data that needs to be displayed, unlike an image with a predefined size.

HTML graphs always use a horizontal bar layout, which can easily be extended to display any number of items. In most cases where scaling is not an issue, it is recommended to use standard graphs, since they offer more customization options and graphical flexibility.

Like other reporting tools, HTML graphs retrieve the data to be displayed using queries. The queries must return at least two columns: the first column is used for items and the others for their values. If more than two columns are specified, the values of these additional columns will be displayed below each other as differently colored bars.

By default, data is displayed in descending order, i.e. with the newest items at the top of the graph.

When creating or editing a HTML graph, the following properties are available:

Default:

| | |
|---------------------|---|
| Display name | Display name of the graph shown in the user interface. |
| Code name | Code name of the graph. |
| Enable export | If enabled, users who view the graph are able to export the displayed data to external files using the Microsoft Excel (XLSX), CSV or XML format. The data export feature may be accessed by right-clicking the graph in the report, which opens a context menu with possible export actions. |
| Enable subscription | If enabled, users will be able to subscribe to the currently edited HTML graph. To allow subscriptions, it is also necessary to have the Enable subscription box checked on the General tab of the given report. |

Query:

| | |
|---------------------|---|
| Query | Database query that extracts the data that will be displayed in the graph. It must return at least two columns: first one for categories, the other columns are used for values. |
| Is stored procedure | Indicates if the specified query is a stored procedure. |
| Connection string | <p>Sets the database connection string used by the graph's query.</p> <p>Only users who have the Set connection string permission for the <i>Reporting</i> module are allowed to change this value.</p> <p>The system loads the list of connection strings from the <code><connectionStrings></code> section of the application's <code>web.config</code> file. The <i>(default)</i> option represents the <code>CMSConnectionString</code> added by the application's initial database installer.</p> <p>You can check the Inherit box to load the Connection string value set for the parent report.</p> |
| No record text | Text to be displayed if the query doesn't return any data. |

Title:

| | |
|-------|------------------------------|
| Title | Sets the title of the graph. |
|-------|------------------------------|

Legend:

| | |
|----------------|--|
| Legend title | Sets the text caption of the legend. |
| Display legend | Indicates if the legend should be displayed. |

Series:

| | |
|-------------------|--|
| Item name format | <p>Can be used to specify the format of item descriptions on the X axis that are in numerical or date-time format.</p> <p>Numeric formatting:</p> <p>Numbers can be formatted using .NET Custom numeric format strings.</p> <p>Examples:</p> <p><i>Item #</i> - X axis descriptions will be displayed as <i>Item 1</i>, <i>Item 2</i> etc.
 <i>{0.00}</i> - numeric X axis descriptions will be displayed with precision of two decimal places.</p> <p>Date and time formatting:</p> <p>The format can be set using single-letter Standard date and time format specifiers without quotes.</p> <p>In addition, any custom formatting can be defined. For example, <i>yyyy - MM - dd - hh:mm</i> would specify a date and time format like: 2010 - 08 - 19 - 12:30</p> |
| Item value format | <p>Sets the format of the text displaying the values of series items on the Y axis of the graph.</p> <p>This field supports all types of Kentico CMS macro expressions. The following context macros should be used most frequently:</p> <ul style="list-style-type: none"> • {%ser%} - resolves into the name of the current item's series, i.e. the type of the value. • {%xval%} - resolves into the X axis value of the current item. • {%yval%} - resolves into the Y axis value of the current item. • {%pval%} - resolves into the percentage that the value of the current item represents out of the sum of all values in the graph. If there are multiple types of Y axis values, they are all included in the total sum. <p>The format of the values can additionally be specified using the macro parameters listed in the topic linked above.</p> <p>Examples:</p> <ul style="list-style-type: none"> • {%ser%} = {%yval%} - displays the name of the series and its value (e.g. <i>Visits = 287</i>). • {%pval (todouble)0.0 (format){0:0.0}%}% - displays the item's percentage value rounded to one decimal place (e.g. <i>5.1%</i>). |
| Item tooltip | <p>Determines the content and format of the tooltip that is displayed when hovering over a series item in the graph. The macro expressions described in the Item value format property can also be used in this field.</p> |
| Item link | <p>Causes the series items in the graph to serve as links to the specified</p> |

| | |
|--|--|
| | URL when clicked. The macro expressions described in the Item value format property can also be used in this field. |
|--|--|

HTML graphs are entered into the report layout editor as an expression in the following format:

`%%control:ReportHtmlGraph?<report code name>.<graph code name>%%`

This is done automatically when the **Insert** button is used.

HTML graphs on the live site

Because of the way they are constructed, HTML graphs are only displayed correctly in the administration interface. The necessary styles will not be applied on the live site.

Therefore, it is recommended to avoid publishing reports containing HTML graphs on your website (more information about this process can be found in the [Displaying a report on the website](#) topic).

8.41.3.5 Creating new values

A value is an object that you can place into the layout of a report, which can be used to display a single scalar value returned by a query in a specified string format.

The following properties of a value can be configured:

| | |
|---------------------|--|
| Default | |
| Display name | The name of the item in the list |
| Code name | Name used in your code |
| Enable subscription | If enabled, users will be able to subscribe to the currently edited report value. To allow subscriptions, it is also necessary to have the Enable subscription box checked on the General tab of the given report. |
| Query | |
| Query | Here you can add the SQL query used to retrieve data to be displayed by the value. |
| Is stored procedure | Indicates if the query is a stored procedure or not. |
| Connection string | <p>Sets the database connection string used by the value's query.</p> <p>Only users who have the Set connection string permission for the <i>Reporting</i> module are allowed to change this value.</p> <p>The system loads the list of connection strings from the <code><connectionStrings></code> section of the application's web.config file. The <i>(default)</i> option represents the <i>CMSConnectionString</i> added by the application's initial database installer.</p> |

| | |
|-------------------|--|
| | You can check the Inherit box to load the Connection string value set for the parent report. |
| Format | |
| Formatting string | You can format the displayed value using standard .NET expressions. For example: <ul style="list-style-type: none"> • {0} - displays the value • {0:F1} - displays the value as a floating point number with one digit displayed after the decimal point |

Values are entered into the report layout editor as an expression in the following format:

```
%%control:ReportValue?<report code name>.<value code name>%%
```

This is done automatically when the **Insert** button is used.

Writing queries for scalar value

The queries for scalar values may return any number of columns and rows, but the only value that will be displayed is the value in the first column of the first row of the result set.

Example

1. Switch back to the **General** tab. Click the **New** button in the **Values** section below the layout editor. Enter the following values:

- **Display name:** Number of pages with page template
- **Code name:** PagesWithTemplate
- **Query:**

```
SELECT COUNT(DocumentID)
FROM View_CMS_Tree_Joined
WHERE DocumentPageTemplateID IS NOT NULL
```

- **Is stored procedure:** no
- **Formatting string:** Pages with template: {0}

Click **OK**.

2. Place the cursor in the layout editor under the graph, select the new value from the drop-down list in the **Values** section and click **Insert**. A string like `%%control:ReportValue?PagesByPageTemplate.PagesWithTemplate%%` is added to the text area.

Click  **Save** to confirm the changes and switch to the **View** tab. You will see a text like this:

Pages with template: 229

Continued in the example section of the [Defining report parameters](#) topic.

8.41.4 Defining report parameters

Reports may be filtered using parameters. You can define custom parameters on the **Parameters** tab of the **Report properties** dialog.

Context Parameters

In your queries, you can use parameters that provide information about the current context when the report is viewed, such as current user, current site, etc. Here's a list of all available context variables:

- @CMSContextCurrentUserID
- @CMSContextCurrentUserName
- @CMSContextCurrentUserDisplayName
- @CMSContextCurrentSiteID
- @CMSContextCurrentSiteName
- @CMSContextCurrentSiteDisplayName
- @CMSContextCurrentDomain
- @CMSContextCurrentTime
- @CMSContextCurrentURL
- @CMSContextCurrentNodeID
- @CMSContextCurrentCulture
- @CMSContextCurrentDocumentID
- @CMSContextCurrentAliasPath
- @CMSContextCurrentDocumentName
- @CMSContextCurrentDocumentNamePath

For example, if you want to display a list of all expired documents of the current website, you can use a query like this:

```
SELECT DocumentNamePath AS [Document path]
FROM View_CMS_Tree_Joined
WHERE DocumentPublishTo < @CMSContextCurrentTime AND NodeSiteID =
@CMSContextCurrentSiteID
```

Displaying Parameter Values in the Report

If you need to display the parameter values in the report, you can place the following macro expression in the report text:

{%parametername%}

For example:

List of documents expired on or before `{%CMSContextCurrentTime%}`

displays:

List of documents expired on or before `8/12/2007 12:06:49 PM`

You can use this syntax for both custom report parameters and context parameters.

Example

1. Switch to the **Parameters** tab, click **New attribute** (+) and enter the following values:

- **Column name:** UserID
- **Attribute type:** Integer number
- **Default value:** 53
- **Field caption:** Created by user
- **Form control:** User selector

The screenshot shows the 'Parameters' tab in the Reporting tool. The breadcrumb path is 'Reporting > User reports > Pages by page template'. The 'Parameters' sub-tab is active. A list on the left contains 'UserID*'. The configuration panel on the right is as follows:

- Database:**
 - Column name: UserID
 - Attribute type: Integer number
 - Attribute size: (empty)
 - Allow empty value:
 - Default value: 53
- Display attribute in the editing form
- Field appearance:**
 - Field caption: Created by user
 - Form control: User selector
 - Field description: (empty)
- Editing control settings:**
 - Show site filter:

Quick links: Database, Field appearance, Editing control settings, Validation, CSS styles.

Click  **Save**.

2. Now we need to add this parameter to our queries. For the purposes of this example, we will modify only the table query. Switch to the **General** tab, select the **Pages by page template** table and click **Edit**. Now modify the table SQL query like this:

```
SELECT PageTemplateName AS [Template Name], DocumentNamePath AS [Document]
FROM View_CMS_Tree_Joined
```

```
LEFT JOIN CMS_PageTemplate
ON CMS_PageTemplate.PageTemplateID = View_CMS_Tree_Joined.DocumentPageTemplateID
WHERE PageTemplateDisplayName IS NOT NULL AND DocumentCreatedByUserID = @UserID
ORDER BY PageTemplateDisplayName
```

As you can see we added the parameter to the WHERE condition of the query. All parameters that you define can be used in the query using the @<parametername> expression. Click **OK** and go to the **View** tab. You will see that the report now has a filter like this:

Created by user: Select Clear
Update

Pages by page template

| Template Name | Document |
|---------------|----------|
|---------------|----------|

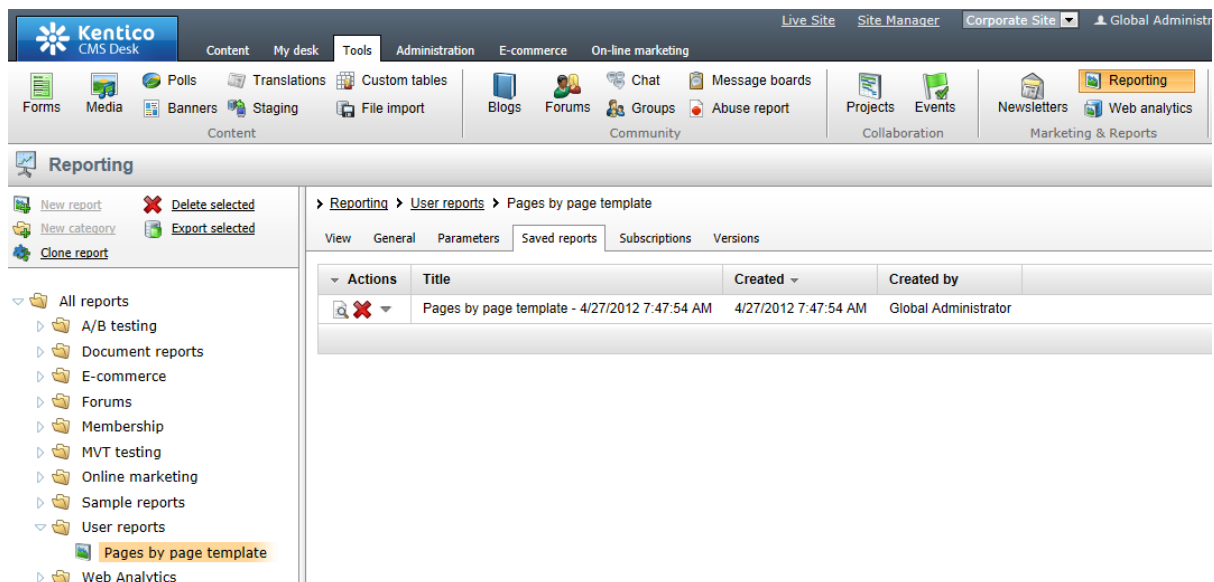

The table now only displays template names of documents that were created by the user specified in the filter.

Continued in the [Saving reports](#) topic.

8.41.5 Saving reports

When viewing a report on the **View** tab of its editing dialog, there are several ways to store the displayed data.

You can archive the entire report into the system history using the  **Save** button. To view saved reports at a later time, switch to the **Saved reports** tab. If the data displayed in the report changes, the saved reports will not be affected.

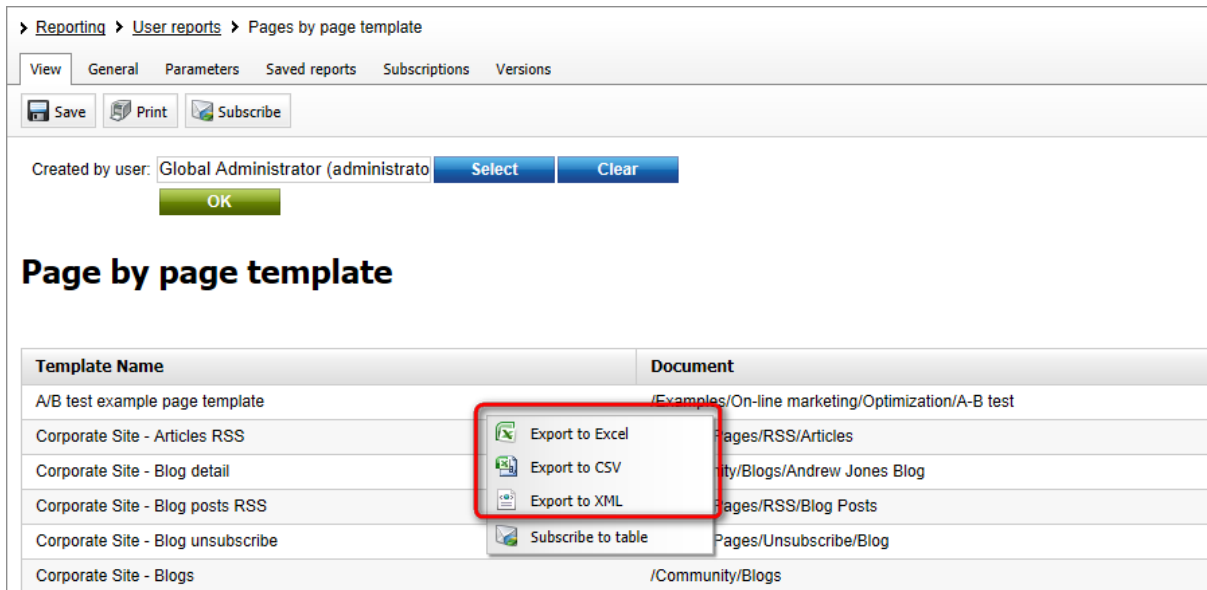

You can open the details of saved reports using the **Edit** () action.

This tutorial is concluded in the example section of the [Displaying reports on the website](#) topic.

Exporting report data to files

Additionally, the data displayed in a report on the **View** tab may be exported into external files using various formats. This can be done by right-clicking on a graph or table in the given report, which will open a context menu offering the following options:

-  **Export to Excel** - exports the data displayed by the given object to an XLSX spreadsheet.
-  **Export to CSV** - exports data to a CSV file.
-  **Export to XML** - exports data to an XML file.

The screenshot shows the 'Reporting' interface for 'User reports' > 'Pages by page template'. The 'View' tab is active. Below the navigation tabs are 'Save', 'Print', and 'Subscribe' buttons. A user selection area shows 'Global Administrator (administrato)' with 'Select' and 'Clear' buttons, and an 'OK' button. The main content area is titled 'Page by page template' and contains a table with two columns: 'Template Name' and 'Document'. A context menu is open over the table, highlighting the 'Export to Excel', 'Export to CSV', and 'Export to XML' options.

| Template Name | Document |
|-----------------------------------|---|
| A/B test example page template | /Examples/On-line marketing/Optimization/A-B test |
| Corporate Site - Articles RSS | Pages/RSS/Articles |
| Corporate Site - Blog detail | ty/Blogs/Andrew Jones Blog |
| Corporate Site - Blog posts RSS | Pages/RSS/Blog Posts |
| Corporate Site - Blog unsubscribe | Pages/Unsubscribe/Blog |
| Corporate Site - Blogs | /Community/Blogs |

After you select an action from the menu, your browser's standard file download dialog will pop up, letting you open or save the file with the exported data just like when downloading any other type of file. For more details on the data export feature, please refer to the [Modules -> UI data export](#) chapter of this guide.

Please note that the data export function may be disabled for some tables and graphs, depending on the configuration of the given reporting object.

8.41.6 Displaying reports on the website

If you want to display a report on the website or include it on a custom page in the CMS administration interface, you can use the [Reporting -> Report](#) web part. All you need to configure are the following properties:

- **Report name** - select the required report.
- **Display filter** - indicates if a parameter filter should be displayed on the page (if the report has some parameters specified).
- **Enable export** - if enabled, users will be able to export the data displayed in the report's charts and tables to other formats (Excel, CSV or XML). The export feature may be accessed using a context menu that can be opened by right clicking the rendered chart/table. Please note that data export will

not be allowed if it is disabled for the given chart/table using the properties in the main reporting interface.

- **Enable subscription** - indicates whether authenticated users should be allowed to subscribe to the components (graphs, tables or values) in the displayed report. Subscription can be done by right clicking on the appropriate item and selecting the *Subscribe to* option in the context menu. In addition to this property, subscription also needs to be enabled for the given report and the specific graph, table or value in the main reporting interface. Please see the [Report subscriptions](#) topic for more information.

If the selected report has some parameters defined, their values can be entered here by using the **Set parameters** button. However, if the **Display filter** property is enabled, these settings will be ignored, as the parameters will be configurable on the live site using the filter.

Report properties

Report name*: Pages by page template ▾

Set parameters
Clear parameters

Display filter: ▶

Enable export: ▶

Enable subscription: ▶

If you only wish to display a certain graph, table or value from the report, this can be done by using one of the other web parts from the **Reporting** category:

- **Report chart**
- **Report table**
- **Report value**

The exact chart/table/value must be specified in the respective property of the web part.

Chart properties

Chart*: Pages by page template ▾

Set parameters

▶ Favorite Page Templates ▾

Width: ▶

Height: ▶

Enable export: ▶

Enable subscription: ▶

The first drop-down list is used to select the report, the second one specifies the chart, table or value. Values of the report's parameters can be specified using the **Set parameters** button.

These web parts are also available as [Widgets](#).

Example

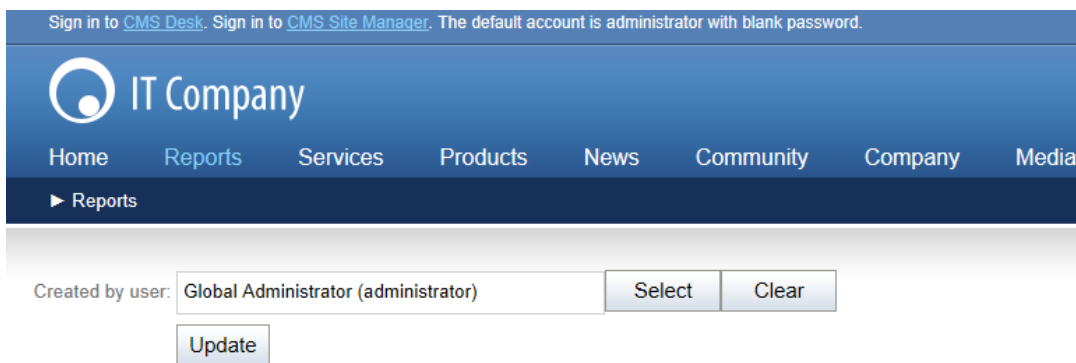

1. To display this report on your website, switch to the **Content** tab of CMS Desk. Select the root of your website and create a new **Page (menu item)** type document. Name it *Reports*, choose the **Create a blank page** option and click **Save**.

2. Now add the **Reporting/Report** web part to the page's web part zone on the **Design** tab and set its properties to the following:

- **Report name** - select *Pages by page template*
- **Display filter** - enabled

3. Now go to **Live site** mode and you should see something similar to the following:

Sign in to [CMS Desk](#). Sign in to [CMS Site Manager](#). The default account is administrator with blank password.

Home Reports Services Products News Community Company Media

| 12345678 | |

As you can see, the report is displayed just like on the **View** tab of the **Report Properties** dialog and the parameter filter can be used by site visitors.

8.41.7 Report subscriptions

If a user is interested in the content of a specific report or wants to follow the progress of its data, they can use the subscription feature of the reporting module. Subscribers will regularly receive e-mails with the up-to-date status of the given report. This way, users can easily keep track of the data provided by the report simply by checking their e-mail, without having to access the website or its administration interface.

Requirements

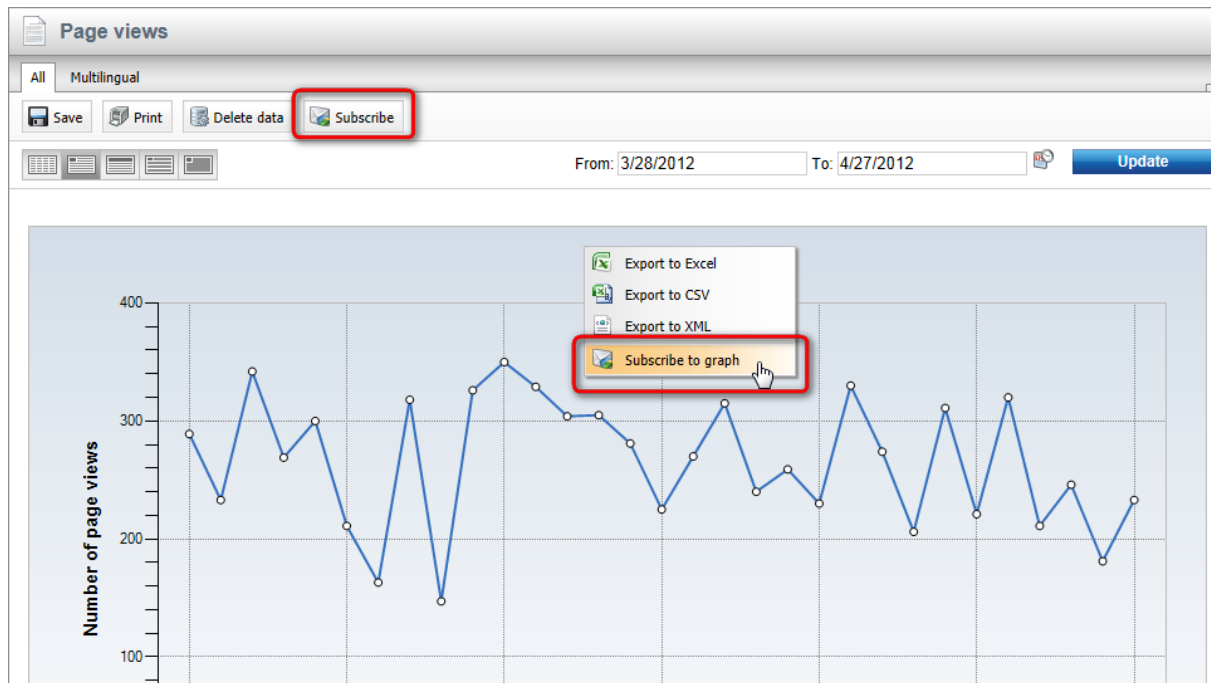

Each report has settings that determine whether subscriptions to it should be allowed. On the **General** tab of the report editing interface, the **Enable subscription** checkbox applies to the entire report. The same setting is available when configuring the details of individual components (graphs, tables or values) . If both settings are enabled, it is possible to subscribe to specific components. For reports published on the website's pages, subscription also needs to be allowed through the **Enable subscription** property of the web part or widget used to display the given report.

Additionally, the subscription feature is only available for users who belong to a role that has the **Subscribe** or **Modify** permission for the *Reporting* module.

Subscribing to reports

If all of the conditions above are met, users can subscribe to entire reports displayed in the administration interface by clicking on the  **Subscribe** action in the header of the given page. This can either be done on a report's **View** tab in **CMS Desk -> Tools -> Reporting** or in any other sections of the UI that provide reports, such as [Web analytics](#).

Subscriptions to individual components can be created by right-clicking on the appropriate item in the report and selecting the **Subscribe to** option in the offered context menu. This way of subscribing is also available for authenticated users when viewing reports on the live site.

Both of these actions open a subscription dialog, where the following details can be configured:

- **Send to** - sets the e-mail address to which the subscription e-mails will be sent. By default, the address of the current user is loaded, but a different one may be specified.
- **Subject** - sets the subject that will be used for the subscription e-mails.
- **Time range** - this setting is only available for reports that offer the possibility of displaying data from a specific time range, selected using *From* and *To* parameters, e.g. most web analytics and on-line marketing reports in the system. Users can choose to either have *All available data* included in every subscription e-mail, or only a certain range of the most recent data according to the date and time when the e-mail is sent. With the second option, the exact time range can be specified through the *Data from last* field below.
- **Sending interval** - the interval settings define how often and when exactly the report subscription e-mails should be sent.
- **Condition** - may be used to enter an additional macro condition that must be fulfilled in order for the subscription e-mails to be sent. You can write any condition according to your specific requirements. For detailed information about macro conditions, please see the [Development -> Macro expressions -> Macro conditions](#) topic.
- **Send only if data found** - if checked, subscription e-mails will only be sent if the report contains data at the given time (the subscriber will not receive empty reports).

New subscription
? □ ×

You will be subscribed to report **Page views - Daily report**.

Subscription settings

Subject:

Time range : All available data
 Only chosen period

Data from last:

Period:

Every: Day

Days: Monday Saturday
 Tuesday Sunday
 Wednesday
 Thursday
 Friday

Condition:

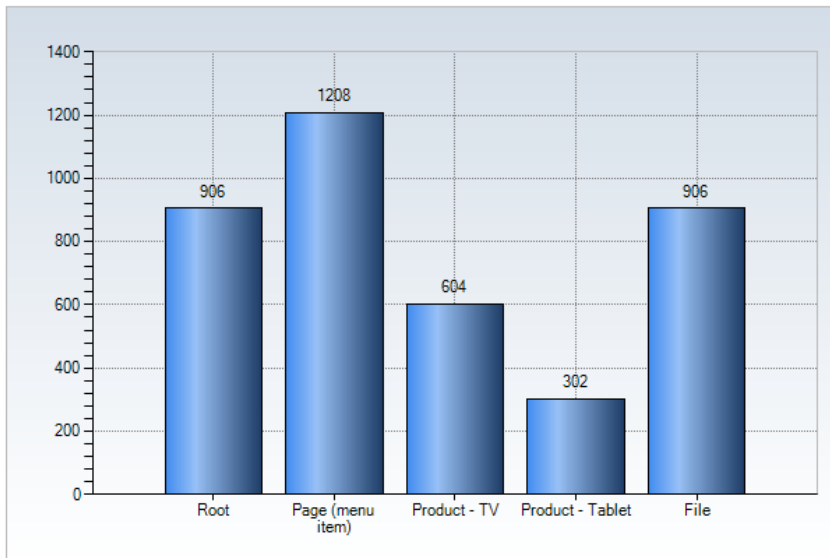

Send only if data found:

If the report has any parameters that affect how its data is displayed, the report e-mails will always be sent according to the values set before the subscribe action was used.

Unsubscription

Users can cancel their subscription to a report at any time by clicking on the unsubscription link included in every e-mail (when using the default e-mail template).

Full report subscription

| Class name | Random value |
|------------------|--------------|
| Root | 1068 |
| Page (menu item) | 1424 |
| Product - TV | 712 |
| Product - Tablet | 356 |
| File | 1068 |

Report value: 20

[Click here to unsubscribe](#)

The link leads to the `~/CMSModules/Reporting/CMSPages/Unsubscribe.aspx` system page, where the user can confirm that they wish to unsubscribe from the given report. The appropriate subscription to be removed is automatically identified using parameters passed in the query string of the link's URL.

Alternatively, users with access to CMS Desk can view their report subscriptions in **My Desk -> My profile -> Subscriptions** and manually **Unsubscribe** (✘) as needed. All report subscriptions created by the current user are listed here, even if the target e-mail address belongs to someone else.

Report subscriptions

You are currently subscribed to receive the following reports:

| Actions | Subject | E-mail |
|---------|---|-------------------------------|
| ✘ ✎ | A/B test - Conversions by variations - Daily report | administrator@localhost.local |
| ✘ ✎ | Pages by page templates | administrator@localhost.local |
| ✘ ✎ | Sample report - Table | private@localhost.local |

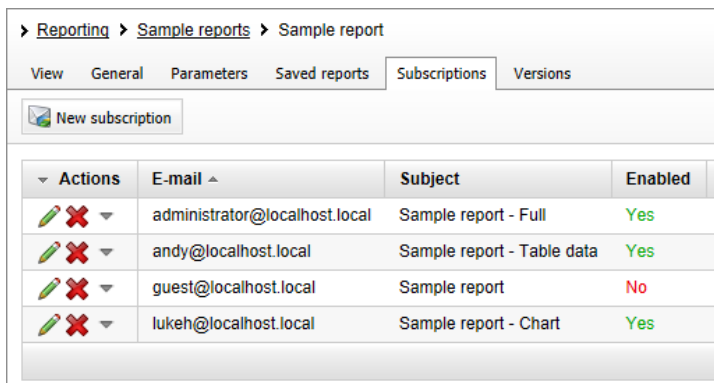

For live site users, the same option can be provided by the [My account](#) web part, as long as its **Display**

my subscriptions and **Display report subscriptions** properties are enabled.

After unsubscribing through any of the described ways, a notification e-mail is automatically sent to the given address.

Managing report subscriptions

When editing a report in **CMS Desk -> Tools -> Reporting**, it is possible to view and manage all of its subscriptions on the **Subscriptions** tab. The **Edit** (✎) icon can be used to modify the details of existing subscriptions. Individual subscriptions may be manually removed using the **Delete** (✖) action and new ones can be added to the report by clicking the **New subscription** button in the tab's header.

| Actions | E-mail | Subject | Enabled |
|---|-------------------------------|----------------------------|---------|
|   | administrator@localhost.local | Sample report - Full | Yes |
|   | andy@localhost.local | Sample report - Table data | Yes |
|   | guest@localhost.local | Sample report | No |
|   | lukeh@localhost.local | Sample report - Chart | Yes |

Creating or editing a subscriptions here offers the standard subscription dialog as described above, but with several additional options.

- The **Subscription item** selector may be used to choose whether the subscription e-mails should include the full content of the report or only a specific graph, table or value component.
- Individual subscriptions may be manually disabled by unchecking the **Enabled** property.
- If the currently edited report has [parameters](#), the **Subscription parameters** section below the main settings provides a way to enter the values that should be used for the reports sent to the subscriber. Only parameters that are configured to be visible when viewing the report can be edited (i.e. those that have the **Display attribute in the editing form** checkbox enabled on the **Parameters** tab).

Conversion name:

Time range parameters

Some reports offer the possibility of displaying data from a specific time span selected through parameters (e.g. most web analytics and on-line marketing reports in the system). This functionality is ensured by two parameters with **Column names** set to *FromDate* and *ToDate* respectively on the **Parameters** tab.

These two parameters are not displayed in the **Subscription parameters** section. Instead, subscriptions to reports that contain them provide the **Time range** and **Data from last** settings, which may be used to specify the appropriate values.

Every authenticated user may also configure the options described above for their own report subscriptions by going to **My Desk -> My profile -> Subscriptions** or a page containing the [My account](#) web part, and editing () the appropriate subscription.

Scheduling subscription mailout

To ensure that the report subscription e-mails are sent correctly and at the appropriate time, the system uses a global [scheduled task](#) called **Report subscription sender**. When executed, this task goes through all enabled reporting subscriptions and checks their settings. If the time interval requirements and condition of a subscription are fulfilled, an e-mail with the current content of the given report is sent out.

By default, the task is executed every minute. If necessary, you can change its configuration in **Site Manager -> Administration -> Scheduled tasks**. However, if you wish to use report subscriptions, the task must always be enabled and scheduled frequently.

Important!

To be able to send e-mails, the system needs to be connected to a working SMTP server. To learn how this can be done, please see the [SMTP server configuration](#) topic.

E-mail templates

The content of the reporting e-mails sent to subscribers is based on [e-mail templates](#). If you wish to customize the e-mails in some way, you can edit the templates in **Site Manager -> Administration -> E-mail templates**. The following templates are available:

- **Reporting - Subscription template** - defines the content of the main subscription e-mails used to send the report status.
- **Reporting - Subscription confirmation** - used for the automatic notification e-mails sent to the recipient when a new subscription is created.
- **Reporting - Unsubscription confirmation** - used for the notifications that users receive after unsubscribing (or when the subscription is removed by an administrator).

Reports in plain text

If your system is configured to send e-mails in plain text format, the content of report subscription e-mails will be limited. In this case, image based graphs are included as attachments and the data from tables is sent in an a CSV file. HTML graphs are not represented at all.

You can choose the preferred e-mail format using the **E-mail format** setting that can be found in **Site Manager -> Settings -> System -> E-mails**.

The following context [macros](#) may be used in report subscription e-mail templates:

- **{% SubscriptionBody %}** - this macro is resolved into the content of the subscribed report or component.
- **{% DefaultSubscriptionCSS %}** - used to add the CSS styles that are required to properly display report content in the e-mail. This should always be included in the `<head/><style>` element in the HTML version of the subscription template.
- **{% ItemName %}** - for subscriptions to individual reporting components, this macro resolves into the name and type (graph, table or value) of the given item. In the case of full report subscriptions, it

returns an empty string.

- **{% UnsubscriptionLink %}** - generates a link that can be used to cancel the given subscription.

It is also possible to access the following related objects and their properties (e.g. **{% Report.ReportDisplayName %}**):

- **{% Report %}** - *ReportInfo* object representing the report to which the user is subscribed.
- **{% ReportSubscription %}** - *ReportSubscriptionInfo* object of the subscription for which the e-mail is being sent.

8.41.8 Security

You can configure access to the Reporting module in **Site manager / CMS Desk -> Administration -> Permissions**. Choose the permission matrix for **Module -> Reporting** and assign the available permissions to the appropriate user roles.

| Permission | Description |
|-----------------------|--|
| Read | Allows users to view existing reports. |
| Save reports | Allows users to save reports into the report archive. |
| Modify | Allows users to create, modify and delete reports. This also grants permission to subscribe to reports. |
| Destroy | Allows users to delete the version history of reporting objects. |
| Edit SQL queries | Allows editing of the queries used to retrieve data for reporting components (graphs, tables and values). This permission is needed to create new reports, but it can be a security risk, since it allows users to run queries against the website's database. |
| Subscribe | Allows users to subscribe to reports and their components. Subscription also needs to be allowed for individual reports through their properties. Unauthenticated (public) users cannot subscribe to reports. |
| Set connection string | Allows users to change the connection string property of reports and their components. The report uses the specified connection string to access the database when loading data. |

| Permissions | | | | | | | |
|------------------------------|-------------------------------------|--|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| Site: | Corporate Site | | | | | | |
| Permissions for: | Module | Reporting | | | | | |
| Report for user: | (none) | <input type="checkbox"/> Show only this user's roles | | | | | |
| Role | Read | Save reports | Modify | Destroy | Edit SQL Queries | Subscribe | Set connection string |
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Designers | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Editors | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Readers | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| CMS Wireframe editors | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Facebook users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Gold Partners | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| LinkedIn users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Live ID users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Marketing Manager | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Not authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

Permission matrix of the Reporting module

Making reports available on the live site

The **Allow public users to see this report** property available on the **General** tab when **Editing** (✎) reports indicates if the system displays the given report on the live site to non-authenticated (public) users. If false, the report and all of its components (graphs, tables or values) are always hidden from public users.

Specifying connection strings for reports

You can restrict the database-level permissions of the SQL queries used for reporting by registering custom connection strings and assigning them to reports.

1. Prepare a user account for your Kentico CMS database with the required security configuration.
2. Edit your application's *web.config* and add a new connection string into the `<configuration><connectionStrings>` section. Enter authentication information (the *user id* and *password*) for the appropriate database user account.

```
<add name="CMSReadOnlyConnectionString" connectionString="Persist Security
Info=False;database=DBName;server=ServerName;user id=DBUser;password=password;
Current Language=English;Connection Timeout=240;" />
```

3. Go to **Site Manager -> Settings**, select the **Security & Membership** category and choose the **Default report connection string** (in the **Reporting** section).

Connection string names

The setting loads the list of connection strings from the web.config and displays their *name* attribute values. The *(default)* option represents the *CMSConnectionString* added by the application's initial database installation.

The system assigns the specified connection string to newly created reports. By default, all existing reports also inherit the connection string value from this setting.

4. Open the **CMS Desk -> Tools -> Reporting** interface and edit any reports for which you wish to set a non-default connection string. On the **General** tab, uncheck the **Inherit** box below the **Connection string** property and select a different option. You can also override the connection string value for individual reporting components (graphs, tables and values).

The screenshot shows the 'Reporting > Sample reports > Sample report' configuration page. The 'General' tab is active. The 'Connection string' dropdown is set to 'CMSReadOnlyConnectionString'. The 'Inherit' checkbox is unchecked. Other fields include 'Report display name' (Sample report), 'Report code name' (SampleReport), and 'Report category' (Sample reports). There are also checkboxes for 'Allow public users to see this report' and 'Enable subscription', both of which are checked.

Assigning a connection string to a specific report

The system now uses the assigned connection string when executing the queries of reports. This limits the functionality of the queries according to the database permissions of the user account specified in the connection string. Only users who have the **Set connection string** permission for the *Reporting* module are allowed to change the connection strings of individual reports.

8.41.9 Reporting internals and API

8.41.9.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Reporting module. You will also see the most common [API examples](#).

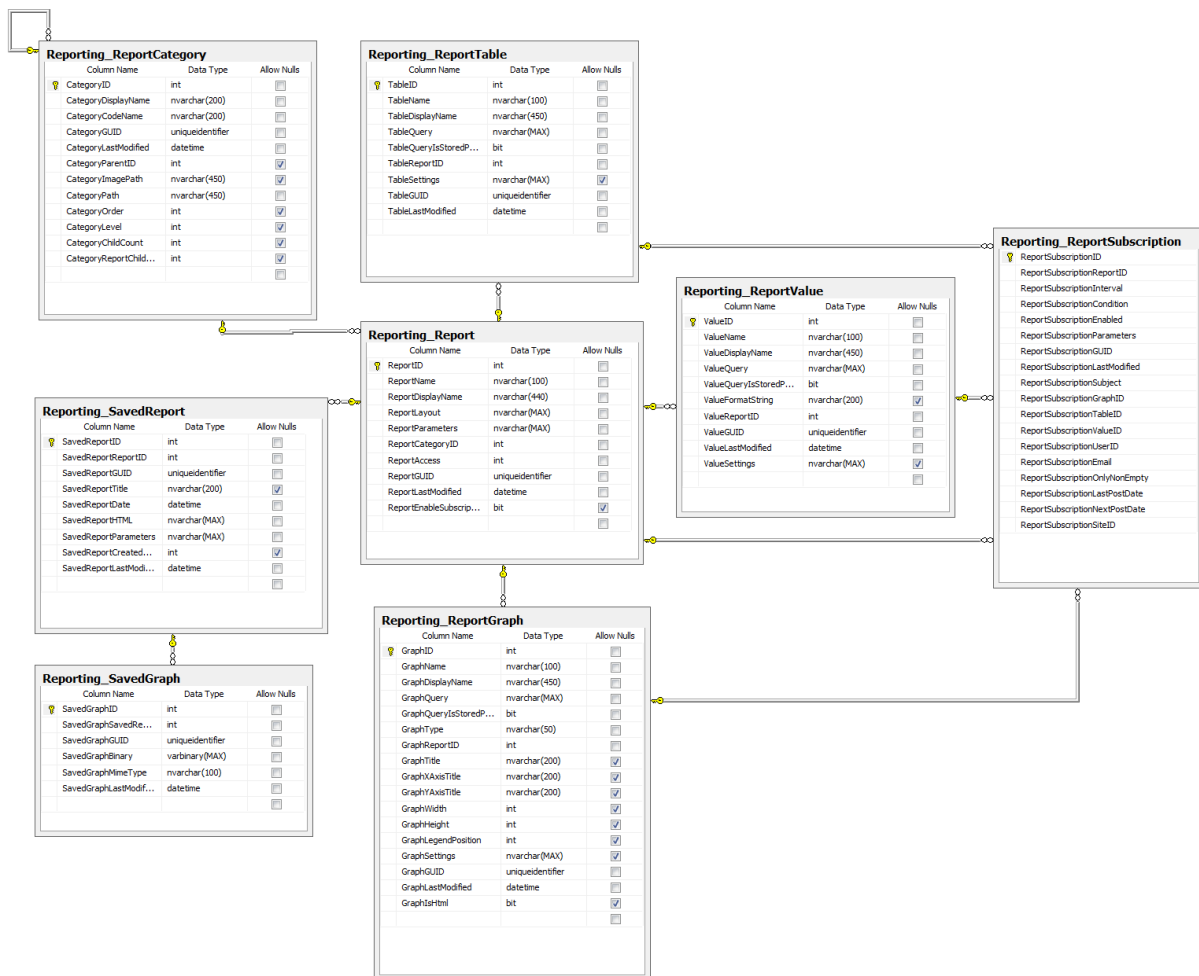

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the module's classes, please refer to [Kentico CMS API Reference](#).

8.41.9.2 Database tables

The following database tables are used to store information about reports:

- **Reporting_ReportCategory** - contains records representing report categories.

- **Reporting_Report** - contains records representing reports and their content.
- **Reporting_ReportGraph** - contains records representing report graphs.
- **Reporting_ReportTable** - contains records representing report tables.
- **Reporting_ReportValue** - contains records representing report values.
- **Reporting_SavedReport** - contains records representing saved reports in the system.
- **Reporting_SavedGraph** - stores graphs contained in saved reports (in binary format).
- **Reporting_ReportSubscription** - contains records representing report subscriptions.

8.41.9.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Reporting module can be found in the **CMS.Reporting** namespace.

Reporting_ReportCategory table API:

- **ReportCategoryInfo** - represents one report category object.
- **ReportCategoryInfoProvider** - provides management functionality for report categories.

Reporting_Report table API:

- **ReportInfo** - represents one report object.
- **ReportInfoProvider** - provides management functionality for reports.

Reporting_ReportGraph table API:

- **ReportGraphInfo** - represents one report graph.
- **ReportGraphInfoProvider** - provides management functionality for report graphs.

Reporting_ReportTable table API:

- **ReportTableInfo** - represents one report table.
- **ReportTableInfoProvider** - provides management functionality for report tables.

Reporting_ReportValue table API:

- **ReportValueInfo** - represents one report value object.
- **ReportValueInfoProvider** - provides management functionality for report values.

Reporting_SavedReport table API:

- **SavedReportInfo** - represents one saved report.
- **SavedReportInfoProvider** - provides management functionality for saved reports.

Reporting_SavedGraph table API:

- **SavedGraphInfo** - represents one saved graph.
- **SavedGraphInfoProvider** - provides management functionality for saved graphs.

Reporting_ReportSubscription table API:

- **ReportSubscriptionInfo** - represents a subscription to a report.
- **ReportSubscriptionInfoProvider** - provides management functionality for reporting subscriptions.

8.41.9.4 API examples

8.41.9.4.1 Overview

These topics show examples of how the API of the Groups module can be used:

- [Managing report categories](#)
- [Managing reports](#)
- [Managing report graphs](#)
- [Managing report tables](#)

- [Managing report values](#)
- [Adding elements to the layout of a report](#)

**Please note**

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Tools\Reporting\Default.aspx.cs**.

The reporting API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.Reporting;
```

8.41.9.4.2 Managing report categories

The following example creates a report category.

```
private void CreateReportCategory()
{
    // Create new report category object
    ReportCategoryInfo newCategory = new ReportCategoryInfo();

    // Set the properties
    newCategory.CategoryDisplayName = "My new category";
    newCategory.CategoryCodeName = "MyNewCategory";

    // Save the report category
    ReportCategoryInfoProvider.SetReportCategoryInfo(newCategory);
}
```

The following example gets and updates a report category.

```
private bool GetAndUpdateReportCategory()
{
    // Get the report category
    ReportCategoryInfo updateCategory =
    ReportCategoryInfoProvider.GetReportCategoryInfo("MyNewCategory");
    if (updateCategory != null)
    {
```

```
        // Update the properties
        updateCategory.CategoryDisplayName =
updateCategory.CategoryDisplayName.ToLower();

        // Save the changes
ReportCategoryInfoProvider.SetReportCategoryInfo(updateCategory);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates report categories.

```
private bool GetAndBulkUpdateReportCategories()
{
    // Prepare the parameters
    string where = "CategoryCodeName LIKE N'MyNewCategory%'";

    // Get the data
    DataSet categories = ReportCategoryInfoProvider.GetCategories(where, null);
    if (!DataHelper.DataSourceIsEmpty(categories))
    {
        // Loop through the individual items
        foreach (DataRow categoryDr in categories.Tables[0].Rows)
        {
            // Create object from DataRow
            ReportCategoryInfo modifyCategory = new ReportCategoryInfo
(categoryDr);

            // Update the properties
            modifyCategory.CategoryDisplayName =
modifyCategory.CategoryDisplayName.ToUpper();

            // Save the changes
            ReportCategoryInfoProvider.SetReportCategoryInfo(modifyCategory);
        }

        return true;
    }

    return false;
}
```

The following example deletes a report category.

```
private bool DeleteReportCategory()
{
    // Get the report category
    ReportCategoryInfo deleteCategory =
```

```
ReportCategoryInfoProvider.GetReportCategoryInfo("MyNewCategory");

// Delete the report category
ReportCategoryInfoProvider.DeleteReportCategoryInfo(deleteCategory);

return (deleteCategory != null);
}
```

8.41.9.4.3 Managing reports

The following example creates a report.

```
private bool CreateReport()
{
    // Get the report category
    ReportCategoryInfo category = ReportCategoryInfoProvider.GetReportCategoryInfo
("MyNewCategory");
    if (category != null)
    {
        // Create new report object
        ReportInfo newReport = new ReportInfo();

        // Set the properties
        newReport.ReportDisplayName = "My new report";
        newReport.ReportName = "MyNewReport";
        newReport.ReportCategoryID = category.CategoryID;
        newReport.ReportAccess = ReportAccessEnum.All;
        newReport.ReportLayout = "";
        newReport.ReportParameters = "";

        // Save the report
        ReportInfoProvider.SetReportInfo(newReport);

        return true;
    }

    return false;
}
```

The following example gets and updates a report.

```
private bool GetAndUpdateReport()
{
    // Get the report
    ReportInfo updateReport = ReportInfoProvider.GetReportInfo("MyNewReport");
    if (updateReport != null)
    {
        // Update the properties
        updateReport.ReportDisplayName = updateReport.ReportDisplayName.ToLower();
    }
}
```

```
        // Save the changes
        ReportInfoProvider.SetReportInfo(updateReport);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates reports.

```
private bool GetAndBulkUpdateReports()
{
    // Prepare the parameters
    string where = "ReportName LIKE N'MyNewReport%'";
    string orderby = "";
    int topN = 0;
    string columns = "";

    // Get the data
    DataSet reports = ReportInfoProvider.GetReports(where, orderby, topN,
columns);
    if (!DataHelper.DataSourceIsEmpty(reports))
    {
        // Loop through the individual items
        foreach (DataRow reportDr in reports.Tables[0].Rows)
        {
            // Create object from DataRow
            ReportInfo modifyReport = new ReportInfo(reportDr);

            // Update the properties
            modifyReport.ReportDisplayName =
modifyReport.ReportDisplayName.ToUpper();

            // Save the changes
            ReportInfoProvider.SetReportInfo(modifyReport);
        }

        return true;
    }

    return false;
}
```

The following example deletes a report.

```
private bool DeleteReport()
{
    // Get the report
    ReportInfo deleteReport = ReportInfoProvider.GetReportInfo("MyNewReport");
}
```

```
// Delete the report
ReportInfoProvider.DeleteReportInfo(deleteReport);

return (deleteReport != null);
}
```

8.41.9.4.4 Managing report graphs

The following example creates a graph and assigns it to a report.

```
private bool CreateReportGraph()
{
    // Get report object by report code name
    ReportInfo report = ReportInfoProvider.GetReportInfo("MyNewReport");

    // If report exists
    if (report != null)
    {
        // Create new report graph object
        ReportGraphInfo newGraph = new ReportGraphInfo();

        // Set the properties
        newGraph.GraphDisplayName = "My new graph";
        newGraph.GraphName = "MyNewGraph";
        newGraph.GraphQuery = "SELECT TOP 10 DocumentName, DocumentID FROM
CMS_Document";
        newGraph.GraphReportID = report.ReportID;
        newGraph.GraphQueryIsStoredProcedure = false;
        newGraph.GraphType = "bar";

        // Save the report graph
        ReportGraphInfoProvider.SetReportGraphInfo(newGraph);

        return true;
    }

    return false;
}
```

The following example gets and updates a report graph.

```
private bool GetAndUpdateReportGraph()
{
    // Get the report graph
    ReportGraphInfo updateGraph = ReportGraphInfoProvider.GetReportGraphInfo
("MyNewGraph");
    if (updateGraph != null)
    {
        // Update the properties
        updateGraph.GraphDisplayName = updateGraph.GraphDisplayName.ToLower();
    }
}
```

```
        // Save the changes
        ReportGraphInfoProvider.SetReportGraphInfo(updateGraph);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates report graphs.

```
private bool GetAndBulkUpdateReportGraphs()
{
    // Prepare the parameters
    string where = "GraphName LIKE N'MyNewGraph%'";

    // Get the data
    DataSet graphs = ReportGraphInfoProvider.GetGraphs(where, null);
    if (!DataHelper.DataSourceIsEmpty(graphs))
    {
        // Loop through the individual items
        foreach (DataRow graphDr in graphs.Tables[0].Rows)
        {
            // Create object from DataRow
            ReportGraphInfo modifyGraph = new ReportGraphInfo(graphDr);

            // Update the properties
            modifyGraph.GraphDisplayName = modifyGraph.GraphDisplayName.ToUpper();

            // Save the changes
            ReportGraphInfoProvider.SetReportGraphInfo(modifyGraph);
        }

        return true;
    }

    return false;
}
```

The following example deletes a report graph.

```
private bool DeleteReportGraph()
{
    // Get the report graph
    ReportGraphInfo deleteGraph = ReportGraphInfoProvider.GetReportGraphInfo(
        "MyNewGraph");

    // Delete the report graph
    ReportGraphInfoProvider.DeleteReportGraphInfo(deleteGraph);
}
```

```
    return (deleteGraph != null);  
}
```

8.41.9.4.5 Managing report tables

The following example creates a table and assigns it to a report.

```
private bool CreateReportTable()  
{  
    // Get report object by report code name  
    ReportInfo report = ReportInfoProvider.GetReportInfo("MyNewReport");  
  
    // If report exists  
    if (report != null)  
    {  
        // Create new report table object  
        ReportTableInfo newTable = new ReportTableInfo();  
  
        // Set the properties  
        newTable.TableDisplayName = "My new table";  
        newTable.TableName = "MyNewTable";  
        newTable.TableQuery = "SELECT TOP 10 DocumentName, DocumentID FROM  
CMS_Document";  
        newTable.TableReportID = report.ReportID;  
        newTable.TableQueryIsStoredProcedure = false;  
  
        // Save the report table  
        ReportTableInfoProvider.SetReportTableInfo(newTable);  
  
        return true;  
    }  
  
    return false;  
}
```

The following example gets and updates a report table.

```
private bool GetAndUpdateReportTable()  
{  
    // Get the report table  
    ReportTableInfo updateTable = ReportTableInfoProvider.GetReportTableInfo  
("MyNewTable");  
    if (updateTable != null)  
    {  
        // Update the properties  
        updateTable.TableDisplayName = updateTable.TableDisplayName.ToLower();  
  
        // Save the changes  
        ReportTableInfoProvider.SetReportTableInfo(updateTable);  
    }  
}
```

```
        return true;
    }

    return false;
}
```

The following example gets and bulk updates report tables.

```
private bool GetAndBulkUpdateReportTables()
{
    // Prepare the parameters
    string where = "TableName LIKE N'MyNewTable%'";

    // Get the data
    DataSet tables = ReportTableInfoProvider.GetTables(where, null);
    if (!DataHelper.DataSourceIsEmpty(tables))
    {
        // Loop through the individual items
        foreach (DataRow tableDr in tables.Tables[0].Rows)
        {
            // Create object from DataRow
            ReportTableInfo modifyTable = new ReportTableInfo(tableDr);

            // Update the properties
            modifyTable.TableDisplayName = modifyTable.TableDisplayName.ToUpper();

            // Save the changes
            ReportTableInfoProvider.SetReportTableInfo(modifyTable);
        }

        return true;
    }

    return false;
}
```

The following example deletes a report table.

```
private bool DeleteReportTable()
{
    // Get the report table
    ReportTableInfo deleteTable = ReportTableInfoProvider.GetReportTableInfo(
("MyNewTable"));

    // Delete the report table
    ReportTableInfoProvider.DeleteReportTableInfo(deleteTable);

    return (deleteTable != null);
}
```

8.41.9.4.6 Managing report values

The following example creates a value and assigns it to a report.

```
private bool CreateReportValue()
{
    // Get report object by report code name
    ReportInfo report = ReportInfoProvider.GetReportInfo("MyNewReport");

    // If report exists
    if (report != null)
    {
        // Create new report value object
        ReportValueInfo newValue = new ReportValueInfo();

        // Set the properties
        newValue.ValueDisplayName = "My new value";
        newValue.ValueName = "MyNewValue";
        newValue.ValueQuery = "SELECT COUNT(DocumentName) FROM CMS_Document";
        newValue.ValueQueryIsStoredProcedure = false;
        newValue.ValueReportID = report.ReportID;

        // Save the report value
        ReportValueInfoProvider.SetReportValueInfo(newValue);

        return true;
    }

    return false;
}
```

The following example gets and updates a report value.

```
private bool GetAndUpdateReportValue()
{
    // Get the report value
    ReportValueInfo updateValue = ReportValueInfoProvider.GetReportValueInfo(
("MyNewValue"));
    if (updateValue != null)
    {
        // Update the properties
        updateValue.ValueDisplayName = updateValue.ValueDisplayName.ToLower();

        // Save the changes
        ReportValueInfoProvider.SetReportValueInfo(updateValue);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates report values.

```
private bool GetAndBulkUpdateReportValues()
{
    // Prepare the parameters
    string where = "ValueName LIKE N'MyNewValue%'";

    // Get the data
    DataSet values = ReportValueInfoProvider.GetValues(where, null);
    if (!DataHelper.DataSourceIsEmpty(values))
    {
        // Loop through the individual items
        foreach (DataRow valueDr in values.Tables[0].Rows)
        {
            // Create object from DataRow
            ReportValueInfo modifyValue = new ReportValueInfo(valueDr);

            // Update the properties
            modifyValue.ValueDisplayName = modifyValue.ValueDisplayName.ToUpper();

            // Save the changes
            ReportValueInfoProvider.SetReportValueInfo(modifyValue);
        }

        return true;
    }

    return false;
}
```

The following example deletes a report value.

```
private bool DeleteReportValue()
{
    // Get the report value
    ReportValueInfo deleteValue = ReportValueInfoProvider.GetReportValueInfo
("MyNewValue");

    // Delete the report value
    ReportValueInfoProvider.DeleteReportValueInfo(deleteValue);

    return (deleteValue != null);
}
```

8.41.9.4.7 Adding elements to the layout of a report

The following example inserts elements into the layout of a report.

```
private bool InsertElementsToLayout()
{
    // Get report object by report code name
```

```
ReportInfo report = ReportInfoProvider.GetReportInfo("MyNewReport");

// If report exists
if (report != null)
{
    ReportGraphInfo graph = ReportGraphInfoProvider.GetReportGraphInfo
("MyNewGraph");
    if (graph != null)
    {
        report.ReportLayout += "<br/>%%control:Report" +
ReportItemType.Graph + "?" + report.ReportName + "." + graph.GraphName + "%<br/
>";
    }

    ReportTableInfo table = ReportTableInfoProvider.GetReportTableInfo
("MyNewTable");
    if (table != null)
    {
        report.ReportLayout += "<br/>%%control:Report" +
ReportItemType.Table + "?" + report.ReportName + "." + table.TableName + "%<br/
>";
    }

    ReportValueInfo value = ReportValueInfoProvider.GetReportValueInfo
("MyNewValue");
    if (value != null)
    {
        report.ReportLayout += "<br/>%%control:Report" +
ReportItemType.Value + "?" + report.ReportName + "." + value.ValueName + "%<br/
>";
    }

    ReportInfoProvider.SetReportInfo(report);

    return true;
}

return false;
}
```

8.42 SharePoint integration

8.42.1 Overview

Kentico CMS allows you to access data stored on a SharePoint (Windows SharePoint Services 3.0 (WSS) or MOSS - Microsoft Office SharePoint Server) server and display them on your site. This can be done using the [web parts](#) of the SharePoint module.

The [Usage examples](#) sub-chapter contains sample tutorials on using the SharePoint web parts for various tasks.

Default logon settings, used to access a SharePoint server, can be configured as described in the [Settings](#) topic.

What it can do

- Get list and list item data from SharePoint and provide it to Kentico CMS.
- Download documents or images.

What it can't do

- Modify SharePoint data.
- Display Kentico CMS data in SharePoint.

How it works

SharePoint web parts use pre-generated proxy classes of selected SharePoint web services to get data from the server. The following services are used:

- *http://server/_vti_bin/Lists.asmx* - methods for working with lists
- *http://server/_vti_bin/Imaging.asmx* - methods for working with picture libraries
- *http://server/_vti_bin/Copy.asmx* - methods for retrieving file content

The returned data is in CAML (XML) format, which needs to be further processed to display the data in a meaningful way. XSLT or ASCX transformations may be used for this purpose. For ASCX, the CAML response must be transformed to an ASP Dataset.

8.42.2 Web parts

Web parts for connecting to SharePoint are stored in the **Microsoft SharePoint** category in the web part catalog. This includes the following four web parts:

- **SharePoint datasource**
- **SharePoint datagrid**
- **SharePoint datalist**
- **SharePoint repeater**

The following text contains information about the specific properties of these web parts.

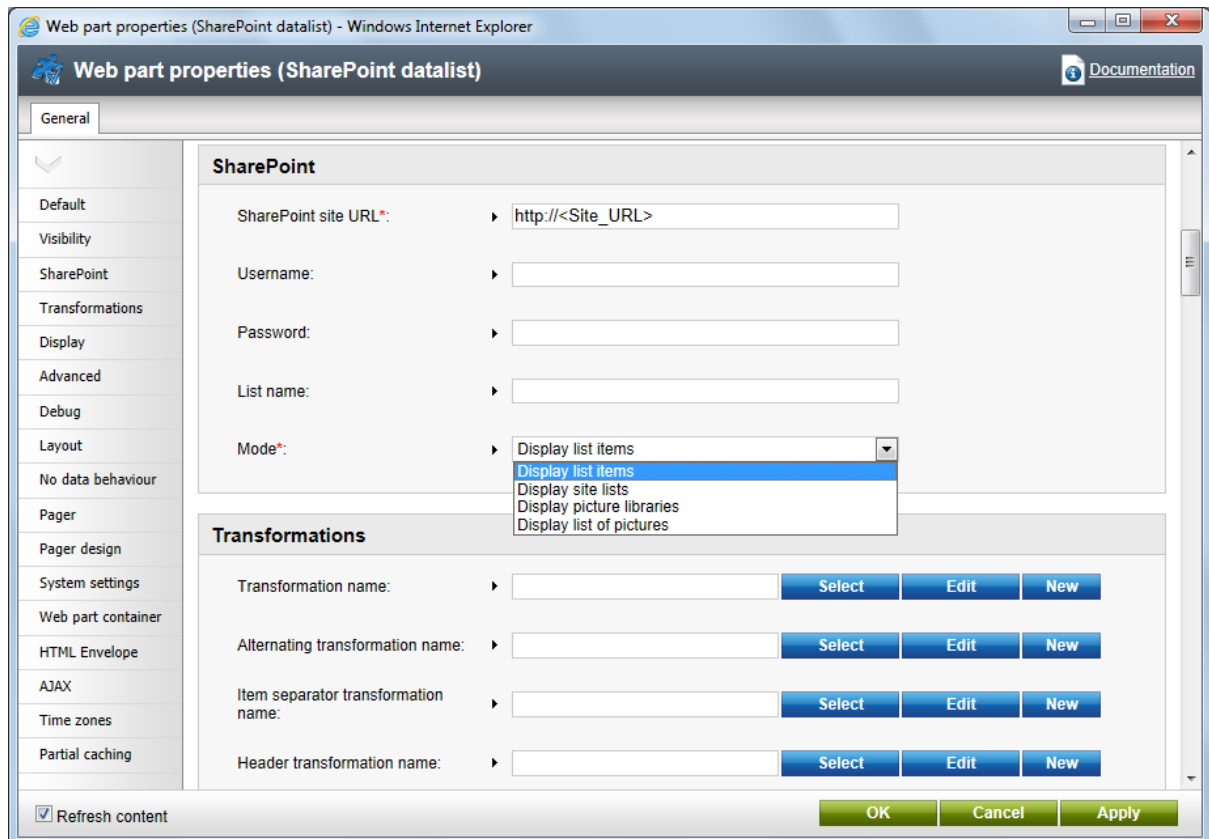

SharePoint

The following properties can be configured in the **SharePoint** section. All the web parts listed above have these settings in common.

- **Mode** - determines what the web part will do (what data will be retrieved from the SharePoint server) and therefore which web service should be used.
- **SharePoint site URL** - specifies the URL of the SharePoint site that should be used. Based on the value of the *Mode* property, the full URL of the required web service is determined by this option (it is not configured directly).
- **Username, Password** - you can specify the username and password for authentication directly in the web part properties, or you can inherit global values from *Site Manager* -> *Settings* -> *Integration* -> *Microsoft SharePoint*. If you want to use the credentials from the Site Manager [settings](#), leave the fields empty.

- **List name** - if you use the *Display list items* or *Display list of pictures* options, you must specify the list from which the items should be loaded. In the other two modes, you can leave it empty. Please note: this field is case sensitive.

Just these settings should make the **SharePoint datagrid** display data or the **SharePoint datasource** to provide them. The other two web parts still need to have a transformation specified.

Transformations

The **SharePoint datalist** and **SharePoint repeater** need to have a transformation specified in order to display the retrieved data.

There is a number of pre-defined transformations which you can use almost right-off and of course modify them according to your needs. The transformations are stored under the **SharePoint - Transformations** document type (can be edited in **Site Manager -> Development -> Document types**). Their names are self-explaining - they correspond to what they should be used for.

The only thing you need to do to get them to work is edit (✎) them and **replace the sample server or field names with the real names** used on the SharePoint server.

Advanced

In the **Advanced** section, you can specify (limit) in more detail what you want to retrieve. These settings are applied only in the "Get list items" mode.

- **Row limit** - sets the maximum number of retrieved items.
- **Query** - filters or sorts the returned items. Its purpose is similar to that of a WHERE condition in SQL, but it has completely different syntax based on CAML. For more information on how to construct such queries, search SharePoint documentation or use Google with keywords like "SharePoint query".
- **View fields** - directly specifies which fields (columns) of a SharePoint list should be retrieved.

Display

In this section, you can control how the retrieved data will be processed and displayed.

- **Selected item querystring key name** - if entered, items will be selected based on the presence of this key in the URL query string.
- **Selected item field name** - allows you to specify the field that is used to select items. The default approach is to select items by ID — the web part tries to get the query string parameter specified in the *Selected item querystring key* property and uses its value, e.g. If you entered `id` into the property above, `aspx?id=2` will select the item with 2 in its ID field. Note: the original field name is used here — without the `ows_` prefix. This field is case sensitive.
- **Selected item field type** - specifies the type of the *ItemID* field. For IDs, you should use the *Counter* type, for strings, use the *Text* type. These two should be sufficient for most cases, but you can search SharePoint documentation for other types.
- **Use dataset** - if enabled, the retrieved XML data will be converted to a dataset that can be used with standard ASCX transformations. If disabled, the data will not be modified and can be converted directly to HTML using XSLT.
- **Dataset fields** - if you want to use the dataset format, but you don't need all fields, you can specify which fields should be included in the dataset by entering their names separated by semicolons. This property can be particularly useful if you want to use caching.

Please note: Properties in the **Display** section are not available for the **SharePoint datagrid** web part.

Debug

Because it is sometimes hard to tell or remember how SharePoint addresses list fields, we implemented the **Show raw response** function. It displays all retrieved SharePoint data in its raw XML form. You can look for fields which contain valuable information and can be displayed. Note: if the data is fetched from the cache, the response can't be printed.

8.42.3 Usage examples

8.42.3.1 Site hierarchy

In this example, you will see how to display site lists which resemble the site hierarchy panel in the SharePoint site. It is quite simple. In fact, it only requires setting the *Display site lists* mode.

This can be done by adding one of the SharePoint web parts (e.g. **Microsoft SharePoint -> SharePoint repeater**) and configuring them the following way:

- **SharePoint site URL:** URL of your SharePoint server.
- **Mode:** Display site lists.
- **Username, password:** enter your username and password or leave the fields empty if you have them configured in *Site manager -> Settings -> Integration -> Microsoft SharePoint*.
- **Transformation:** there is a prepared transformation for displaying a site hierarchy called *SiteHierarchy* under the *SharePoint – Transformations* document type. For correct behavior, you must only change the name of the SharePoint server.

Leave default values for the rest of the properties and click **OK**. You should see a result similar to the screenshot below - it simply creates a link to each of the lists on the SharePoint server.

8.42.3.2 List items

The *Display list items* mode enables you to display items from any list from the SharePoint server.

| CustomerNum | CustomerName | Company | Street | City | State | ZipCode | Phone |
|-------------|-----------------------|--------------------------|-------------------------|-------------|-------|---------|----------------|
| 101 | Mr. Walter Reed | | 150 Hall Road | Brooklyn | NY | 03038 | (603) 124-1824 |
| 102 | Mr. Toby Stein | | 431 North Phillips Road | Brooklyn | NY | 03038 | (603) 332-8847 |
| 103 | Mr. Donald Bench | | 409 King Street | Brooklyn | NY | 03053 | (603) 336-2046 |

| 154 | Ms. Betty Shevin | Betty's BSB | 37 Queue Highway | Queens | NY | 01827 | (508) 966-5364 |

Let's say that in SharePoint, there is a custom list called *Customers*, storing information about company customers in fields like *Customer name*, *Street*, *City*, *Phone*, etc. Let's say that we want to display data from this list on our Kentico CMS website.

1. This can be done by adding one of the SharePoint web parts (e.g. **Microsoft SharePoint -> SharePoint repeater**) and configuring them the following way:

- **SharePoint site URL:** URL of your SharePoint server.
- **Mode:** Display list items.
- **Username, password:** enter your username and password or leave the fields empty if you have it configured in *Site manager -> Settings -> Integration -> Microsoft SharePoint*.
- **Transformation:** there is a prepared transformation for item lists called **ListItems** under the **SharePoint – Transformations** document type; for correct behavior, you must only change the name of the SharePoint server.
- **Show raw response:** enabled; this is because we will need to inspect the retrieved data and change the transformation to suit our needs.

Leave the default values for the rest of the properties and click **OK**. You should see a result similar to the screenshot below.

```
(2009-06-26 13:24:54)
(2009-06-26 13:24:54)
(2009-06-26 13:24:54)
(2009-06-26 13:24:54)
(2009-06-26 13:24:54)
```

```
<rs:data ItemCount="49" xmlns:rs="urn:schemas-microsoft-com:rowset">
  <:row ows_Attachments="0" ows_LinkTitle="101" ows_CustomerName="Mr. Walter Reed" ows_Street="150 Hall Road" ows_City="Brooklyn" ows_State="NY" ows_Stat
  <:row ows_Attachments="0" ows_LinkTitle="102" ows_CustomerName="Mr. Toby Stein" ows_Street="431 North Phillips Road" ows_City="Brooklyn" ows_Stat
  <:row ows_Attachments="0" ows_LinkTitle="103" ows_CustomerName="Mr. Donald Bench" ows_Street="409 King Street" ows_City="Brooklyn" ows_State="NY"
  <:row ows_Attachments="0" ows_LinkTitle="104" ows_CustomerName="Ms. Joan Hoffman" ows_Street="350 Garfield Avenue" ows_City="Westchester" ows_Sta
  <:row ows_Attachments="0" ows_LinkTitle="105" ows_CustomerName="Ms. Barbara Pasaco" ows_Company="Pasaco Premiums" ows_Street="230 South Phillips
  <:row ows_Attachments="0" ows_LinkTitle="106" ows_CustomerName="Mr. Herb Merritt" ows_Company="Herb's Heaven" ows_Street="130 Willow Street" ows_Stat
  <:row ows_Attachments="0" ows_LinkTitle="107" ows_CustomerName="Ms. Doris Reaume" ows_Company="Green Glory" ows_Street="82 Seneca Street" ows_Cit
```

2. That's not exactly what we want. We would like to see the customers' name and city. We must look into the raw output and search for those fields. We find them there under the *ows_CustomerName* and *ows_Street* attributes.

Now that we know the names of the attributes, we need to edit the transformation code or create a new

transformation.

Replace the original **Transformation**:

```
<%# Eval("ows_Title") %> (<%# Eval("ows_Created")%>) <br />
```

With something like this:

```
<%# Eval("ows_CustomerName") %> - <%# Eval("ows_City")%> <br />
```

The output looks better now, it displays the desired values.

```
Ms. Janice Stapleton - Flushing
Mr. Joe Markovicz - Queens
Mr. Paul Jenson - Queens
Mr. Lee Guazzo - Queens
Ms. Kim Hajek - Queens
rss:data ItemCount="49" xmlns:rs="urn:schemas-microsoft-com:rowset">
  <:row ows_Attachments="0" ows_LinkTitle="101" ows_CustomerName="Mr.
  <:row ows_Attachments="0" ows_LinkTitle="102" ows_CustomerName="Mr.
  <:row ows_Attachments="0" ows_LinkTitle="103" ows_CustomerName="Mr.
  <:row ows_Attachments="0" ows_LinkTitle="104" ows_CustomerName="Ms.
  <:row ows_Attachments="0" ows_LinkTitle="105" ows_CustomerName="Ms.
```

3. Now we would like to be able to click each item and see more detail about it. We must prepare the **Selected item transformation**. The transformation may look like the following code sample:

```
<strong><%# Eval("ows_CustomerName") %></strong><br/>
<%# Eval("ows_City")%> <br/>
<%# Eval("ows_Street")%> <br/>
<%# Eval("ows_Phone")%> <br/>
```

4. In web part properties, we must enter the field name of the field by which we want to select items. In this case, it is the *ID* field. In raw response output, it can be seen as *ows_ID*. So enter the following values:

- **Selected item querying key name:** id
- **Selected item field name:** ID
- **Selected item field type:** Counter

Finally we must alter the original **Transformation** to suit the values we just entered, i.e. to create a link to customer details using the *id* parameter in query string. It can look like this.

```
<a href="<%# CMS.GlobalHelper.URLHelper.AddParameterToUrl(CMSContext.RawUrl,"id",
(string)Eval("ows_ID")) %>">
<%# Eval("ows_CustomerName") %> - <%# Eval("ows_City")%> </a><br />
```

The final result looks like this - a simple text list of customers with links:

[Mr. Gregory Olsen - Brooklyn](#)
[Ms. Shirley Woodruff - Queens](#)
[Mr. Wayne Bouwman - Queens](#)
[Mr. Ken Hodge - Hampton](#)
[Ms. Pam Leonard - Hampton](#)
[Ms. Michele Yasenak - Boxford](#)

After clicking a customer name, a detail of the customer is displayed.

Mr. Wayne Bouwman
 Queens
 400 Salmon Street
 (508) 966-9827

```
<rs:data ItemCount="1" xmlns:rs="urn:schemas-microsoft-com:rowset">
  <s:row ows_Attachments="0" ows_LinkTitle="123" ows_CustomerName="Mr. Wayne Bouwman" ows_Street="400 Salmon Street"
</rs:data>
```

5. Now let's configure the **Advanced** settings. We will want a maximum of 10 customers to be displayed and we want to display only customers from *Queens*.

Enter number 10 into the **Row limit** field and use this code as the **Query**:

```
<Query>
<Where><Eq><FieldRef Name="City" /><Value Type="Text">Queens</Value></Eq></Where>
</Query>
```

The `<Eq>` tag means equals; field name is *City*, and its value of type *Text* should be equal to *Queens*.

Click **OK**, you should see the filtered output now as in the following screenshot:

[Ms. Shirley Woodruff - Queens](#)
[Mr. Wayne Bouwman - Queens](#)
[Ms. Betty Shevlin - Queens](#)
[Ms. Deborah Wolfe - Queens](#)
[Ms. Kelly Smith - Queens](#)
[Mr. Paul Griffin - Queens](#)
[Mr. Joe Markovicz - Queens](#)
[Mr. Paul Jenson - Queens](#)
[Mr. Lee Guazzo - Queens](#)
[Ms. Kim Hajek - Queens](#)

```
<rs:data ItemCount="10" xmlns:rs="urn:schemas-microsoft-com:rowset">
  <s:row ows_Attachments="0" ows_LinkTitle="122"
  <s:row ows_Attachments="0" ows_LinkTitle="123"
  </rs:data>
```

8.42.3.3 Picture libraries

In this example, we use SharePoint to retrieve only a picture library type list. For setup, you must only set the following properties:

- **SharePoint site URL:** URL of your SharePoint server.
- **Mode:** Display picture libraries.
- **Username, password:** enter your username and password or leave the fields empty if you have it configured in *Site manager -> Settings -> Integration -> Microsoft SharePoint*.
- **Transformation:** there is a prepared transformation for picture libraries called **PictureLibLists** under the **SharePoint – Transformations** document type. For correct behavior, you must only change the name of the SharePoint server.

Leave default values for the rest of the properties and click **OK**. You should see a result similar to the screenshot below - it shows a list of picture libraries with links to the SharePoint server.

[Empty](#)
[Images](#)
[My Pictures](#)
[sites](#)

8.42.3.4 List of pictures

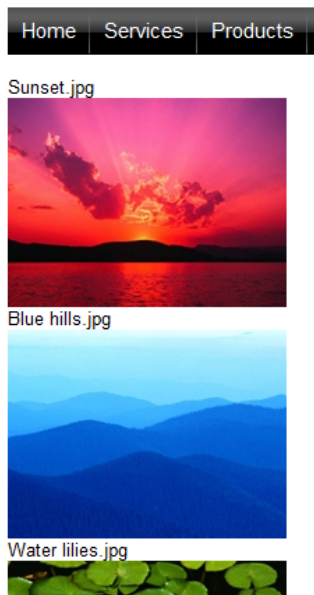

The *Display list of pictures* mode enables you to display pictures from picture libraries on a SharePoint server.

On the SharePoint server, we have a picture library named *Images* and 3 pictures in it. We want to display these pictures in our Kentico CMS site. For setup, you must enter the following properties of the web part (e.g. SharePoint repeater):

- **SharePoint site URL:** URL of your SharePoint server.
- **Mode:** Display list of pictures.
- **Username, password:** enter your username and password or leave the fields empty if you have it configured in *Site manager* -> *Settings* -> *Integration* -> *Microsoft SharePoint*.
- **List name:** Images
- **Transformation:** there is a prepared transformation for picture lists called *Pictures* under the *SharePoint – Transformations* document type. For correct behavior, you must only change the name of the SharePoint server.

Leave default values for the rest of the properties and click **OK**. You should see a result similar to the screenshot below.

The transformation code looks like this:

```
<%# SharePointFunctions.SplitSharePointField((string)Eval("ows_FileLeafRef"),1) %
><br/>
&maxsize=200" /> <br />
```

The images are downloaded through the **GetSharePointFile.aspx** page, same as documents. So we create `` tags with `src` attributes pointing to this page in the transformation. For ease of use, there is the **GetSharePointFileUrl** function in the **SharePointFunctions** class, which takes two parameters and returns the URL which downloads the file. The first parameter is server name (or site url), the second parameter is the location of the file in SharePoint. The final URL looks like this:

- `~/CMSModules/Sharepoint/CMSPages/GetSharePointFile.aspx?server=server_name&name=Images/Sunset.jpg`

Please note: Credentials from settings are always used for downloading the file when the **GetSharePointFile** page is used.

There is another useful function in the **SharePointFunctions** class called **SplitSharePointField**. SharePoint for some reason creates combined attribute values for some fields. It looks like this - `ows_FileLeafRef="2;#Blue hills.jpg"`. We would often like to use only a part of such a value. The **SplitSharePointField** function serves this purpose. The first argument is a combined value and the second one is the index of the part we want in the output.

8.42.3.5 GetSharePointFile page

The **GetSharePointFile.aspx** page is a special page located under the `~/CMSModules/Sharepoint/CMSPages` directory. The correct URL to access the page looks like the following:

- `~/CMSModules/Sharepoint/CMSPages/GetSharePointFile.aspx?`

`server=server_name&name=Images/Sunset.jpg`

It downloads the specified file from the SharePoint server and sends it further to the user. Credentials configured in **Site Manager -> Settings -> Integration -> Microsoft SharePoint** are used for authentication by the web service. You can control the Content-Disposition HTTP header using the *disposition* query parameter.

For images, it supports *maxsize*, *width* and *height* parameters to control the image size. Kentico CMS cache is used for images, you can configure it in **Site Manager -> Settings -> System -> Performance -> Cache images (minutes)**.

You can also specify servers, from which files can be retrieved. Enter the servers, delimited by semicolons, into the setting **Site Manager -> Settings -> Integration -> Microsoft SharePoint -> Allowed servers**.

Important!

Because the settings configured in **Site Manager -> Settings -> Integration -> Microsoft SharePoint** are automatically used for authentication by the **GetSharePointFile.aspx** page and since the URL to access the page can be entered manually, it is highly recommended to enter the credentials of a user that is authorized to access only the files you want to display on your website.

8.42.4 Settings

Default logon credentials used to access the SharePoint server can be configured in **Site Manager -> Settings -> Integration -> Microsoft SharePoint**. If you configure a **Username** and **Password** here, it will be used by default if you leave the *Username* and *Password* fields **blank** in the properties of SharePoint web parts.

If you enable the **Use Windows Authentication** option, the current user's windows domain credentials will be used to access the SharePoint server.

The address of the SharePoint server itself needs to be specified in the properties of SharePoint web parts.

The screenshot shows the Kentico CMS 7.0 Settings page for Microsoft SharePoint. The interface includes a top navigation bar with tabs for Sites, Administration, Settings (selected), Development, Tools, Dashboard, Licenses, Support, and Buy. The user is logged in as Global Administrator. On the left, a tree view shows the Settings hierarchy, with 'Microsoft SharePoint' selected under 'Integration'. The main content area displays the 'Microsoft SharePoint' settings, including a 'Save' button and a 'Reset these settings to default' link. A note states: 'These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.' The 'General' section contains three fields: 'Username' (administrator), 'Password' (masked with dots), and 'Use Windows Authentication' (unchecked). An 'Export these settings' link is located below the fields.

Important!

The settings configured here are automatically used for authentication by the [GetSharePointFile.aspx page](#) and since the URL to access the page can be entered manually, it is highly recommended to enter the credentials of a user that is authorized to access only the files you want to display on your website.

8.43 Smart search

8.43.1 Overview

The Smart search module allows index-based searching through the content of websites and various types of data within the system. It is based on **Lucene.Net** (version 2.1.0) which is a source code, class-per-class, API-per-API port of the Java **Lucene** search engine to the C# and .NET platform.

The module uses **indexes** to store information about the website content. When a users sends a search request, the system searches through the appropriate indexes, which results in **significantly better performance** compared to linear SQL query search. For more information on **how the module works**, please refer to the [How it works](#) topic.

To set up the smart search functionality on your website, you need to perform the following three steps:

1. [Enable](#) Smart search indexing in the system.
2. Create search indexes. Assign the indexes to your site (and culture) and define their exact content.

See the [Managing indexes](#) sub-chapter for more details.

3. Add Smart search web parts to the pages of your site. You can find an overview of these web parts, including explanations of the most important web part properties, in the [Available web parts](#) and [Using the Smart search filter](#) topics.

The following topics provide additional information about search related issues:

- [Search syntax](#)
- [Related scheduled tasks](#)
- [Searching attachments](#)
- [Search results in transformations](#)
- [Security](#)

In older versions, Kentico CMS supported only linear SQL search functionality. To keep the system backward compatible, this functionality is still available. It is now referred to as **SQL Search** and you can find further information about it in the [SQL Search overview](#) topic.

The [Smart search internals and API](#) sub-chapter provides information about the database tables and classes used by the module and examples of how smart search indexes can be managed using the API and how search results can be displayed in transformations.

8.43.2 How it works

Information about the content specified for smart search indexes is stored in physical **index files** on the local disk. The index files are located in the `~/App_Data/CMSModules/SmartSearch/<Index code name>` folder within your web project directory.

Documents, forums and other objects in Kentico CMS are reflected in the index file as **index documents**. The data structure of the index documents is much more suitable for being searched through, resulting in significantly higher search performance compared to linear SQL search.

The index documents contain the same fields as the corresponding Kentico CMS objects, based on the [search settings of individual object types](#). Depending on these settings, the **Index writer** creates representations of objects in the index files. When an object included in the index is created, removed or has one of its fields modified, the system automatically schedules an **Indexing task**, which update the corresponding index document. The **Index searcher** searches through the index file and returns the relevant results.

Example

The following model scenario explains the life cycle of a document in a search index file:

1. A user creates a new document.
2. Upon the document's creation, the system logs a new indexing task in the database.
3. The Smart search either runs the indexing task immediately or processes it later using a scheduled task.
4. When executed, the indexing task adds the new document to the appropriate search indexes. The system indexes the document's content based on the search field settings defined for the given

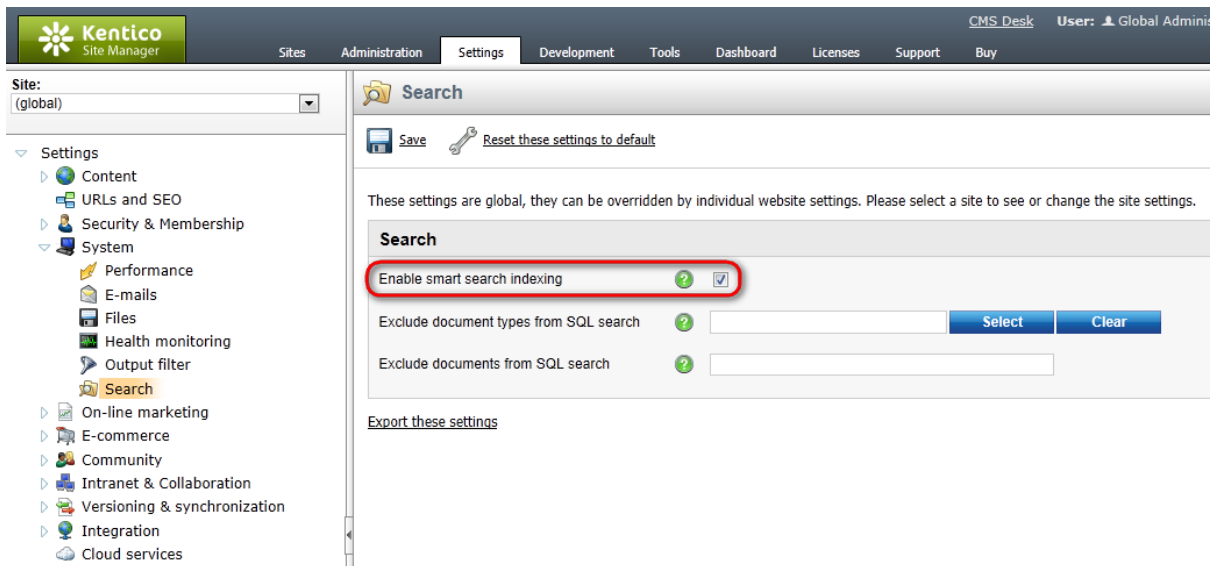

document type.

5. A user arrives on the website and sends a search request via a Smart search web part.
6. The web part searches through the assigned indexes and returns results based on the found data.

8.43.3 Enabling Smart search indexing

To enable Smart search indexing for all websites in the system:

1. Go to **Site Manager -> Settings -> System -> Search**.
2. Check **Enable smart search indexing** box.
3. Click  **Save**.

The screenshot shows the Kentico CMS Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The 'Settings' tab is active, and the 'Search' sub-tab is selected. The left sidebar shows a tree view of settings categories, with 'Search' highlighted under the 'System' category. The main content area displays the 'Search' settings for the 'global' site. The 'Enable smart search indexing' checkbox is checked and highlighted with a red circle. Below it, there are two input fields for 'Exclude document types from SQL search' and 'Exclude documents from SQL search', each with a 'Select' or 'Clear' button. At the bottom, there is an 'Export these settings' link.

Note: Your application must have the **write permission** for the `~/App_Data` folder on the server's file system. This folder stores the search index files, so the system cannot create and update indexes without the required permissions. See the [Disk permission problems](#) chapter to learn how to grant the write permission for the folder.

Scheduling the search indexing process

By default, the smart search creates and executes indexing tasks immediately whenever content covered by a [search index](#) is created or modified.

You can disable automatic running of indexing tasks upon creation by adding the **CMSProcessSearchTasksByScheduler** key to the `/configuration/appSettings` section of your application's web.config file:

```
<add key="CMSProcessSearchTasksByScheduler" value="true" />
```

When you set this key to *true*:

- The system only logs the search indexing tasks into the database without running them. You need to process the tasks periodically, for example using the **Execute search tasks** [scheduled task](#).
- You cannot manually **Rebuild** indexes unless you also run the process that executes the indexing tasks.

8.43.4 Managing indexes

8.43.4.1 Creating an index

Before you can use the Smart search module, you need to prepare the appropriate indexes for storing information about the website's content in an efficiently searchable format.

The following types of search indexes are available:

- [Documents](#) - stores information about the content of documents in the content tree.
- [Documents crawler](#) - directly indexes the HTML output of documents (pages).
- [Forums](#) - stores information about the content of discussion [forums](#) in the system.
- [Custom tables](#) - indexes records stored in [custom tables](#).
- [Users](#) - stores information about users in the system.
- [General](#) - stores information about system objects of a specified type.
- [Custom](#) - allows you to use your own custom-coded search index. Stores any kind of data depending on the implementation.

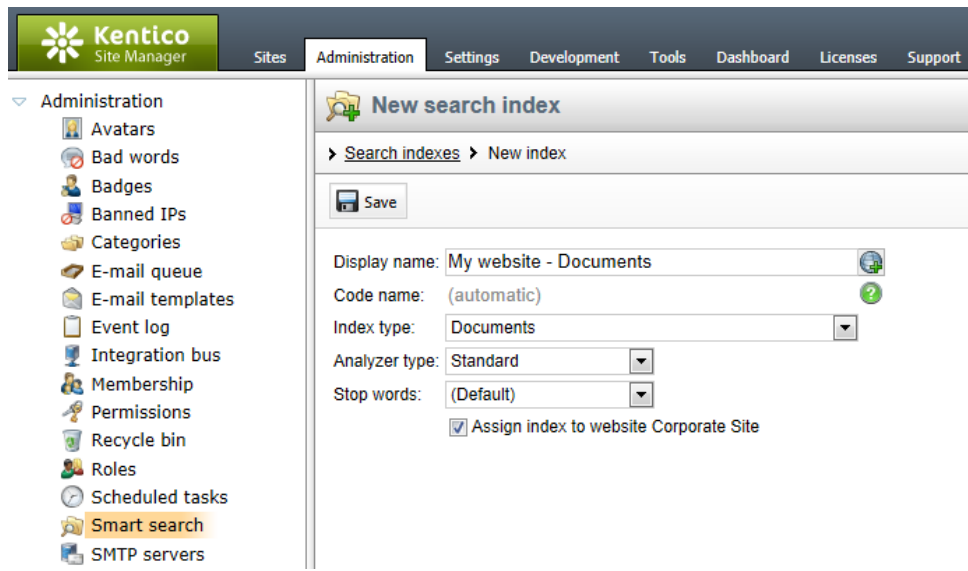

The following steps describe how to create smart search indexes for your website:

1. Go to **Site Manager -> Administration -> Smart search**.
2. Click  **New index**. The **New search index** dialog opens.
3. Fill in the following details for the index:

| | |
|--------------|--|
| Display name | Name of the index displayed in the administration interface. |
| Code name | Name of the index used as a unique identifier, typically in web part properties or in the API. You can leave the default (<i>automatic</i>) option to have the system generate a code name based on the display name.

Warning: This name is also used for the physical index file. The fully qualified name of the file must be less than 260 characters long, including the directory path. |
| Index type | Determines what type of content is stored in the index. The following index types are available: <ul style="list-style-type: none"> • Custom index - indexes any kind of data depending on the implementation. • Custom tables - indexes records in custom tables. • Documents - indexes the content of documents in the content tree. • Documents crawler - indexes the HTML output of the website's documents (pages). • Forums - indexes the content of discussion forums. • General - indexes system objects of a specified type. General indexes allow you to search through any objects within the CMS. • Users - indexes details about users in the system (fields of the |

| | |
|---------------------------------------|---|
| | <i>CMS_User</i> system table). |
| Analyzer type | <p>Sets the type of text analyzer that the index uses to process (tokenize) content. The following analyzer types are available:</p> <ul style="list-style-type: none"> • Custom - allows you to assign a custom-written analyzer. This provides a way to perform text tokenization according to your own specific requirements. If selected, you need to specify the names of the assembly and class where the custom analyzer is implemented. See Using custom analyzers for more information. • Keyword - returns the entire text stream as a single token. This is useful for structured data fields like zip codes or IDs. • Simple - divides text at non-letter characters. • Standard - grammar-based analyzer (stop words, shortcuts, ...). This option is very efficient for English, but may not produce satisfactory results with other languages. • Starts with - tokenizes all prefixes contained in words, which allows searching for words that start with the search keyword. Divides text at whitespace characters. For example, searching for <i>test</i> returns words such as <i>test</i>, <i>tests</i>, <i>tester</i>, etc. • Stop - uses a predefined collection of stop words to divide text. • Subset - tokenizes all possible substrings in words. Divides text at whitespace characters. Indexes with this analyzer type return results for all words that contain the search keyword. For example, searching for <i>net</i> returns words such as <i>net</i>, <i>Internet</i>, <i>network</i>, etc. • White space - divides text at whitespace characters. |
| Stop words | <p>Selects the stop word dictionary for <i>Stop</i> or <i>Standard</i> analyzers.</p> <p>Stop words (e.g., 'and', 'or') are excluded from the index content and the analyzer uses them to divide text into tokens.</p> <p>You can edit the content of the dictionaries or add new ones. The application stores the dictionaries as text files in the <code>~\App_Data\CMSModules\SmartSearch_StopWords</code> folder.</p> |
| Assign index to website
<sitename> | Check this box to automatically assign the new index to the currently active site. |

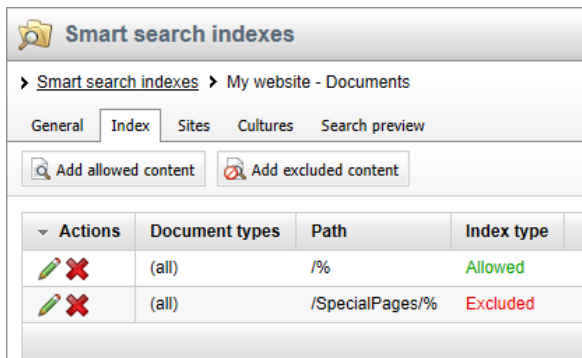

Creating a new document index

4. Click  **Save** to create the search index. The **General** tab of the index's editing interface opens, where you can edit the same properties that you configured when creating the index.

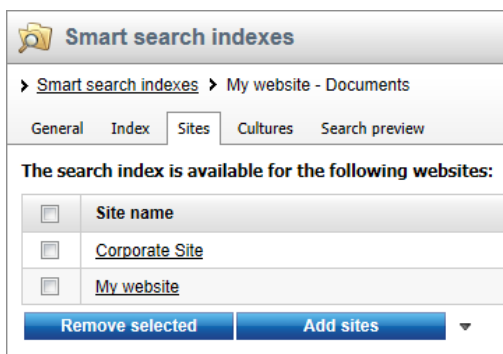

Additionally, you can set the **Batch size** property for the index, which sets the maximum amount of records that the system retrieves in a single database query when rebuilding (or creating) the index. This allows you to optimize indexing performance. The default value is 10. Increasing the value reduces the amount of queries required for large numbers of records, which may improve performance, but also increases memory consumption. The optimal value depends on the type (size) of the indexed objects and on the resources available in your hosting environment. When indexing large objects (e.g. documents), it is recommended to set a reasonably small batch size.

5. Switch to the **Index** tab and define which documents, forums, custom tables, users or other objects should be included in the index. The options available on the Index tab depend on the type of the index. You can find detailed information about setting the content of individual index types in the following topics:

- [Defining document index content](#)
- [Defining forums index content](#)
- [Defining custom tables index content](#)
- [Defining user index content](#)
- [Defining general index content](#)
- [Defining custom index content](#)

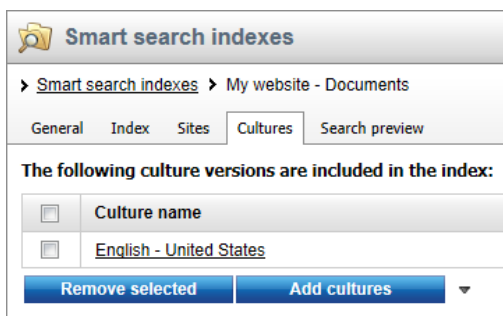

6. Open the **Sites** tab and assign the index to the websites where you wish to use it. You can implement multi-site search functionality by assigning the index to more than one website.

Note: If the index includes global objects that are not site-specific, the selection made on the Sites tab does not affect the index's content. However, the index is only available for use (through [Smart search web parts](#)) on the assigned sites.

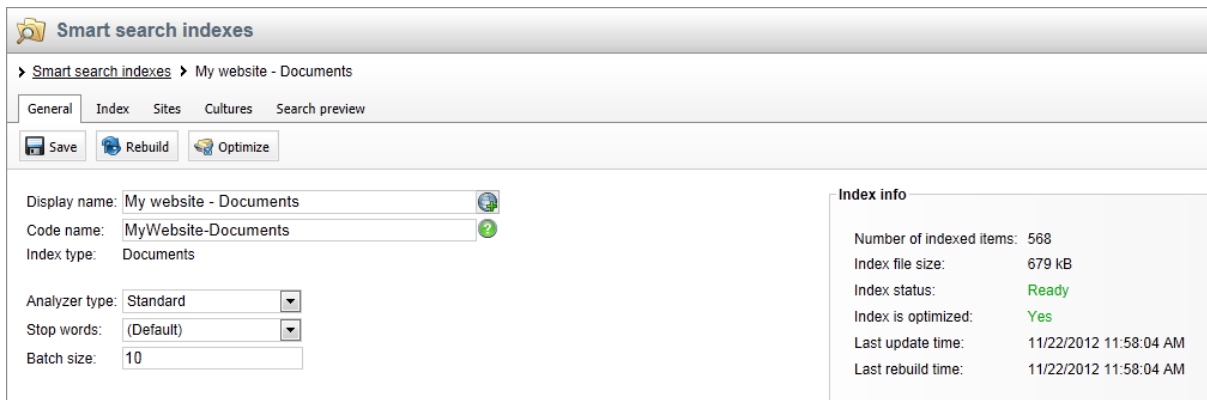

7. If you are creating a *Documents* or *Documents crawler* type index, switch to the **Cultures** tab. Here you need to select which language versions of the website's documents should be indexed.

- You must assign at least one culture in order for the index to be functional.
- If you have a multi-site index, you can select the cultures separately for each site.

8. Go back to the **General** tab and **Rebuild** the index.

- The **Index info** box on the right side of the General tab displays current information about the status and properties of the index.

Once the system finishes building the index, you can start using it on your website. The **Search preview** tab allows you to test the functionality of the index.

Maintaining search indexes

You can manage existing search indexes using the actions available on the **General** tab of the index editing interface.

The system automatically updates search indexes to reflect all changes made to the indexed content. Over time, these updates can make indexes less efficient, particularly in the case of large indexes.

To restore optimal search performance for an index, defragment it by clicking the **Optimize** action. You can enable the **Optimize search indexes** [scheduled task](#) to have the system automatically optimize all smart search indexes once per week.

The **Rebuild** action deletes the current index file and indexes all specified content again.

- Use the rebuild action to apply changes made to the index's configuration. This includes modifications of the analyzer settings (*Analyzer type*, *Stop words*), all options on the *Index*, *Sites* or *Cultures* tabs, and adjustments of the [search field settings](#) for the indexed objects.
- The system automatically optimizes the index after a successful rebuild.

Note

Clicking the **Rebuild** action does not always guarantee that the index starts rebuilding immediately. The process may be delayed if another index is already being rebuilt or if the rebuilding tasks are configured to be handled by the scheduler.

8.43.4.2 Defining document index content

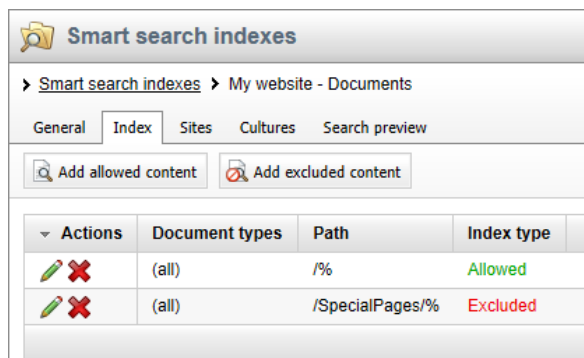

There are two types of search indexes available for the documents in a website's content tree.

Documents type indexes include information from general document fields such as metadata, the text content of certain web parts placed on page (menu item) documents, as well as the selected fields of

individual documents types (described in the [Settings for particular object types](#) topic). Data from other documents or objects displayed by web parts is not indexed. For example, the content of news documents displayed by a **Repeater** web part placed on an indexed document will not be added to the index etc.

Documents crawler type indexes directly parse the HTML output generated by documents, which means that all text located on or associated with a document is searchable. This allows document content to be searched more accurately than using a **Documents** type index. However, building and updating a **Documents crawler** index may require more time and resources, particularly in the case of large indexes and complex documents. The crawler accesses documents under a specific user account (the **administrator** account by default). You can set the details of the crawler account by adding keys to your project's web.config file. All keys related to smart search indexes are listed in the [Smart search settings](#) section of Appendix B - Web.config parameters.

The process used to define which documents on the site should be indexed is the same for both document index types. Specify allowed or excluded content on the **Index** tab of the index's editing interface by clicking  **Add allowed content** or  **Add excluded content** respectively.

Adding allowed content

Allowed content defines which of the website's documents are included in the index. Specify documents using a combination of the following options:

- **Path** - [path expression](#) identifying the documents that should be indexed.
- **Document types** - allows you to limit which [document types](#) are included in the index.

The following properties define types of additional content that you can include in *Documents* search indexes. They are not available for *Documents crawler* indexes:

- **Include ad-hoc forums** - if checked, the index also includes the content of ad-hoc forums placed on the specified documents (if there are any).
- **Include blog comments** - if checked, the index also includes blog comments posted for the blog post documents.
- **Include message boards** - if checked, the index also includes message boards placed on the specified documents.
- **Include categories** - if enabled, the index stores the display names of [Categories](#) assigned to the specified documents. This means that the search results also include documents that belong to categories whose name matches the search expression.

Smart search indexes

> Smart search indexes > Corporate Site - Default

General
Index
Sites
Cultures
Search preview

> Item list > New allowed item

Save

Path: Select

Document types: Select Clear

Leave the field empty if you wish to choose all document types.

Include ad-hoc forums:

Include blog comments:

Include message boards:

Include categories:

Examples:

| Allowed content settings | Result |
|--|--|
| <ul style="list-style-type: none"> Path: /% Document types: empty | Indexes all documents on the site. |
| <ul style="list-style-type: none"> Path: /Partners Document types: empty | Only indexes the <i>/Partners</i> page, without the child pages placed under it. |
| <ul style="list-style-type: none"> Path: empty Document types: CMS.News | Indexes all documents of the <i>CMS.News</i> document type on the entire site.

In this case, an empty path field value is equal the <i>/%</i> expression. |
| <ul style="list-style-type: none"> Path: /Products/% Document types: CMS.Smartphone;CMS.Laptop | Indexes all documents of the <i>CMS.Smartphone</i> and <i>CMS.Laptop</i> document types found under the <i>/Products</i> section. |

Adding excluded content

Excluded content allows you to remove documents or entire website sections from the allowed content. For example, if you allow */%* and exclude ***/Special-pages/%*** at the same time, the index will include all documents on the site except for the ones found under the ***/Special-pages*** node.

You can specify the following options:

- Path** - [path expression](#) identifying the documents that should be excluded.
- Document types** - allows you to limit which [document types](#) are excluded from the index.

 **Smart search indexes**

> [Smart search indexes](#) > Corporate Site - Default

General | **Index** | Sites | Cultures | Search preview

> [Item list](#) > Current item

Path:

Document types:

Leave the field empty if you wish to choose all document types.

Examples:

| Excluded content settings | Result |
|--|---|
| <ul style="list-style-type: none"> Path: /Partners Document types: empty | Excludes the <i>/Partners</i> page from the index. Child pages are not excluded. |
| <ul style="list-style-type: none"> Path: empty Document types: CMS.News | Excludes all documents of the <i>CMS.News</i> document type from the index.

In this case, an empty path field value is equal the <i>/%</i> expression. |
| <ul style="list-style-type: none"> Path: /Products/% Document types: CMS.Smartphone;CMS.Laptop | Excludes all documents of the <i>CMS.Smartphone</i> and <i>CMS.Laptop</i> document types found under the <i>/Products</i> section from the index. |

Excluding individual documents from all indexes

You can also exclude specific documents from all smart search indexing:

1. Go to **CMS Desk** and select the given document in the content tree.
2. In **Edit** mode, open the **Properties -> Navigation** tab.
3. Enable the **Exclude from search** property.
4. Click  **Save**.

Customizing how document crawler indexes process page content (API)

By default, the system converts the HTML output of documents to plain text (stripped of all HTML tags, JavaScript and whitespace formatting) before saving it to document crawler indexes. If you wish to index the content of any tags or exclude parts of the page output, you can customize how the crawlers process the HTML.

You need to implement your custom functionality in a handler for the **OnHtmlToPlainText** event of the **CMS.SiteProvider.SearchHelper** class. This event occurs whenever a document search crawler processes the HTML output of a page.

To assign a method as the handler for the *OnHTMLToPlainText* event, add a new class to the *~/App_Code* folder of your web project (or *~/Old_App_Code* on web application installations). You can define the content of the class as shown below:

[C#]

```
using CMS.SettingsProvider;
using CMS.SiteProvider;

[DocumentCrawlerContentLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Attribute class for assigning event handlers.
    /// </summary>
    private class DocumentCrawlerContentLoaderAttribute : CMSLoaderAttribute
    {
        /// <summary>
        /// Called automatically when the application starts.
        /// </summary>
        public override void Init()
        {
            // Assigns a handler for the OnHtmlToPlainText event
            SearchHelper.OnHtmlToPlainText += new
            SearchHelper.HtmlToPlainTextHandler(SearchHelper_OnHtmlToPlainText);
        }

        static string SearchHelper_OnHtmlToPlainText(string plainText, string
originalHtml)
        {
            // Add your custom HTML processing actions and return the result as a
string
        }
    }
}
```

The *OnHTMLToPlainText* event provides the following string parameters to the handler:

- **plainText** - contains the page output already stripped of all tags and converted to plain text.
- **originalHTML** - allows you to access the raw page code without any modifications.

8.43.4.3 Defining forums index content

On the **Index** tab of a **forum index**, you can define which forums from the system will be indexed. This is done by defining allowed and excluded forums.

The dialogs for defining new allowed/excluded content can be accessed using  **Add allowed forums** and  **Add excluded forum**.

The screenshot shows the Kentico Site Manager Administration interface. The left sidebar contains a navigation menu with the following items: Administration, Avatars, Bad words, Badges, Banned IPs, Categories, E-mail queue, E-mail templates, Event log, Integration bus, Membership, Permissions, Recycle bin, Roles, Scheduled tasks, Smart search (highlighted), and SMTP servers. The main content area is titled "Smart search indexes" and shows the configuration for "Corporate Site - Forums". It has tabs for "General", "Index", "Sites", and "Search preview". Below the tabs are two buttons: "Add allowed forums" and "Add excluded forum". A table lists the current forum configurations:

| Actions | Forums | Site name | Index type |
|---------|-------------------------|---------------|------------|
| | GeneralDiscussionGroups | CorporateSite | Allowed |
| | Groupannouncements | CorporateSite | Excluded |

Adding allowed forums

1. Click **Add allowed forums**.

2. In the following dialog, first use the **Site name** drop-down to choose the site whose forums will be indexed. If you select **(all)**, all forums on all sites in the system will be indexed. Only websites assigned to the index on the **Sites** tab are available for selection.

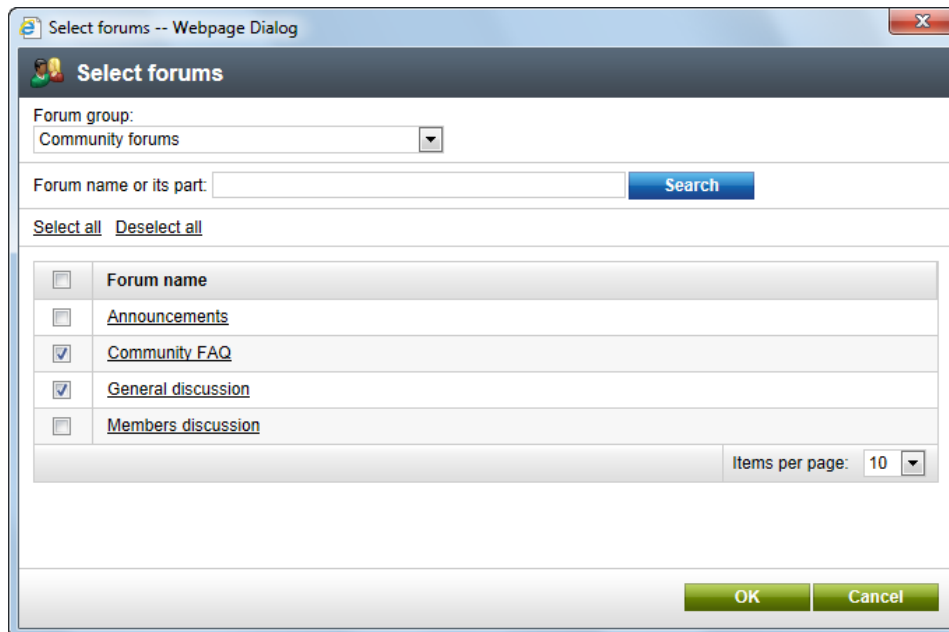

The screenshot shows the "Smart search indexes" dialog for adding a new allowed item. It has tabs for "General", "Index", "Sites", and "Search preview". Below the tabs are two buttons: "Add allowed forums" and "Add excluded forum". A table lists the current forum configurations:

| Actions | Forums | Site name | Index type |
|---------|-------------------------|---------------|------------|
| | GeneralDiscussionGroups | CorporateSite | Allowed |
| | Groupannouncements | CorporateSite | Excluded |

Below the table, there is a "Save" button and a "Site name" drop-down menu with "Corporate Site" selected. Below that is a "Forums" field with a "Select" button. A note below the field reads: "Leave the field empty if you wish to choose all forums on the selected site."

3. If you selected a particular site in the previous step, click the **Select** button next to the **Forums** field. The dialog depicted in the screenshot below will be displayed.

Use the **Forum group** drop-down to select a forum group. Its child forums will be listed below. To include a forum in the index, enable () the appropriate check-boxes. Click **OK** to save the settings.

Alternatively, you can manually enter the code names of forums into the **Forums** field, separated by semicolons. All forums on the selected site can be added to the index this way, including group forums. The asterisk character (*) can be used as a wildcard for any number of characters. For example, entering **community** adds all forums that contain the string *community* in their code name to the index.

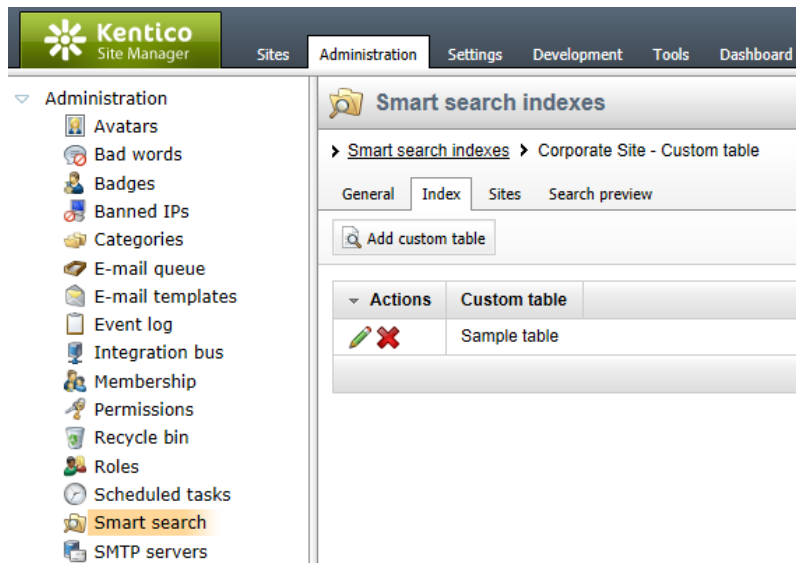

Adding excluded forums

Excluded forums make sense only when you have all forums defined as allowed. By defining a forum as excluded, it will not be indexed and all forums except for the excluded one will be indexed.

You can define an excluded forum using  **Add excluded forums**, while the procedure is the same as when adding allowed forums.

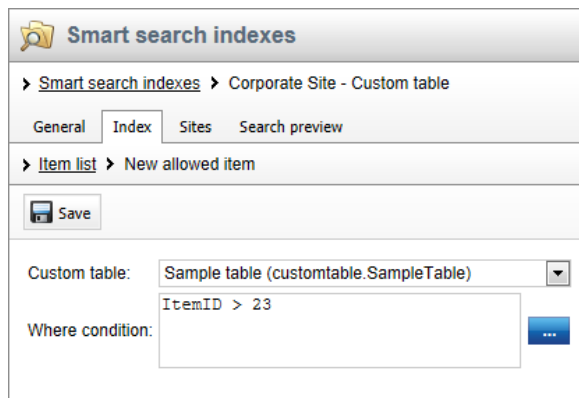

8.43.4.4 Defining custom tables index content

When editing () a custom table index on the **Index** tab in **Site Manager -> Administration -> Smart search**, you can see a list of custom tables included in the index. Custom tables can be added to the index using the  **Add custom table** button. You can also **Edit** () the way listed custom tables are indexed or **Delete** () them from the list.

When adding a new custom table to the index or editing an existing one, you have the following options:

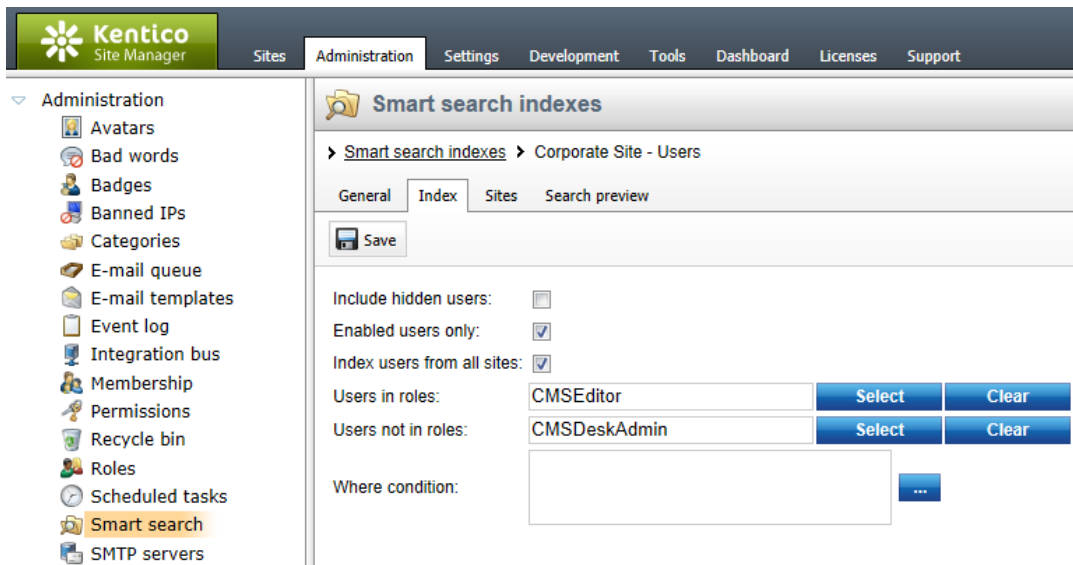

- **Custom table** - custom table to be indexed.
- **Where condition** - WHERE clause of the queries run against the custom table when building the index. This can be used to limit which records (rows) in the table should be included.

8.43.4.5 Defining user index content

When editing (✎) a user index on the **Index** tab in **Site Manager -> Administration -> Smart search**, you can limit which users will be indexed. The dialog allows you to set the following limitations:

- **Include hidden users** - if enabled, hidden users will be indexed.
- **Enabled users only** - if enabled, only enabled users will be indexed.
- **Index users from all sites** - if enabled, users from all sites will be indexed. If disabled, only users from the sites assigned on the *Sites* tab will be indexed.
- **Users in roles** - if entered, only users from the entered roles will be indexed.
- **Users not in roles** - if entered, only users who are not in the entered roles will be indexed.
- **Where condition** - WHERE clause of the queries run against the *View_CMS_User* view in order to retrieve users when building the index. This can be used to limit which users should be included.

You can also define which user fields are indexed:

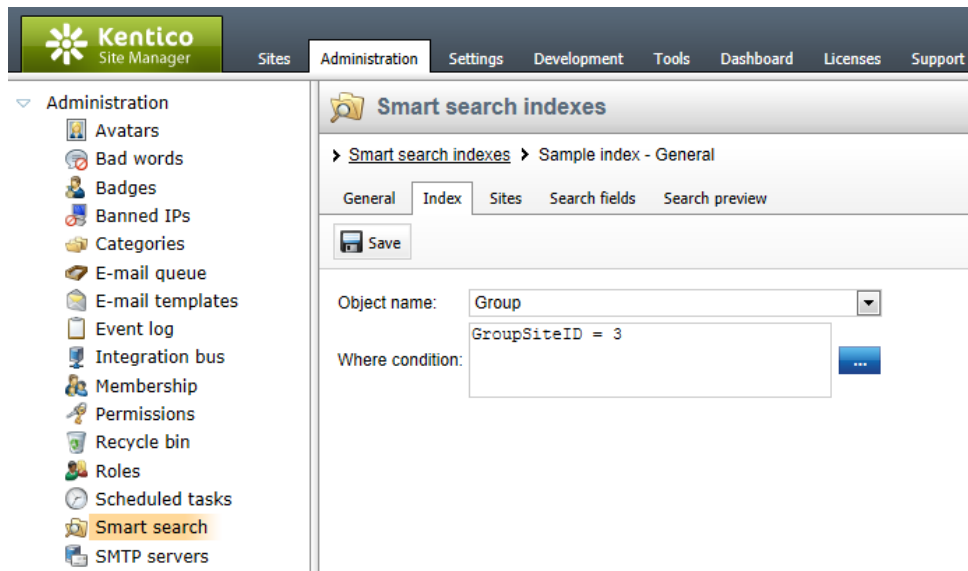

1. Go to **Site Manager -> Development -> System tables**.
2. Edit (✎) the **User (CMS_User)** system table.
3. Configure the [field settings](#) on the **Search fields** tab.

8.43.4.6 Defining general index content

General indexes allow searching through any type of objects used within the Kentico CMS system. This includes items you may recognize from various sections of the administration interface, module related objects and more. Specific examples could be web parts, page templates, groups, sites etc.

While editing an index, its content can be specified on the **Index** tab by defining the following two properties:

- **Object name** - sets the type of objects that should be searched for by the index. The index will store information representing objects in the system of the specified type. When an object is created, removed or has one of its fields modified, the index will automatically be updated to reflect these changes. Since there is a very large amount of object types in the CMS system, it will in most cases be necessary to choose the *(more items...)* option and use the full dialog to make your selection.
- **Where condition** - allows a custom WHERE clause to be set for the queries used to retrieve data when building the index. This can be used to limit which records should be included.

Once the object type is selected, it is necessary to configure which fields should be included in the index on the **Search fields** tab. The settings here affect how objects can be searched for.

Using the drop-down lists at the top, you can specify what kind of data should be displayed in search results:

- **Title field** - specifies which field will be used as the title of result items.
- **Content field** - specifies which field will be used for the content extract of result items.
- **Image field** - specifies which field will be used for the image of result items.
- **Date field** - specifies which field will be used for the date and time displayed with result items.

The rows of the main table contain the fields available for the specified type of objects. These fields correspond with the columns of the database table used to store objects of the given type. The following options can be set for individual fields:

- **Content** - if checked, the content of the field will be indexed and searchable the standard way. Otherwise, objects will not be included in the search results even if they contain the searched for expression in this field.
- **Searchable** - if checked, the content of the field will be searchable by entering an expression in format: `<field code name>:<searched phrase>`. Please refer to the [Search syntax](#) topic for more information about field searches.
- **Tokenized** - indicates if the content of the field should be processed by the analyzer when indexing. The general rule is to use this for *Content* fields and not for *Searchable* fields.
- **Custom search name** - relevant for *Searchable* fields. The specified value is used as a substitute for the field code name in the `<field code name>:<searched phrase>` search expression. If a value is entered, the original code name can't be used.

Smart search indexes

Smart search indexes > Sample Index - General

General Index Sites Search fields Search preview

Title field: GroupDisplayName
 Content field: GroupDescription
 Image field: (none)
 Date field: GroupCreatedWhen

[Set automatically](#)

| Field name | Content | Searchable | Tokenized | Custom search name |
|--------------------|-------------------------------------|-------------------------------------|-------------------------------------|--------------------|
| GroupID | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | |
| GroupGUID | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | |
| GroupLastModified | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | |
| GroupSiteID | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | |
| GroupDisplayName | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | |
| GroupName | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | |
| GroupDescription | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | |
| GroupNodeGUID | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | |
| GroupAnnoveMembers | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | |

The configuration of search fields is global for objects of the given type. If there are multiple general indexes for a single object type (i.e. using the same **Object name**), changing the search field settings for one index will also affect the others.

You can use the **Set automatically** link to apply the default configuration for the specific object type. Any changes must be confirmed by clicking the **OK** button below the table.

General indexes and Sites

The content of general indexes is not affected by the selection made on the **Sites** tab. It only determines on which websites the index will be available for use (through smart search web parts).

If you wish to configure a general index to search only through objects assigned to a specific site, we recommend using the **Where condition** property on the **Index** tab.

For example, a general index with the *Group* **Object name** and *GroupSiteID = 3* set in its **Where condition** would only index groups created under the site with a SiteID equal to 3.

This approach is of course only possible for site-bound object types.

8.43.4.7 Defining custom index content

When creating a custom index, you do not define the content on the **Index** tab. Instead, you must implement all functionality of the index by writing code. In the administration interface, you only need to specify the names of the assembly and class that contain the custom index logic.

To define a custom index, create a class that implements the **CMS.Siteprovider.ICustomSearchIndex** interface.

To integrate this type of class into the application, you can:

- Create a new assembly (Class library) in your web project and include the index class there. When using this approach, you must add the appropriate references to both the assembly and the main CMS project. You can find a sample search index in the **CustomSearchIndex** project located in your Kentico CMS installation directory (typically *C:\Program Files\KenticoCMS\<version>\CodeSamples\CustomSearchIndex*).
- Define the custom index in **App_Code** and load the class via the API. This ensures that the system automatically compiles the index class and you do not need to use a separate assembly. The example below demonstrates this approach.

Writing custom index code

The following example shows how to create a custom index that searches the content of text files:

1. Open your web project in Visual Studio and add a new class into the **App_Code** folder (or **Old_App_Code** if the project is installed as a web application). For example, name the class **TextFileIndex.cs**.

2. Edit the class and add the following references:

[C#]

```
using CMS.EventLog;
using CMS.SiteProvider;
using CMS.SettingsProvider;
using CMS.GlobalHelper;
using CMS.IO;

using Lucene.Net.Index;
using Lucene.Net.Documents;
```

3. Make the class implement the **ICustomSearchIndex** interface.

[C#]

```
public class TextFileIndex : ICustomSearchIndex
```

4. Define the **Rebuild** method inside the class. You must always include this method when writing a custom index. It fills the index with data, which determines what kind of searches the index provides. The system calls the method when building the index for the first time and on each subsequent rebuild.

[C#]

```
/// <summary>
```

```
/// Fills the index with content.
/// </summary>
/// <param name="srchInfo">Info object representing the search index</param>
public void Rebuild(SearchIndexInfo srchInfo)
{
    // Checks whether the index info object is defined.
    if (srchInfo != null)
    {
        // Gets an index writer object for the current index.
        IndexWriter iw = srchInfo.GetWriter(true);

        // Checks the whether writer is defined.
        if (iw != null)
        {
            try
            {
                // Gets an info object of the index settings.
                SearchIndexSettingsInfo sisi = srchInfo.IndexSettings.Items
[SearchHelper.CUSTOM_INDEX_DATA];

                // Gets the search path from the Index data field.
                string path = Convert.ToString(sisi.GetValue("CustomData"));

                // Checks whether the path is defined.
                if (!String.IsNullOrEmpty(path))
                {
                    // Gets all text files from the specified directory.
                    string[] files = Directory.GetFiles(path, "*.txt");

                    // Loops through all files.
                    foreach (string file in files)
                    {
                        // Gets the current file info.
                        FileInfo fi = FileInfo.New(file);

                        // Gets the text content of the current file.
                        string text = fi.OpenText().ReadToEnd();

                        // Checks that the file is not empty.
                        if (!String.IsNullOrEmpty(text))
                        {
                            // Converts the text to lower case.
                            text = text.ToLower();
                            // Removes diacritics.
                            text = TextHelper.RemoveDiacritics(text);

                            // Creates a new Lucene.Net search document for the current
text file.
                            Document doc = SearchHelper.CreateDocument
(SearchHelper.CUSTOM_SEARCH_INDEX, Guid.NewGuid().ToString(),
SearchHelper.INVARIANT_FIELD_VALUE, fi.CreationTime,
SearchHelper.INVARIANT_FIELD_VALUE);

                            // Adds a content field. This field is processed when the
search looks for matching results.
                            SearchHelper.AddField(doc, SearchHelper.CONTENT_FIELD, text,
false, true);
                        }
                    }
                }
            }
            catch { }
        }
    }
}
```

```
        // Adds a title field. The value of this field is used for the
        search results title.
        SearchHelper.AddField(doc, SearchHelper.CUSTOM_TITLE,
fi.Name, true, false);

        // Adds a content field. The value of this field is used for
        the search result excerpt.
        SearchHelper.AddField(doc, SearchHelper.CUSTOM_CONTENT,
TextHelper.LimitLength(text, 200), true, false);

        // Adds a date field. The value of this field is used for the
        date in the search results.
        SearchHelper.AddField(doc, SearchHelper.CUSTOM_DATE,
fi.CreationTime, true, false);

        // Adds a url field. The value of this field is used for link
        urls in the search results.
        SearchHelper.AddField(doc, SearchHelper.CUSTOM_URL, file,
true, false);

        // Adds an image field. The value of this field is used for
        the images in the search results.
        //SearchHelper.AddField(doc, SearchHelper.CUSTOM_IMAGEURL,
"textfile.jpg", true, false);

        // Adds the document to the index.
        iw.AddDocument(doc);
    }

    // Optimizes the index.
    iw.Optimize();
}

// Logs any potential exceptions.
catch (Exception ex)
{
    EventLogProvider.LogException("CustomTextFileIndex", "Rebuild", ex);
}
// Always close the index writer.
finally
{
    iw.Close();
}
}
}
```

You need to write the code of the *Rebuild* method according to the specific purpose of the index, but all indexes use the following general steps:

- a. Get an instance of the **Lucene.Net.IndexWriter** object for the search index.
- b. Define search **Documents** (*Lucene.Net.Documents.Document* objects) and their fields for the items that you wish to add to the index.
- c. Call the **AddDocument** method of the *IndexWriter* for every search document.
- d. Optimize the index using the **Optimize** method of the *IndexWriter* once you have added all required

search documents.

e. Call the **Close** method of the *IndexWriter*.

Index data parameters

The **SearchIndexInfo** parameter of the *Rebuild* method allows you to access the data fields of the corresponding search index object. The sample code loads the content of the **Index data** field and uses it to define the path to the searched text files.

When writing your own custom indexes, you can use this field as a string parameter for any required purpose. This way, you may easily modify the behavior of the index directly from the administration interface without having to edit its code.

Loading App_Code index classes

For indexes defined in the *App_Code* folder, you need to ensure that the system loads the appropriate class when building the index. You can find additional information related to this topic in [Registering custom classes in App_Code](#).

1. Create another class in the **App_Code** folder (or **Old_App_Code** if the project is installed as a web application). For example, name the class **ClassLoader.cs**.

2. Edit the class and add the following reference:

[C#]

```
using CMS.SettingsProvider;
```

3. Delete the default class declaration and its content. Instead, extend the **CMSModuleLoader** partial class and define a new attribute inheriting from *CMS.SettingsProvider.CMSLoaderAttribute*:

[C#]

```
[ClassLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Attribute class for loading custom classes.
    /// </summary>
    private class ClassLoader : CMSLoaderAttribute
    {
    }
}
```

4. Enter the following code into the **ClassLoader** attribute class:

[C#]

```
/// <summary>
/// Called automatically when the application starts.
/// </summary>
public override void Init()
{
    // Assigns a handler for the OnGetCustomClass event.
    ClassHelper.OnGetCustomClass += ClassHelper_OnGetCustomClass;
}

/// <summary>
/// Gets a custom class object based on the given parameters.
/// </summary>
private void ClassHelper_OnGetCustomClass(object sender, ClassEventArgs e)
{
    if (e.Object == null)
    {
        // Checks the name of the requested class.
        switch (e.ClassName)
        {
            // Gets an instance of the TextFileIndex class.
            case "TextFileIndex":
                e.Object = new TextFileIndex();
                break;
        }
    }
}
```

For custom indexes, the value of the **ClassName** property of the **ClassHelper_OnGetCustomClass** handler's **ClassEventArgs** parameter matches the **Class name** specified for the given index on its **Index** tab (*TextFileIndex* in this example). The handler checks the class name to identify which index is being rebuilt and then passes on an instance of the appropriate class.

Registering custom search indexes

1. Open Kentico CMS, go to **Site Manager -> Administration -> Smart Search** and click  **New Index**. Fill in the following properties:

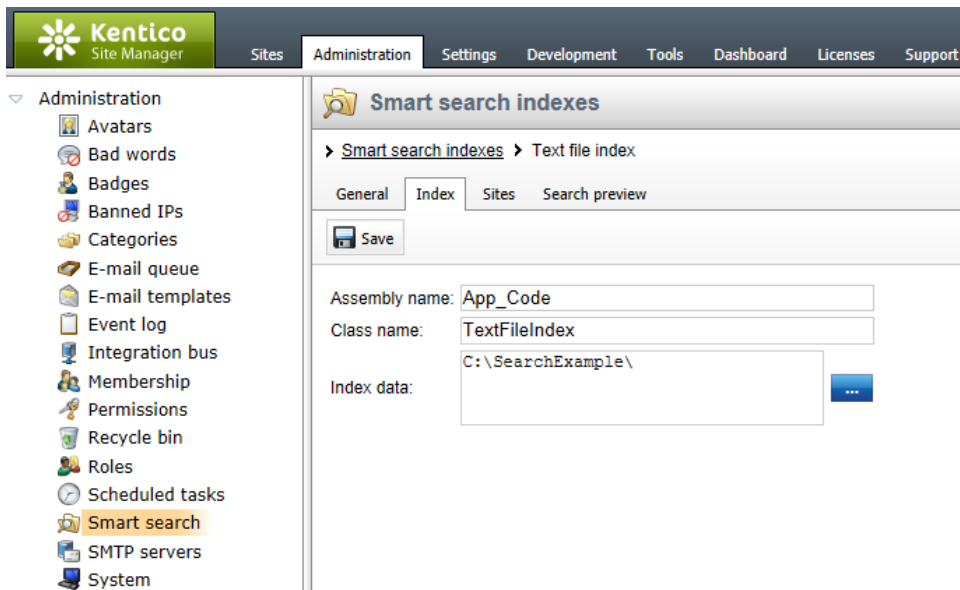

- **Display name:** Text file index
- **Index type:** Custom Index

Click  **Save**.

2. Switch to the **Index** tab and enter the names of the assembly and class where the custom index is implemented:

- **Assembly name:** App_Code
- **Class name:** TextFileIndex

3. Type any required parameters into the **Index data** field. In this example, you need to specify the file system path of the folder containing the text files that the index will search. You can create a new folder for this purpose, e.g. *C:\SearchExample* and add some text files into it.

Click  **Save**.

4. Go to the **General** tab and  **Rebuild** the index.

Result

The index is now fully functional. To test the index, switch to **Search preview** tab and try searching for any words from the text files created in the *SearchExample* folder.

8.43.4.8 Using a custom analyzer

In case the selection of built-in indexing analyzers is insufficient, a custom-written or third-party analyzer may be specified for a search index. This gives you the option of performing tokenization according to your particular requirements.

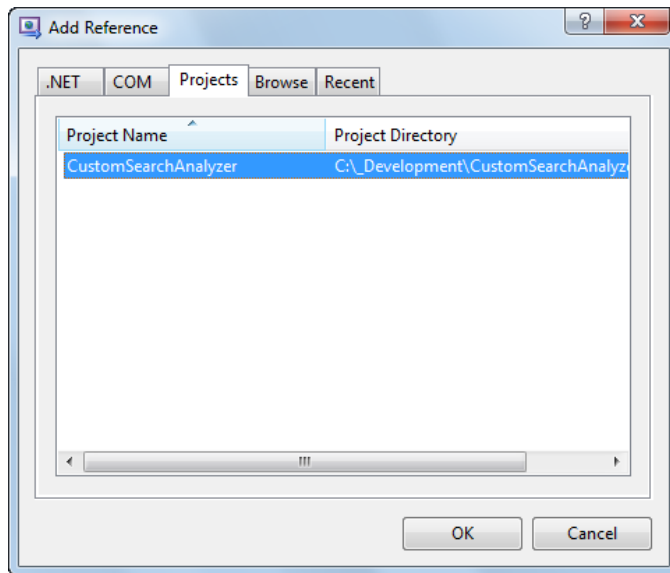

A custom analyzer may be used with any type of smart search index, but its code files must first be created and added to your web project. The class defining a custom analyzer must inherit from the **Lucene.Net.Analysis.Analyzer** class.

The following example demonstrates how a custom analyzer can be assigned to a smart search index. This sample analyzer divides text into tokens only at space characters and is purely for demonstrative purposes.

1. Copy the **CustomSearchAnalyzer** project from your Kentico CMS installation directory (by default `C:\Program Files\KenticoCMS\<version>\CodeSamples\CustomSearchAnalyzer`) to a development folder (not under the web project).
2. Open your CMS web project using the **WebProject.sln** file (**WebApp.sln** if you installed the project as a web application). Click **File -> Add -> Existing Project** and select the **CustomSearchAnalyzer.csproj** file in the folder where you copied the **CustomSearchAnalyzer** project. Your Solution Explorer window should now look like this:

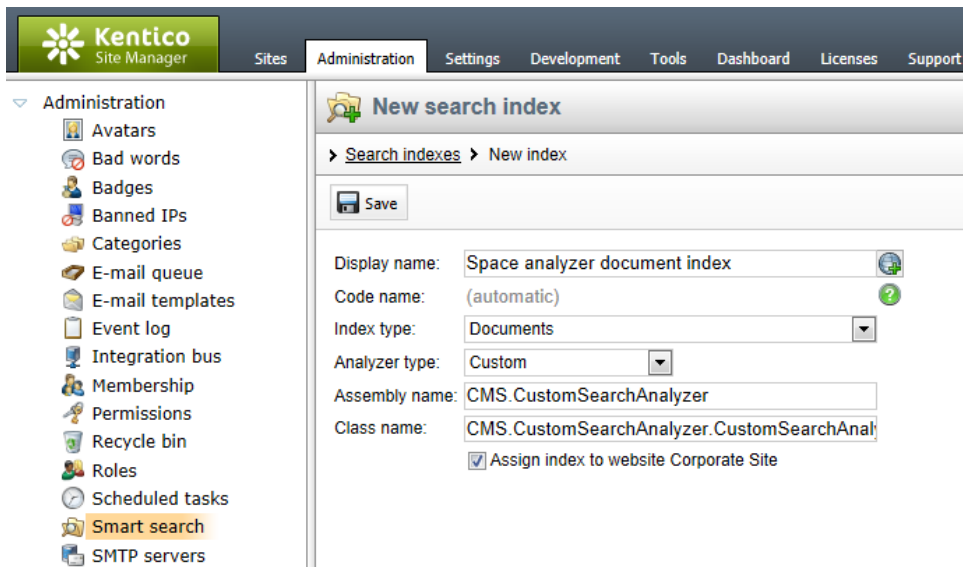

3. Right-click the CMS website object (or the **CMSApp** project if your installation is a web application) and choose **Add Reference**. Switch to the **Projects** tab, select the **CustomSearchAnalyzer** project and click **OK** to add the project reference.

4. Right-click your solution and select **Rebuild Solution**.

5. Open Kentico CMS, go to **Site Manager -> Administration -> Smart Search** and click  **New Index**. Fill in the following properties:

- **Display name:** Space analyzer document index
- **Analyzer type:** Custom
- **Assembly name:** CMS.CustomSearchAnalyzer
- **Class name:** CMS.CustomSearchAnalyzer.CustomSearchAnalyzer
- **Index type:** Documents

This defines the new index and specifies the assembly and class names where the custom analyzer is implemented in the **CustomSearchAnalyzer** project that you added to your solution. Click **Save**.

6. Next, switch to the **Index** tab, click **Add allowed content**, enter `/%` into the **Path** field to index all documents and click **Save**.

7. Switch over to the **Cultures** tab and add the culture(s) used by your website.

8. Finally, go to the **General** tab and **Rebuild** the index. Once complete, the index should be functional. If you wish, you can test the index and its analyzer by switching to the **Search preview** tab and trying to search for words from the content of the website's documents.

Defining custom analyzers in App_Code

If you do not wish to add a new project to the application, you may alternatively create the required classes under the **App_Code** folder, and register the custom analyzer class using the same approach described in the [Defining custom index content](#) topic.

In this case, you need to change the *Assembly* and *Class name* set for the analyzer accordingly.

8.43.5 Settings for particular object types

Documents and other objects in Kentico CMS are often complex data structures with many different fields. In most cases, not all of these fields will be relevant to the search that you are trying to implement. Additionally, it is always a good idea to avoid indexing unnecessary fields to keep your indexes as small (and fast) as possible. For this reason, most types of objects have the option of adjusting search settings for fields.

The sections below describe how these settings may be configured for particular object types.

Document types, Custom tables and Users

Settings for [document types](#), [custom tables](#) and [users](#) are almost identical. You can find them on the **Search fields** tab in the editing interfaces at **Site Manager -> Development -> Document types / Custom tables / System tables -> Edit (✎) User**.

In the top part of the tab, you can specify how the objects will be displayed in search results:

- **Title field** - specifies which field will be used as the title of result items.
- **Content field** - specifies which field will be used for the content extract of result items.
- **Image field** - specifies which field will be used for the image of result items (not available for users, [Avatar](#) images are used for users by default).
- **Date field** - specifies which field will be used for the date and time displayed with result items.

The rows of the table in the bottom part of the page represent fields as defined on the **Fields** tab. The following options can be set for individual fields:

- **Content** - if checked, the content of the field will be indexed and searchable the standard way.
- **Searchable** - if checked, the content of the field will be searchable by entering an expression in format: `<field code name>:<searched phrase>`. Please refer to the [Search syntax](#) topic for more information about field searches. This option must also be enabled in order for the field to be usable in [Smart search filters](#).
- **Tokenized** - indicates if the content of the field should be processed by the analyzer when indexing. This allows the search to find results that match individual tokens (subsets) of the field's value. If disabled, items will only be considered a match if the full value of the field exactly matches the search expression. The general rule is to use this for *Content* fields and not for *Searchable* fields.
- **Custom search name** - relevant for *Searchable* fields. The specified value is used as a substitute for the field code name in the `<field code name>:<searched phrase>` search expression. If a value is entered, the original code name can't be used.

The screenshot shows the 'Document type properties' dialog box in the Kentico CMS 7.0 Site Manager. The 'Search fields' tab is selected, and the 'Set automatically' section is expanded. The table below shows the configuration for four fields:

| Field name | Content | Searchable | Tokenized | Custom search name |
|---------------------|-------------------------------------|-------------------------------------|-------------------------------------|--------------------|
| MenuItemID | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | |
| MenuItemName | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input checked="" type="checkbox"/> | |
| MenuItemTeaserImage | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | |
| MenuItemGroup | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | |

Please note

Documents crawler type search indexes directly index the HTML output of documents and as a result are not affected by the field settings of document types.

E-commerce SKUs (and general document fields)

Similar settings are available for **E-commerce SKUs** (products). These can be configured in **Site Manager -> Development -> System tables** by editing (✎) the **Ecommerce - SKU** table on the **Search fields** tab. Here, SKU fields are joined together with general document fields, such as those used to store the content of editable regions on the page (*DocumentContent*) or the content of text web parts (*DocumentWebParts*). The search settings of general fields affect all documents, even those that are not products.

In this case, only the following options are available:

- **Content** - if checked, content of the field will be indexed and searchable the standard way.
- **Searchable** - if checked, content of the field will be searchable by entering an expression in format: *<field code name>:<searched phrase>*. Search requests of this type only search through the given field and not through the other fields.
- **Tokenized** - indicates if the content of the field should be processed by the analyzer when indexing. The general rule is to use this for *Content* fields and not for *Searchable* fields.

Important!

It is highly recommended that you do not modify settings other than those of your custom fields. If you modify the settings of some of the default fields, the functionality of searching through SKUs may get broken.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The user is logged in as 'Global Administrator'. The left sidebar shows a tree view of settings categories, with 'System tables' selected. The main content area displays the 'System tables' configuration for 'Ecommerce - SKU'. It includes tabs for 'Tables', 'Views', and 'Stored procedures', and sub-tabs for 'Fields', 'Queries', 'Alternative forms', and 'Search fields'. A warning message states: 'It is highly recommended not to change default field settings. If you remove or change some of the mandatory fields, smart search module can stop working.' Below this is a table with columns for 'Field name', 'Content', 'Searchable', and 'Tokenized'.

| Field name | Content | Searchable | Tokenized |
|---------------------|-------------------------------------|-------------------------------------|--------------------------|
| SKUID | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| SKUNumber | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| SKUName | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| SKUDescription | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| SKUPrice | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| SKUEnabled | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| SKUDepartmentID | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| SKUManufacturerID | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| SKUInternalStatusID | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| SKUPublicStatusID | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| SKUSupplierID | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| SKUAvailableInDays | <input type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> |

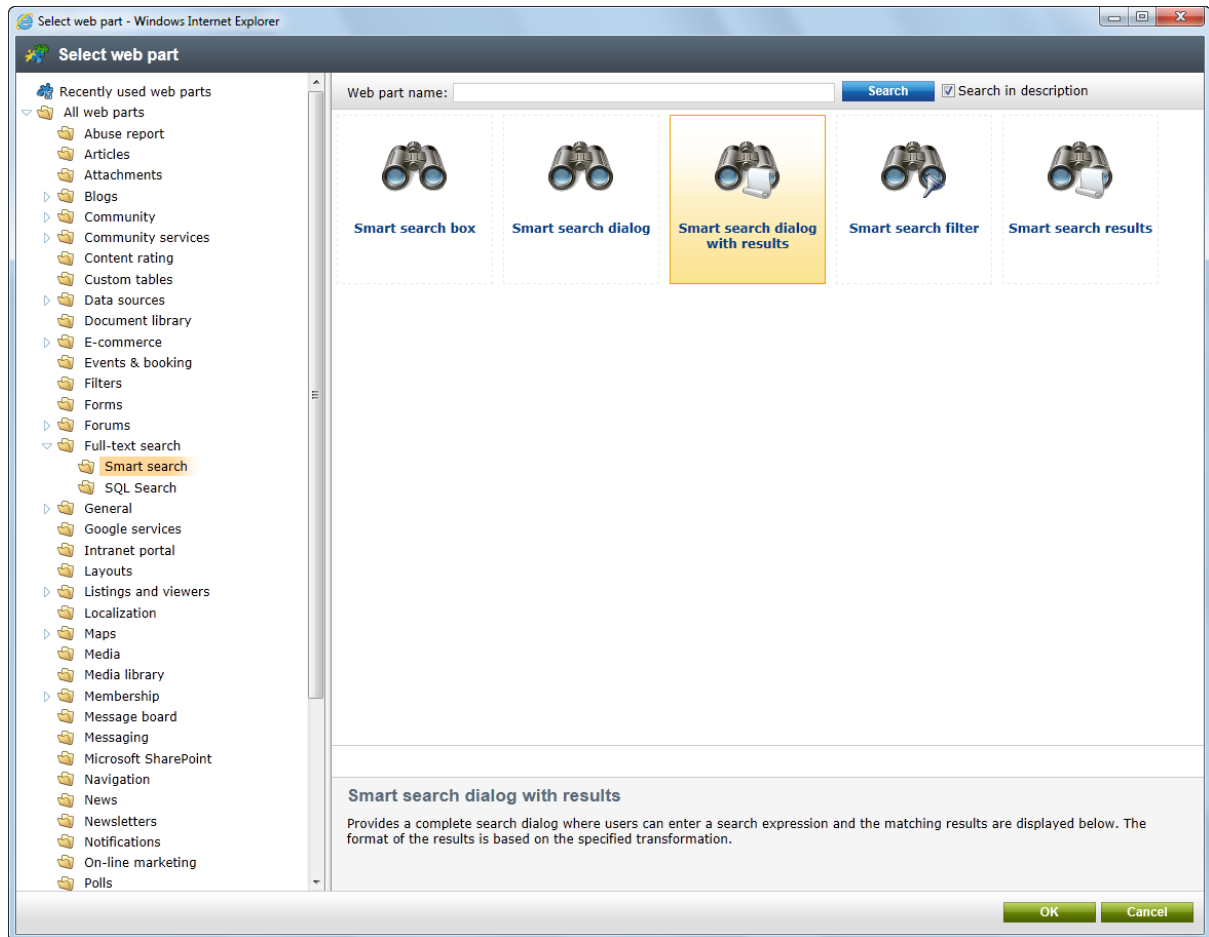

General objects

For objects searchable by *General* indexes, these settings are available directly on the **Search fields** tab when editing an index in **Site Manager -> Administration -> Smart search** (as described in [Managing indexes -> Defining general index content](#)).

8.43.6 Available web parts

The Smart search module comes with a set of [web parts](#) that can be used to build a search interface on the pages of your website. Only the most important web part properties are mentioned here. For a complete list and explanations of the web part properties, please refer to the [Kentico CMS Web Parts](#) reference or click the help icon (?) in the top right corner of the web part properties window.

Smart search web parts are located in the **Full-text search -> Smart search** category.

The following web parts are included with the Smart search module by default:

Smart search dialog with results

This is an all-in-one web part that allows both searching and displaying of the results.

Search for:

Search mode:

Example conference

Here come the details and additional information of **Example** conference.

http://localhost/KenticoCMS_4245.13515/Examples/Web-parts/Events-booking/Event-registration/Example-conference.aspx 5/7/2009 2:22:09 PM

ASPX

An **example** of the ASPX development model can be temporarily seen in the Mixed (PE & ASPX) section. This is only a temporary solution for the BETA version. In the final version, this section will contain a separate **example** of the ASPX development model.

http://localhost/KenticoCMS_4245.13515/Examples/Development-models/ASPX.aspx 6/23/2011 1:44:59 PM

Sample article 1

Sample article for RSS feed webpart **example**.

http://localhost/KenticoCMS_4245.13515/Examples/Web-parts/Syndication/Articles-RSS-feed/Sample-article-1.aspx 6/29/2011 3:45:36 PM

The following properties are the most important for setting up the smart search:

| Property Name | Description |
|----------------------|--|
| Indexes | Determines which index will be searched. Multiple indexes can be entered and then searched at the same time. |
| Transformation name | Name of the transformation used to display search results.

There are two default transformations suitable for this purpose: <ul style="list-style-type: none"> • CMS.Root.SmartSearchResults • CMS.Root.SmartSearchResultsWithImages |
| Search options | Sets the level of syntax that is allowed in search expressions: <ul style="list-style-type: none"> • Basic - users are allowed to input special syntax, but cannot search specific fields. • None - users can only enter text, everything is processed as a part of the search expression. • Full - all search options can be used, including field searching. More information can be found in the Search syntax topic. |
| Search condition | Sets a condition that is added to any submitted search expressions. The condition is built using the smart search syntax, i.e. special symbols (+ -) and field conditions.

For example: <code>+articleid:[(int)25 TO (int)150]</code> |
| Search results order | Defines the order in which search results are displayed. |

You can specify one or more search fields (separated by commas) according to which the results will be sorted. The `##SCORE##` macro can be used to order results by their score (relevance). The default order is ascending, you can change this using the `DESC` keyword (e.g. `articleid DESC`).

If you encounter the "field <fieldname> does not appear to be indexed" error when using multiple indexes, try specifying the type of the field using the following syntax: `(date)documentcreatedwhen`

Smart search dialog

This web part needs to be placed on a page together with the **Smart search results** web part. The combined functionality of the two web parts is nearly identical to a Smart search dialog with result. The main difference between them is that these two web parts can be placed separately at different locations on the page.

Search for:

Search mode: ▼

The web part also supports a special mode that can be enabled through the **Show only search button** property. In this case, only the search submit button is displayed without the search textbox and mode selector. This is intended for scenarios that utilize [Smart search filters](#) to specify all of the search parameters. When combined with a textbox filter, it also provides a way to separate the textbox from the search button.

Smart search box

This web part is similar to the Smart search dialog, with the difference that users cannot select the Search mode, which is hard-set in its web part properties. It is useful where limited space is available for the web part, e.g. in menus, etc. Additionally, it can redirect users to a different result page, where the appropriate **Smart search results** or **Smart search dialog with results** web part is located.

Smart search results

This web part is used to display results of a search request sent from a **Smart search box** or **Smart search dialog** web part. It can be placed either on the same page as one of the two web parts or on a different one. If it is placed on a different page, the page needs to be specified by their **Search results page URL** property. The web part can be configured using the same properties described for the Smart search dialog with results.

Example conference

Here come the details and additional information of **Example** conference.

http://localhost/KenticoCMS_4245.13515/Examples/Web-parts/Events-booking/Event-registration/Example-conference.aspx 5/7/2009 2:22:09 PM

Smart search filter

This web part allows users to set parameters that affect the scope of the search or the order of the displayed results. It may also be used as a separate search textbox. You can find a detailed description of how this works in the [Using the Smart search filter](#) topic.

Filter product type:

All Cell phones Laptops PDAs

8.43.7 Using the Smart search filter

The **Smart search filter** web part allows users to limit the range of objects that will be searched (conditional filter), or define the order of the search results. It is designed to be connected to the **Smart search dialog** or **Smart search dialog with results**. You can connect more than one filter to these web parts.

The behavior of the smart search filter is primarily defined by the properties explained below. You can find descriptions of the web part's other properties in the [Kentico CMS Web Parts](#) reference by clicking on the help icon (??) in the top right corner of the web part properties window.

| Property Name | Description |
|----------------------|--|
| Search webpart ID | ID of the Smart search dialog or Smart search dialog with results web part to which the filter should be connected. |
| Filter mode | Determines what type of user interface element will be used to set the filtering options. Possible choices are a drop-down list, checkboxes, radio buttons or a text box. |
| Filter auto postback | Indicates whether the search results should automatically be refreshed (via postback) whenever a different filtering option is selected by a user. Not applicable when using the text box Filter mode . |
| Values | This property is used to specify the options that will be available for selection in the filter. Please see the Defining filtering options section below for details. |
| Query name | Name of the query which can be used instead of the <i>Values</i> property to |

| | |
|-----------------------|---|
| | <p>dynamically create the filtering options. The query must return the appropriate values depending on the type of the filter.</p> <p>For example, for a standard conditional filter, three columns need to be loaded, which will then be used in the following order: <i><index field name></i>, <i><value of the field></i>, <i><displayed text></i></p> <p>The following is a sample query that loads all document types as conditional filtering options:</p> <pre>SELECT TOP 1000 '+classname', ClassName, ClassDisplayName FROM CMS_Class WHERE ClassIsDocumentType = 1</pre> |
| Filter clause | <p>Sets a clause that overrides the logical values specified for filtering options. Possible choices are:</p> <ul style="list-style-type: none"> • None - no clause is added and the original logical values set for individual filtering options are used. • Must - indicates that the conditions in all filtering options must be fulfilled (adds the + symbol). • Must not - indicates that the conditions in all filtering options must not be fulfilled (adds the - symbol). Conditions are inverted compared to the <i>Must</i> option. |
| Filter is conditional | <p>If true, the filter limits the scope of the objects that are searched (where condition). If false, the filter determines the order in which the search results are displayed (order by condition).</p> |

Examples of how filters work can be found on the sample Corporate Site, specifically on the **Examples -> Web parts -> Full-text search -> Smart search -> Smart search filter** and **Faceted search** pages.

Defining filtering options

The most important part of a Smart search filter web part's configuration is the definition of the options that should be offered to users. In most cases, this will be done through the **Values** property of the web part. If you wish to use the **Query name** property to load the options dynamically, the rules described below also apply to the results retrieved by the query.

The format used when entering the options depends on the type of the filter:

- **Conditional filters:**

In the case of conditional filters, define one option per line in format:

<index field name>;<value of the field>;<displayed text>

The logical meaning of each filtering option must also be specified. If the + symbol is added before the option, then only objects whose value in the given field matches the value specified in the second part of the definition will be included in the search. If the - symbol is added, only results that do **not** match the

value will be returned.

When entering integer or double type fields as filter options, the type of the value needs to be specified in the following way:

`+DocumentCreatedByUserID;(int)53;Administrator`

Examples:

- `;;All`
- `+classname;cms.smartphone;Smartphones`
- `+_created;[{{%CurrentDateTime.AddDays(-7)}(tosearchdatetime)%} TO {%CurrentDateTime}(tosearchdatetime)%}];Past week`
- `+_content;product;Results related to products`

- **Search result order filters:**

When creating filters that change the order of the results (i.e. the **Filter is conditional** property is disabled), the option definition format described above is also used, but the second part that contains the field value should be left empty. The order will be determined by the values in the specified field.

Examples:

- `##SCORE##;;Score`
- `documentcreatedwhen;;Creation date`
- `SKUPrice DESC;;Price descending`

- **Text box filter mode:**

Because text box filters do not offer any selection options, the **Values** property is instead used to determine which index fields should be searched when a user enters an expression into the text box. Multiple fields can be specified, each one on a new line. Like with standard conditional filters, the + and - symbols determine whether the search should return results that contain the text box value in the given field, or only those that do not.

For example, a text box filter could have `+DocumentTags` in its Value definition. Visitors would then be able to enter the names of [document tags](#) into this text box and perform a standard search. The retrieved results would be filtered to contain only those documents that are marked by the specified tags.

If you wish to create a text box filter that behaves like a regular search box, use `+_content` as its only field name.

A text box filter may also be used to determine the order of the search results. In this case, the **Filter is conditional** property must be disabled and the **Values** property should be left empty. The name of the field used for ordering can then be entered by users into the text box. This scenario is not recommended for use by regular visitors on the live site.

**Important!**

Please note that in order for the filter to work correctly, the data fields used in the option definitions must be set as **Searchable** in the smart search field configuration of the given object type.

It is also possible to create filtering options for the fields that are marked as **Content** by using `_content` as the field name. Such a condition would be fulfilled if the value is found in any of the content fields.

Information about the search field configuration of objects can be found in the [Settings for particular object types](#) topic.

Filtering without search text (Faceted search)

In some cases, you may wish to implement a faceted search based purely on filters. This allows users to get search results simply by selecting filtering options, without the need to enter and submit search text. To achieve this result, **Configure** (⚙️) the properties of the web part used to display the search results ([Smart search results](#) or [Smart search dialog with results](#)) according to the following instructions:

1. First, make sure that the **Search text required** property is disabled.
2. Unless you wish to force users to use a filtering option that works with standard content fields (those that have `_content` as their field name), also leave the **Block field-only search** property disabled.
3. Then enable **Search on each page load**, which ensures that the results are automatically displayed whenever the page is loaded, even without input from a search dialog.
4. For additional convenience, enable the **Filter auto postback** property of the used Smart search filter web part(s). Users are then able to instantly refresh the results simply by changing the filtering options.

8.43.8 Search syntax

A detailed description of Lucene query parser syntax can be found at http://lucene.apache.org/core/old_versioned_docs/versions/2_9_0/queryparsersyntax.html.

Based on the level of allowed syntax specified by the **Search options** property of **Smart search dialog with results** or **Smart search results** web parts, users can enter search queries with restrictions as described below:

- **Basic** - all Lucene search query syntax (as described on the page linked above) are recognized *except for field searching*.
- **None** - no query syntax is recognized. All text entered by users is processed as a part of the searched for expression.
- **Full** - all search query syntax is processed, including field searching.

**Search syntax errors**

If special search expressions are allowed by the **Search options** property, a parsing

error occurs if a user enters the query syntax incorrectly.

By default, the standard "no results" message is shown to the user in this case, and the error is entered into the application's [Event log](#). If you wish to have syntax errors displayed in place of the results directly on the live site, you can enable the **Show parsing errors** property of the given smart search results web part.

Field search

Field searching may be used to define additional conditions in search expressions. All conditions must start with either the + or - symbol. The + symbol indicates that only results which fulfill the field condition should be returned. The - symbol has the opposite meaning, only results that do **not** contain the specified value in the given field will be retrieved.

For example:

- `+network +NewsReleaseDate:[20080101 TO 20091231]`

When searching for this expression using a document index, only news documents containing the word *network*, released in the year 2008 or 2009 will be returned.

Keep in mind that only fields set as **Searchable** in the field configuration of the given object type may be included in field searches. If there is no field name specified before a value in the expression (such as the word *network* in the example above), the system will search the index fields marked as **Content**. Information about the search field configuration of objects can be found in the [Settings for particular object types](#) topic.

Additionally, field searches will only be processed correctly if the search dialog web part has its **Search mode** set to *Any words*.

Unless the web part used to display the search results has its **Block field-only search** property enabled, it is also possible to perform direct field searches without any standard content keywords. This allows users to find records simply by entering an exact field value:

- `DocumentNodeID:(int)17` - returns the document with a nodeID equal to 17.
- `NewsTitle:"New features"` - returns the news document titled *New features*.
- `SKUDepartmentID:(int)4` - returns all products that belong to the department that has 4 as its ID.

Using field search queries provides a great deal of flexibility, but it is not very convenient for regular website visitors. If you wish to allow users to limit the scope of searches through conditions on the live site, it is recommended to prepare appropriate [Smart search filters](#).

Searching numeric fields

When performing field searches, the values specified are understood as strings by default. If you know that you are searching in **integer** or **double** fields, you will need to specify the type of the field the following way:

- `NewsID:(int)22`
- `SKUPrice:(double)255.0`
- `DocumentNodeID:[(int)1 TO (int)100]`

Searching date and time fields

Due to the same reason, search in **DateTime** fields also requires special syntax in format **<field name>:yyyymmddhhmm**. So for example:

- DocumentCreatedWhen:200812230101
- DocumentCreatedWhen:[200902020101 TO 200906020101]

If you need to specify date and time using a macro, you will need to use the **(tosearchdatetime)** parameter to convert the returned value to a format suitable for Lucene.

- {%CurrentDateTime|(tosearchdatetime)%}

You can also use the **(add)** parameter, which adds the specified amount of **minutes** to the value.

- {%CurrentDateTime|(add)-1440|(tosearchdatetime)%}

Field search with Stop and Simple analyzers

Indexes created by Stop and Simple analyzers cannot be searched using the standard field search format. This is by design, but you can use a workaround with a range query containing identical boundaries:

- newsid:[(int)22 TO (int)22]

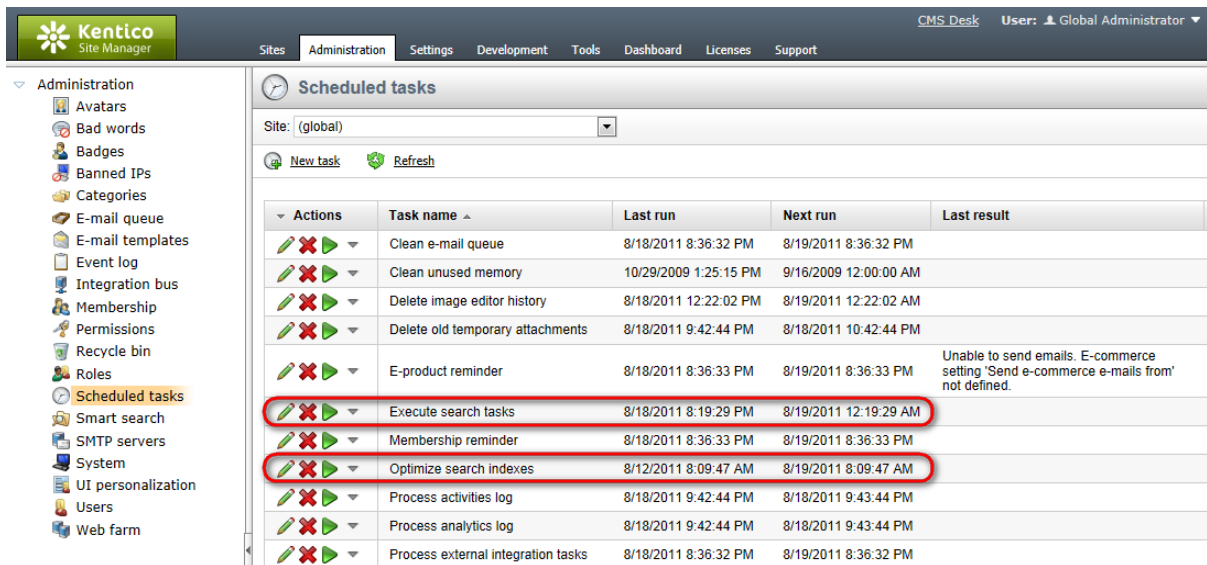

8.43.9 Related scheduled tasks

The following two scheduled tasks are related to the Smart search module:

| Scheduled task name | Description |
|-------------------------|--|
| Optimize search indexes | Allows you to set up automatic optimization of search indexes. Optimization defragments indexes, which can help maintain their performance (only significant in the case of very large indexes).

This task is <i>disabled</i> by default. |
| Execute search tasks | Runs all existing search indexing tasks . Performed every 4 hours by default.

Note: By default, the smart search automatically creates and executes indexing tasks whenever the indexed content changes. If you wish to run search indexing only through this scheduled task, disable automatic indexing task execution via the CMSProcessSearchTasksByScheduler web.config key. See Enabling Smart search indexing . |

Refer to the [Development -> Scheduler](#) chapter for general information about scheduled tasks.

8.43.10 Searching attachments

Users can search through the content of attachment files uploaded to the database. The system searches attachments using the Microsoft SQL Server full-text search.

Note: You need to have your SQL server [configured to support full-text search in files](#).

Once you have the SQL server configured, enable attachment searching through the following properties of the **Smart search dialog with results** or **Smart search results** web part:

| Property Name | Description |
|-----------------------|--|
| Search in attachments | If enabled, the web part searches document attachments. |
| WHERE condition | WHERE condition used to limit the scope of the attachment search for the web part. In addition to specifying which documents have their attachments searched, you can also use the columns of the CMS_Attachment table to search only attachments of a specific type, for example:

<i>AttachmentExtension = '.txt'</i> |
| ORDER BY expression | ORDER BY expression that determines the order of documents retrieved by the attachment search in the results. |

When users perform a search and the system finds a match in the attachment of a document, the given document is added to the search results. The attachment results are always interlaced with the other results provided by the specified smart search indexes. This behavior is by design and cannot be modified.

The attachment search is performed by the SQL server, so it is not affected by the settings and

restrictions of the used search indexes. To limit the attachment search scope, enter an appropriate value into the **WHERE condition** property of the used web part. For example, if you have a search results web part using a document index that is limited to the `/News/%` section of your website, you need to add the following **WHERE condition** to ensure that the attachment search is also restricted to these documents: `NodeAliasPath LIKE '/News/%'`

Please note

The search only returns documents if they are directly connected to the matching attachment through one of the following methods:

- Attachment files added to documents through fields that have their **Field type** set to **File** or **Document attachments** in the document type definition.
- Attachments uploaded in CMS Desk on the **Properties -> Attachments** tab of documents.

8.43.11 Search results in transformations

You can use the following default transformations to display search results using the **Smart search dialog with results** and **Smart search results** web parts:

- **CMS.Root.SmartSearchResults**
- **CMS.Root.SmartSearchResultsWithImages**

Search results are returned in a so-called **search dataset**. No matter how the fields are named in the found objects, the search dataset always contains the following fields that are automatically mapped to the corresponding object fields:

| | |
|----------------|---|
| score | Expresses the relevance of the found document in a numeric value ranging from 0 to 1, where higher values indicate higher relevance. |
| title | This field is mapped to the field specified by the Title field drop-down list on the Search fields tab for the particular object. |
| content | This field is mapped to the field specified by the Content field drop-down list on the Search fields tab for the particular object. |
| created | This field is mapped to the field specified by the Date field drop-down list on the Search fields tab for the particular object. |
| image | This field is mapped to the field specified by the Image field drop-down list on the Search fields tab for the particular object. |

In transformations, you can get the values from the dataset by using the **Eval("<field name>")** function: `Eval("score")`, `Eval("title")`, etc.

You can also use the following functions in your transformations:

- **SearchResultUrl(bool absolute)** - returns the URL of the page where the details of the search result can be found. The parameter indicates if the returned URL should be absolute.

Search result URLs for general index results

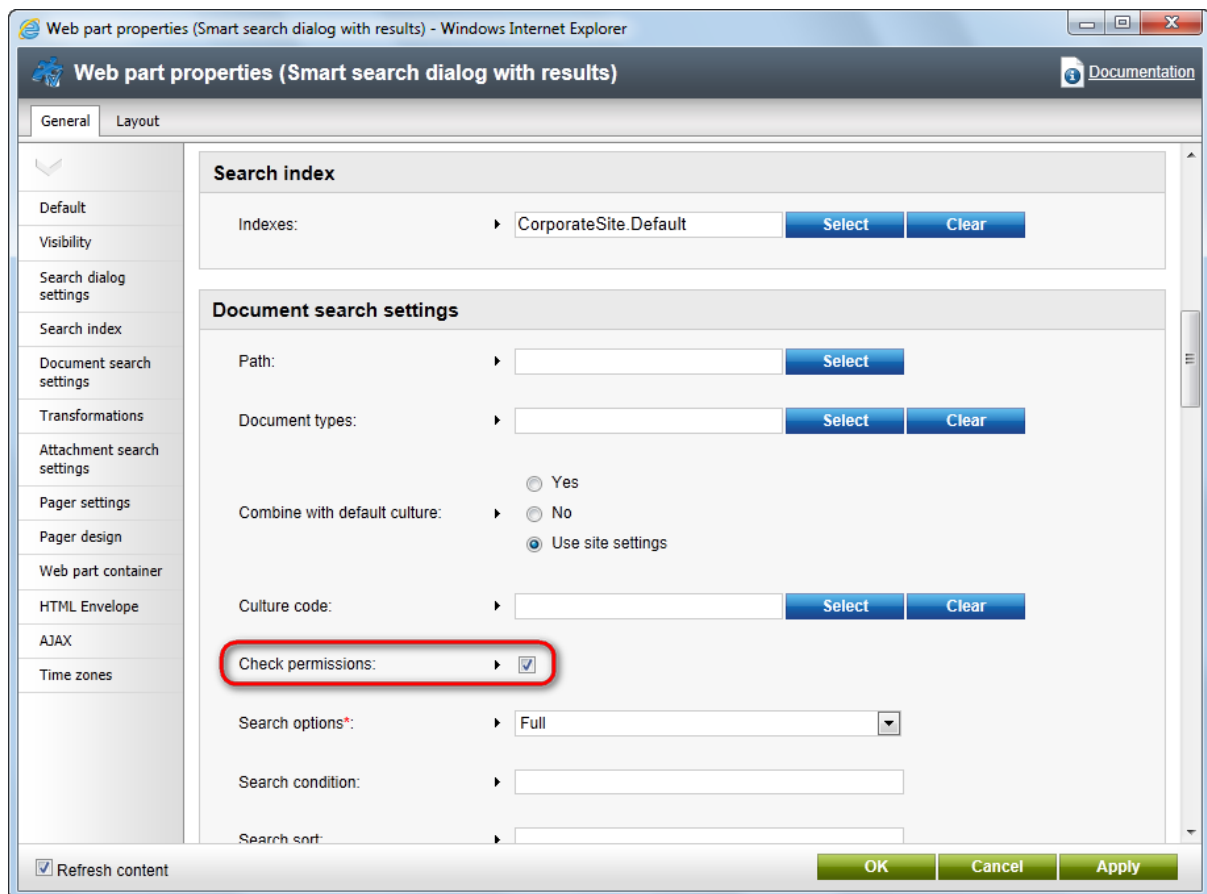

This method does not return valid URLs for search results produced by a [general index](#), since the indexed objects are not documents and there is no default page where the details are displayed.

A [custom transformation function](#) must be written and used in order to generate the correct URL of a custom page displaying the appropriate information.

- **SearchHighlight(string text, string startTag, string endTag)** - wraps the text entered in the first attribute into the tags specified by the other two attributes.
- **GetSearchImageUrl(string noImageUrl, int maxSideSize)** - returns the URL of the current search result image. The first attribute specifies the URL returned if no image is found, the second one specifies the maximum side size to which the image will be resized.
- **GetSearchValue(string columnName)** - returns the value of the specified field for the current search result. This may be used to access both the general fields of the given object type (document, custom table etc.) and any other fields included in the search index.

8.43.12 Security

Smart search web parts have the **Check permissions** property. If this option is enabled, pages for which the current user does not have read permissions will not be displayed in search results.

8.43.13 SQL search overview

The SQL search is an obsolete search engine for documents in the content tree of websites (pages). We highly recommend using the index-based [Smart search](#) instead. The system continues supporting the SQL search for the following reasons:

- Backward compatibility with older versions
- Searching files uploaded as document attachments

This search engine uses standard SQL queries to search for expressions:

- The system automatically generates queries for the data of individual [document types](#). To override the search query for a document type, create a new query named **searchtree** in *Site Manager* -> *Development* -> *Document types* -> *Edit document type* -> *Queries*.
- The **cms.root.searchdocuments** query searches fields that are shared by all documents (such as the document name).
- The **cms.root.searchattachments** query searches files uploaded as document attachments. To search attachments, you need to configure the system as described in [Configuration of full-text search in files](#).

Adding the SQL search onto your website

To integrate the SQL search into website pages, use the web parts in the **Full-text search** category

(SQL search dialog, SQL search box, etc.) or the **CMSSearchDialog** and **CMSSearchResults** server controls (in your ASP.NET code).

Excluding documents from search

You can **exclude document types** by setting the **Exclude document types from SQL search** value in **Site Manager -> Settings -> System -> Search**. You need to enter the code name, such as *cms.article*. You can enter multiple document types separated by semicolons (;).

You can **exclude website sections** from the search by setting the **Exclude documents from SQL search** value in **Site Manager -> Settings -> System -> Search**:

- To exclude a single document, enter the alias path, for example: */news/news1*
- To exclude entire website sections, enter a [path expression](#), for example: */news/%*.

You can enter multiple values separated by semicolons (;).

To directly exclude individual documents from the SQL search:

1. Select the document in the content tree in CMS Desk.
2. Go to **Edit -> Properties -> Navigation**.
3. Check **Exclude from search**.
4. Click **Save**.

Modifying the search result format

If you wish to modify the format of the SQL search results, modify the **searchresults** transformation in **Site Manager -> Development -> Document Types -> edit (✎) Root -> Transformations**.

Development of Custom Search Provider

If you need to integrate a custom search engine or make additional modifications to the search results returned by the SQL search engine, you can develop your own search provider. You can find more details in [API programming and Kentico CMS internals-> Custom providers -> Custom Search Provider](#).

8.43.14 Smart search internals and API

8.43.14.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Smart search module. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the module's classes, please refer to [Kentico CMS API Reference](#).

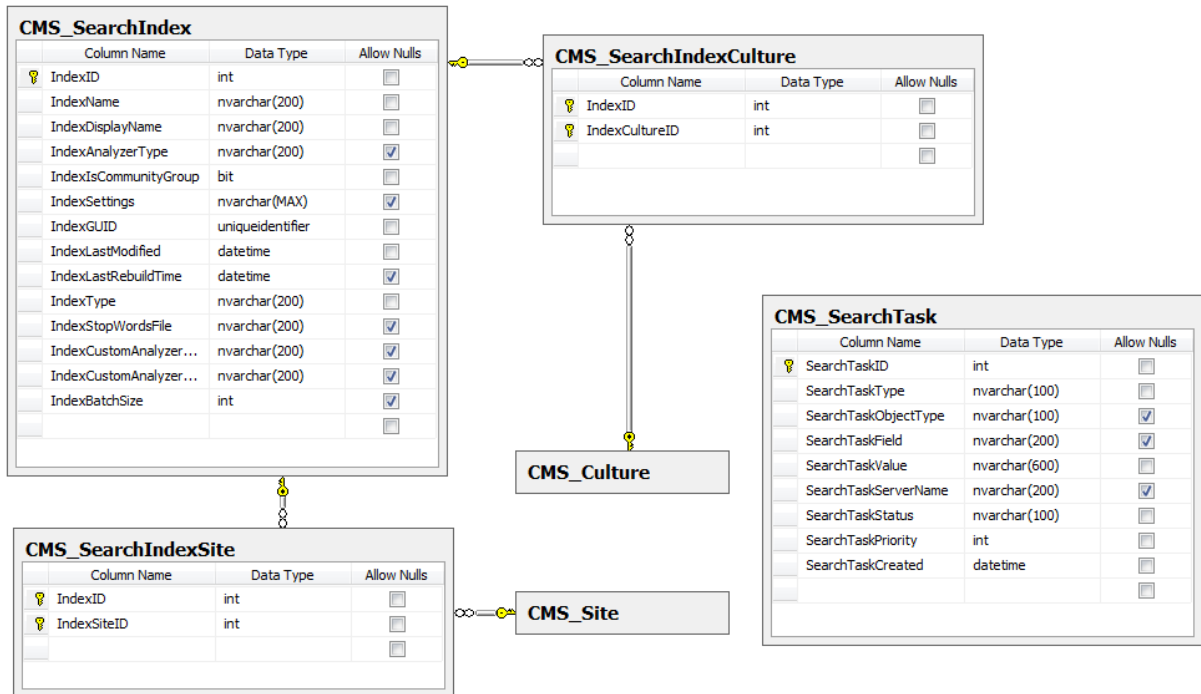

8.43.14.2 Database tables

The following database tables are used to store information for the smart search module:

- **CMS_SearchIndex** - contains records representing smart search indexes.
- **CMS_SearchIndexSite** - stores relationships between smart search indexes and sites. Each entry

in this table indicates that an index is assigned to a site.

- **CMS_SearchIndexCulture** - stores relationships between indexes and cultures. Each entry indicates that documents of the specified culture should be included in the given index.
- **CMS_SearchTask** - stores smart search indexing tasks.

8.43.14.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Smart search module can be found in the **CMS.SiteProvider** namespace.

CMS_SearchIndex table API:

- **SearchIndexInfo** - represents one search index.
- **SearchIndexInfoProvider** - provides management functionality for search indexes.

CMS_SearchIndexSite table API:

- **SearchIndexSiteInfo** - represents a relationship between a search index and a site.
- **SearchIndexSiteInfoProvider** - provides management functionality for site-index relationships.

CMS_SearchIndexCulture table API:

- **SearchIndexCultureInfo** - represents a relationship between a search index and a culture.
- **SearchIndexCultureInfoProvider** - provides management functionality for index-culture relationships.

CMS_SearchTask table API:

- **SearchTaskInfo** - represents one indexing task.
- **SearchTaskInfoProvider** - provides management functionality for smart search indexing tasks.

Other classes:

- **SearchHelper** - provides general smart search functionality and data.
- **CMS.SettingsProvider.SearchIndexSettingsInfo** - represents the settings that can be configured for a search index.
- **CMS.SettingsProvider.SearchIndexSettings** - used to manage *SearchIndexSettingsInfo* objects and assign them to indexes.
- **CMS.SettingsProvider.SearchSettingsInfo** - represents the search field settings of an object.
- **CMS.SettingsProvider.SearchSettings** - provides management functionality for *SearchSettingsInfo* objects.

8.43.14.4 API examples

8.43.14.4.1 Overview

These topics show examples of how the API of the Smart search module can be used:

- [Managing search indexes](#)
- [Managing search index sites](#)
- [Managing search index cultures](#)
- [Performing indexing and search actions](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Administration\Search\Default.aspx.cs**.

The smart search API examples use the following namespaces:

```
using System;  
using System.Data;  
using System.Configuration;
```

```
using CMS.GlobalHelper;  
using CMS.CMSHelper;  
using CMS.SiteProvider;  
using CMS.SettingsProvider;  
using CMS.DocumentEngine;
```

8.43.14.4.2 Managing search indexes

The following example creates a smart search index.

```
private void CreateSearchIndex()  
{  
    // Create new search index object  
    SearchIndexInfo newIndex = new SearchIndexInfo();  
  
    // Set the properties  
    newIndex.IndexDisplayName = "My new index";  
    newIndex.IndexName = "MyNewIndex";  
    newIndex.IndexIsCommunityGroup = false;  
    newIndex.IndexType = PredefinedObjectType.DOCUMENT;  
    newIndex.IndexAnalyzerType = AnalyzerTypeEnum.StandardAnalyzer;  
    newIndex.StopWordsFile = "";  
  
    // Save the search index  
    SearchIndexInfoProvider.SetSearchIndexInfo(newIndex);  
}
```

The following example creates and configures the settings of a search index.

```
private bool CreateIndexSettings()  
{  
    // Get the search index  
    SearchIndexInfo index = SearchIndexInfoProvider.GetSearchIndexInfo  
("MyNewIndex");  
    if (index != null)  
    {  
        // Create new index settings  
        SearchIndexSettingsInfo indexSettings = new SearchIndexSettingsInfo();  
  
        // Set setting properties  
        indexSettings.IncludeBlogs = true;  
        indexSettings.IncludeForums = true;  
        indexSettings.IncludeMessageCommunication = true;  
        indexSettings.ClassNames = ""; // for all document types  
        indexSettings.Path = "%";  
        indexSettings.Type = SearchIndexSettingsInfo.TYPE_ALLOWED;  
        indexSettings.ID = Guid.NewGuid();  
  
        // Save index settings  
        SearchIndexSettings settings = new SearchIndexSettings();
```

```
        settings.SetSearchIndexSettingsInfo(indexSettings);
        index.IndexSettings = settings;

        // Save to database
        SearchIndexInfoProvider.SetSearchIndexInfo(index);

        return true;
    }

    return false;
}
```

The following example gets and updates a search index.

```
private bool GetAndUpdateSearchIndex()
{
    // Get the search index
    SearchIndexInfo updateIndex = SearchIndexInfoProvider.GetSearchIndexInfo
("MyNewIndex");
    if (updateIndex != null)
    {
        // Update the properties
        updateIndex.IndexDisplayName = updateIndex.IndexDisplayName.ToLower();

        // Save the changes
        SearchIndexInfoProvider.SetSearchIndexInfo(updateIndex);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates search indexes.

```
private bool GetAndBulkUpdateSearchIndexes()
{
    // Prepare the parameters
    string where = "IndexName LIKE N'MyNewIndex%'";

    // Get the data
    DataSet indexes = SearchIndexInfoProvider.GetSearchIndexes(where, null);
    if (!DataHelper.DataSourceIsEmpty(indexes))
    {
        // Loop through the individual items
        foreach (DataRow indexDr in indexes.Tables[0].Rows)
        {
            // Create object from DataRow
            SearchIndexInfo modifyIndex = new SearchIndexInfo(indexDr);

            // Update the properties
        }
    }
}
```

```
        modifyIndex.IndexDisplayName = modifyIndex.IndexDisplayName.ToUpper();

        // Save the changes
        SearchIndexInfoProvider.SetSearchIndexInfo(modifyIndex);
    }

    return true;
}

return false;
}
```

The following example deletes a search index.

```
private bool DeleteSearchIndex()
{
    // Get the search index
    SearchIndexInfo deleteIndex = SearchIndexInfoProvider.GetSearchIndexInfo
("MyNewIndex");

    // Delete the search index
    SearchIndexInfoProvider.DeleteSearchIndexInfo(deleteIndex);

    return (deleteIndex != null);
}
```

8.43.14.4.3 Managing search index sites

The following example assigns a smart search index to a site.

```
private bool AddSearchIndexToSite()
{
    // Get the search index
    SearchIndexInfo index = SearchIndexInfoProvider.GetSearchIndexInfo
("MyNewIndex");
    if (index != null)
    {
        int indexId = index.IndexID;
        int siteId = CMSContext.CurrentSiteID;

        // Save the binding
        SearchIndexSiteInfoProvider.AddSearchIndexToSite(indexId, siteId);

        return true;
    }

    return false;
}
```

The following example removes a search index from a site.

```
private bool RemoveSearchIndexFromSite()
{
    // Get the search index
    SearchIndexInfo removeIndex = SearchIndexInfoProvider.GetSearchIndexInfo
("MyNewIndex");
    if (removeIndex != null)
    {
        int siteId = CMSContext.CurrentSiteID;

        // Get the binding
        SearchIndexSiteInfo indexSite =
SearchIndexSiteInfoProvider.GetSearchIndexSiteInfo(removeIndex.IndexID, siteId);

        // Delete the binding
        SearchIndexSiteInfoProvider.DeleteSearchIndexSiteInfo(indexSite);

        return true;
    }

    return false;
}
```

8.43.14.4.4 Managing search index cultures

The following example assigns a culture to a smart search index.

```
private bool AddCultureToSearchIndex()
{
    // Get the search index and culture
    SearchIndexInfo index = SearchIndexInfoProvider.GetSearchIndexInfo
("MyNewIndex");
    CultureInfo culture = CultureInfoProvider.GetCultureInfo("en-us");

    if ((index != null) && (culture != null))
    {
        // Save the binding
        SearchIndexCultureInfoProvider.AddSearchIndexCulture(index.IndexID,
culture.CultureID);

        return true;
    }

    return false;
}
```

The following example removes a culture from a search index.

```
private bool RemoveCultureFromSearchIndex()
{
```

```
// Get the search index
SearchIndexInfo removeIndex = SearchIndexInfoProvider.GetSearchIndexInfo
("MyNewIndex");
CultureInfo culture = CultureInfoProvider.GetCultureInfo("en-us");

if ((removeIndex != null) && (culture != null))
{
    // Get the binding
    SearchIndexCultureInfo indexCulture =
SearchIndexCultureInfoProvider.GetSearchIndexCultureInfo(removeIndex.IndexID,
culture.CultureID);

    // Delete the binding
    SearchIndexCultureInfoProvider.DeleteSearchIndexCultureInfo(indexCulture);

    return true;
}

return false;
}
```

8.43.14.4.5 Performing indexing and search actions

The following example creates a task that rebuilds a smart search index.

```
private bool RebuildIndex()
{
    // Get the search index
    SearchIndexInfo index = SearchIndexInfoProvider.GetSearchIndexInfo
("MyNewIndex");

    if (index != null)
    {
        // Create rebuild task
        SearchTaskInfoProvider.CreateTask(SearchTaskTypeEnum.Rebuild,
index.IndexType, null, index.IndexName);

        return true;
    }

    return false;
}
```

The following example performs a search through the content of an index and retrieves the results in a dataset.

```
private bool SearchText()
{
    // Get the search index
    SearchIndexInfo index = SearchIndexInfoProvider.GetSearchIndexInfo
```

```
("MyNewIndex");

int numberOfResults = 0;

if (index != null)
{
    // Set the properties
    string searchText = "home";
    string path = "/%";
    string classNames = "";
    string cultureCode = "EN-US";
    string defaultCulture = CultureHelper.DefaultCulture.IetfLanguageTag;
    Lucene.Net.Search.Sort sort = SearchHelper.GetSort("##SCORE##");
    bool combineWithDefaultCulture = false;
    bool checkPermissions = false;
    bool searchInAttachments = false;
    string searchIndexes = index.IndexName;
    int displayResults = 100;
    int startingPosition = 0;
    int numberOfProcessedResults = 100;
    UserInfo userInfo = CMSContext.CurrentUser;
    string attachmentWhere = "";
    string attachmentOrderBy = "";

    // Get search results
    DataSet ds = SearchHelper.Search(searchText, sort, path, classNames,
    cultureCode, defaultCulture, combineWithDefaultCulture, checkPermissions,
    searchInAttachments, searchIndexes, displayResults, startingPosition,
    numberOfProcessedResults, userInfo, out numberOfResults, attachmentWhere,
    attachmentOrderBy);

    // If found at least one item
    if (numberOfResults > 0)
    {
        return true;
    }
}

return false;
}
```

The following example creates a task that updates the content of a search index.

```
private bool UpdateIndex()
{
    // Tree provider
    TreeProvider provider = new TreeProvider
(CMS.CMSHelper.CMSContext.CurrentUser);

    // Get document of specified site, aliaspath and culture
    TreeNode node = provider.SelectSingleNode
(CMS.CMSHelper.CMSContext.CurrentSiteName, "/", "en-us");
}
```

```
// If node exists
if ((node != null) && (node.PublishedVersionExists) &&
(SearchIndexInfoProvider.SearchEnabled))
{
    // Edit and save document node
    node.NodeDocType += " changed";
    node.Update();

    // Create update task
    SearchTaskInfoProvider.CreateTask(SearchTaskTypeEnum.Update,
PredefinedObjectType.DOCUMENT, SearchHelper.ID_FIELD, node.GetSearchID());

    return true;
}

return false;
}
```

8.44 Syndication (RSS, Atom, XML)

8.44.1 Overview

The Syndication module allows you to create [syndication feeds](#) of your site's content. The whole functionality is provided by a set of web parts stored under the **Syndication** web part category. These web parts generate feeds which conform to the [RSS](#), [Atom](#) or general [XML](#) format. The name of the feed format generated by each web part is included in the name of the web part.

Detailed overview of the web parts can be found in the [Syndication web parts and widgets](#) topic. Use of transformations is essential with these web parts. Information related to use of transformations in syndication web parts can be found in the [Syndication transformations](#) topic.

We have also prepared three examples of typical usage:

- [Example 1](#): Creating a **document RSS feed** using the *CMS RSS feed* web part.
- [Example 2](#): Creating an **object RSS feed** using the *RSS feed* web part and a *data source*.
- [Example 3](#): Creating a **dedicated page with an RSS feed** using the *RSS repeater* web part and a *data source*.
- [Example 4](#): Displaying content of an **external RSS feed** on your website using the *RSS data source* and *Basic repeater* web parts.

Live usage examples of these web parts can be found on the sample **Corporate Site**, under the **/ Examples/Web-parts/Syndication/** node.

All specific web part properties are explained in [Kentico CMS Web Parts Reference](#) or after clicking the **Documentation** (🔗) link in the top right corner of the *Web part properties* dialog.

Creating RSS feeds manually

Due to backward compatibility with Kentico CMS versions prior to 5.5, it is still possible to create a page with an RSS feed manually. Even though it is not recommended to take this approach, you can learn more about it in [this chapter](#).

8.44.2 Syndication web parts and widgets

Syndication web parts are stored under the **Syndication** category in the web part catalog. There is a large number of them, but most of them are similar and can be grouped into several categories:

From the functional point of view, there are two basic types of syndication web parts - repeaters and feeds:

- **Syndication feeds** show the feed icon with an optional text. The icon and text are clickable and when clicked, a querystring parameter with the feed ID is appended to its URL and the page renders the feed.
- **Syndication repeaters** change the page on which they are placed to a feed. If you place one of the syndication repeaters on a page, it changes the page response type to *application/xml*, transforms retrieved data to the required feed format and uses the transformed data as the content of the feed. This means that the page is no longer a standard HTML page - it becomes a syndication feed.

The web parts can also be divided in terms of what data they are used for. From this perspective, you can divide them as follows:

Basic feed web parts

These are universal web parts which can create a feed of data provided by a connected [data source](#). Without a data source, the web parts are not functional. The data provided by the data source can be of any type, it just needs to be handled properly by the used transformation.

- **XML repeater**
- **RSS repeater**
- **Atom repeater**
- **RSS feed**
- **Atom feed**

Document feed web parts

These web parts are based on the **RSS feed** web part, but have a built-in data source for the **document types** in their names. This means that you don't need a connected data source - all you need is included in a single web part. They are a kind of "all-in-one" solutions for frequently used document types.

- **CMS RSS Feed**
- **Articles RSS Feed**
- **Blog posts RSS Feed**
- **Events RSS Feed**
- **News RSS Feed**

The **CMS RSS Feed** can even be used for **documents of any type**, which makes it a universal web part for any document feed.

Object feed web parts

Similarly to object feeds described above, object feeds also have a built-in data source, letting you create feeds from **Kentico CMS objects** by adding just a single "all-in-one" web part.

- **Blog comments RSS feed**
- **Custom tables RSS feed**
- **Media files RSS feed**
- **Message board RSS feed**
- **Products RSS feed**
- **Forum posts RSS feed**

Other syndication web parts

Custom feeds can be created using the following two web parts:

- **Query RSS feed** - generates a feed based on a custom database query and transformation.
- **Web service RSS feed** - transforms a dataset provided by a web service into an RSS feed.

The last web part does not create any feed, but can be used as a link to a feed:

- **Feed link** - displays the RSS icon with a link leading to a URL set in its web part properties. Typically used for links to feeds created by syndication repeaters.

Syndication widgets

The default installation of Kentico CMS contains a set of widgets which are derived from the web parts listed above. They provide the same functionality and look, while only a limited set of properties can be configured. The following widgets are available:

- **Articles RSS Feed**
- **Blog comments RSS feed**
- **Blog posts RSS Feed**
- **Events RSS Feed**
- **Forum posts RSS feed**
- **Media files RSS feed**
- **News RSS Feed**
- **Products RSS feed**

Further information

All specific properties of these web parts or widgets are explained in [Kentico CMS Web Parts Reference](#) or after clicking the **Documentation** (🔗) link in the top right corner of the *Web part (widget) properties* dialog.

8.44.3 Syndication transformations

Use of transformations is of the highest importance when creating feeds, as all syndication web parts render the feeds using them. They need to be set in the **Transformation** property of each feed web part.

Default transformations

All document types in Kentico CMS have the **RSSItem** and **AtomItem** transformations. When you create a new document type, these transformations are created for it automatically.

The screenshot shows the 'Document type properties' page for the 'Article' document type. The 'Transformations' tab is active, displaying a table of transformations. The 'AtomItem' and 'RSSItem' rows are highlighted with red circles.

| Actions | Transformation name | Transformation type |
|---------|-----------------------|---------------------|
| | ArticleText | ASCX |
| | AtomItem | ASCX |
| | Default | ASCX |
| | DefaultWithoutTeasers | ASCX |
| | fancybox | ASCX |
| | PreviewWithTeasers | ASCX |
| | RSSItem | ASCX |
| | SimplePreview | ASCX |

The default RSS, Atom and XML transformations can also be generated when editing or creating transformations of a document type or a custom table. To do this, you only need to select the required format from the **Code** drop-down list and click the **Generate default transformation** button.

The screenshot shows the 'Document type properties' page for the 'RSSItem' transformation. The 'Code' dropdown is set to 'RSS', and the 'Generate default transformation' button is highlighted with a red circle.

Transformation name: RSSItem
Transformation type: ASCX

Code: Default Generate default transformation

```

language="C#" AutoEventWireup="true" Inherits="CMS.Controls.CMSAbstractTransformation" %>
tagPrefix="cc1" Namespace="CMS.Controls" Assembly="CMS.Controls" %>
<?xml version="1.0" encoding="utf-8" ?>
<item?xml:space="preserve" Permalink="false"><# Eval("NodeGUID") ?></guid>
<title><# EvalCDATA("ArticleName") ?></title>
<description><# EvalCDATA("#ArticleTeaserText") ?></description>
<pubDate><# GetRSSDateTime(Eval("DocumentCreatedWhen")) ?></pubDate>
<link><![CDATA[<# GetAbsoluteUrl(GetDocumentUrlForFeed(), Eval("SiteName")) ?>]]></lin
</item>

```

RSS transformations document type

Other feed transformations are found in a special document type called **RSS transformations (CMS.RSSTransformations)**. This is a special document type used just to store transformations for **Kentico CMS objects**. Transformations for blog comments, board messages, forum posts, media library files and products are contained in the document type.

CDATA in feed transformations

If you need to include [CDATA](#) sections in your feeds, you may utilize the **EvalCDATA** method. This method works in a similar manner as the commonly used **Eval** method. The difference is that the retrieved string is wrapped in a CDATA section and all occurrences of the `]]>` character sequence in the string are escaped.

Escaping is performed the way that each occurrence of `]]>` is replaced with `]]]]><!CDATA[>` and the whole text is then wrapped in standard `<![CDATA["wrapped text"]>` enclosure.

The method has two overrides:

- **EvalCDATA("FieldName")** - the first one has only one parameter - the actual name of the retrieved field.
- **EvalCDATA("FieldName", true)** - the second override has one extra boolean parameter, which determines if the wrapping will be performed. If the second parameter is set to *false*, value of the field will be retrieved, escaping of the `]]>` sequence will be performed, but the whole retrieved text will not be wrapped in the standard `<![CDATA["wrapped text"]>` enclosure.

The second override with the second parameter set to *false* is particularly useful if you use the method within another CDATA section. Because nesting of CDATA sections is not possible, you will only want to have the retrieved string escaped, but not wrapped in the enclosure. The code example below is a transformation extract where the method is used exactly this way.

```
...
<description>
  <![CDATA[
    <strong><%# EvalCDATA( "CommentUserName" ,false) %></strong><br /><%# EvalCDATA
    ( "CommentText" ,false) %>
```

```

]]>
</description>

...

```

8.44.4 Usage examples

8.44.4.1 CMS RSS feed

The **CMS RSS feed** web part can be used to easily create RSS feeds from documents in the content tree. It has a **built-in Documents data source**, which means that the web part can work separately without any connected data source and that it can be used to create feeds from documents of any type.

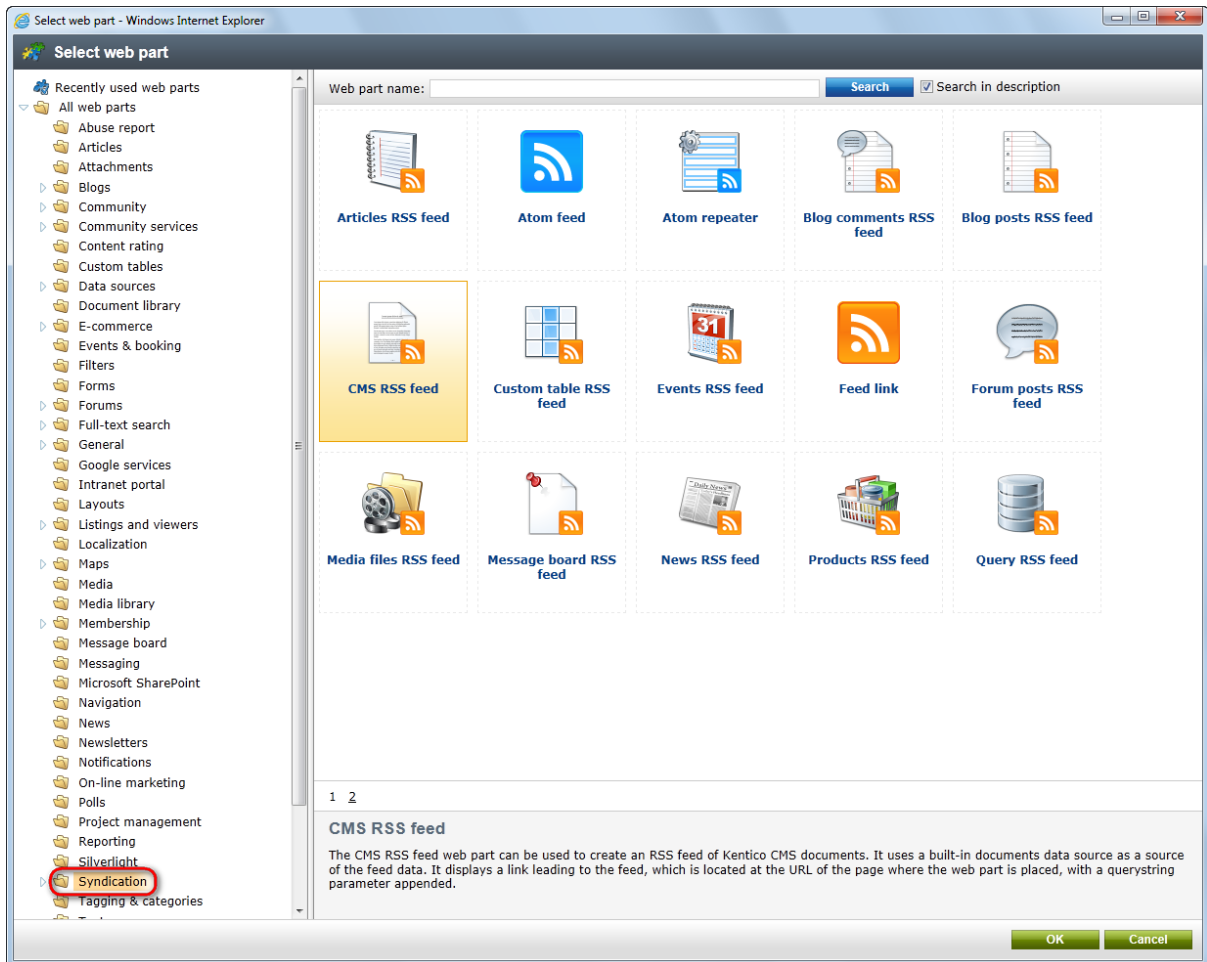

Apart from this universal web part, there are other web parts in the **Syndication** category which are pre-configured for one particular document type. See the listing in the [Syndication web parts and widgets](#) chapter.

In the following example, you will learn how to use this web part to create a feed link on the **/Products** page of the sample **Corporate site**. We will configure it so that it provides an RSS feed with products stored in all three categories under the page. The same procedure can be used on any other page and for documents of any other type, you just need to specify your required path, document type and transformation in the web part properties.

1. Sign in to CMS Desk and select the **/Products** page from the content tree. Switch to the **Design** tab and click the **Add web part (+)** icon of the **Left zone** web part zone.

The screenshot shows the Kentico CMS Desk interface in Design mode. The left sidebar displays the content tree with 'Products' selected. The main workspace shows the design of the '/Products' page. The 'Left zone' is highlighted with a red circle and a plus sign icon, indicating where to add a new web part. The page content includes a 'Products' header, a description, and a 'Featured Products' section displaying three items: Apple iPad 2 (\$510.99), Dell XPS 15z (\$1596.99), and Motorola Atrix 4G (\$529.98).

2. In the **Select web part** dialog, select the **Syndication** category. Choose the **CMS RSS feed** web part and click **OK**.

3. The **Web part properties** dialog opens. To achieve the required behavior, use the following configuration:

- **Link text:** *Products RSS feed*
- **Feed name:** *MyProductsFeed*
- **Feed title:** *Corporate Site Products*
- **Feed description:** *This is a sample RSS feed of products on the Corporate Site.*
- **Path:** */Products/%/%%*
- **Transformation name:** *CMS.RSSTransformations.Products*

Leave default values for the rest of the properties and click **OK**.

4. Sign out of CMS Desk and browse to the **Products** page. You should see the RSS icon and link as highlighted in the screenshot below.

Home Services Products News Community Company Media

Products

Smartphones

Laptops and Tablets

Software

E-Books

IT Services

Products

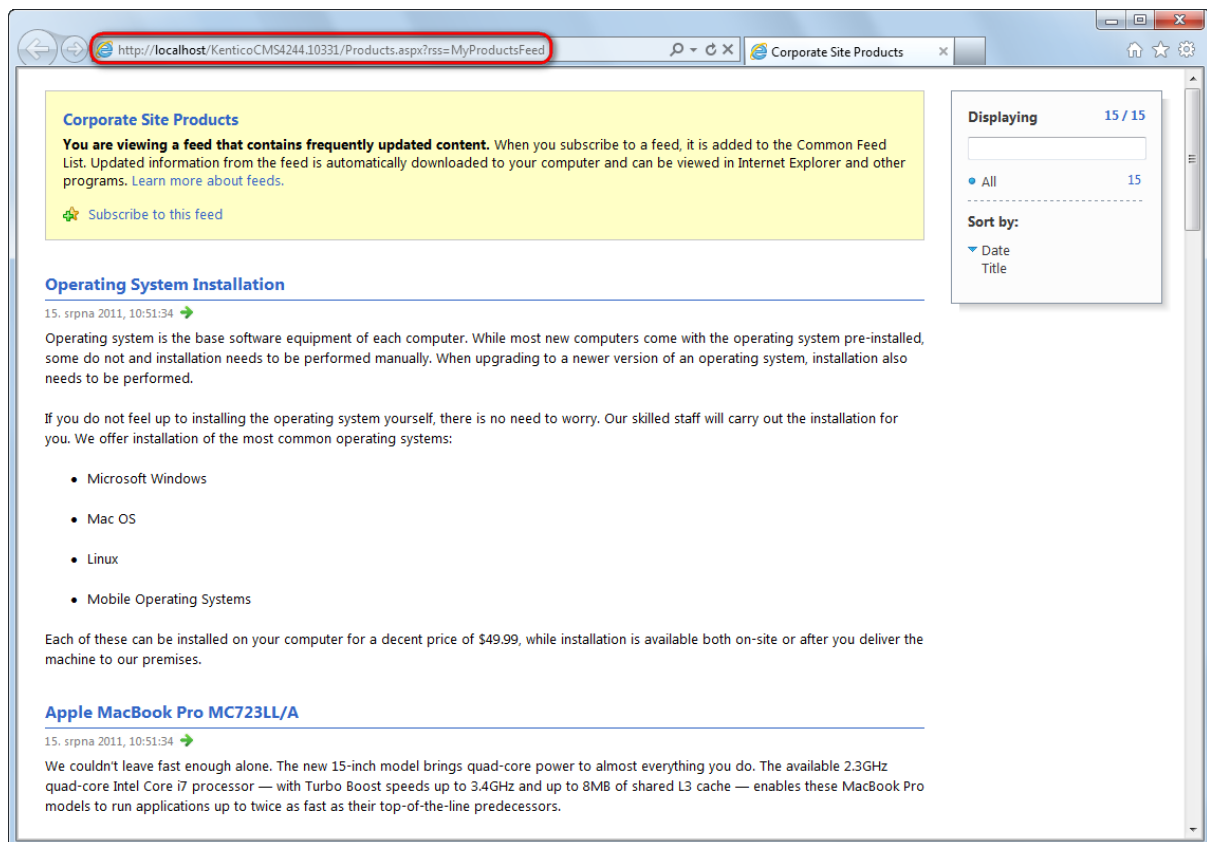

This section represents a simple web shop created using the **E-commerce** module. This module provides everything you might need to sell products on-line, including customizable checkout process, payment gateways integration, stock monitoring, invoices, tax classes and many more. For full reference on the module's capabilities, please refer to [Kentico CMS E-commerce Guide](#). You can also install the **E-commerce Site**, which is a dedicated sample website demonstrating capabilities of the module in more detail.

Featured Products

Products RSS feed

| | | |
|---|---|--|
|  <p>Apple MacBook Pro MC723LL/A</p> <p>\$2199.00</p>  |  <p>HP EliteBook 8440p WJ681AW</p> <p>\$1899.00</p>  |  <p>HTC Sensation</p> <p>\$799.99</p>  |
|---|---|--|

5. Click the icon or link, your browser will detect that you are accessing an RSS feed and display its content. As you can see, the URL of the feed is actually the URL of the page where the web part is placed with the **?rss=MyProductsFeed** querystring appended (this can be modified using the *Feed querystring key* and *Feed name* web part properties). The same URL can be used to access the feed directly both from a browser or a dedicated RSS reader program.

8.44.4.2 RSS feed + Data source

By connecting the **RSS feed** web part to a **data source**, you can create an RSS feed of the data provided by the data source. The **Atom feed** web part can be used exactly the same way, but the rendered feed is in the *Atom* format. You can use this approach to create feeds from Kentico CMS objects (forum posts, board comments, media files, ...).

The following example demonstrates how to create an RSS feed containing forum posts on the sample Corporate site. You can achieve this using the **RSS feed** and **Forum posts data source** web parts. The same procedure can be used for any other data. You only need to use a properly configured data source and process the provided data using a suitable transformation.

Please note

The result of the following example can also be achievable using a single web part - the **Forum posts RSS feed** web part, which has a built-in *Forum posts data source*.

Similarly, there are all-in-one web parts for other frequently used document types and objects (see the list in [Syndication web parts and widgets](#)).

1. Sign in to CMS Desk and select the **Community** -> **Forums** page from the content tree. Switch to the **Design** tab and click the **Add web part** (+) icon of the *Content zone* web part zone.

2. Select the **Data sources/Forum posts data source** web part and click **OK**. Leave all its properties at the default values, which will result in the data source providing all forum posts from all forum groups on the site. Click **OK**. The data source will be added to the bottom of *Content zone*.

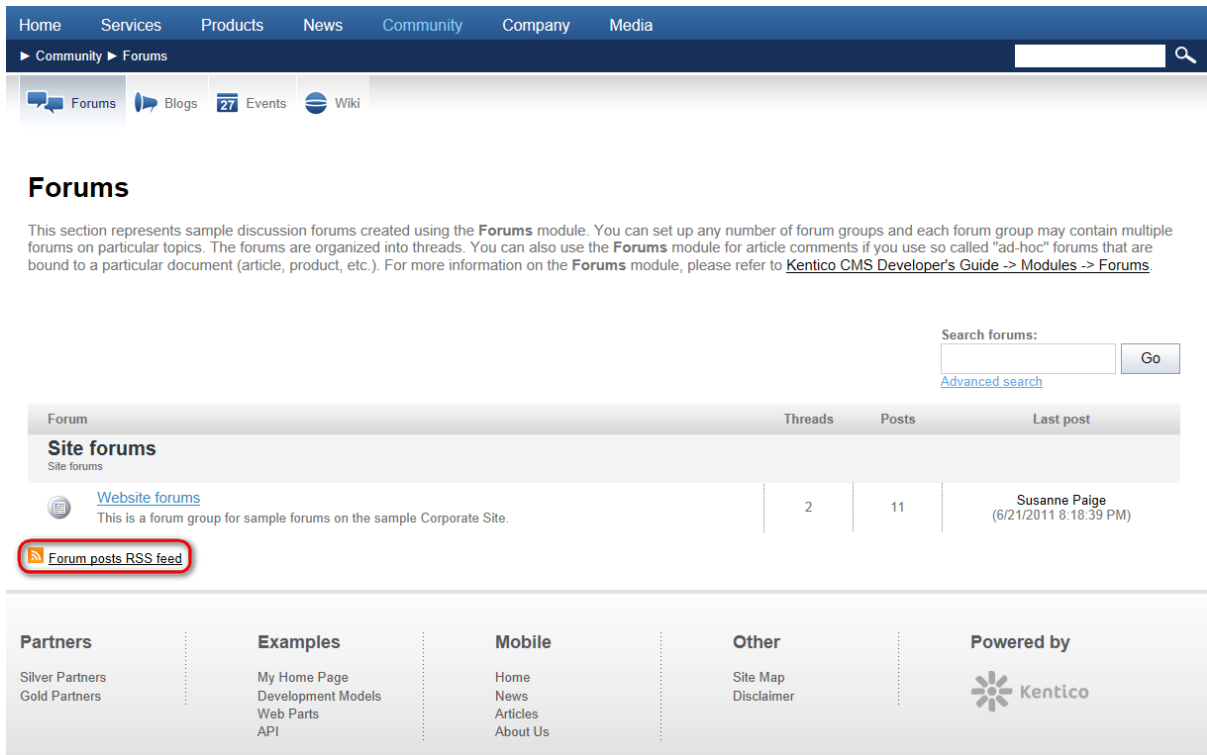

3. Click the **Add web part (+)** icon again and select the **Syndication/RSS feed** web part. Click **OK** and enter the following in the *Web part properties* dialog:

- **Link text:** *Forum posts RSS feed*
- **Feed name:** *MyForumPostsFeed*
- **Feed title:** *Corporate Site Forum Posts*
- **Feed description:** *This is a sample feed of all forum posts on the Corporate Site.*
- **Data source name:** *ForumPostsDataSource*
- **Transformation name:** *CMS.RSSTransformations.ForumPosts*

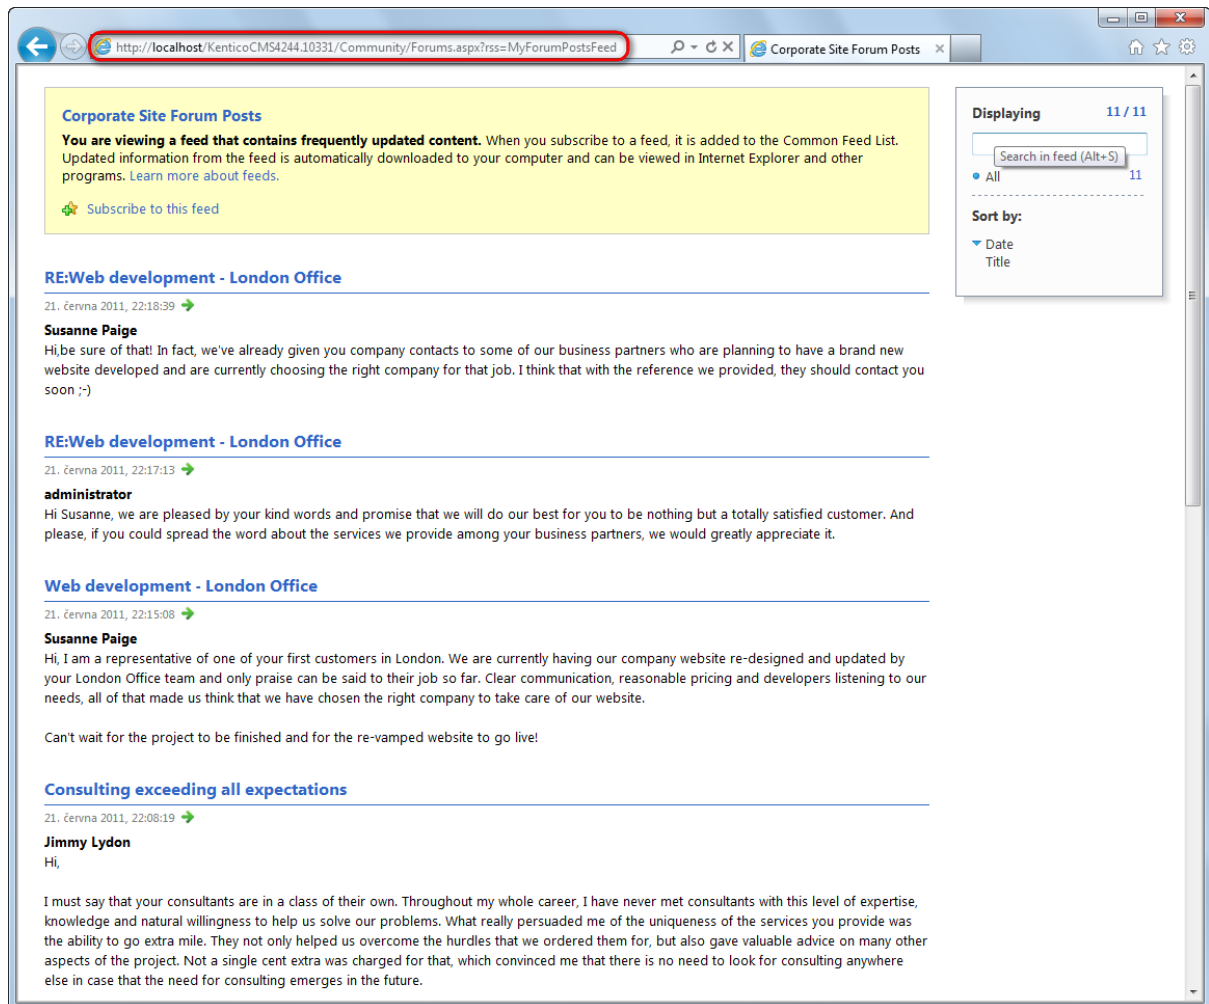

Leave defaults for the rest of the properties and click **OK**. The two web parts should now be at the bottom of the web part zone and fully configured for the required behavior.

| Forum group | Threads | Posts | Last post |
|--|---------|-------|---|
| Website forums
This is a forum group for sample forums on the sample Corporate Site.
Lock | 2 | 11 | Susanne Paige
(6/21/2011 8:18:39 PM) |

4. Sign out of CMS Desk and browse to the **Forums** page. You should see the RSS icon and link as highlighted in the screenshot below.

5. Click the icon or link, your browser will detect that you are accessing an RSS feed and display its content. As you can see, the URL of the feed is actually the URL of the page where the web part is placed with the **?rss=MyForumPostsFeed** querystring appended (this can be modified using the *Feed querystring key* and *Feed name* web part properties). The same URL can be used to access the feed directly both from a browser or a dedicated RSS reader program.

8.44.4.3 RSS repeater + Data source

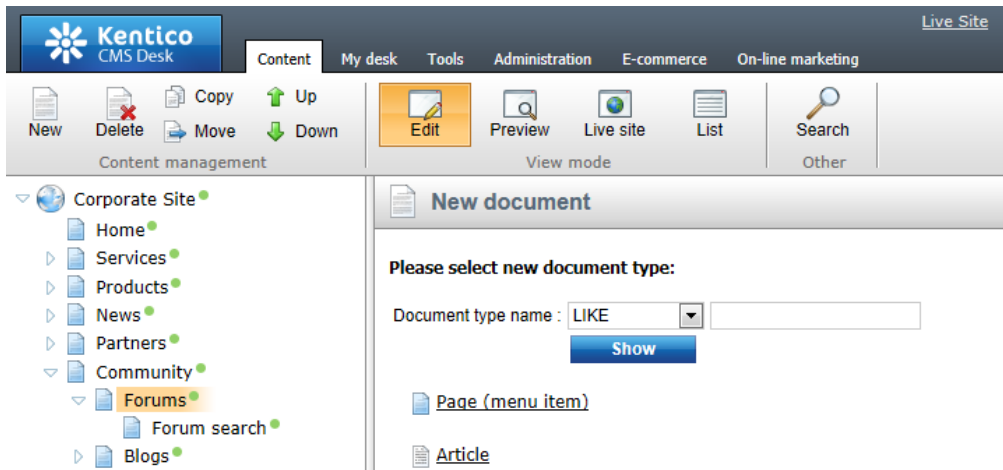

The **RSS repeater** web part allows you to transform pages into RSS feeds. When a page containing the web part is accessed, the response type is changed to *application/xml* and the page renders the content of the feed. This is useful if you want your feed to have a dedicated URL, without the need for a querystring parameter. The **Atom repeater** and **XML repeater** web parts can be used exactly the same way, but the rendered feed is in the *Atom* or *XML* format.

The following example demonstrates how to create an RSS feed containing the data of forum posts on the sample Corporate site. The example uses a dedicated feed page containing the **RSS repeater** web part.

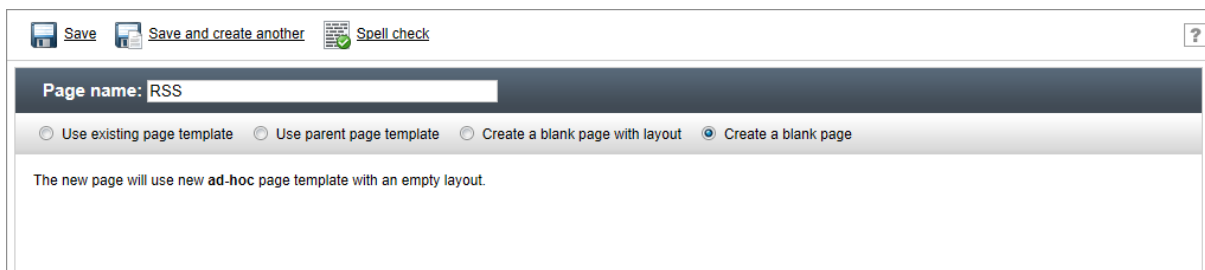

Please note

The result of the following example can also be achieved using a single web part - the **Forum posts RSS feed** web part, which has a built-in Forum posts data source. Similarly, there are all-in-one web parts for other frequently used document types and objects (see the list in [Syndication web parts and widgets](#)).

1. Sign in to CMS Desk and select the **Forums** page from the content tree. Click **New** and choose the **Page (menu item)** document type.

2. Choose the **Create a blank page** option. Enter **RSS** as the **Page name** and click **Save**.

3. The page opens in **Design** mode. Click the **Add web part (+)** icon of the only web part zone on the page. Select the **Data sources/Forum posts data source** web part and click **OK**. Leave all properties at the default values, which causes the data source to load all forum posts from all forum groups on the site. Click **OK**.

4. Click the **Add web part (+)** icon again and select the **Syndication/RSS repeater** web part. Click **OK** and enter the following in the *Web part properties* dialog:

- **Feed name:** *MyForumPostsFeed*
- **Feed title:** *Corporate Site Forum Posts*
- **Feed description:** *This is a sample feed of all forum posts on the Corporate Site.*
- **Data source name:** *ForumPostsDataSource*
- **Transformation name:** *CMS.RSSTransformations.ForumPosts*

Leave defaults for the rest of the properties and click **OK**.

5. The RSS feed is now ready. To allow visitors to access the feed, create a link using the **Feed link** web part, which displays the RSS icon with a link leading to a URL specified in its properties.

Select the **/Forums** page in the content tree, switch to the **Design** mode and click the **Add web part** (+) icon of the *Content zone* web part zone. Select **Syndication/Feed link** and click **OK**. Enter the following properties:

- **Link text:** *Forum posts RSS feed*
- **Feed URL:** *~/Community/Forums/RSS.aspx*
- **Feed title:** *My Forum Posts Feed*

Leave defaults for the rest of the properties and click **OK**.

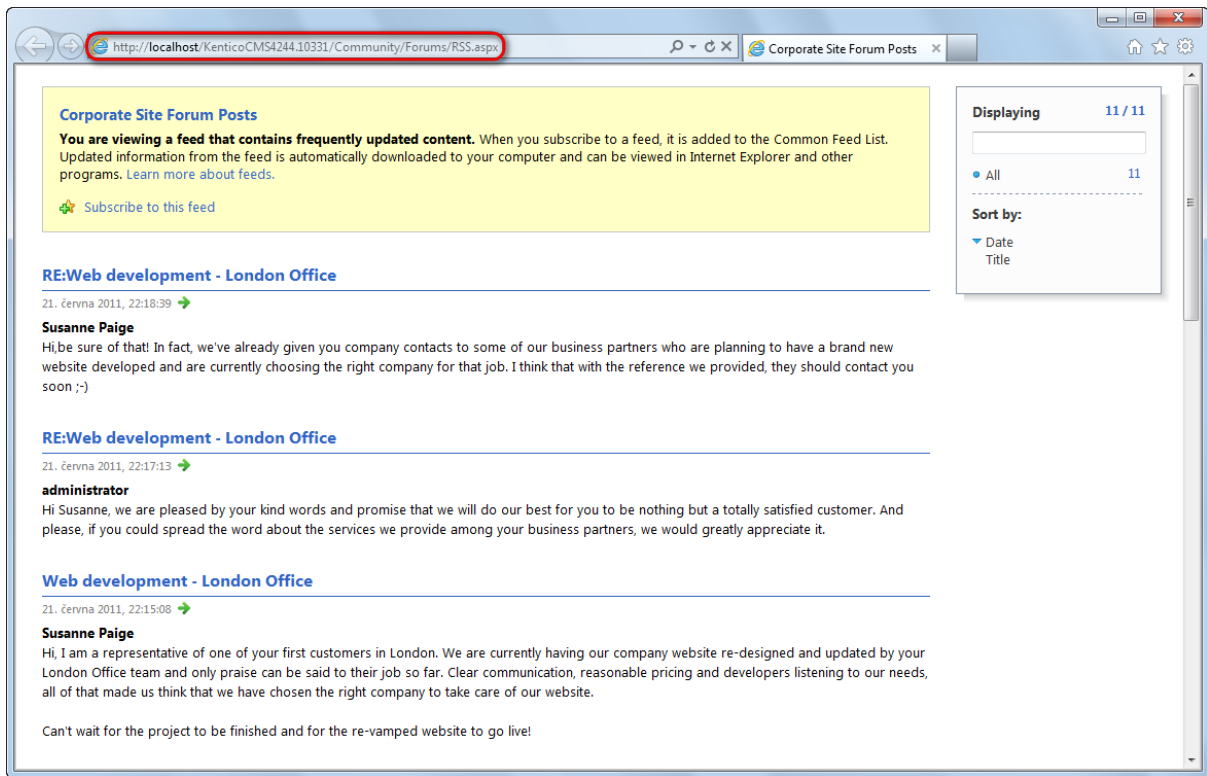

6. Sign out of CMS Desk and browse to the **Forums** page. You should see the RSS icon and link.

The screenshot shows the Kentico CMS Forums page. The navigation bar includes Home, Services, Products, News, Community, Company, and Media. The breadcrumb trail is Community > Forums. Below the navigation are icons for Forums, Blogs, Events (27), and Wiki. The main heading is "Forums". A search box is present with a "Go" button and a link to "Advanced search". A table lists forum groups:

| Forum | Threads | Posts | Last post |
|---|---------|-------|---|
| Site forums
Site forums | | | |
| Website forums
This is a forum group for sample forums on the sample Corporate Site. | 2 | 11 | Susanne Paige
(6/21/2011 8:18:39 PM) |

Below the table, a red box highlights the "Forum posts RSS feed" link. The footer contains sections for Partners, Examples, Mobile, Other, and Powered by Kentico.

7. Click the icon or link. Your browser detects that you are accessing an RSS feed and displays the content. The URL of the feed matches the URL of the page containing the **RSS repeater** web part. You can use the same URL to access the feed from both browsers and dedicated RSS reader programs.

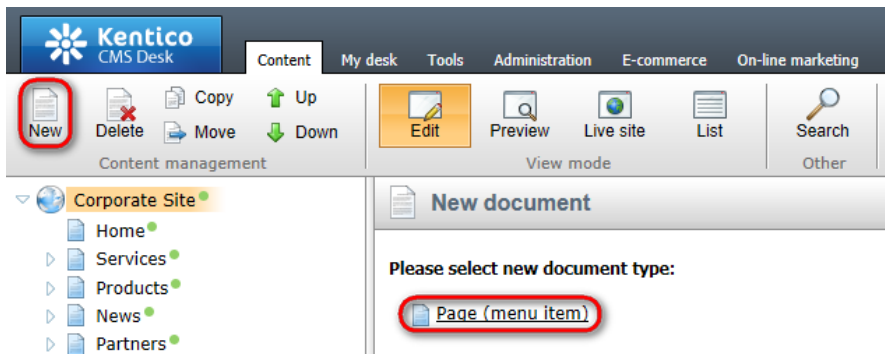

8.44.4.4 External RSS feed

Apart from creating RSS feeds from the CMS content, it is also possible to use external RSS feeds (i.e. feeds published on other websites) as a source of data and display the data on your website.

In the following example, you will learn how to use the **RSS data source** and **Basic repeater** web parts to display content of an external feed on your website. For the purpose of the example, we will use the main blog posts feed from Kentico DevNet: <http://devnet.kentico.com/CMSPages/BlogRss.aspx>

1. Sign in to CMS Desk and select the root of your website's content tree. Click **New** above the content tree and choose to create a document of the **Page (menu item)** type.

2. In the following dialog, choose to **Create a blank page**, enter *External RSS* into the **Page name** field and click **Save**.

3. The page will get created and you will see it selected in the content tree. View the page on the **Design** tab and click the **Add web part** (+) icon in the top right corner of the only web part zone on the page. In the web part selection dialog, choose the **Data sources -> RSS data source** web and click **OK**. In its **Web part properties** dialog which pops-up, enter the following values:

- **Web part control ID:** *KenticoBlogsRSS*; this ID will be used in step 4 to connect the repeater that will display the data.
- **RSS feed URL:** *http://devnet.kentico.com/CMSPages/BlogRss.aspx*, this is the URL of the external RSS feed that you want to get data from.

Leave the rest of the properties at their default values and click **OK**.

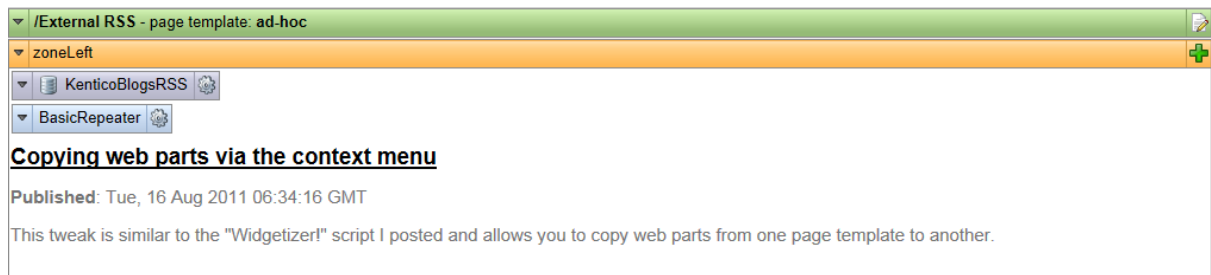

4. Click the **Add web part** (+) icon again. This time, choose the **Listings and viewers -> Basic repeater** web part and configure its properties as follows:

- **Data source name:** *KenticoBlogsRSS*;
- **Transformation name:** click **New** and create a new transformation with the code listed below.

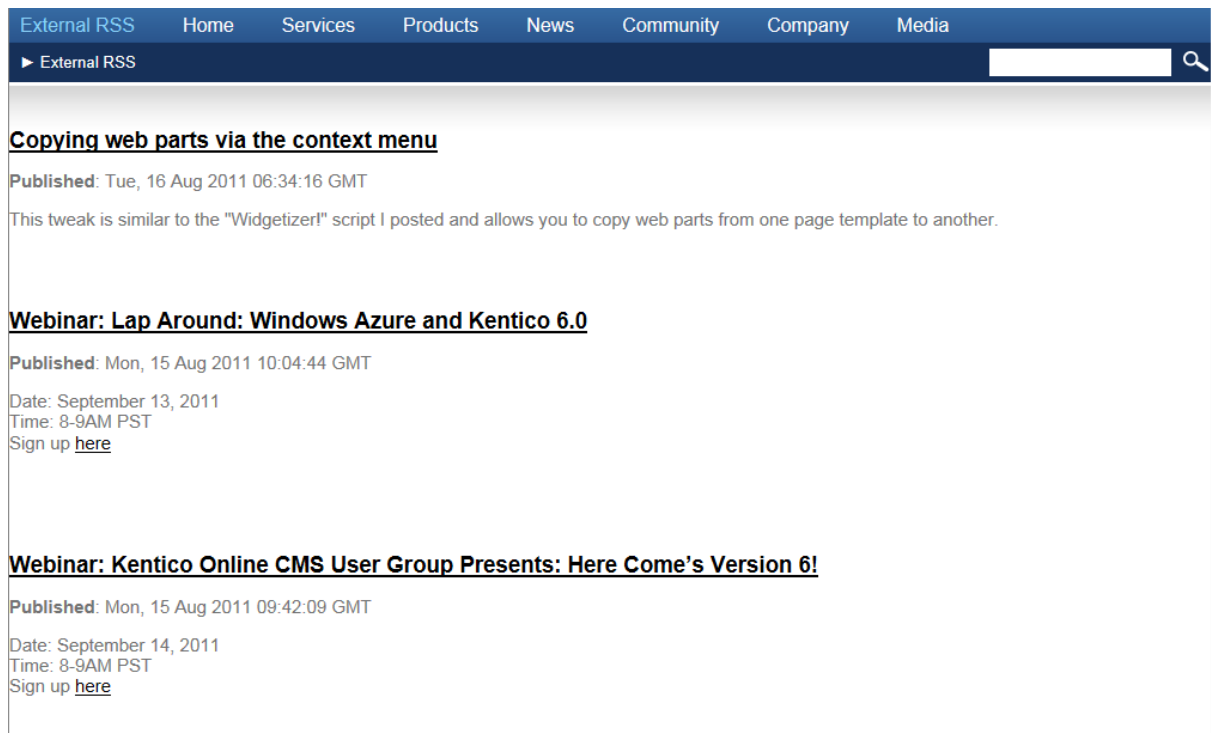

The following is a sample transformation code which transforms the *link*, *pubdate* and *description* elements of each record provided by the feed. Content of the elements is retrieved using the **Eval(string columnName)** method, while the element name is used in the parameter. This way, you can get data from any elements in any external RSS feed that you want to get the data from.

```
<h2>
  <a href="<## Eval("link")%>">
    <## Eval("title") %>
  </a>
</h2>
<p>
  <strong>Published</strong>: <## Eval("pubdate") %>
</p>
<p>
  <## Eval("description") %>
</p>
<br/>
```

Leave the rest of the web part properties at their default values and click **OK**. On the **Design** tab, the page should now look as in the following screenshot.

5. As visible in the screenshot above, the repeater is already displaying some data. To see the result the way your site visitors will see it, switch to the live site and navigate to the new page. You will see that the page really displays content of the RSS feed, as can be seen in the screenshot below.

8.44.5 Creating RSS feed pages manually (obsolete)

Due to backward compatibility with Kentico CMS versions prior to 5.5, it is also possible to create a dedicated page with an RSS feed. This way of creating RSS feeds is **obsolete** now, as syndication web parts provide a much more convenient way of creating RSS feeds.

The default installation contains a simple **CMSPages\NewsRss.aspx** page which shows how to build your own RSS feed. It works with news items, but you can modify the code so that it displays a different type of documents.

The following code example shows the code of the *NewsRss.aspx* page.

Please note: If you installed the Kentico CMS project as a web application, you need to rename the *CodeFile* property on the first line to *Codebehind* for the code example to be functional.

```

<%@ Page Language="C#" AutoEventWireup="true" CodeFile="RSS.aspx.cs"
    Inherits="RSSNews" %>
<%@ Register Assembly="CMS.Controls" Namespace="CMS.Controls"
    TagPrefix="cc1" %><?xml version="1.0" encoding="utf-8" ?>
<rss version="2.0">
  <channel>
    <title>News RSS</title>
    <link><![CDATA[<%=HttpContext.Current.Request.Url.AbsoluteUri.Remove
(HttpContext.Current.Request.Url.AbsoluteUri.Length -
HttpContext.Current.Request.Url.PathAndQuery.Length) +
HttpContext.Current.Request.ApplicationPath%>]]></link>
    <description>News RSS Feed</description>
    <cc1:cmsrepeater ID="NewsRepeater" runat="server" OrderBy="NewsReleaseDate DESC"
      ClassNames="cms.news"
      TransformationName="cms.news.rssitem"
      SelectedItemTransformationName="cms.news.rssitem"
      Path="/news/%"></cc1:cmsrepeater>
  </channel>
</rss>

```

As you can see, the page contains only RSS elements with dynamic code. The RSS items are rendered using a *CMSRepeater* control with appropriate transformation.

The code behind looks like this:

[C#]

```

protected void Page_Load(object sender, EventArgs e)
{
    Response.ContentType = "text/xml";
}

```

This code changes the output content type to XML.

How to create an RSS feed page for a different document type

If you want to display articles instead of news in your RSS feed, you will need to follow these steps:

1. Create a new ASPX page called `articles_rss.aspx`.
2. Copy and paste all code from the `NewsRss.aspx` file except for the `<%@ Page %>` directive.
3. Change the following properties of the `CMSRepeater` control:
 - **OrderBy:** DocumentModifiedWhen DESC
 - **ClassName:** cms.article
 - **TransformationName:** cms.article.rssitem
 - **SelectedItemTransformationName:** cms.article.rssitem
 - **Path:** /%
 - **WhereCondition:** leave empty
4. Add the same line of code as used in the `NewsRss.aspx.cs` code behind file (`Response.ContentType`

= "text/xml") to articles_rss.aspx.cs.

5. Create the transformation `cms.article.rssitem` like this in **Site Manager -> Development -> Document Types -> ... edit Article ... -> Transformations**:

```
<item>
  <guid isPermaLink="true"><![CDATA[<# GetAbsolutePath(GetDocumentUrl()) %>]]
</guid>
  <title><![CDATA[<# Eval("ArticleTitle") %>]]></title>
  <description><![CDATA[<# Eval("ArticleText") %>]]></description>
  <pubDate><# Convert.ToDateTime(Eval("DocumentModifiedWhen")).ToString("r") %
</pubDate>
  <link><![CDATA[<# GetAbsolutePath(GetDocumentUrl()) %>]]></link>
</item>
```

This code renders the particular items.

8.45 System integration bus

8.45.1 Overview

The System integration bus module enables integration of Kentico CMS with external systems. Detailed information about the module, implementation of custom integration connectors, management of integration tasks and usage examples of the module can be found in [Kentico CMS Integration Guide](#).

8.46 Staging

8.46.1 Overview

The **Staging** module allows you to easily transfer changes made to documents or objects in a Kentico CMS instance on one server to another instance on another server. It is also possible to perform complete synchronization of all documents and objects this way. This is particularly useful if you need to separate website content in development, editing (staging) and live (production) environment.

All documents stored in CMS Desk's content tree can be synchronized using the module. However, not all objects in a Kentico CMS system can be synchronized this way. The [What can be synchronized](#) topic gives you an overview of which data can be synchronized using the module.

For the synchronization to be possible, you need to configure Kentico CMS instances on particular servers as described in the [Staging configuration](#) topic. Each instance can be configured as a source server or as a target server. Changes from the source server are transferred to the target servers, as depicted in the diagram above. Every site can use different target servers for content staging. You can

even synchronize between different sites in the same Kentico CMS instance (in the same database).

It is also possible to have servers configured as both a target and a source server at the same time, so that changes can be transferred in both directions. This possibility and the configuration required for it is described in the [Bi-directional staging](#) topic.

Once all instances are configured, you can start synchronizing the changes. All changes are logged as staging tasks in **CMS Desk -> Tools -> Staging**. The [Synchronizing the content](#) topic explains how staging tasks can be transferred to the other servers, as well as all other operations possible in this section of the user interface. Synchronization can also be performed automatically, based on a pre-defined scheduled task named **Content synchronization**. The [Automatic synchronization](#) topic explains this scheduled task can be enabled.

The synchronized data is transferred over a secured web service. Management of content staging tasks and performing of the actual synchronization can be allowed only to certain roles. The [Security](#) topic provides more information about permissions that need to be granted to roles in order to perform these actions.

Another way of transferring your content from one Kentico CMS instance to another is to export the data from one instance and import them to another one. The [Managing sites -> Export and import](#) chapter of this guide gives you an extensive overview of the built-in export and import functionality.

In the [Staging internals and API](#) sub-chapter, you can find information about database tables and classes that are used by the Staging module, as well as several examples of how staging can be performed using Kentico CMS API.

8.46.2 What can be synchronized

The Staging module **supports** synchronization of the following data:

- [Document data](#) - documents in the website content tree. Timeout defined for documents that are part of a workflow is not synchronized for consistency reasons.
- [Document attachments](#) - if a document contains attachments or file fields, the files are synchronized together with the document.
- [Document relationships](#) - relationships between documents are synchronized if the relationship type and both documents exist on the target server. Synchronization is NOT supported for relationships between documents on different sites.
- [Workflow process](#) - only published document versions are synchronized to the target server and both servers need to have the same workflow schemas defined.
- [Custom tables](#) and their data.
- [Media libraries](#) and the files and folders in them
- [ACLs \(document-level permissions\)](#)
- **Global objects** - all global objects except for the cases mentioned in the list below.

The Staging module **does not support** synchronization of the following data:

- [Abuse reports](#)
- [Accounts](#)
- [Activities](#)
- [Blog comments](#) (blogs and blog posts are synchronized as documents)
- [Booking event attendees](#)
- [Contacts](#) (the state of contacts in automation processes is also not synchronized)

- Event log
- [Export history](#)
- [Forms data](#) (the actual form objects are synchronized)
- [Forum posts](#) (forum objects are synchronized)
- [Friends](#)
- [Message board messages](#) (message board objects are synchronized)
- [Messaging module messages](#)
- Physical files associated with global objects (for example web part source file, form control files, ASPX page template files)
- Web templates

Staging of Media library content

Kentico CMS supports staging of **physical files and folders** stored in the [Media library](#) file system. Staging tasks related to Media library files are logged in [CMS Desk -> Tools -> Staging -> Objects](#).

You can limit the maximum size of synchronized media library files as described in the [Staging large files topic](#).

Please note

Changes in media library files and folders are logged as content staging tasks only when performed via the UI. If you make changes directly in the library folder in the file system, e.g., upload or update files using FTP, the changes are not logged.

Also, if you make a change to a file via the UI and then update the file using FTP, the current file (the one updated using FTP) will be transferred to the target server, even if the staging task was created before the file upload. This happens because binary data of the files are loaded in synchronization time, not when the synchronization task is logged.

8.46.3 Staging configuration

Configuration of the Staging module consists of the following three parts:

1. [Microsoft WSE configuration](#) - renaming of a .dll library on all servers.
2. [Source server configuration](#) - configuration of the server from which changes will be transferred to the target servers.
3. [Target server configuration](#) - configuration of the server to which changes will be transferred from the source servers.
4. [Configuring servers for staging macro expressions](#)

Apart from this configuration, you also need to ensure that all instances use the same settings (document types, templates, web parts ...), code files and that both servers use the same version of Kentico CMS.

Microsoft WSE configuration

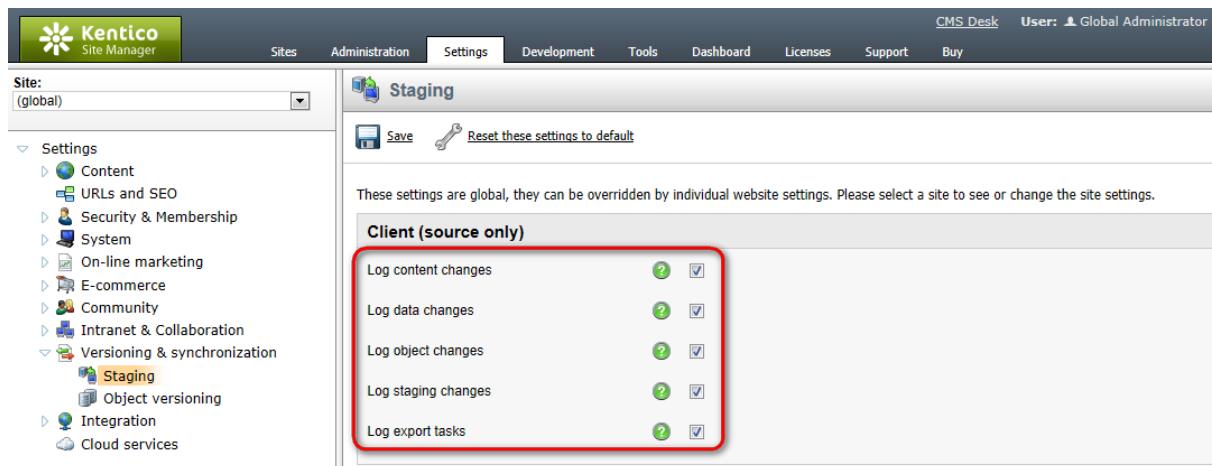

To enable content staging, you first need to open the **bin** folder under your web project and rename the **Microsoft.Web.Services3.dll.rename** file to **Microsoft.Web.Services3.dll**. This needs to be done on both source and target servers.

Source server configuration

1. To configure a Kentico CMS instance as a source server, you first need to enable logging of content staging tasks using the following settings in **Site Manager -> Settings -> Versioning & synchronization -> Staging**.

- **Log content changes** - if enabled, synchronization tasks are automatically logged when content (a document) is modified.
- **Log data changes** - if enabled, synchronization tasks are automatically logged when custom tables data are modified.
- **Log object changes** - if enabled, synchronization tasks are automatically logged when an object is modified.
- **Log staging changes** - if enabled, synchronization tasks are logged for changes made by synchronization from another server to this server. See [Bi-directional staging](#) for more details.
- **Log export tasks** - if enabled, synchronization tasks are logged when an object is deleted (incremental update support).

With these settings enabled, all changes to the corresponding content are logged as content staging tasks. These tasks can then be transferred to the target servers and performed there to synchronize the content.

2. Then, you need to specify the target server(s). Go to **CMSSDesk -> Tools -> Staging -> Servers**.

This is where you can manage the list of target servers. To add a new server, click **New server** (🔧), enter the server properties and save them:

- **Server display name** - server display name displayed to the users in the administration interface.
- **Server code name** - server name used in website code.
- **Server URL** - staging service URL that points to the content staging web service of the target server; the web service page is located at `~/CMSPages/syncserver.aspx`, so the URL should look like this: `http://www.example.com/CMSPages/syncserver.aspx`. The **Check Server availability** button (🔧) checks if the server with the entered URL is available and displays the result.

- **Enabled** - if checked, the target server is enabled, it means that synchronization tasks are automatically generated for the server and that synchronization is enabled for this server; you can temporarily disable the server by un-checking the box, e.g. in case of server maintenance.
- **Server authentication** - server authentication settings; you should set the same parameters that are configured for your target server (described below); the default user name is **admin** and the default password is **pass**; if you want to use X509 authentication, please consult the [Using X.509 authentication](#) topic.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The 'Tools' menu is expanded, showing options like 'Forms', 'Media', 'Polls', 'Custom tables', 'Staging', 'File import', 'Blogs', 'Forums', 'Message boards', 'Groups', 'Abuse report', 'Projects', and 'Events'. The 'Staging' section is active, and the 'Servers' tab is selected. The form for creating a new server is displayed with the following fields:

- Server display name:
- Server code name:
- Server service URL:
- Enabled:
- Server authentication:
 - User name / password
 - User name:
 - Password:
 - X509
 - Client key ID:
 - Server key ID:

An 'OK' button is located at the bottom of the form.

Please note

Tasks are logged only when there is at least one target server created and enabled. If there is no server created or if no server is running, no tasks are logged.

Target server configuration

On the target server, the staging service is disabled by default. For it to work, you need to set the following values in **Site Manager -> Settings -> Versioning & synchronization -> Staging**:

- **Enable staging service** - if checked, the staging service is enabled for the given site;
- **Staging service authentication** - staging service authentication type; it is recommended that you choose *USERNAME* authentication to configure staging first, test synchronization and then optionally configure the site for *X509* certificates
 - *USERNAME* – username/password authentication (fast, recommended for the data without high security requirements)

- **X509** – X509 certificate authentication (more secure, slower, requires certificates); more details can be found in the [Using X509 authentication](#) topic
- **Staging service username and password** - username and password for the *USERNAME* authentication
- **Server key ID and Client key ID** - certificate keys for the X509 authentication

The screenshot shows the Kentico CMS 7.0 Staging settings page. The page is titled "Staging" and has a "Save" button and a "Reset these settings to default" link. The settings are global, but can be overridden by individual website settings. The page is divided into two main sections: "Client (source only)" and "Staging service (target only)".

Client (source only)

| | |
|---------------------|--------------------------|
| Log content changes | <input type="checkbox"/> |
| Log data changes | <input type="checkbox"/> |
| Log object changes | <input type="checkbox"/> |
| Log staging changes | <input type="checkbox"/> |
| Log export tasks | <input type="checkbox"/> |

Staging service (target only)

| | |
|--------------------------------|-------------------------------------|
| Enable staging service | <input checked="" type="checkbox"/> |
| Staging service authentication | User name and password |
| Staging service user name | admin |
| Staging service password | pass |

X509 Certificates

| | |
|---------------|------------------------------|
| Client key ID | gBfo0147IM6cKnTbbMSuMVvmFY4= |
| Server key ID | bBwPfltvKp3b6TNDq+14qs58VJQ= |

Configuring servers for staging macro expressions

The system uses signatures to ensure the security of [macro expressions](#). Macro signatures contain the user name of the macro's author and a hash of the given expression.

The hash function used to create the signatures appends a [salt](#) to the input. The default salt is the application's main database connection string, so the signatures are only valid in the environment where the macros were originally saved. To allow macros to work correctly on all staging servers, you need to set the same custom hash salt for all servers:

- Add the **CMSHashStringSalt** key to the *appSettings* section of the *web.config* file on all staging servers. You can use any string as the value, but the salt should be random and at least 16 characters long. For example, a randomly generated [GUID](#) is a strong salt:

```
<add key="CMSHashStringSalt" value="e68b9ad6-a461-4707-8e3e-ec73f03dd02" />
```

The best option is to set the hash salt value before you start creating content for your website. Changing the salt causes all current hash values to become invalid. To fix existing macro expressions in the

system after changing the hash salt, you need to re-sign the macros. See [Macro security](#) for more information.

Warning

In addition to macro signatures, the system uses the **CMSHashStringSalt** value for other hash functions. Changing the hash salt on a website that already has defined content may break dialog links and images on your website.

If you encounter such problems, you need to re-save the given content (the system then creates the hashes using the new salt).

8.46.4 Bi-directional staging

Bi-directional content staging, i.e. content staging where servers are not exclusively source or target ones, but can act both ways, is achievable with some extra settings. The advantage of such configuration is that you can make changes not only on the source server, but also on the other server (s), while the changes are transferred to the rest of the servers too.

There are two types of bi-directional content staging, depending on the number of servers between which you want to synchronize:

- [Simple](#) - used for synchronization between 2 servers only
- [Advanced](#) - used for synchronization between more than 2 servers

Both configuration procedures are described in the text below, click the respective link to scroll directly to the beginning of the description.

Simple bi-directional staging

If you want to perform content staging bi-directionally between **two servers**, i.e. you want to transfer changes made on Server 1 to Server 2 and also in the other direction from Server 2 to Server 1, you need to configure both servers as a source and a target server at the same time, as described in the [Staging configuration](#) topic.

On top of it, you also need to **disable** the **Log staging changes** option in **Site Manager -> Settings -> Versioning & Synchronization -> Staging** on both servers.

If this option is enabled, changes made to the system via content staging synchronization (i.e. transferred from Server 1 to Server 2) are logged as new synchronization tasks on the target server (on Server 2). Now if you perform synchronization in the reversed direction, i.e. back from Server 2 to Server 1, these tasks are also performed and logged back on Server 1 as new staging tasks. This goes on and on in a never-ending loop, which results in the tasks remaining and not being deleted on both servers.

In order to prevent this behavior, you need to disable the **Log staging changes** option on both servers so that the staging changes are not logged as new synchronization tasks.

The screenshot shows the Kentico CMS 7.0 Staging settings page. The left sidebar contains a navigation menu with categories like Content, Security & Membership, System, On-line marketing, E-commerce, Community, Intranet & Collaboration, Versioning & Synchronization, Staging, Object versioning, Integration, and Cloud services. The main content area is titled 'Staging' and includes a 'Save' button and a 'Reset these settings to default' link. Below this, a message states: 'These settings are global, they can be overridden by individual website settings. Please select a site to see or change the site settings.' The settings are organized into three sections: 'Client (source only)', 'Staging service (target only)', and 'X509 Certificates'. In the 'Client (source only)' section, the 'Log staging changes' checkbox is highlighted with a red rectangle. Other checkboxes include 'Log content changes', 'Log data changes', 'Log object changes', and 'Log export tasks'. The 'Staging service (target only)' section includes 'Enable staging service', 'Staging service authentication' (set to 'User name and password'), 'Staging service user name' (set to 'admin'), and 'Staging service password'. The 'X509 Certificates' section includes 'Client key ID' (set to 'gBfo0147IM6cKnTbbMSuMVvmFY4=') and 'Server key ID' (set to 'bBwPfltvKp3b6TNDq+14qs58VJQ='). At the bottom, there is a link to 'Export these settings'.

Advanced bi-directional staging

Bi-directional content staging is also possible on more than two servers. In this case, a list of servers where a staging task has already been processed is transferred with each task. This prevents redundant staging tasks from being logged for servers where the changes have already been performed.

The rule is that there has to be **only one path between any two servers in both directions**. The following figures show examples of supported server topologies. The rectangles represent particular servers, while the arrows indicate the flow of content staging synchronization tasks.

The first option is to have the servers connected using **star topology**.

Another possible topology is the **circle topology**.

Other topologies are not supported. The following diagram shows an unsupported environment. It doesn't follow the rule which says that there should be only one path between any two servers. There are two paths from the LIVE server to the TEST server, which breaks the rule.

Configuring advanced bi-directional staging

Follow the instructions below to configure bi-directional staging for three servers—development server, test server and live server, using star topology.

1. On each of the servers that you want to be part of the bi-directional staging, navigate to **Site Manager -> Settings -> Versioning & Synchronization -> Staging**.
2. [Configure](#) the servers as **Source** by turning all the check-boxes on.

| Client (source only) | |
|----------------------|-------------------------------------|
| Log content changes | <input checked="" type="checkbox"/> |
| Log data changes | <input checked="" type="checkbox"/> |
| Log object changes | <input checked="" type="checkbox"/> |
| Log staging changes | <input checked="" type="checkbox"/> |
| Log export tasks | <input checked="" type="checkbox"/> |

3. [Configure](#) the servers as **Target**, using the **user name and password** authentication.

| Staging service (target only) | |
|--------------------------------|-------------------------------------|
| Enable staging service | <input checked="" type="checkbox"/> |
| Staging service authentication | User name and password |
| Staging service user name | admin |
| Staging service password | •••••••• |

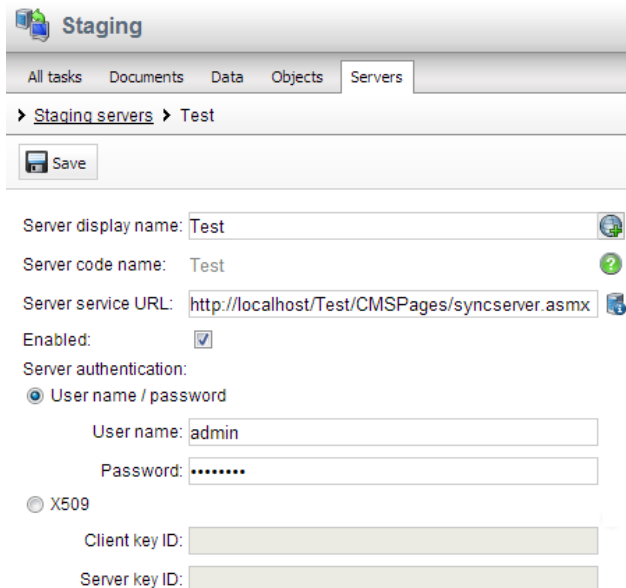

Configuring Development server

1. Into the *AppSettings* section of the *web.config* file of the server, enter the following value to name the server **Dev**.

```
<add key="CMSStagingServerName" value="Dev" />
```

2. Navigate to **CMS Desk -> Tools -> Staging**.
3. Switch to the **Servers** tab and add **New server** (📁).
4. [Configure](#) the new server to target the **Test** server. You will configure the **Test** server later.

Make sure the value of **Server code name** is set to **Test**, which is the value that you will use in the **Test** server's *web.config* file.

The screenshot shows the 'Staging' section of the CMS Desk interface. The 'Servers' tab is active, and a new server named 'Test' is being configured. The configuration fields are as follows:

- Server display name: Test
- Server code name: Test
- Server service URL: http://localhost/Test/CMSPages/syncserver.aspx
- Enabled:
- Server authentication: User name / password
 - User name: admin
 - Password:
- X509
 - Client key ID: [empty field]
 - Server key ID: [empty field]

Configuring Test server

1. Into the *AppSettings* section of the *web.config* file of the server, enter the following value to name the server **Test**.

```
<add key="CMSStagingServerName" value="Test" />
```

2. Navigate to **CMS Desk -> Tools -> Staging**.
3. Switch to the **Servers** tab and add **New server** (📁).
4. [Configure](#) the new server to target the **Dev** server that you created previously.

Make sure the value of **Server code name** is set to **Dev**, which is the value used in the **Dev** server's *web.config* file.

5. Add another **New server** (📁).

6. [Configure](#) the new server to target the **Live** server. You will configure the **Live** server later.

Make sure the value of **Server code name** is set to **Live**, which is the value that you will use in the **Live** server's *web.config* file.

Configuring Live server

1. Into the *AppSettings* section of the *web.config* file of the server, enter the following value to name the server **Live**.

```
<add key="CMSStagingServerName" value="Live" />
```

2. Navigate to **CMS Desk -> Tools -> Staging**.

3. Switch to the **Servers** tab and add **New server** (📁).

4. [Configure](#) the new server to target the **Test** server that you created previously.

Make sure the value of **Server code name** is set to **Test**, which is the value that you will use in the **Test** server's *web.config* file.

You have now set up bi-directional staging between three servers.

8.46.5 Synchronizing the content

All changes made to the documents and objects are tracked in the database, in the synchronization log. You can view the changes in **CMS Desk -> Tools -> Staging**.

Please note

It is recommended that both the target and source sites have the same *Code name* prior to synchronizing content between them. You can change the value by going to *Site manager* and *Editing* (✎) the site.

The interface for viewing changes and performing synchronization is divided into the following tabs:

All tasks tab

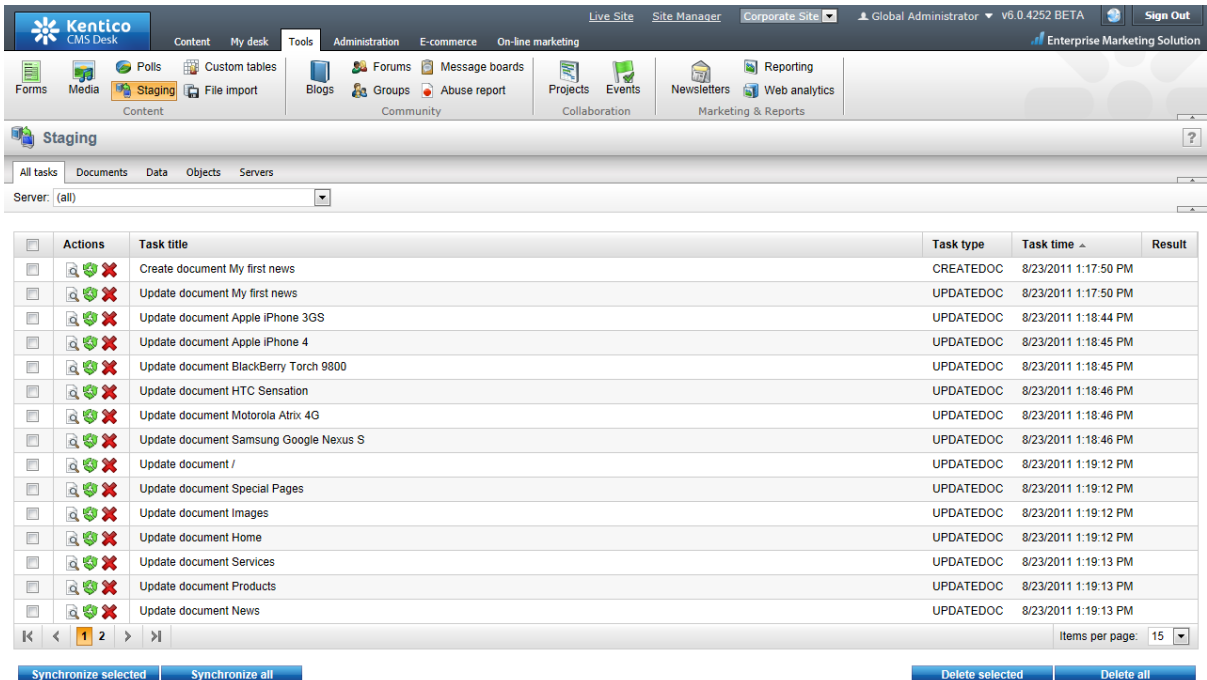

On the **All tasks** tab, you can see a list of all content staging tasks, i.e. all changes made to the system that can be synchronized on the target server.

Using the **Server** drop-down, you can choose the target server that you want to synchronize. By choosing **(all)**, you perform synchronization for all available target servers. Then you can perform one of the following actions using the buttons at the bottom:

- **Synchronize selected** - performs synchronization for all tasks selected by the check-boxes (☑) on the target server;
- **Synchronize all** - performs synchronization for all listed tasks on the target server; in case you made any changes to content on the target server in the meantime, these changes will be overwritten
- **Delete selected** - deletes all tasks selected by the check-boxes (☑) on the target server
- **Delete all** - deletes all listed tasks on the target server

You can also perform the following actions separately with particular staging tasks:

-  **View** - opens a new window with detailed information about the staging task
-  **Synchronize** - performs the synchronization task on the target server
-  **Delete** - deletes the synchronization task from the list

The screenshot shows the Kentico CMS Staging interface. At the top, there is a navigation bar with tabs for Content, My desk, Tools, Administration, E-commerce, and On-line marketing. Below this is a sub-navigation bar with icons for Forms, Media, Staging, File import, Blogs, Groups, Abuse report, Projects, Events, Newsletters, and Web analytics. The main area is titled "Staging" and has a sub-tab for "All tasks". A dropdown menu for "Server" is set to "(all)". Below this is a table of staging tasks.

| Actions | Task title | Task type | Task time | Result |
|--|--|-----------|----------------------|--------|
| <input type="checkbox"/>    | Create document My first news | CREATEDOC | 8/23/2011 1:17:50 PM | |
| <input type="checkbox"/>    | Update document My first news | UPDATEDOC | 8/23/2011 1:17:50 PM | |
| <input type="checkbox"/>    | Update document Apple iPhone 3GS | UPDATEDOC | 8/23/2011 1:18:44 PM | |
| <input type="checkbox"/>    | Update document Apple iPhone 4 | UPDATEDOC | 8/23/2011 1:18:45 PM | |
| <input type="checkbox"/>    | Update document BlackBerry Torch 9800 | UPDATEDOC | 8/23/2011 1:18:45 PM | |
| <input type="checkbox"/>    | Update document HTC Sensation | UPDATEDOC | 8/23/2011 1:18:46 PM | |
| <input type="checkbox"/>    | Update document Motorola Atrix 4G | UPDATEDOC | 8/23/2011 1:18:46 PM | |
| <input type="checkbox"/>    | Update document Samsung Google Nexus S | UPDATEDOC | 8/23/2011 1:18:46 PM | |
| <input type="checkbox"/>    | Update document / | UPDATEDOC | 8/23/2011 1:19:12 PM | |
| <input type="checkbox"/>    | Update document Special Pages | UPDATEDOC | 8/23/2011 1:19:12 PM | |
| <input type="checkbox"/>    | Update document Images | UPDATEDOC | 8/23/2011 1:19:12 PM | |
| <input type="checkbox"/>    | Update document Home | UPDATEDOC | 8/23/2011 1:19:12 PM | |
| <input type="checkbox"/>    | Update document Services | UPDATEDOC | 8/23/2011 1:19:13 PM | |
| <input type="checkbox"/>    | Update document Products | UPDATEDOC | 8/23/2011 1:19:13 PM | |
| <input type="checkbox"/>    | Update document News | UPDATEDOC | 8/23/2011 1:19:13 PM | |

At the bottom of the table, there are navigation controls and buttons for "Synchronize selected", "Synchronize all", "Delete selected", and "Delete all". The "Items per page" is set to 15.

Documents tab

In the screenshot below, you can see the **Documents** tab. By clicking the website root in the content tree on the left, you can view a list of all changes (synchronization tasks) made to all the documents of your website. By clicking a particular document, you can view only the changes made to it.

You can perform the same actions as on the **All tasks** tab, as described [above](#).

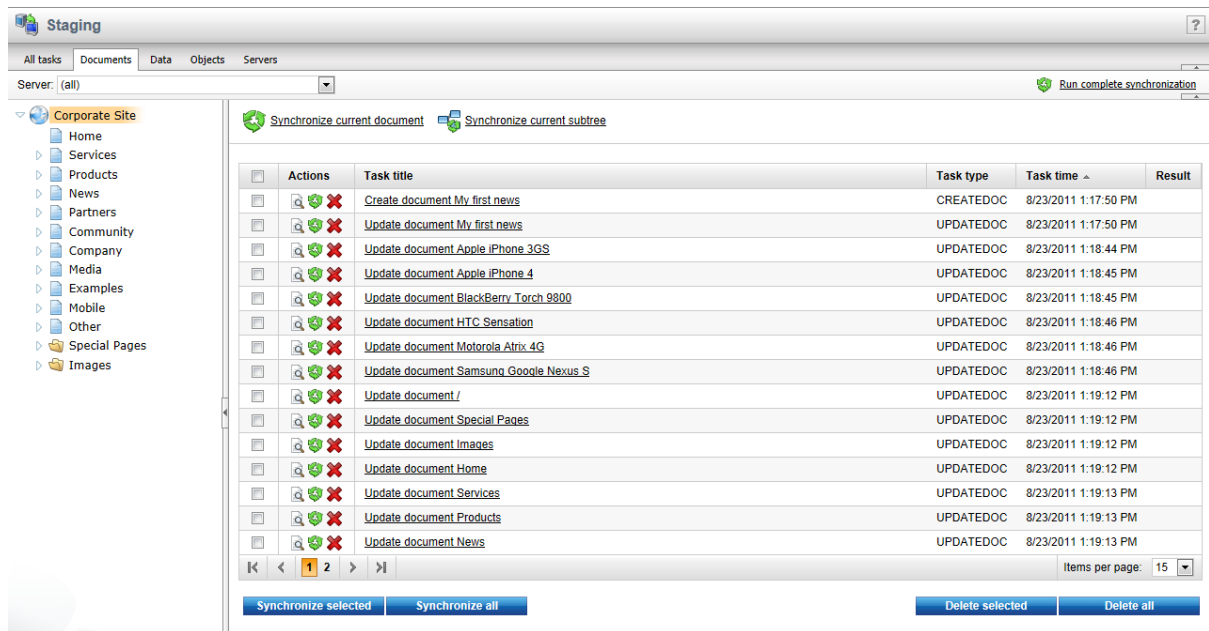

You can also perform the following manual actions. These actions are manual because they are not

related to the listed tasks and they can be performed even if there are no synchronization tasks logged:

-  **Run complete synchronization** - performs complete synchronization of all documents in the content tree
-  **Synchronize current document** - synchronizes the currently selected document
-  **Synchronize current sub-tree** - synchronizes all documents in the selected sub-tree

The following types of tasks are logged for documents. You can see the type in the **Task type** column:

- **CREATEDOC** - document was created
- **UPDATEDOC** - document was modified
- **DELETEDOC** - document was deleted
- **DELETEALLCULTURES** - all cultural versions of the document were deleted
- **PUBLISHDOC** - document was published
- **ARCHIVEDOC** - document was archived
- **REJECTDOC** - document was rejected
- **MOVEDOC** - document was moved to another location in the content tree

Data tab

In the screenshot below, you can see the **Data** tab. This is where changes made to data in **custom tables** are logged.

You can perform the same actions as on the **All tasks** tab, as described [above](#).

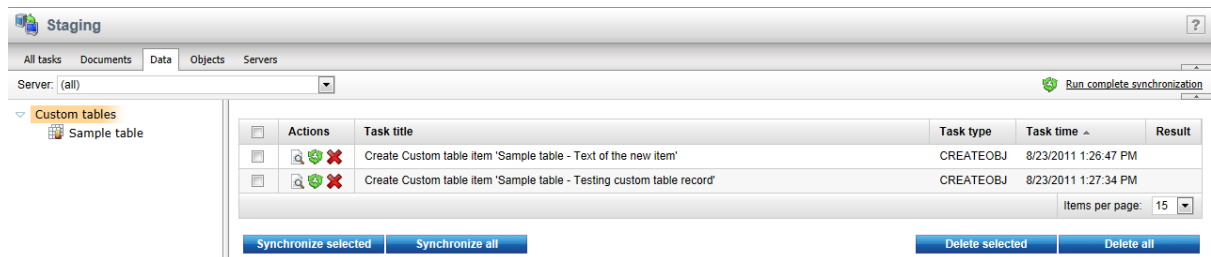

You can also perform the following manual actions. These actions are manual because they are not related to the listed tasks and they can be performed even if there are no synchronization tasks logged:

-  **Run complete synchronization** - performs complete synchronization of all data in all custom tables
-  **Synchronize current sub-tree** - synchronizes all data in the selected custom table

The following types of tasks are logged for custom tables data. You can see the type in the **Task type** column:

- **CREATEOBJ** - new item was added to a table
- **UPDATEOBJ** - an item in a table was updated
- **DELETEOBJ** - an item in a table was deleted

Please note: Staging tasks for custom table items are logged based on their *ItemGUID* columns. Changes made to items that do not have this column (typically custom tables imported from older versions of Kentico CMS) are not logged. You can edit custom tables in CMS Desk -> Tools -> Custom tables. You will see a warning message with a link letting you generate the GUIDs for the respective tables.

Objects tab

In the following screenshot, you can see the **Objects** tab. This is where changes made to objects are logged.

The main categories are **website** and **Global objects**. The first category contains object changes connected to the current website, whilst the second one contains object changes for global objects.

You can perform the same actions as on the **All tasks** tab, as described [above](#).

When you select a particular object category, you get also the following manual action offered. This action is manual because it is not related to the listed tasks and can be performed even if there are no synchronization tasks logged:

-  **Synchronize current sub-tree** - synchronizes all objects in the selected category

The following types of tasks are logged for objects. You can see the type in the **Task type** column:

- **CREATEOBJ** - new object was created
- **UPDATEOBJ** - object was modified
- **DELETEOBJ** - object was deleted
- **ADDTOSITE** - object was assigned to a site; applicable only to site-related objects
- **REMOVEFROMSITE** - object was removed from a site; applicable only to site-related objects

The following types of tasks are logged for folders in media libraries:

- **CREATEFOLDER** - folder was created
- **RENAMEFOLDER** - folder was renamed
- **COPYFOLDER** - folder was copied
- **MOVEFOLDER** - folder was moved
- **DELETEFOLDER** - folder was deleted

Please note

Global metadata changes such as changes to document types, custom tables and system tables produce staging tasks for all staging servers of all sites. In such case, it is recommended to synchronize such changes to all servers of all sites at the same time to prevent overwriting of such metadata and losing the data by synchronizing the older tasks later.

You can use the `<add key="CMSStagingTreatServerNamesAsInstances" value="true" />` key to make sure that once the global task is synchronized, it is deleted from all other servers with the same name to prevent such possibility. The default value is false since staging can use multiple target instances targeted with the same names.

The screenshot shows the 'Staging' application interface. On the left is a navigation tree with categories like 'All objects', 'Website', and 'Global objects'. The main area displays a table of tasks with columns for 'Actions', 'Task title', 'Task type', 'Task time', and 'Result'. Below the table are buttons for 'Synchronize selected', 'Synchronize all', 'Delete selected', and 'Delete all'.

| Actions | Task title | Task type | Task time | Result |
|--------------------------|-----------------------------------|-----------|----------------------|--------|
| <input type="checkbox"/> | Create Media library 'My library' | CREATEOBJ | 8/23/2011 1:33:33 PM | |
| <input type="checkbox"/> | Update Media library 'My library' | UPDATEOBJ | 8/23/2011 1:33:33 PM | |
| <input type="checkbox"/> | Create Media file 'Desert' | CREATEOBJ | 8/23/2011 1:33:40 PM | |
| <input type="checkbox"/> | Create Media file 'Penguins' | CREATEOBJ | 8/23/2011 1:33:45 PM | |

8.46.6 Automatic synchronization

Automatic synchronization is available **only for document changes**. Object changes cannot be synchronized this way. Manual synchronization remains the only way to perform object synchronization tasks.

If you want the changes to be synchronized from the staging to the live site on a regular basis without waiting for the administrator's approval, you can configure the scheduled task called **Content synchronization** in **Site Manager -> Administration -> Scheduled tasks**. This task is disabled by default, so you need to enable it and configure the synchronization interval.

The screenshot shows the Kentico CMS Administration interface. The left sidebar contains a navigation menu with items like Avatars, Bad words, Badges, Banned IPs, Categories, E-mail queue, E-mail templates, Event log, Integration bus, Membership, Permissions, Recycle bin, Roles, Scheduled tasks (highlighted), and Smart search. The main content area is titled 'Scheduled tasks' and shows a list of tasks for the 'Corporate Site'. The tasks are listed in a table with columns for Actions, Task name, Last run, and Next run. The 'Content synchronization' task is highlighted with a red circle.

| Actions | Task name | Last run | Next run |
|---------|---------------------------------|----------------------|----------------------|
| | Check bounced e-mails | 8/23/2011 1:31:09 PM | 8/23/2011 2:31:09 PM |
| | Content publishing | 8/23/2011 1:38:21 PM | 8/23/2011 1:39:21 PM |
| | Content synchronization | 7/9/2008 10:53:38 AM | 7/9/2008 11:53:38 AM |
| | Delete old shopping carts | 8/23/2011 9:30:01 AM | 8/24/2011 9:30:01 AM |
| | Users delete non activated user | 8/23/2011 1:31:09 PM | 8/23/2011 2:31:09 PM |

More information about the built-in scheduler in Kentico CMS can be found in the [Development -> Scheduler](#) chapter of this guide.

8.46.7 Using X.509 authentication

In order to use **X.509** authentication, install your own certificates or you use our sample ones.

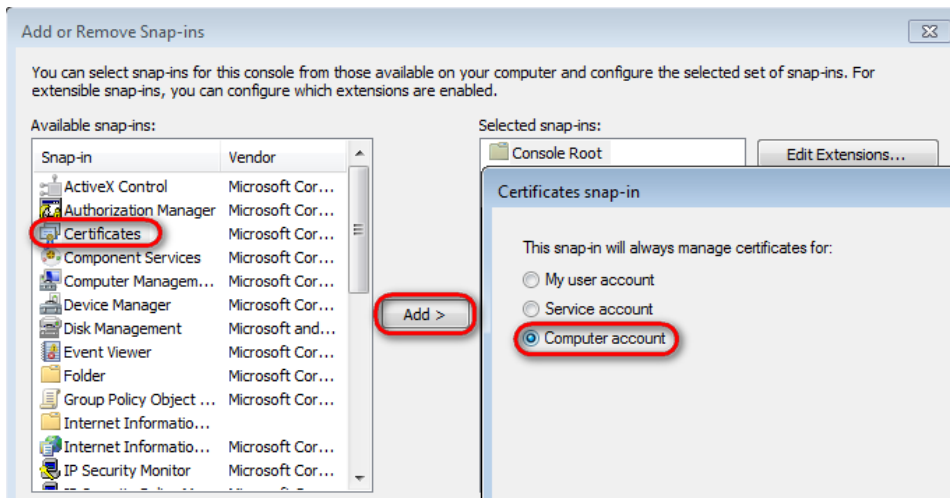

Using the sample certificates

Kentico CMS is delivered with sample client and server private certificates. In order to install them, do the following on the source server and on the target server:

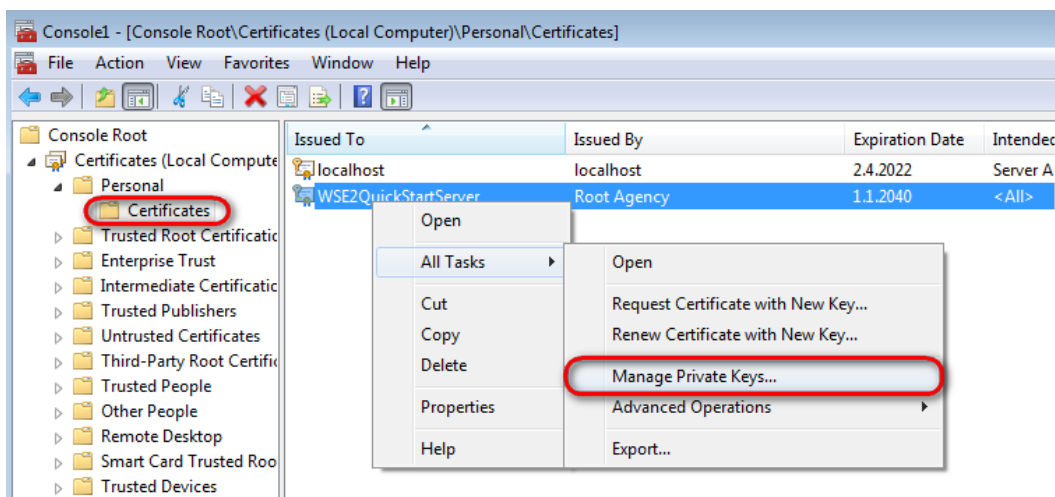

Server certificate

Install the server certificate:

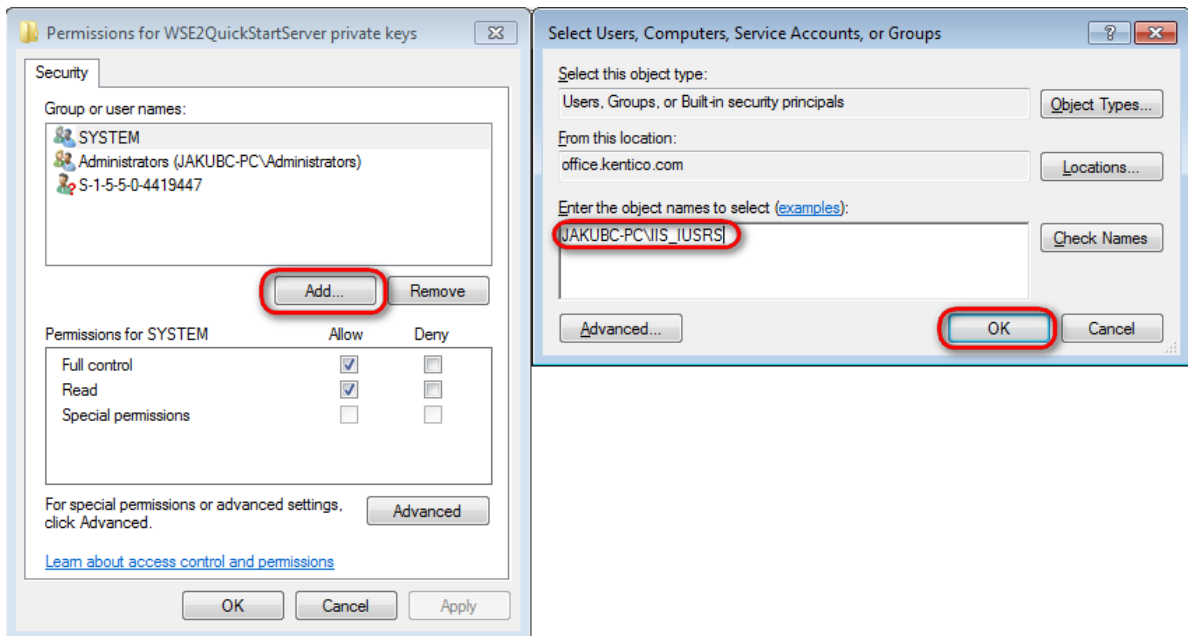

1. Choose **Start -> Run**, type **mmc** and press **Enter**.
2. In the console window, choose **File -> Add/Remove Snap-in**.
3. Choose **Certificates** and click **Add**.
4. Choose **Computer account** and click **Next**.

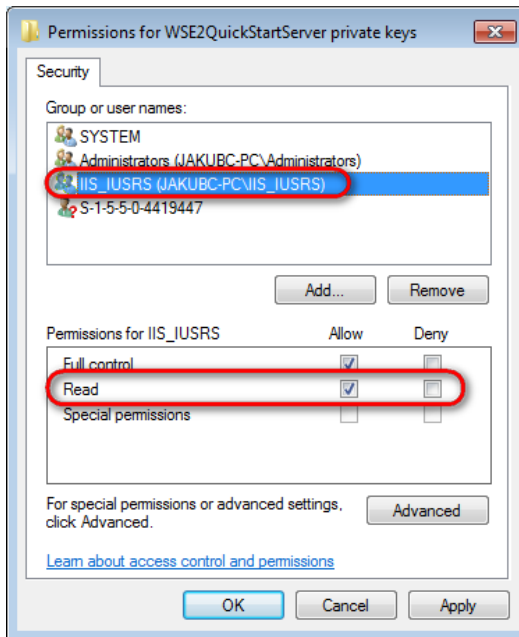

5. Choose **Local computer (the computer this console is running on)** and press **Finish**.
6. Close the **Add or Remove Snap-ins** window by clicking **OK**.
7. Unfold **Certificates (Local Computer)** under the console root, right-click **Personal** and choose **All Tasks -> Import...** The **Certificate Import Wizard** starts.
8. Import the *Server private.pfx* file located in **C:\Program Files\Kentico CMS\<version>\SampleCertificates**.
9. Enter the following password for the sample certificate: **wse2qs**.
10. Don't change any other settings and finish the **Certificate Import Wizard**.
11. Now, grant **Read** permission to the certificate file for the ASP.NET account. Do that by right-clicking the imported *WSE2QuickStartServer* certificate and choosing **All tasks -> Manage private keys**.

12. Click on **Add...**, fill in the [name of the account](#) and click **OK**.

13. Make sure the account's permission is set to **Read - Allow** and click **OK**.

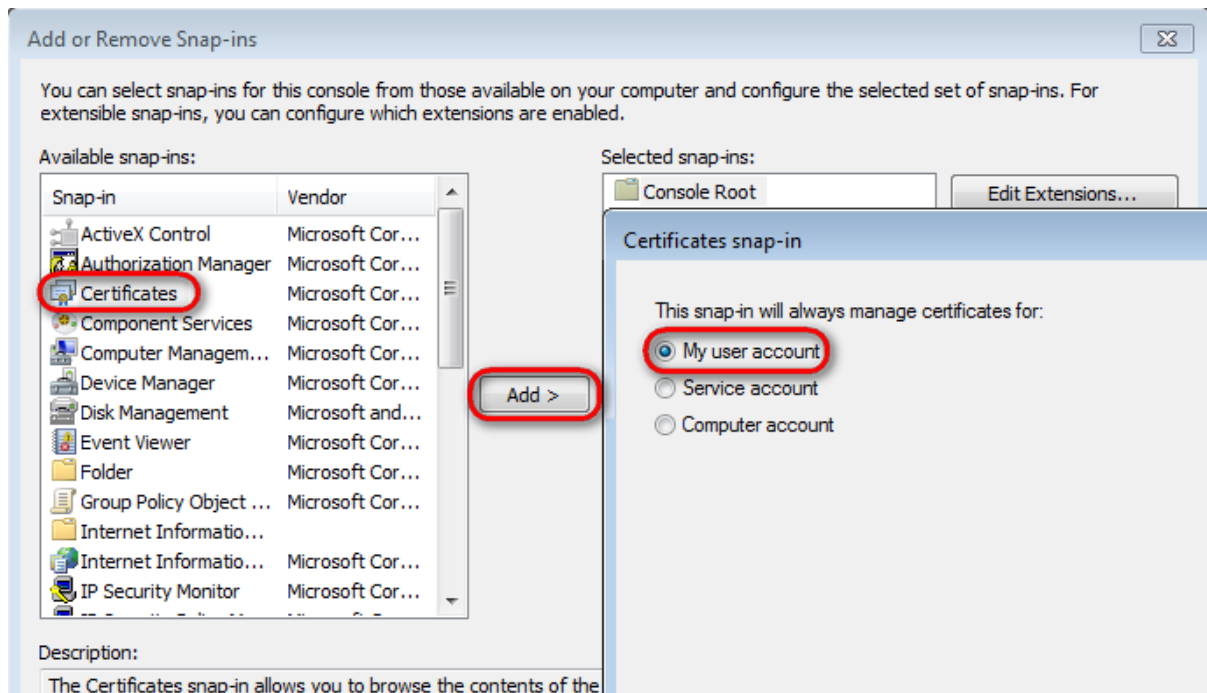

Client certificate

Install the client certificate:

1. Choose **Start -> Run**, type **mmc** and press **Enter**.
2. In the console window, choose **File -> Add/Remove Snap-in**.
3. Choose **Certificates** and click **Add**.

4. Choose **My user account** and click **Finish**.

5. Close the **Add or Remove Snap-ins** window by clicking **OK**.

6. Unfold **Certificates - Current User** under the console root, right-click **Personal** and choose **All Tasks -> Import...** The **Certificate Import Wizard** starts.

8. Import the *Client private.pfx* file located in **C:\Program Files\Kentico CMS\<version>\SampleCertificates**.

9. Enter the following password for the sample certificate: **wse2qs**.

10. Don't change any other settings and finish the **Certificate Import Wizard**.

11. Now you need to grant the **Read** permissions for the certificate file to the ASP.NET account. For the *Client certificate*, do that using the **WseCertificate3.exe** tool that can also be found in **C:\Program Files\Kentico CMS\<version>\Sample Certificates** folder.

12. Run the **WseCertificate3.exe** tool.

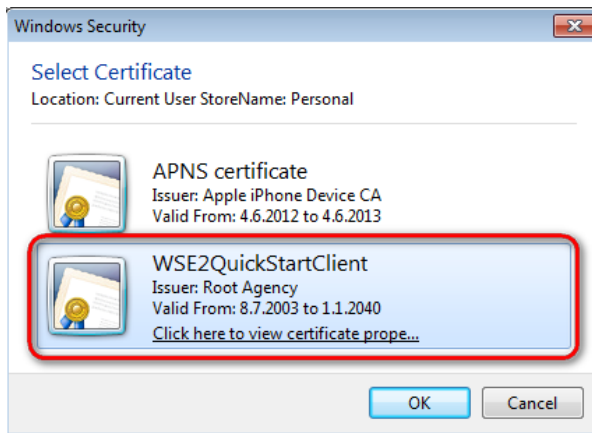

13. Choose **Current User** in the **Certificate Location** field.

14. Choose **Personal** in the **Store Name** field.

15. Click **Open Certificate**.

16. Choose the *WSE2QuickStartClient* certificate and click **OK**.

17. Click **View Private Key File Properties...** and grant the **Read** permission for this file to the ASP.NET account.

18. Click on **Add...**, fill in the [name of the account](#) and click **OK**.

19. Make sure the account's permission is set to **Read - Allow** and click **OK**.

Important: Sample certificates

Using the sample certificates is not secure and it's also very slow. It's highly recommended that you use your own certificate issued by a certification authority.

Using your own certificates

If you're using your own certificates (highly recommended), you will need to update the following values in **Site Manager -> Settings -> Versioning & Synchronization -> Staging**:

- Client key ID
- Server key ID

To get these IDs, you can use the **WseCertificate3.exe** tool located in **C:\Program files\KenticoCMS\<version>\SampleCertificates**.

1. Run the **WseCertificate3.exe** tool.
2. Choose **Local Computer** in the **Certificate Location** field.

3. Choose **Personal** in the **Store Name** field.
4. Click **Open certificate** and select either client or the server certificate. In the **Key identifiers group** you can now see the certificate key, **Windows key identifier (Base64)** should be used within Kentico CMS settings.

Tip

If you encounter problems with content staging when using SLL (X.509), you may try adding the following key to your *web.config* file:

```
<add key="CMSStagingAcceptAllCertificates" value="true" />
```

This key ensures that all certificates will be accepted. If set to false, only certificates issued by a certification authority will be accepted.

Configuring staging for the use of certificates

Now that you have installed and configured the certificates, configure staging inside Kentico CMS to use the certificates for authentication.

Target server

On the target server, change the staging service authentication service as follows:

1. Navigate to **Site manager -> Settings -> Versioning & Synchronization**.
2. Under the **Staging service (target only)** settings group, change the form to X.509.
3.  **Save** the settings.
4. Note that you need to copy the **Client** and **Server key ID** to your source server's settings.

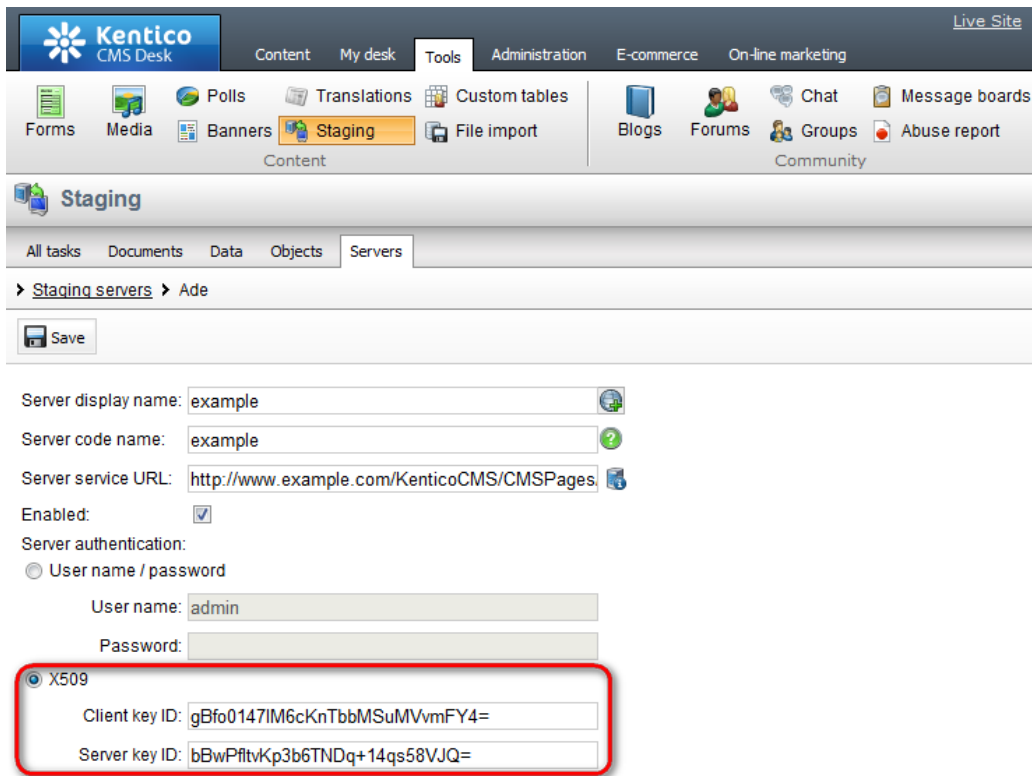

The screenshot shows the Kentico CMS 7.0 Staging settings page. The navigation menu on the left includes 'Settings', 'Content', 'URLs and SEO', 'Security & Membership', 'System', 'On-line marketing', 'E-commerce', 'Community', 'Social networks', 'Intranet & Collaboration', 'Versioning & Synchronization', 'Staging', 'Object versioning', 'Integration', and 'Cloud services'. The 'Staging' section is active, showing a 'Save' button and a 'Reset these settings to default' button. The main content area is titled 'Staging' and contains the following sections:

- Client (source only)**
 - Log content changes:
 - Log data changes:
 - Log object changes:
 - Log staging changes:
 - Log export tasks:
- Staging service (target only)**
 - Enable staging service:
 - Staging service authentication:
 - Staging service user name:
 - Staging service password:
- X509 Certificates**
 - Client key ID:
 - Server key ID:

Source server

On the source server, change the settings as follows:

1. Navigate to **CMS Desk -> Tools -> Staging**.
2. Choose the **Servers** tab and **Edit** (🔧) the server you want to configure.
3. Change **Server authentication** to **X509** and copy the **Client** and **Server key ID's** from the target server.
4. **Save** the configuration.

You have now successfully configured staging in Kentico CMS for the use of certificates in authentication.

8.46.8 Security

You can control access to the Staging module in **Administration -> Permissions**. You need to select:

- **Site:** your site
- **Permission type:** Modules
- **Permission matrix:** Staging

In the permission matrix, you can grant the following permissions to the particular roles:

- **Manage all tasks** - displays the **All tasks** tab and allows synchronization and management of synchronization tasks on it
- **Manage data tasks** - displays the **Data** tab and allows synchronization and management of synchronization tasks on it
- **Manage document tasks** - displays the **Documents** tab and allows synchronization and management of synchronization tasks on it
- **Manage object tasks** - displays the **Objects** tab and allows synchronization and management of synchronization tasks on it
- **Manage servers** - allows members of the roles to manage target server configurations on the **Servers** tab

| Permissions | | | | | | |
|------------------------------|-------------------------------------|--|-------------------------------------|-------------------------------------|-------------------------------------|--|
| Site: | Corporate site | | | | | |
| Permissions for: | Module | Staging | | | | |
| Report for user: | (none) | <input type="checkbox"/> Show only this user's roles | | | | |
| Role | Manage servers | Manage all tasks | Manage document tasks | Manage object tasks | Manage data tasks | |
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | |

8.46.9 Staging large files

Kentico allows you to modify the size of files in [Media libraries](#) that you want to stage. You can set the size in order to avoid too large files from being synchronized. You may also want to modify the values in order to stage files larger than the values set by default.

Changing maximum content and request size

1. On both the **target and source server**, open the `web.config` file located in the root of the website.
2. Modify the value of the `maxRequestLength` property. The value is in **kilobytes**.

```

...
<system.web>
  ...
  <httpRuntime maxRequestLength="2097151" ... />
  ...
</system.web>
...

```

3. Add the following code into the `system.webServer` part of the `web.config` file. The value of `maxAllowedContentLength` is in **bytes**.

Note that there are two `system.webServer` parts in the `web.config` file by default. The first one is related to WebDav configuration. Enter the code into the second part.

```

...

```

```

<system.webServer>
  ...

  <security>
    <requestFiltering>
      <requestLimits maxAllowedContentLength="2147483648" />
    </requestFiltering>
  </security>

  ...
</system.webServer>

...

```

By default, IIS limits this value to 30000000 bytes (28.6 megabytes). Synchronizing files larger than the set value results in an *HTTP status 404: Not Found* error.

4. Save the web.config file.

Limiting maximum media library file size

To limit the maximum size of a file staged from the media library:

1. On the **source server**, open the web.config file located in the root of the website.
2. Add the following key into the file. The *value* is entered in kilobytes.

Note that files above the limit aren't synchronized and the tasks including the files leave the task list. The system transfers database definitions of the files only. You can find a record of the file not being synchronized in the [Event log](#).

```
<add key="CMSMediaFileMaxStagingSize" value="102400" />
```

3. Save the web.config file.

8.46.10 Synchronization using API

In special cases, you may want to use Kentico CMS API to perform your own synchronization process. There are several methods you can use to work with synchronization.

| | |
|--|--|
| DocumentEngine.DocumentSynchronizationHelper.LogDocumentChange | Creates synchronization tasks for the specified document or a set of documents under the specified path. The method returns the resulting tasks in a list. Loop through the list to synchronize the tasks. |
| CMS.Synchronization.SynchronizationHelper.LogObjectChange | Creates synchronization tasks for the specified object under the current site. The method returns the resulting tasks in a list. Loop through the list to synchronize the tasks. |
| CMSStaging.StagingHelper.RunSyn | Runs the synchronization of specified task for the specified |

| | |
|--------------|--------------------|
| chronization | server or servers. |
|--------------|--------------------|

Here is an example code how to synchronize the content of the document “/Home” to server “Staging.Target1”:

[C#]

```
using CMS.CMSHelper;
using CMS.DocumentEngine;
using CMS.SettingsProvider;
using CMS.Synchronization;

TreeProvider tree = new TreeProvider(CMSContext.CurrentUser);
// Get the base document record
TreeNode node = tree.SelectSingleNode(CMSContext.CurrentSiteName, "/Home", "en-us", false, null, false);
if (node != null)
{
    // Get the server
    ServerInfo si = ServerInfoProvider.GetServerInfo("Staging.Target1", CMSContext.CurrentSiteID);
    if (si != null)
    {
        // Log the synchronization task
        List<ISynchronizationTask> tasks =
        DocumentSynchronizationHelper.LogDocumentChange(node, TaskTypeEnum.UpdateDocument,
        tree, false, tree, si.ServerID, null, false);

        // Loop through the list of tasks
        foreach (TaskInfo ti in tasks)
        {
            // Run the task synchronization
            StagingHelper.RunSynchronization(ti.TaskID, si.ServerID);
        }
    }
}
```

You can also use low level operations from TaskInfoProvider, SynchronizationInfoProvider and ServerInfoProvider to achieve synchronization. Though the previous operations are enough to perform any simple synchronization action.

The following example shows how you can synchronize the administrator user account. Synchronization of any other objects is done the same way using the API.

[C#]

```
using CMS.SiteProvider;
using CMS.Synchronization;
using CMS.CMSHelper;

// Gets the object
UserInfo userObj = UserInfoProvider.GetUserInfo("administrator");
```

```
if (userObj != null)
{
    // Gets the server
    ServerInfo si = ServerInfoProvider.GetServerInfo("Staging.Target1",
CMSContext.CurrentSiteID);
    if (si != null)
    {
        // Log the synchronization task
        List<ISynchronizationTask> tasks = SynchronizationHelper.LogObjectChange
(userObj.ObjectType, 0, userObj.UserlastModified, TaskTypeEnum.Object, true,
false, false, false, false, CMSContext.CurrentSiteID);

        // Loop through the list of tasks
        foreach (TaskInfo ti in tasks)
        {
            // Run the task synchronization
            StagingHelper.RunSynchronization(ti.TaskID, si.ServerID);
        }
    }
}
```

8.46.11 Staging internals and API

8.46.11.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Staging module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.46.11.2 Database tables

The Staging module uses the following database tables:

- **Staging_Task** - contains records representing staging synchronization tasks.
- **Staging_SyncLog** - contains records representing performed synchronizations, while only those that produced an error are stored in this table.
- **Staging_Synchronization** - contains records representing performed synchronizations.
- **Staging_Server** - contains records representing staging servers.

8.46.11.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The Staging module classes can be found in the **CMS.Synchronization** namespace.

Staging Server table API:

- **ServerInfo** - represents one staging server.
- **ServerInfoProvider** - provides functionality for management of staging servers.

Staging_Task table API:

- **TaskInfo** - represents one staging synchronization task.
- **TaskInfoProvider** - provides functionality for management of staging synchronization tasks.

8.46.11.4 API examples

8.46.11.4.1 Overview

In the following topics, you can find examples of you can use the Staging module API:

- [Managing staging servers](#)
- [Managing staging tasks](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Tools\Staging\Default.aspx.cs**.

The Staging API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.CMSHelper;
using CMS.GlobalHelper;
using CMS.Synchronization;
using CMS.UIControls;
```

8.46.11.4.2 Managing staging servers

The following example demonstrates how a staging server can be created.

```
private bool CreateStagingServer()
{
    // Create new staging server object
    ServerInfo newServer = new ServerInfo();
}
```

```
// Set the properties
newServer.ServerDisplayName = "My new server";
newServer.ServerName = "MyNewServer";
newServer.ServerEnabled = true;
newServer.ServerSiteID = CMSContext.CurrentSiteID;
newServer.ServerURL = "http://localhost/KenticoCMS/CMSPages/SyncServer.aspx";
newServer.ServerAuthentication = ServerAuthenticationEnum.UserName;
newServer.ServerUsername = "admin";
newServer.ServerPassword = "pass";

// Save the staging server
ServerInfoProvider.SetServerInfo(newServer);

return true;
}
```

The following example gets and updates the staging server created by the code example above.

```
private bool GetAndUpdateStagingServer()
{
    // Get the staging server
    ServerInfo updateServer = ServerInfoProvider.GetServerInfo("MyNewServer",
CMSContext.CurrentSiteID);
    if (updateServer != null)
    {
        // Update the properties
        updateServer.ServerDisplayName = updateServer.ServerDisplayName.ToLower();

        // Save the changes
        ServerInfoProvider.SetServerInfo(updateServer);

        return true;
    }

    return false;
}
```

The following example demonstrates how to get multiple staging servers based on a WHERE condition and bulk update them.

```
private bool GetAndBulkUpdateStagingServers()
{
    // Prepare the parameters
    string where = "ServerName LIKE N'MyNewServer%'";

    // Get the data for the current site
    DataSet servers = ServerInfoProvider.GetSiteServers(CMSContext.CurrentSiteID,
where, null, -1, null, false);
    if (!DataHelper.DataSourceIsEmpty(servers))
    {

```

```
// Loop through the individual items
foreach (DataRow serverDr in servers.Tables[0].Rows)
{
    // Create object from DataRow
    ServerInfo modifyServer = new ServerInfo(serverDr);

    // Update the properties
    modifyServer.ServerDisplayName =
modifyServer.ServerDisplayName.ToUpper();

    // Save the changes
    ServerInfoProvider.SetServerInfo(modifyServer);
}

return true;
}

return false;
}
```

The following example deletes the staging server created by the first code example on this page.

```
private bool DeleteStagingServer()
{
    // Get the staging server
    ServerInfo deleteServer = ServerInfoProvider.GetServerInfo("MyNewServer",
CMSContext.CurrentSiteID);

    // Delete the staging server
    ServerInfoProvider.DeleteServerInfo(deleteServer);

    return (deleteServer != null);
}
```

8.46.11.4.3 Managing staging tasks

The following example gets all staging tasks for a particular server and performs their synchronization.

```
private bool GetAndSynchronizeTasks()
{
    // Get server
    ServerInfo server = ServerInfoProvider.GetServerInfo("MyNewServer",
CMSContext.CurrentSiteID);

    if (server != null)
    {
        // Get tasks for the server
        DataSet tasks = TaskInfoProvider.SelectTaskList(CMSContext.CurrentSiteID,
server.ServerID, null, null);
    }
}
```

```
if (!DataHelper.DataSourceIsEmpty(tasks))
{
    foreach (DataRow taskDr in tasks.Tables[0].Rows)
    {
        // Create task info object from data row
        TaskInfo task = new TaskInfo(taskDr);

        // Synchronize the task
        if (!string.IsNullOrEmpty(StagingHelper.RunSynchronization
(task.TaskID, server.ServerID)))
        {
            apiGetAndSynchronizeTasks.ErrorMessage = "Synchronization
failed.";
            return false;
        }
    }

    return true;
}

apiGetAndSynchronizeTasks.ErrorMessage = "No tasks found.";
}

return false;
}
```

The following example deletes all staging synchronization tasks for a particular server.

```
private bool DeleteTasks()
{
    // Get server
    ServerInfo server = ServerInfoProvider.GetServerInfo("MyNewServer",
CMSContext.CurrentSiteID);

    if (server != null)
    {
        // Get tasks for the server
        DataSet tasks = TaskInfoProvider.SelectTaskList(CMSContext.CurrentSiteID,
server.ServerID, null, null);

        if (!DataHelper.DataSourceIsEmpty(tasks))
        {
            foreach (DataRow taskDr in tasks.Tables[0].Rows)
            {
                // Create task info object from data row
                TaskInfo deleteTask = new TaskInfo(taskDr);

                // Delete the task
                TaskInfoProvider.DeleteTaskInfo(deleteTask);
            }

            return true;
        }
    }
}
```

```
    }  
  
    apiDeleteTasks.ErrorMessage = "No tasks found."  
  }  
  
  return false;  
}
```

8.47 Tags

8.47.1 Overview

The Tags module enables users to tag documents with key words, called tags, depending on their content. Tags are associated with the documents and are convenient for their simple marking according to various criteria, e.g. your interests.

Posted to [Holiday in Australia](#) by [Kelly Taylor](#) on 10/26/2008 3:05:12 PM | with [0 comments](#)

[Flying tomorrow](#)

 Hi everybody, my name is Kelly Taylor and I come from Brno, Czech Republic. Tomorrow is my big day. Finally, after six months of hard everyday work, I decided to have some nice time and go on holiday. Australia has always been one of the places I had wanted to visit one day, and now, with my great new job and the wage I get for it, it is finally affordable for me to get there.

Tag cloud

airport Australia Austria bus
cuisine Czech Republic flight
France Germany
hitchhiking holiday
hostel Italy luggage sacher torte
Spain subway tourism traffic train

Top bloggers

 [Ahi](#)

Please note that analogous to the [Categories](#) module, the Tags module enables you to categorize your documents.

- To learn how to tag individual documents, please refer to the [Tagging documents](#) topic.
- To learn how to display documents associated with the selected tag, please refer to the [Using the Tag cloud web part](#) topic.
- To learn how to create, alter or delete a tag group, please refer to the [Managing tag groups](#) topic.
- The internals and API of the Tags module are described in the [Tags internals and API](#) subchapter.

8.47.2 Tagging documents

If you need to learn how to tag a document, the following examples describe this process. There are two ways of tagging documents:

- You can add tags to individual documents by using the **Properties** tab of the **CMS Desk -> Content -> Edit** interface (as described [here](#)).
- Or you can use the **Fields** tab in **Site Manager -> Development -> Document types -> Edit** ( **<document_type>**) (as described [here](#)).

Tagging documents using Properties

1. Go to **CMS Desk**, switch to the **Edit** mode and select the document that you wish to tag from the content tree.

2. Switch to its **Properties -> Metadata** tab.

3. Choose a tag group using the **Page tag group** drop-down list. If you check the **Inherit** check-box, tag group will be inherited from the document's parent.

Please note

There needs to be **at least one tag group defined** for you to be able to tag a document. If there are no tag groups created, you will not be able to tag a document as each tag needs to belong to some tag group. You can learn about creating tag groups in the [next chapter](#).

It is also recommended to select a tag group for the root of the content tree so that it could be inherited by the pages located under it.

4. Enter the tags into the **Page tags** field. Tags can be entered either manually or can be selected using the **Select** button. This button displays a list of all tags in the selected tag group. Check the appropriate tags' check-boxes and click **OK**.

5. Click  **Save**. The entered tags will be saved and attached to the document.

Tag formats

When entering more than one tag into the **Page tags** field, the tags should be separated with a comma or a blank space. A combination of both in a single entry is also valid. The following examples are all valid entries for adding three tags - *tag1*, *tag2* and *tag3*:

tag1, tag2, tag3
tag1 tag2 tag3
tag1, tag2 tag3

In case that you are entering a tag consisting of more than one word, you should enclose it within quotation marks. Multiple long tags can also be entered and can be also divided by both blank spaces and commas:

"long tag1", tag, "long tag2"
"long tag1" tag "long tag2"

Quotation marks can also be used for tags containing special characters that couldn't be used otherwise:

"tag@1", "tag#2", "long, strange: tag@#"

The page tags field has also an insinuation function implemented. This functions offers you tags from the selected tag group while you are writing:

Page tags:
(separated by comma)

Tagging documents using Fields

1. Go to **Site Manager -> Development -> Document types** and choose to **Edit** (✎) a document type.

The screenshot shows the Kentico CMS 7.0 Site Manager interface. The 'Development' menu is open, and 'Document types' is selected. The 'Document types' page shows a table of document types with 'Blog' highlighted in red. The 'Display name' and 'Code name' fields are set to 'LIKE'.

| Actions | Display name | Code name |
|---------|----------------------------------|-------------------------------|
| | Article | CMS.Article |
| | Blog | CMS.Blog |
| | Blog month | CMS.BlogMonth |
| | Blog post | CMS.BlogPost |
| | Bundle | CMS.Bundle |
| | Cell phone | CMS.CellPhone |
| | Community - Transformations | Community.Transformations |
| | Corporate site - Transformations | CorporateSite.Transformations |

2. Switch to the **Fields** tab, click the **New system attribute** (🌐) icon to create a new system attribute and select the following values from the corresponding drop-down lists:

- **Group:** Document attributes
- **Column name:** DocumentTags
- **Form control:** Tag selector

Document type properties

> Document types > Blog

Form control: Tag selector

Field description:

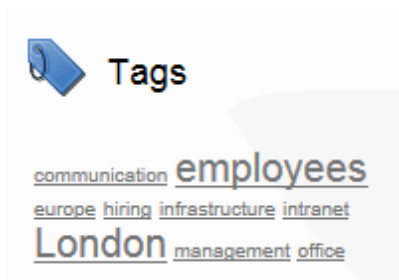

Click **Save** to confirm the changes.

Please note

If you need to create a custom document type with a tag selector, the tag selector must be bound to a system field.

8.47.3 Using the Tag cloud web part

The **Tag cloud** web part is used to display tags that are associated with the current document. Tags are displayed in the form of links and those with higher occurrence are displayed in higher font size. If the site visitor clicks on some of the links, a list of all documents tagged with the given tag will be displayed.

The web part has the following specific properties:

| Tag filter | |
|------------------------------|--|
| Site name | Code name of the website from which you want to display the tags. If you leave the value empty, the content is retrieved from the current website. |
| Tag group name | Name of the tag group from which the tags will be displayed. |
| Select top N tags | Number of tags which will be displayed. Top tags according to the order specified by the <i>ORDER BY expression</i> property will be displayed. |
| ORDER BY expression | ORDER BY part of the SQL query used to retrieve the tags. |
| Tag cloud settings | |
| Document list URL | URL of the page on which the documents list will be displayed after clicking some of the tags (see below for an example). |
| Query string parameter name | Name of the parameter by means of which the tag ID will be transferred. |
| Tag separator | Separator that will be placed between tags in the tag cloud. |
| Minimal tag font size | Size of tags with the lowest occurrence. |
| Maximal tag font size | Size of tags with the highest occurrence. |
| Document filter | |
| Use document filter | Indicates if the document filter will be used. If true, the web part will display only tags used in the documents specified by the properties below. |
| Path | Path of the documents the tags of which will be displayed by the web part. |
| Combine with default culture | Indicates if tags from the default language version of the document should be displayed if the document is not translated to the current language. |
| Culture code | Culture version of the displayed tags. |
| Maximum nesting level | Maximum nesting level. It specifies the number of sub-levels in the content tree of the document specified by the <i>Path</i> property that should be included in the displayed content (i.e. whose tags will be displayed). |
| Select only published | Indicates if only tags from published documents should be displayed. Applied only when 'Site name' or 'Alias path' property is defined. If disabled, all tags from the selected tag group will be displayed. |
| Where condition | WHERE part of the SQL query used to retrieve tags. |

Common usage

The Tag cloud is designed to "work in pair" with some repeater web part. When a tag link is clicked in the tag cloud, a list of all documents tagged with this tag is displayed in the repeater. The repeater can be placed either on the same page as the tag cloud or on some other page so that the site visitor will be redirected. You can see an example of this behavior on the Corporate Site sample website under

Examples -> Web parts -> Tagging & Categories -> Tag cloud.

The image shows two web parts side-by-side. The left web part, titled 'zoneArticles', has a tree view with 'Header text', 'Content text', and 'Articles'. Below the tree, it lists 'Articles' with links: Cascading Style Sheets (CSS), Czech Republic, General Packet Radio Service (GPRS), Global Positioning System, HyperText Markup Language (HTML), Router, Search Engine Optimization (SEO), and Wide XGA. Below that is a 'Blog posts' section with links: Expanding to Europe and Remote Management. The right web part, titled 'zoneLeft', has a tree view with 'Tag cloud articles' and 'Tag cloud web development blog'. Below the tree, it displays two tag clouds. The first tag cloud, under 'Tag cloud articles', shows tags: CSS, Czech republic, GPRS, GPS, HTML, router, SEO, wide XGA, WXGA. The second tag cloud, under 'Tag cloud web development blog', shows tags: communication, employees, europe, hiring, infrastructure, intranet, London, management, office.

In order for the two web parts to cooperate correctly, you have to correctly set some of their properties:

Tag cloud:

- The placement of the repeater is defined by the Tag cloud's **Document list URL** property. In case that the repeater is placed on the same page as the tag cloud, the value should be left blank. In case that it is placed on some other page, you should enter the **alias path** of that page.
- ID of the clicked tag is transferred to the repeater in form of a query string parameter. The name of the parameter can be set using the **Query string parameter name** property. The repeater displays the appropriate list of documents based on the value that it gets by via this parameter.

Repeater:

- Set the value of the **Path** parameter to the location in the content tree where the documents are stored.
- Set the value of the **Document types** parameter to the document type(s) that is (are) to be displayed.
- Select the transformations that you want to use for the **Transformation** and **Selected items transformation**.
- Finally, use the following code as a value for the repeater's **WHERE condition** parameter. The **tagid** value should be replaced by the name set in the Tag cloud's **Query string parameter name**:

```
{?tagid|(to:)?} = 0 AND '{?tagname?}' = ''
```

```
OR (DocumentID IN (SELECT DocumentID FROM CMS_DocumentTag WHERE TagID = {?tagid|
(toint)?}))
OR (DocumentID IN (SELECT DocumentID FROM CMS_DocumentTag WHERE TagID IN (SELECT
TagID FROM CMS_Tag WHERE TagName = '{?tagname?}' AND TagGroupID = {?groupid|
(toint)?})))
```

The first line ensures displaying of all documents when **no query string parameters** (tagid nor tagname nor taggroupid) are received. The second line ensures displaying of documents based on the received **tagid** (or differently named parameter) from a **Tag cloud** web part. The third line ensures displaying of documents based on the received **tagname** and **groupid** from a **blog post's** Filed under section.

Posted by **Abigail Woodwarth** on 6/4/2008 1:43:34 PM

Filed under: [France](#), [hitchhiking](#), [Spain](#), [cuisine](#)

If you would like to learn more on the use of the **Tag cloud** web part, please refer to [Community Site Guide -> Part 2 -> Pre-development tasks -> Creating the tag groups](#). This is a step-by-step tutorial on how to create a tag group.

If you would like to see examples of how the **Tag cloud** web part is added to the site, please refer to:

- [Creating the Blogs section -> Creating the Blogs page](#) in the same section of Community Site Guide
- [Creating the Blog posts page](#)
- [Creating the News page](#)

You will need to have the Community Site sample website installed to follow Kentico CMS Community Site Guide.

8.47.4 Managing tag groups

Tags are divided into tag groups, which are topic-related groups of tags. No global tag groups are defined and each tag group is bound to a particular site. Tag groups can be created and managed by the global administrator in **Site Manager -> Development -> Tag groups**. You can **Edit** (✎) or **Delete** (✖) the listed tag groups in this section.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The left sidebar lists various development options, with 'Tag groups' highlighted. The main area shows the 'Tag groups' configuration page for the 'Corporate Site'. A 'New tag group' button is visible, and a table lists existing tag groups:

| Actions | Name |
|---------|----------------------|
| | Company blog |
| | Content |
| | Products |
| | Web Development Blog |

Please note

If you want to allow users to tag documents, at least one tag group must be defined.

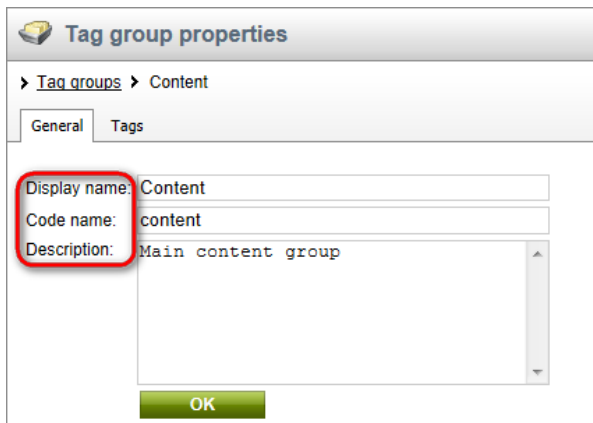

The default tag group **Content** is available for all Kentico CMS sample sites. It is inherited and should not under standard circumstances be deleted from the system.

Creating tag groups

In this example, you will learn how to create a new tag group.

1. To create a new tag group, go to **Site Manager -> Development -> Tag groups** and click **New tag group**. The following properties will have to be entered:

- **Display name** - display name of the tag group
- **Code name** - code name of the tag group
- **Description** - description text of the tag group

The screenshot shows the 'Tag group properties' dialog box with the 'Tags' tab selected. The 'Display name' field is highlighted with a red box. The 'Code name' field contains 'content' and the 'Description' field contains 'Main content group'. An 'OK' button is visible at the bottom.

2. Click **OK** to confirm the values you have entered. The tag group will be created and become visible in the list.

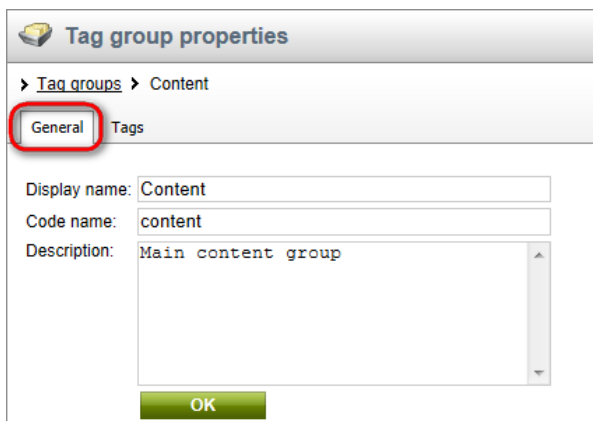

Editing tag groups

In this example, you will learn how to edit an existing tag group.

1. To edit an existing tag group, go to **Site Manager -> Development -> Tag groups** and choose to **Edit** (✎) one of the listed tag groups.

| Actions | Name |
|---------|----------------------|
| ✎ ✖ | Company blog |
| ✎ ✖ | Content |
| ✎ ✖ | Products |
| ✎ ✖ | Web Development Blog |

2. If you would like to change some of its properties, go to the **General** tab and change either the **Display name**, **Code name** or **Description** of the tag group.

The screenshot shows the 'Tag group properties' dialog box with the 'General' tab selected. The 'Display name' field contains 'Content', the 'Code name' field contains 'content', and the 'Description' field contains 'Main content group'. An 'OK' button is visible at the bottom.

3. If you would like to display the list of all tags in the selected tag group, switch to the **Tags** tab:

Tag group properties

> Tag groups > Content

General **Tags**

| Actions | Tag | Count |
|---------|----------------|-------|
| | CSS | 1 |
| | Czech republic | 1 |
| | GPRS | 1 |
| | GPS | 1 |

4. If you would like to display a list of links to documents tagged with a tag, click the icon next to the particular tag.

General Tags

> Tags > HTML

Site: (all)

Document name: LIKE

Document type: LIKE

Show

The tag is used in the following documents:

| Actions | Document name | Document type | Modified | Workflow step | Language | Site |
|---------|----------------------------------|---------------|----------------------|---------------|-------------------------|----------------|
| | Cascading Style Sheets (CSS) | Article | 6/28/2011 2:55:57 PM | - | English - United States | Corporate Site |
| | HyperText Markup Language (HTML) | Article | 6/28/2011 2:56:00 PM | - | English - United States | Corporate Site |
| | Search Engine Optimization (SEO) | Article | 6/28/2011 2:56:02 PM | - | English - United States | Corporate Site |

Items per page: 25

Please note

The global administrator cannot delete a tag from the document in **Site Manager**. This must be done by the user in **CMS Desk**.

8.47.5 Tags internals and API

8.47.5.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Tags module. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this

guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.47.5.2 Database tables

The following database tables are used in the Tags module:

- **CMS_TagGroup** - contains records representing tag groups.
- **CMS_DocumentTag** - contains relationships between documents and tags indicating that particular documents are tagged with particular tags.
- **CMS_Tag** - contains records representing tags.

8.47.5.3 API classes

If you are not familiar with the database table data management by Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The Tags module classes use the **CMS.SiteProvider** namespace.

CMS_TagGroup table API:

- **CMSTagGroupInfo** - represents one tag group.
- **CMSTagGroupInfoProvider** - provides management of tag groups.

CMS_DocumentTag table API:

- **CMSDocumentTagInfo** - represents a relationship between one document and one tag expressing that a particular document is tagged with a particular tag.
- **CMSDocumentTagInfoProvider** - provides management of relationships between documents and tags.

CMS_Tag table API:

- **CMSTagInfo** - represents one tag.
- **CMSTagInfoProvider** - provides management of tags.

8.47.5.4 API examples

8.47.5.4.1 Overview

Please note

All API examples can be simulated in the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Documents\Tags\Default.aspx.cs**.

8.48 Time zones

8.48.1 Overview

The Time zones module enables the configuration of time zones for the physical location of the [server](#), for particular [websites](#) and even for particular [users](#). This can be useful if your site has an international audience and you want the date and time displayed on your site to be correct for users from across the world.

Before it can be used, the module must be enabled as described in the [Enabling the module](#) topic.

To learn how to configure individual time zones in the system, please see the [Managing time zones](#) topic. Time zones can also be set to adjust their time according to [Daylight saving time](#).

Time zones are currently supported in:

- **CMS Desk -> Content**
- **CMS Desk -> My desk**
- **CMS Desk -> Tools -> [Events](#)**
- **Web parts** of the [Blogs](#), [Forums](#), [Message boards](#), [Messaging](#) and [Smart search](#) modules; more information can be found in the [Use in web parts](#) topic

The [Time zones internals and API](#) sub-chapter provides information about the database tables and classes used by the module and examples of how time zones can be managed using the API and how

correct time can be displayed by your code.

A typical example of use is displaying the time of forum posts when you have a global community – while the server may be located in New York (GMT -5:00), visitors coming from Paris (GMT +1:00) may see their new posts were added at 8am, while they would expect to see 2pm according to their current time.

Another example is a website of a global company that runs on a server in New York, but contains content for a French office. In this case, French visitors may wonder why the current time displayed by the server is 8am while it's 2pm in Paris. That's when you use the built-in support for multiple time zones.

8.48.2 Enabling the module

To enable the Time zones module, go to **Site Manager -> Settings -> System** and check the **Enable time zones** check-box. Below it, you can find the following two drop-down lists:

- **Server time zone** - time zone of the physical server location
- **Site time zone** - default time zone of the website selected by the **Site** drop-down list in the top-left part of the page; this time zone can also be set globally and inherited by sites that don't have it set differently

The screenshot shows the Kentico CMS 7.0 Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The 'Settings' tab is active, and the 'System' sub-tab is selected. The left sidebar shows a tree view of settings categories, with 'System' highlighted. The main content area displays the 'System' settings page, which is divided into sections: 'General', 'Scheduler', and 'Time zones'. The 'Time zones' section is highlighted with a red box and contains the following settings:

| Setting | Value |
|-------------------|-------------------------------------|
| Enable time zones | <input checked="" type="checkbox"/> |
| Server time zone | (GMT-06.00) Central America |
| Site time zone | (GMT-07.00) Arizona |

8.48.3 Setting user's time zone

Each user can have their own time zone settings. Where applicable, these time zone settings are used instead of the website's default time zone. A user's time zone can be set in both **CMS Desk** and **Site**

Manager, on the **Administration -> Users -> Edit user -> Settings** tab. On the tab, the selection can be done using the **Time zone** drop-down list.

Users can also select their time zone on the live site if you place the **My Account** or **My Profile** web part on one of your pages. If they have access to **CMS Desk**, they can do this in **My Desk -> Account -> Details**. This is done the same way as above, by using the **Time zone** drop-down list.

8.48.4 Managing time zones

Time zones can be managed in **Site Manager -> Development -> Time zones**.

The screenshot shows the Kentico CMS 7.0 Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The 'Development' menu on the left is expanded, and 'Time zones' is selected. The main content area is titled 'Time zones' and features a 'New time zone' button. Below this is a search filter with the text 'Time zone name: LIKE' and a 'Show' button. A table lists various time zones with their respective GMT offsets and DST settings. Each row includes an 'Actions' column with icons for edit and delete.

| Actions | Time zone name | GMT | DST |
|---------|---|------|-----|
| | International Date Line West | -12 | No |
| | Midway Island, Samoa | -11 | No |
| | Hawaii | -10 | No |
| | Alaska | -9 | Yes |
| | Pacific Time (US & Canada) | -8 | Yes |
| | Tijuana, Baja California | -8 | Yes |
| | Mountain Time (US & Canada) | -7 | Yes |
| | Arizona | -7 | No |
| | Chihuahua, La Paz, Mazatlan - New | -7 | Yes |
| | Chihuahua, La Paz, Mazatlan - Old | -7 | Yes |
| | Central America | -6 | No |
| | Central Time (US & Canada) | -6 | Yes |
| | Guadalajara, Mexico City, Monterrey - New | -6 | Yes |
| | Guadalajara, Mexico City, Monterrey - Old | -6 | Yes |
| | Saskatchewan | -6 | No |
| | Indiana (East) | -5 | Yes |
| | Eastern Time (US & Canada) | -5 | Yes |
| | Bogota, Lima, Quito | -5 | No |
| | Caracas | -4.5 | No |
| | Asuncion | -4 | Yes |
| | Atlantic Time (Canada) | -4 | Yes |
| | Georgetown, La Paz, San Juan | -4 | No |
| | Santiago | -4 | Yes |
| | Manaus | -4 | No |
| | Newfoundland | -3.5 | Yes |

On this page, you can see a list of defined time zones. All time zones are displayed by default, but you can filter displayed items using the filter above the list. The only possible filtering parameter is the time zone **Display name**. If you type in the searched value and click the **Show** button, only those items that match the entered expression will be displayed in the list.

Time zones in the list can be **Edited** () or **Deleted** (). You can also create **New time zone**.

Creating a new time zone

In the following example, you will learn how to create a new time zone:

1. Go to **Site Manager -> Development -> Time zones** and click **New time zone**.
2. Fill in the details that you can see in the following screenshot:

New time zone

> Time zones > New time zone

Time zone name:

Code name:

GMT difference:

Use daylight saving time:

Daylight saving time start rule:

| Month | Condition | Day | Time | Value |
|---------|-----------|--------|----------|-------|
| January | FIRST | Sunday | 1 2 : 00 | 1 |

Daylight saving time end rule:

| Month | Condition | Day | Time | Value |
|---------|-----------|--------|----------|-------|
| January | FIRST | Sunday | 1 2 : 00 | 0 |

3. Click **OK**. You have just created the time zone. Now if you switch back to the time zones list, you should see the new time zone present among the records.

| Actions | Time zone name | GMT | DST |
|---------|------------------------------|-----|-----|
| | International Date Line West | -12 | No |
| | Nowhere land | -12 | Yes |
| | Midway Island, Samoa | -11 | No |
| | Hawaii | -10 | No |
| | Alaska | -9 | Yes |
| | Pacific Time (US & Canada) | -8 | Yes |

8.48.5 Daylight saving time

When creating a time zone or modifying some of the existing ones, you may come across the need to specify the daylight saving time (DST). This is a convention of setting clocks so that afternoons have more daylight and mornings have less of it. The amount of time advance and dates of change vary from country to country, however, it is usually a one hour advance at the beginning of spring and the advance is rolled back in autumn.

For more information about DST, please read this Wikipedia article: http://en.wikipedia.org/wiki/Daylight_saving_time

Daylight saving time can be set separately for each of the time zones. It can be set when creating a new time zone or when editing an existing one.

Time zone properties

> Time zones > Nowhere land

Time zone name:

Code name:

GMT difference:

Use daylight saving time:

Daylight saving time starts at: 1/2/2011 2:00:00 AM

Daylight saving time ends at: 1/2/2011 2:00:00 AM

Daylight saving time start rule:

| Month | Condition | Day | Time | Value |
|---------|-----------|--------|----------|-------|
| January | FIRST | Sunday | 1 2 : 00 | 1 |

Daylight saving time end rule:

| Month | Condition | Day | Time | Value |
|---------|-----------|--------|----------|-------|
| January | FIRST | Sunday | 1 2 : 00 | 0 |

1. The first thing you need to do is to check the **Use daylight saving time** check-box. This enables DST for the time zone.

2. Now when you have DST enabled, you have to set the **DST start rule** and **DST end rule** for the current time zone. First, select the month in which the change will be carried out using the **Month** drop-down list.

3. Here comes the complicated part. You have to specify on which day of the selected month the change will be carried out. This is done by the **Condition** drop-down list and the two **Day** drop-down lists.

The following table explains the meanings of possible options for the **Condition** parameter:

| | |
|-------|--|
| FIRST | Day of the week can be selected. If you select Monday, the time advance will occur on the first Monday of the selected month. |
| LAST | Day of the week can be selected. If you select Monday, the time advance will occur on the last Monday of the selected month. |
| >= | Day of the week and day number can be selected. If you select Monday and 15, the time advance will occur on the first Monday after the 15th day of the selected month. |
| <= | Day of the week and day number can be selected. If you select Monday and 15, the time advance will occur on the last Monday before the 15th day of the selected month. |
| = | Day number can be selected. If you select 15, the time advance will occur on the 15th of the selected month. |

4. Set the time when the change will occur on the specified date using the **Time** fields.

5. The last thing is to set the time difference between the standard time and DST. It should be entered into the **Value** field and represents the **difference from standard time in hours**. Use this value for the **DST start rule** and '0' for the **DST end rule**.

6. Click **OK** to save the settings.

8.48.6 Use in web parts

Web parts of the [Blogs](#), [Forums](#), [Message boards](#), [Messaging](#) and [Smart Search](#) modules have the **Time zones** section in their **web part properties**, where the applied time zone can be set. The section contains the following two properties:

| | |
|------------------|---|
| Time zone | <ul style="list-style-type: none"> • Inherit - inherits the time zone setting from the Page placeholder web part used to display the current page template (typically the one on the master page). • Server - server time zone settings will be used by the web part. • Web site - website time zone settings will be used by the web part. • User - time zone settings of individual users will be used by the web part. • Custom - some other time zone will be used based on the selection done in the <i>Custom time zone</i> property. |
| Custom time zone | If you select one of the time zones, it will be used by the content of this web part, regardless of current user or website time zone settings. |

In the case of the **Calendar** and **Event calendar** web parts, these web part properties take no effect. Instead, displaying of the correct time zone needs to be ensured in the used transformation, as described in the [Displaying correct time in your code](#) chapter.

8.48.7 Time zones internals and API

8.48.7.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Time zones module. You will also see the most common [API examples](#).

The [Displaying correct time in your code](#) topic demonstrates how the correct time can be displayed in transformations and by user controls depending on the current time zone settings.

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the module's classes, please refer to [Kentico CMS API Reference](#).

8.48.7.2 Database tables

The following database tables are used to store information for the time zones module:

- **CMS_TimeZone** - contains records representing time zones.

| CMS_TimeZone | |
|---|-----------------------|
|  | TimeZoneID |
| | TimeZoneName |
| | TimeZoneDisplayName |
| | TimeZoneGMT |
| | TimeZoneDaylight |
| | TimeZoneRuleStartIn |
| | TimeZoneRuleStartRule |
| | TimeZoneRuleEndIn |
| | TimeZoneRuleEndRule |
| | TimeZoneGUID |
| | TimeZoneLastModified |

8.48.7.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the Time zones module can be found in the **CMS.SiteProvider** namespace.

CMS_TimeZone table API:

- **TimZoneInfo** - represents one time zone object.
- **TimeZoneInfoProvider** - provides management functionality for time zones.

Other classes:

- **TimeZoneHelper** - can be used to convert the time according to a specified time zone or get other types of time zone data.

8.48.7.4 API examples

8.48.7.4.1 Overview

This topics shows examples of how the API of the Time zones module can be used:

- [Managing time zones](#)

Please note

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Development\TimeZones\Default.aspx.cs**.

The time zone API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.CMSHelper;
using CMS.SiteProvider;
```

8.48.7.4.2 Managing time zones

The following example creates a time zone.

```
private void CreateTimezone()
{
    // Create new timezone object
    TimeZoneInfo newTimezone = new TimeZoneInfo();

    // Set the properties
    newTimezone.TimeZoneDisplayName = "My new timezone";
    newTimezone.TimeZoneName = "MyNewTimezone";
    newTimezone.TimeZoneGMT = -12;
    newTimezone.TimeZoneDaylight = true;
    newTimezone.TimeZoneRuleStartRule = "MAR|SUN|1|LAST|3|0|1";
    newTimezone.TimeZoneRuleEndRule = "OCT|SUN|1|LAST|3|0|0";
    newTimezone.TimeZoneRuleStartIn = TimeZoneInfoProvider.CreateRuleDateTime
(newTimezone.TimeZoneRuleStartRule);
    newTimezone.TimeZoneRuleEndIn = TimeZoneInfoProvider.CreateRuleDateTime
(newTimezone.TimeZoneRuleEndRule);

    // Save the timezone
    TimeZoneInfoProvider.SetTimeZoneInfo(newTimezone);
}
```

The following example gets and updates a time zone.

```
private bool GetAndUpdateTimezone()
{
    // Get the timezone
    TimeZoneInfo updateTimezone = TimeZoneInfoProvider.GetTimeZoneInfo
("MyNewTimezone");
    if (updateTimezone != null)
    {
        // Update the properties
        updateTimezone.TimeZoneDisplayName =
updateTimezone.TimeZoneDisplayName.ToLower();

        // Save the changes
        TimeZoneInfoProvider.SetTimeZoneInfo(updateTimezone);
    }
}
```

```
        return true;
    }

    return false;
}
```

The following example gets and bulk updates time zones.

```
private bool GetAndBulkUpdateTimezones()
{
    // Prepare the parameters
    string where = "TimeZoneName LIKE N'MyNewTimezone%'";

    // Get the data
    DataSet timezones = TimeZoneInfoProvider.GetTimeZones(where, null);
    if (!DataHelper.DataSourceIsEmpty(timezones))
    {
        // Loop through the individual items
        foreach (DataRow timezoneDr in timezones.Tables[0].Rows)
        {
            // Create object from DataRow
            TimeZoneInfo modifyTimezone = new TimeZoneInfo(timezoneDr);

            // Update the properties
            modifyTimezone.TimeZoneDisplayName =
            modifyTimezone.TimeZoneDisplayName.ToUpper();

            // Save the changes
            TimeZoneInfoProvider.SetTimeZoneInfo(modifyTimezone);
        }

        return true;
    }

    return false;
}
```

The following example deletes a time zone.

```
private bool DeleteTimezone()
{
    // Get the timezone
    TimeZoneInfo deleteTimezone = TimeZoneInfoProvider.GetTimeZoneInfo
    ("MyNewTimezone");

    // Delete the timezone
    TimeZoneInfoProvider.DeleteTimeZoneInfo(deleteTimezone);

    return (deleteTimezone != null);
}
```

The following example gets the time according to the current user's time zone settings.

```
private bool ConvertTime()
{
    // Get user
    UserInfo user = UserInfoProvider.GetFullUserInfo
(CMSContext.CurrentUser.UserID);

    // If user exist
    if (user != null)
    {
        // Get converted time
        System.DateTime convertedTime = TimeZoneHelper.ConvertUserDateTime
(System.DateTime.Now, user);

        return true;
    }

    return false;
}
```

8.48.7.5 Displaying correct time in your code

The following methods can be used in transformation code to display the correct time according to time zone settings.

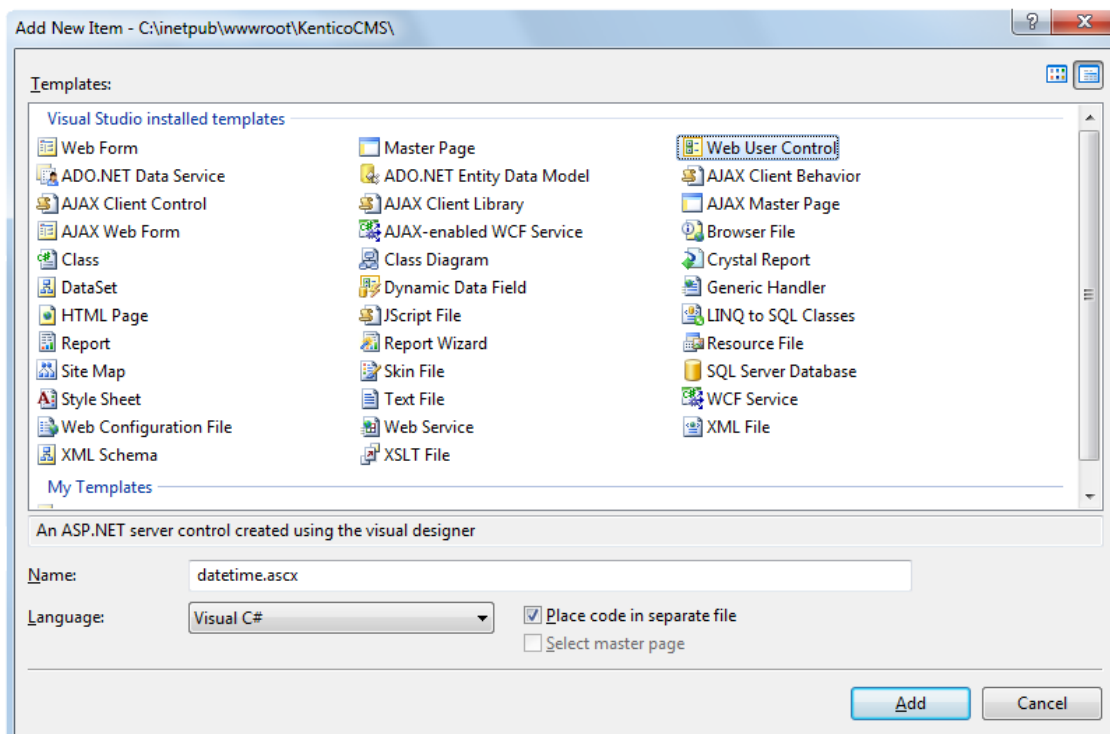

| | |
|--|---|
| <%# GetDateTime
(DateTime.Now) %> | Returns date-time value according to web part time zone settings. |
| <%# GetSiteDateTime
(DateTime.Now) %> | Returns date-time according to site time zone settings. |
| <%# GetUserDateTime
(DateTime.Now) %> | Returns date-time according to the current user's time zone settings. |
| <%# GetCustomDateTime
(DateTime.Now,
"GreenwichMeanTime") %> | Returns date-time according to the time zone given in the second parameter. |

In the following example, you will learn how to use the **General -> User control** web part to display the current date and time on your site, which will reflect the time zone settings of the web part.

1. Open the web project in Visual Studio and create a new subfolder in the project folder. Name it *mycontrols*. Right click the folder and click Add new item.

2. Create a new WebUserControl in the mycontrols folder, name it *datetime.ascx*.

3. Edit the user control on the Design tab. Drag and drop a **Label** control onto the form.
4. Add the following code to the **PageLoad** method of the user control:

[C#]

```
Label1.Text = CMS.CMSHelper.CMSContext.ConvertDateTime(DateTime.Now, this)
.ToString();
```

5. Add the **General -> User control** web part somewhere to some page of your website. Set the

following properties of the web part:

- **User control virtual path:** `~/mycontrols/datetime.ascx`
- **Time zone:** *Custom*
- **Custom time zone:** any time zone of your choice

and click **OK**. If you switch to the live site now, you should see the web part displaying the current date and time in the selected time zone. Now you can also try changing the value of the **Custom time zone** property and verify that the time displayed on the live site changes according to it.

8.49 UI data export

8.49.1 Overview

The UI data export functionality allows you to export data shown in various listings throughout the whole UI to XLSX, CSV or XML files. The export functionality is accessible in a context menu after clicking the ▾ icon in the **Actions** column header.

The [Exporting UI data](#) topic in this chapter provides you with information on the basics of this functionality. Export to the three formats mentioned above can either be performed in a single click with pre-defined options, or using the **Advanced export** dialog, which allows detailed configuration of export options. The [Advanced export](#) topic explains the options available in the dialog.

You can pre-define templates that will be used when exporting data to Excel files, which enables you to include graphics and additional text in the files. The [Excel export templates](#) topic explains how these templates can be created and where they should be uploaded to be used for specific object types. The [CSV delimiters](#) topic explains the use of appropriate separation characters in exported CSV files, necessary for appropriate displaying of these file in spreadsheet editors.

8.49.2 Exporting UI data

The UI data export functionality allows you to export data shown in various listings throughout the whole UI to XLSX, CSV or XML files. To achieve this, click the ▾ icon in the **Actions** column header. A drop-down menu will be displayed, offering the following options:

-  **Export to Excel** - exports data shown on the current page of the listing to an XLSX spreadsheet.
-  **Export to CSV** - exports data shown on the current page of the listing to a CSV file.
-  **Export to XML** - exports data shown on the current page of the listing to an XML file.
-  **Advanced export** - opens a dialog where export to the three formats mentioned above can be performed based on detailed settings. For more details, please refer to the [Advanced export](#) topic.

| Actions | User name ^ | Full name | E-mail | Nickname | Created | Enabled |
|-----------------|----------------------|------------------------|-------------------------------|----------|----------------------|---------|
| Export to Excel | Administrator | Global Administrator | administrator@localhost.local | | | Yes |
| Export to CSV | Andy | Andrew Jones | andy@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| Export to XML | Brad | Brad Summers | brads@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| Advanced export | Designer | CMS Designer | | | 8/15/2011 8:51:36 AM | Yes |
| | cmsdeskadministrator | CMS Desk Administrator | | | 8/15/2011 8:51:36 AM | Yes |
| | cmseditor | CMS Editor | | | 8/15/2011 8:51:36 AM | Yes |

| | cmsreader | CMS Reader | | | 8/15/2011 8:51:36 AM | Yes |
| | gold | Sample Gold Partner | gold@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | LukeH | Luke Hillman | lukeh@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | public | Public Anonymous User | | | | Yes |
| | SeanG | Sean Gaines | seang@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | silver | Sample Silver Partner | silver@localhost.local | | 8/15/2011 8:51:35 AM | Yes |

Items per page: 25

After executing an action from the drop-down menu, your browser's standard file download dialog pops up, letting you open or save the file with exported data just as if you were downloading any other file.

Export to Excel

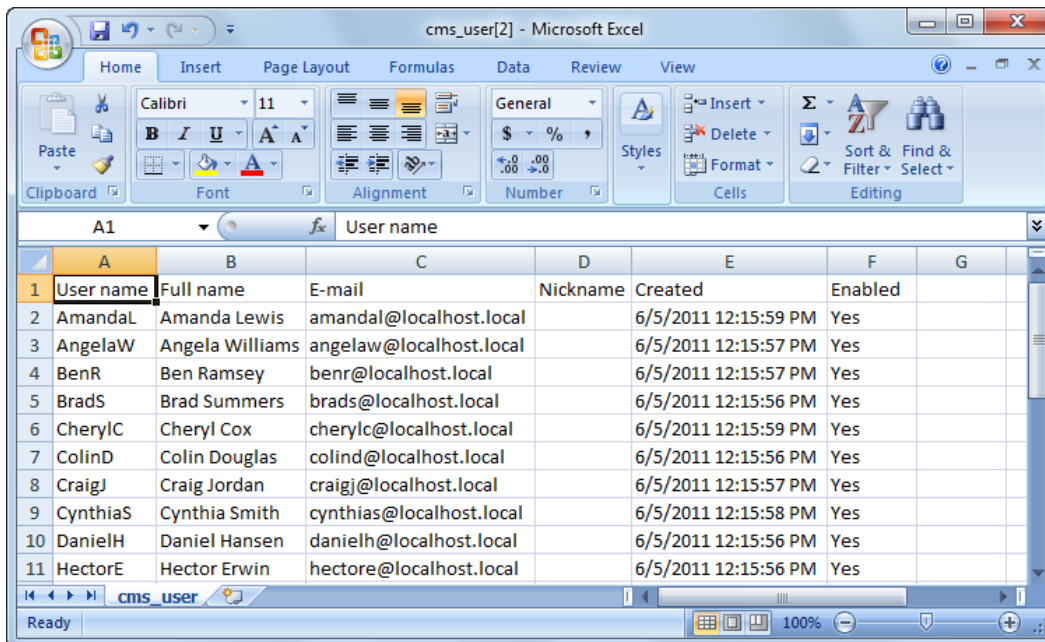

Data exported to an XLSX spreadsheet are displayed just as in the listing. Spreadsheet columns represent the columns of the listing, while rows represent particular records shown in the rows of the listing.

Maximal exported string length

Please note that maximal length of text exported into a single cell of an Excel spreadsheet is **32767 (2¹⁵ - 1) characters**. Longer strings are trimmed to match this length.

In the screenshot below, you can see the default appearance of an exported XLSX file. However, it is also possible to use customized templates for Excel export so that you can for example add graphics to the header of the spreadsheet. More details on this option can be found in the [Excel export templates](#) topic.

Export to CSV

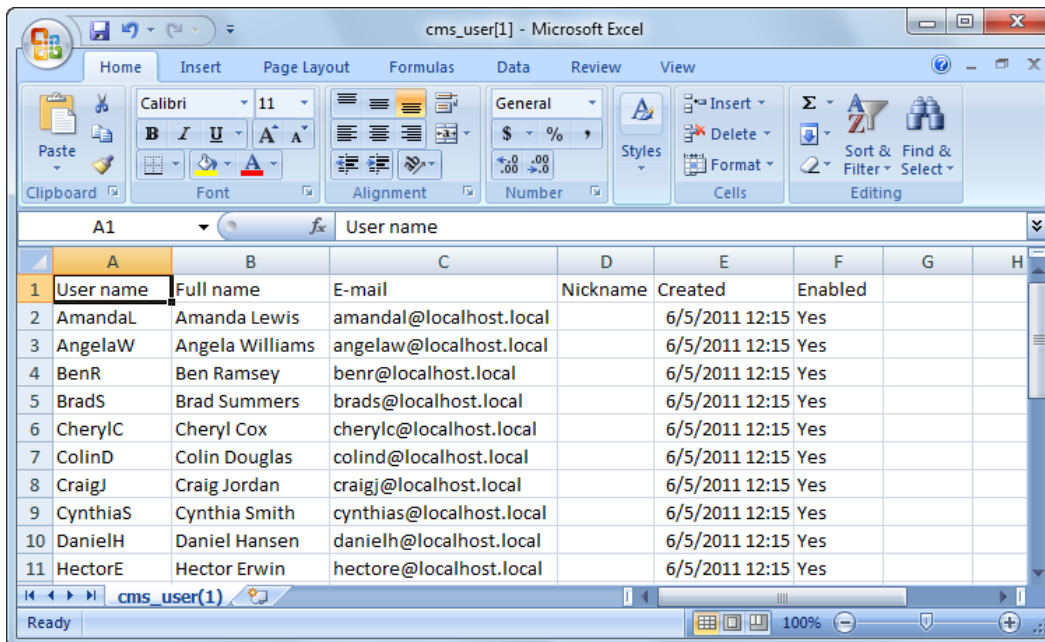

CSV is an abbreviation for [Comma-separated values](#). It is a file format that stores tabular data in text form — each line represents one row of data, while particular values (columns) in each row are separated by a comma (,) or a semicolon (;). If a column value contains the delimiter, the whole value is wrapped in double quotation marks in CSV (e.g. the value *one,two* is exported as "one,two"). If a column value contains double quotation marks, they are backslashed in CSV (e.g. the value "one is exported as \"one).

A comma is used as a column delimiter by default if you select the **Export to CSV** action, while you can choose between the comma and the semicolon in the **Advanced export** dialog. See the [CSV delimiters](#) topic for more information.

The plain text form of exported data stored in a CSV file looks as follows:

```
User name,Full name,E-mail,Nickname,Created,Enabled
AmandaL,Amanda Lewis,amandal@localhost.local,,5/6/2011 12:43:26 PM,Yes
AngelaW,Angela Williams,angelaw@localhost.local,,5/6/2011 12:43:25 PM,Yes
BenR,Ben Ramsey,benr@localhost.local,,5/6/2011 12:43:24 PM,Yes
BradS,Brad Summers,brads@localhost.local,,5/6/2011 12:43:24 PM,Yes
CherylC,Cheryl Cox,cherylc@localhost.local,,5/6/2011 12:43:26 PM,Yes
...
```

If the correct delimiter is used, the file can also be opened in a spreadsheet editor such as Microsoft Excel.

The screenshot shows a Microsoft Excel spreadsheet titled 'cms_user[1]'. The spreadsheet contains a table with the following data:

| | A | B | C | D | E | F | G | H |
|----|-----------|-----------------|--------------------------|----------|----------------|---------|---|---|
| 1 | User name | Full name | E-mail | Nickname | Created | Enabled | | |
| 2 | AmandaL | Amanda Lewis | amandal@localhost.local | | 6/5/2011 12:15 | Yes | | |
| 3 | AngelaW | Angela Williams | angelaw@localhost.local | | 6/5/2011 12:15 | Yes | | |
| 4 | BenR | Ben Ramsey | benr@localhost.local | | 6/5/2011 12:15 | Yes | | |
| 5 | BradS | Brad Summers | brads@localhost.local | | 6/5/2011 12:15 | Yes | | |
| 6 | CherylC | Cheryl Cox | cherylc@localhost.local | | 6/5/2011 12:15 | Yes | | |
| 7 | ColinD | Colin Douglas | colind@localhost.local | | 6/5/2011 12:15 | Yes | | |
| 8 | CraigJ | Craig Jordan | craigj@localhost.local | | 6/5/2011 12:15 | Yes | | |
| 9 | CynthiaS | Cynthia Smith | cynthias@localhost.local | | 6/5/2011 12:15 | Yes | | |
| 10 | DanielH | Daniel Hansen | danielh@localhost.local | | 6/5/2011 12:15 | Yes | | |
| 11 | HectorE | Hector Erwin | hectore@localhost.local | | 6/5/2011 12:15 | Yes | | |

Export to XML

The code sample below illustrates how exported data are stored in XML files. There is always the *NewDataSet* root element, which contains a number of *Table* elements. Each of the *Table* elements represents a single data record. Its sub-elements represent particular columns of the table, have names identical to the physical database column names and contain the respective values.

```
<?xml version="1.0" encoding="windows-1250"?>
<NewDataSet>
  <cms_user>
    <UserName>AmandaL</UserName>
    <FullName>Amanda Lewis</FullName>
    <Email>amandal@localhost.local</Email>
    <Nickname />
    <Created>5/6/2011 12:43:26 PM</Created>
    <Enabled>Yes</Enabled>
  </cms_user>
  <cms_user>
    <UserName>AngelaW</UserName>
    <FullName>Angela Williams</FullName>
    <Email>angelaw@localhost.local</Email>
    <Nickname />
    <Created>5/6/2011 12:43:25 PM</Created>
    <Enabled>Yes</Enabled>
  </cms_user>
  ...
</NewDataSet>
```

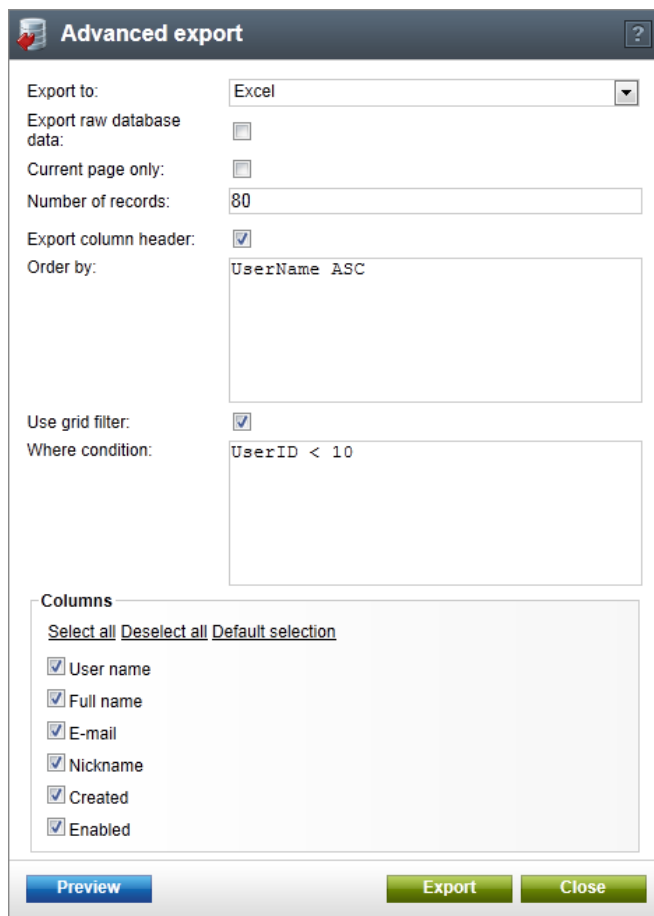

8.49.3 Advanced export

Clicking the  **Advanced export** option can raise two different versions of the **Advanced export** dialog, depending on the type of user performing the operation.

Advanced export - global administrator

When the  **Advanced export** option is selected by a global administrator, the dialog depicted in the following screenshot is displayed.

The following options can be adjusted in the dialog:

| | |
|------------------|--|
| <p>Export to</p> | <p>Type of file to which the data will be exported. You can choose from the following:</p> <ul style="list-style-type: none"> • Excel - exports data to an XLSX spreadsheet. |
|------------------|--|

| | |
|--------------------------|---|
| | <ul style="list-style-type: none"> • CSV - exports data to a CSV file. • XML - exports data to an XML file. |
| Delimiter | Displayed only when export to CSV is selected. Determines the value separation character used by the CSV file. The character can either be a comma (,) or a semicolon (;). See the CSV delimiters topic for more details. |
| Export raw database data | <p>The format of data displayed in listings is not always identical to actual data stored in respective database columns. E.g. the Enabled column in user listing shows <i>Yes/No</i> values, while boolean <i>True/False</i> values are actually stored in the UserEnabled column of the CMS_User table.</p> <p>With this option enabled, raw data will be exported exactly as stored in the database and column headers will be identical to the database column names. If disabled, column headers and the actual data will be exported as shown in the listing.</p> |
| Current page only | If enabled, only records displayed on the current page of the listing will be exported. If disabled, all records on all pages of the listing will be exported. The number of exported records in both cases can be limited by means of the Number of records value below. |
| Number of records | Specifies the number of data records that will be exported. Empty value results in all records being exported. The specified number of exported records can be limited by enabling the Current page only option above. |
| Export column header | If enabled, column headers will be included in the exported file. This option is not available when exporting to XML as column header names are used as names of the respective XML elements. |
| Order by | <p>Standard SQL ORDER BY expression. Exported items will be ordered according to this expression in the exported file.</p> <p>Please note that you can select only columns that have a corresponding physical column in the database.</p> |
| Use grid filter | If enabled, only data matching the filter above the listing will be exported. If disabled, all data will be exported regardless of the filter settings. |
| Where condition | Standard SQL WHERE condition. Only items matching this condition will be included in the export file. |
| Columns | <p>In this section, you can use the check-boxes to choose which columns will be included in the export file. Bulk column selection can be performed using the following link buttons:</p> <ul style="list-style-type: none"> • Select all - selects all columns listed in this section. • Deselect all - deselects all columns listed in this section. • Default selection - selects columns that were selected initially when the dialog was opened. <p>If the Export raw database data option is enabled, listed column names are identical to the actual database columns name. If the option</p> |

| | |
|--|--|
| | is disabled, column names are shown as in the listing. |
|--|--|

When you have the options adjusted, you can click **Export** to get the data exported to the chosen type of file. By clicking the **Preview** button, you get a maximum number of 100 records exported (unless you set a smaller number by means of the **Current page only** or **Number of records** options). This is useful in case that you are exporting large amounts of records and want to get a quick preview of the exported file without waiting for all records to be exported.

Advanced export - standard user

When the  **Advanced export** option is selected by a standard user who is not a global administrator, a dialog with simplified and more secure options (compared to the global administrator version described above) is displayed to them.

The following options can be adjusted in the simplified dialog:

| | |
|-------------------|--|
| Export to | Type of file to which the data will be exported. You can choose from the following: <ul style="list-style-type: none"> Excel - exports data to an XLSX spreadsheet. CSV - exports data to a CSV file. XML - exports data to an XML file. |
| Delimiter | Displayed only when export to CSV is selected. Determines the value separation character used by the CSV file. The character can either be a comma (,) or a semicolon (;). See the CSV delimiters topic for more details. |
| Current page only | If enabled, only records displayed on the current page of the listing will be exported. If disabled, all records on all pages of the listing will be |

| | |
|----------------------|--|
| | exported. The number of exported records in both cases can be limited by means of the Number of records value below. |
| Number of records | Specifies the number of data records that will be exported. Empty value results in all records being exported. The specified number of exported records can be limited by enabling the Current page only option above. |
| Export column header | If enabled, column headers will be included in the exported file. This option is not available when exporting to XML as column header names are used as names of the respective XML elements. |
| Order by | <p>In this section, you can determine how exported records will be ordered in the exported file.</p> <p>Initially, there are two drop-down lists displayed. In the first one, all columns that have a corresponding physical column in a database are offered. The second one determines if values will be exported in ascending or descending order according to values in the selected column.</p> <p>Once you make your choice, another two drop-down lists are displayed below, allowing you to choose how records will be ordered in case of identical values in the column chosen above. After selecting, two other drop-downs are displayed below again. In the end, you can get as many pairs of drop-down lists as the number of offered columns.</p> |
| Columns | <p>In this section, you can use the check-boxes to choose which columns will be included in the export file. Bulk column selection can be performed using the following link buttons:</p> <ul style="list-style-type: none"> • Select all - selects all columns listed in this section. • Deselect all - deselects all columns listed in this section. |

8.49.4 Excel export templates

It is possible to customize the default appearance of exported XLSX templates. On each export, the CMS searches for a *Template.xlsx* file in the following locations:

1. ~\App_Data\CMSModules\DataExport\- 2. ~\App_Data\CMSModules\DataExport\<object type>\Template.xlsx
- 3. ~\App_Data\CMSModules\DataExport\- 4. ~\App_Data\CMSModules\DataExport\Template.xlsx

The *DataExport* folder is not present under ~\App_Data\CMSModules by default, so you have to create it and all its required sub-folders manually in case that you want to use custom templates. The *<object type>* folder name should be identical to the name of the exported file, e.g. *cms_user* for user listings as the exported file name is *cms_user.xlsx* (the actual object type name is *cms.user*, but dots are replaced with underscores in the file names). The *<site code name>* folder is only searched when exporting site-related objects, not for global objects that can be shared among all websites in the system.

The CMS searches for the templates with the priorities as stated above. This means that when exporting listings of an object type on a specified website, the path stated in 1. is searched first. If the

Template.xlsx file is not found there, it searches location 2, and so on. This allows you to have dedicated templates for each object type and website in your system.

Please note

If the *Template.xlsx* file is not found in any of the locations, the default template is used. The same happens if the template is opened for editing at the time of export or if the current user doesn't have the Read and Write permissions for the template file (on operating system level).

Custom data export folder

Excel export templates can also be stored at a different location than the default `~\AppData\CMSModules\DataExport`. The custom location can be defined by adding the following key to the *AppSettings* section of the *web.config* file:

```
<add key="CMSDataExportTemplateFolder" value="\\server1\MyDataExportTemplates" />
```

As the value of the key, you can either use a local disk path (e.g. `C:\MyDataExportTemplates`) or a UNC path (e.g. `\\server1\MyDataExportTemplates`). Using the UNC path may be useful in cases when you want to share the same templates between several Kentico CMS instances running on separate servers.

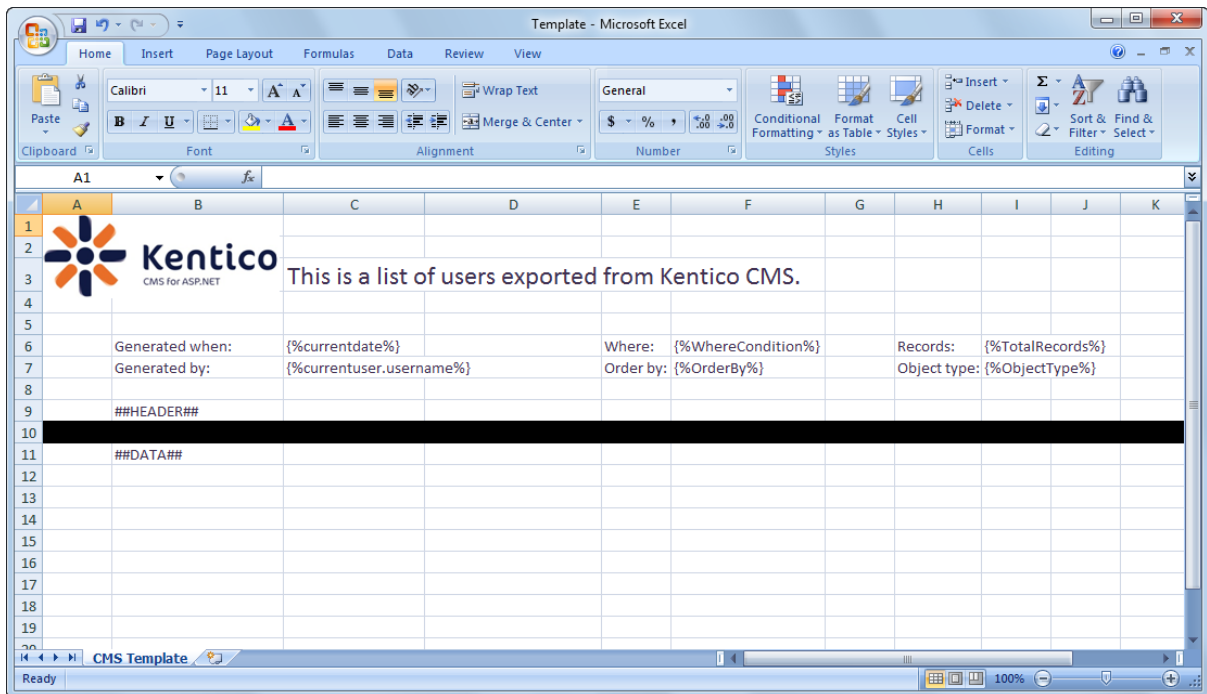

Template format

The template spreadsheet can contain any graphics, text or any other pre-filled data in it, while the following macros can be used in any cells. On export, the macros are replaced with the actual exported data:

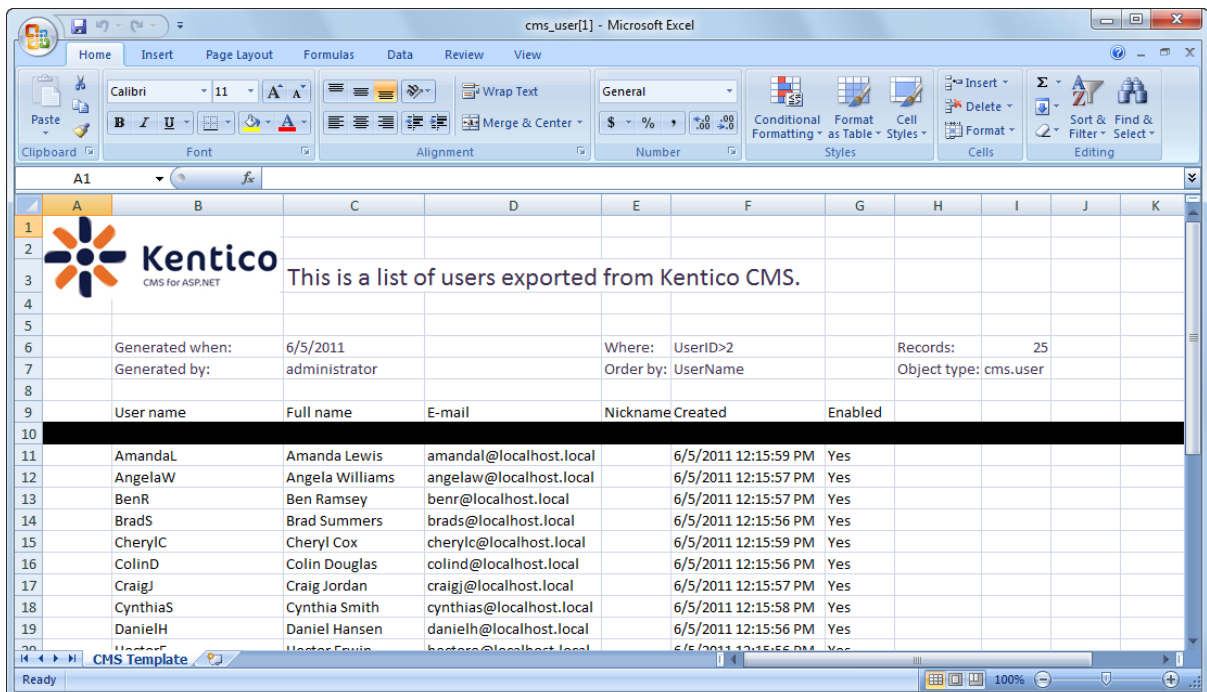

- **##HEADER##** - replaced with the header row. When advanced export is used, it is only replaced if the **Export header row** option is enabled.
- **##DATA##** - replaced with the actual exported data.
- **##TABLE##** - replaced with both the header row and the exported data.
- **{%WhereCondition%}** - replaced with the WHERE condition used for export (only relevant when exporting via the **Advanced export** dialog).
- **{%OrderBy%}** - replaced with the ORDER BY expression used to order exported items (either the expression configured in the **Advanced export** dialog or the default column according to which records are sorted when exporting using the **Export to Excel** action).
- **{%TotalRecords%}** - replaced with the total number of exported records.
- **{%ObjectType%}** - replaced with the type of exported object (e.g. `cms.userlist`).

You can also use all standard [Context \(data\) macros](#) the same way as you are used to within Kentico CMS user interface.

So for example, if you create a *Template.xlsx* file as in the screenshot below and upload it to `~\App_Data\CMSModules\DataExport\cms_user\ ...`

... the XLSX file with exported users will look as you can see below.

8.49.5 CSV delimiters

CSV is an abbreviation for [Comma-separated values](#). It is a file format that stores tabular data in text form — each line represents one row of data, while particular values (columns) in each row are separated by a comma (,) or a semicolon (;). The comma is used as a column delimiter by default if you select the

 **Export to CSV** action, while you can choose between the comma and the semicolon in the **Advanced export** dialog. The choice of the correct delimiter depends on your operating system's regional settings, as described [below](#).

If you use the inappropriate delimiter, data from each row will be displayed in a single cell as the displaying software (e.g. Microsoft Excel) will not be able to identify the boundaries between individual values.

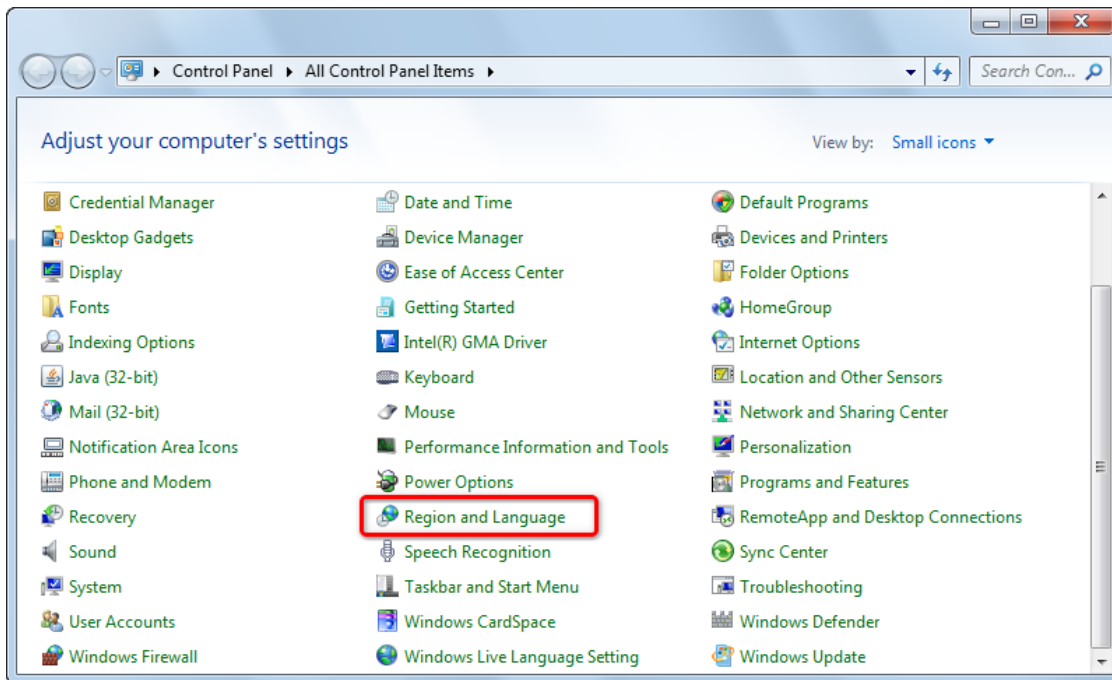

If the appropriate delimiter is used, data from each column will be displayed in individual cells as expected.

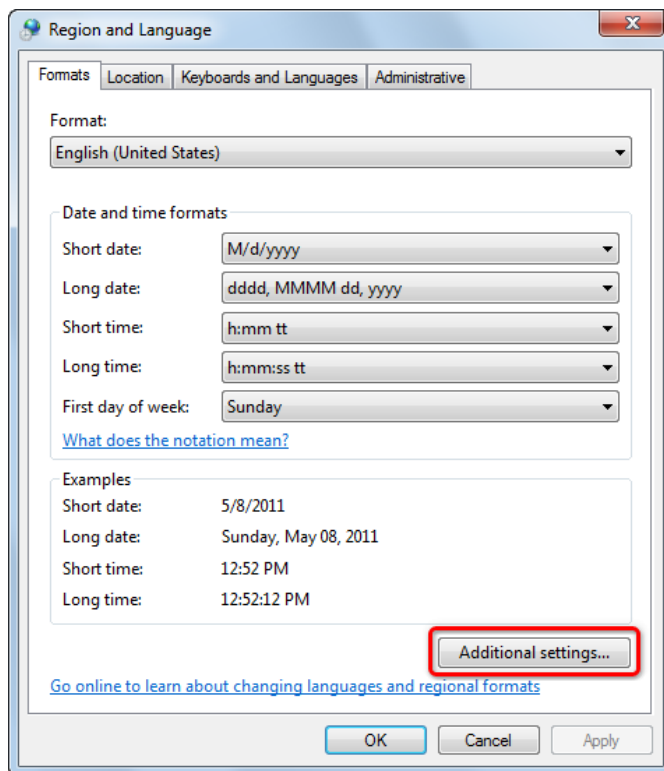

Delimiter settings on operating system level

To find out which delimiter you should use in your environment or to configure your system to use the other one than the one currently used, you need to:

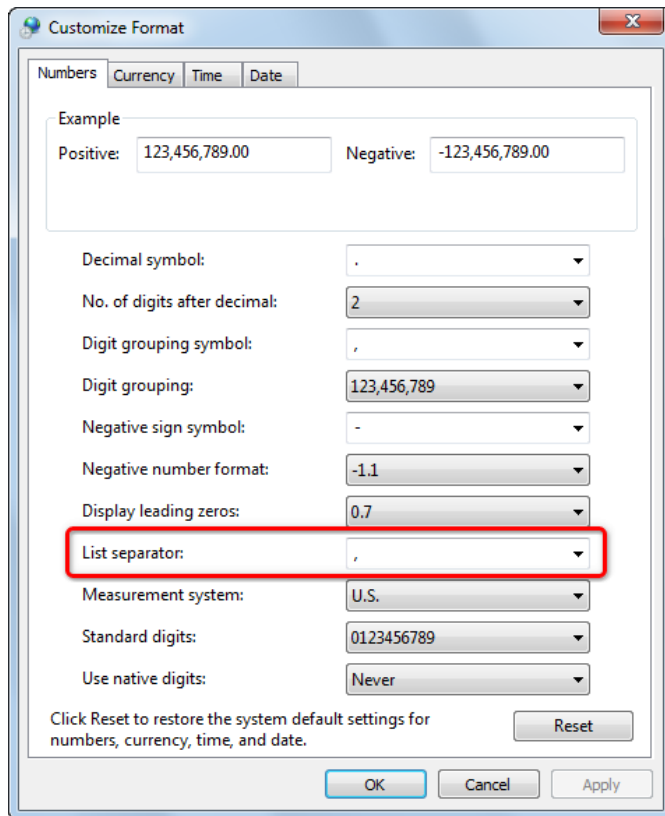

1. Go to **Start menu -> Control Panel** and open the **Region and Language** settings category.

2. In the **Region and Language** dialog, click **Additional settings...** on the **Formats** tab.

3. The **Customize Format** dialog will pop up. On its **Numbers** tab, you can choose the delimiter in the **List separator** field. The separator chosen here is the one that you should use when exporting listings data in order to get it displayed correctly.

Customize Format

Numbers Currency Time Date

Example
Positive: 123,456,789.00 Negative: -123,456,789.00

Decimal symbol: .

No. of digits after decimal: 2

Digit grouping symbol: ,

Digit grouping: 123,456,789

Negative sign symbol: -

Negative number format: -1.1

Display leading zeros: 0.7

List separator: ,

Measurement system: U.S.

Standard digits: 0123456789

Use native digits: Never

Click Reset to restore the system default settings for numbers, currency, time, and date.

Reset

OK Cancel Apply

Important!

If you change the value in the **List separator** field, make sure to confirm both the **Customize Format** and the **Region and Language** dialogs by clicking **OK** or **Apply**. Otherwise, the changes will not take effect and the original settings will be preserved.

8.50 User contributions (Wiki)

8.50.1 Overview

The User contributions module allows you to create a content editing interface for site members. It means that chosen website visitors can create, edit and delete content, even if they are not editors and cannot access CMS Desk or [On-site editing mode](#).

The screenshot shows a web page for 'IT Company' with a navigation menu. The main content area is titled 'Wiki' and contains the following text:

This is an example of a wiki-like section editable by all registered users. This section allows users to create, edit and delete documents directly on the live site, without access to the full-featured administration interface. It can be used for various types of documents and for various scenarios, including wiki, partner profiles, business directory, etc.

The section is created using the **User contributions** module, while particular articles are standard documents of the **Simple article** document type. For more information on this module, please refer to [Kentico CMS Developer's Guide -> Modules -> User contributions \(Wiki\)](#).

Buttons for [New article](#) and [My contributions](#) are visible. Below is a search bar with the text 'Article name:' and a 'Search' button. Two article links are listed:

- [Kentico CMS Information Sources](#): Below, you can find links to various information sources where you can get up-to-date information about Kentico CMS. Web sites Kentico Web Site D...
- [Kentico CMS System Requirements](#): The following configurations are supported by Kentico CMS. Other configurations may work too, but the system was not tested on them. Server-side Requirements Windows XP, 2003, 2008, 2008...

There are several scenarios where you can use this module, for example:

1. Community news

You can create a list of news and allow community members to add news without going to CMS Desk.

2. Partner directory

Your business partners can manage their profile on your website and the list of their reference project.

3. Business directory

You can create a business directory for some town or industry and let the business owners to manage their own profile.

Implementation

You can use the following web parts to implement user contributions:

- **Contribution list** - this web part allows you to display a list of contributions (documents) and the **New document** link.
- **Edit contribution** - this web part allows you to edit an existing document.

You can find the description of both web parts in the [Kentico CMS Web Parts](#) reference.

- If you would like to see an example of how to create a new section for publishing community news, please refer to the [Example: Publishing community news](#) topic.
- If you would like to see an example of how to create a list of partners who will be able to edit their profile on a special page after they have signed in, please refer to the [Example: Editing partner profile](#) topic.

- If you would like to learn about the security possibilities of the User contributions (Wiki) module, please refer to the [Security](#) topic.
- A brief reference on the relationship between the User contributions (Wiki) module and API can be found in the [User contributions and API](#) topic.

You will need to have the E-commerce Site sample website installed to follow Kentico CMS E-commerce Guide.

Several more practical examples of the use of the User contributions (Wiki) module are available in Kentico CMS Community Site Guide; please note that these examples do not concern the whole functionality of the module but focus on its use in a broader context of the Community Site sample website:

- See [Community Site Guide -> Part 2 -> Creating the Blogs section -> Creating the Blogs page](#): An example of the use of the User contributions (Wiki) module web parts in the context of creating the Blogs section.
- See [Creating the Groups section -> Preparing the Group pages section -> Creating the Pages page](#) in the same section of Kentico CMS Community Site Guide: An example of the use of the User contributions (Wiki) module web parts in the context of creating the Groups section.

8.50.2 Example: Publishing community news

In this example, you will create a new section for publishing community news. Each registered site member can create new news items and edit/delete their previously posted news. The example assumes that you are using the **Corporate Site** sample website. In this topic you will learn how to:

- [Create the community news section](#)
- [Add the New document button](#)
- [Add the editing support](#)
- [Create a testing user](#)
- [Create your first news item](#)
- [Approve the news](#)

Creating the community news section

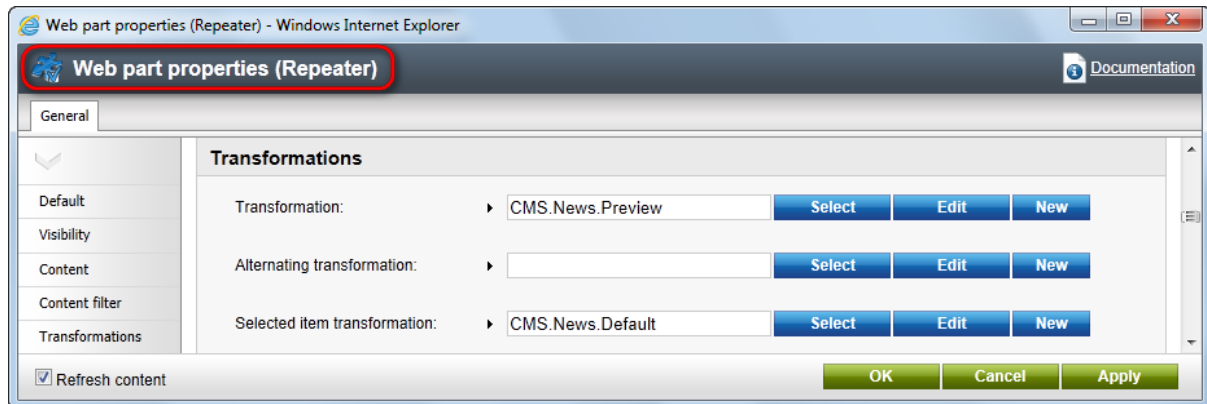

1. Sign in to **CMS Desk** as the administrator, go to the **Content** section and click **Examples** in the content tree. Click **New** and choose to create a new **Page (menu item)**. Enter the name **Community** and choose the **Create a blank page** option.

2. Click **Save**. Switch to the **Design** tab of the newly created page and add the **Listings and Viewers/Repeater** web part. Set the following properties:

- **Web part control ID:** repeaterNews
- **Document types:** cms.news
- **Transformation:** CMS.News.preview

- **Selected item transformation:** CMS.News.default

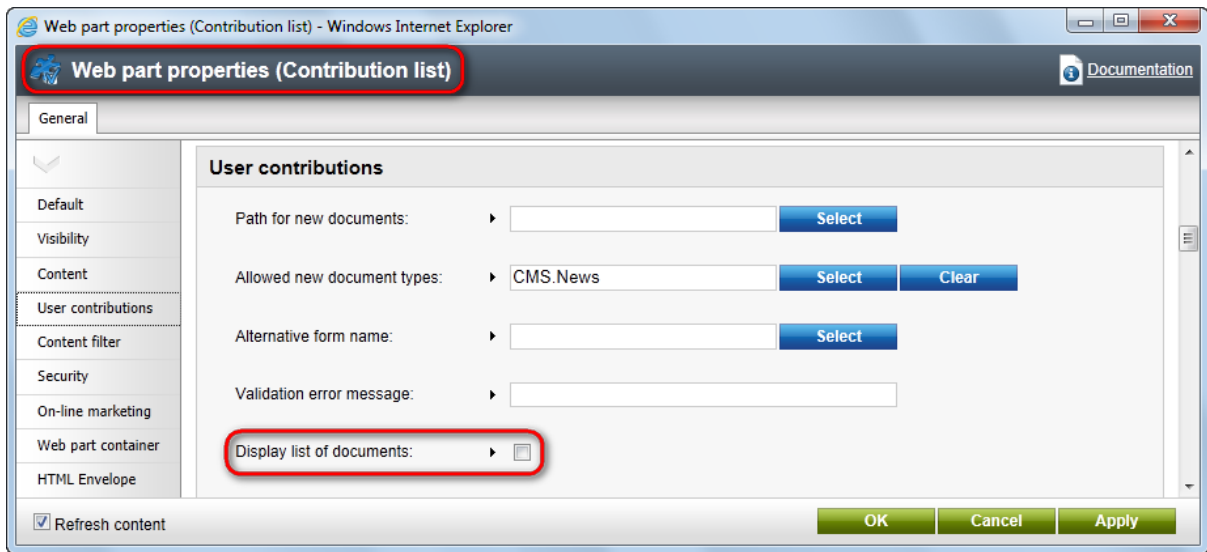

3. Click **OK**.

Adding the New document button

1. Add a new web part **User contributions/Contribution list**. It will display the **New document** link. Set the following values:

- **Show for document types:** cms.menuitem
- *this ensures that the web part is displayed only when the list of news is displayed, not on the news detail page.*
- **Allowed new document types:** CMS.News
- *this means that the users will be allowed to create only news items under this section.*
- **Display list of documents:** no (unchecked)
- *this ensures that the web part displays only the **New document** link, without displaying the list of documents.*
- **Allow editing by users:** Authenticated
- *this means that only authenticated users will be able to edit/delete the document. Authenticated users are those who are signed-in to the website (not to the administration interface).*

Leave the other values as they are by default.

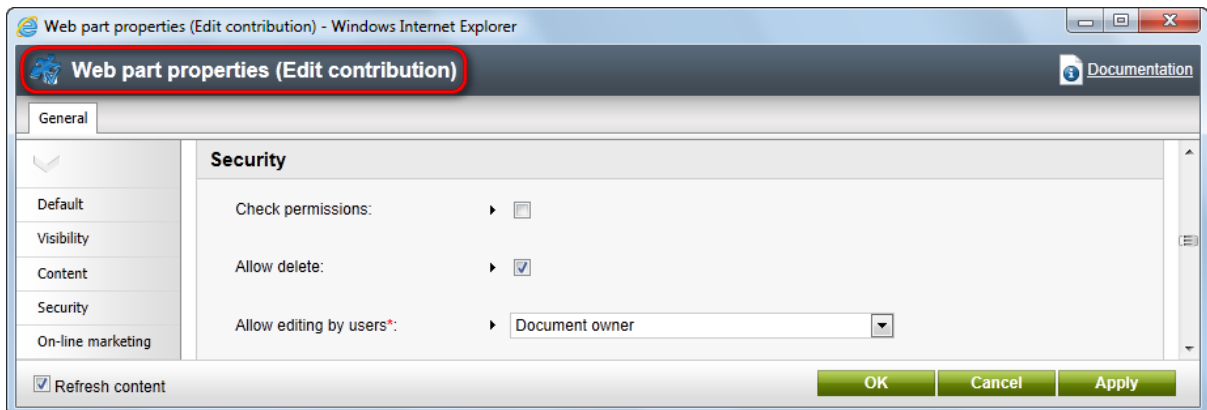

2. Click **OK**.

Adding the editing support

1. Add a new web part **User contributions/Edit contribution**. It will display the **Edit/Delete** icons when some news item is chosen.

- **Show for document types:** cms.news
- *this ensures that the web part is displayed only on the news detail page.*
- **Allow editing by users:** Document owner

Please note that the **Edit contribution** web part is missing the **Allow insert/edit** properties.

2. Click **OK**.

Creating a testing user

1. Go to **CMS Desk -> Administration -> Users** and click the **New user** link to create a new user with user name **test1**. Please note that to create a user, at least the values of the following two compulsory fields: **User name** and **Full name** must be entered.

The screenshot shows the 'Users' management interface in Kentico CMS. A table lists various users with columns for Actions, User name, Full name, E-mail, Nickname, Created, and Enabled. The user 'test1' is highlighted with a red box.

| Actions | User name | Full name | E-mail | Nickname | Created | Enabled |
|---------|----------------------|------------------------|-------------------------------|----------|-----------------------|---------|
| | administrator | Global Administrator | administrator@localhost.local | | | Yes |
| | Andy | Andrew Jones | andy@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | BradS | Brad Summers | brads@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | cmsdesigner | CMS Designer | | | 8/15/2011 8:51:36 AM | Yes |
| | cmsdeskadministrator | CMS Desk Administrator | | | 8/15/2011 8:51:36 AM | Yes |
| | cmseditor | CMS Editor | | | 8/15/2011 8:51:36 AM | Yes |
| | cmsmarketingmanager | Marketing Manager | | | 8/15/2011 8:51:36 AM | Yes |
| | cmsreader | CMS Reader | | | 8/15/2011 8:51:36 AM | Yes |
| | gold | Sample Gold Partner | gold@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | LukeH | Luke Hillman | lukeh@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | public | Public Anonymous User | | | | Yes |
| | SeanG | Sean Gaines | seang@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | silver | Sample Silver Partner | silver@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | test1 | test1 | | | 8/15/2011 10:51:54 AM | Yes |

2. For the purpose of this example, choose no (uncheck the box) in the **Is editor** field - **test1** is a common site member without access to Kentico CMS Desk.

The screenshot shows the configuration page for the user 'test1'. The 'Is editor' checkbox is unselected and highlighted with a red box.

General Password Settings Sites Roles Departments Notifications Categories

Log in as this user

User name:* test1

Full name: * test1

First name:

Middle name:

Last name:

E-mail:

Enabled:

Is hidden:

Click **OK** to save the changes.

Creating your first news item

1. Sign out and go to the **Examples -> Community** section. You will see a blank page since the user contributions are now enabled only for site members. In order to sign in, click the **My account** link at the top and sign in as user **test1**. Then go back to the **Examples -> Community** section. You will see the

New document link:

2. Click this link and you will be displayed with the news editing form:

3. Enter some content and click  **Save**. Now select **Examples -> Community** from the main menu at the top. You will see the **Community** page with your first news item:

4. Click the news item link to see the details page. The  **Edit** and  **Delete** links are displayed below the news item:

5. Choose to  **Edit** the news item and you will be displayed with the editing form where you can edit its content:

6. Make some modifications and click  **Save**. Click the **Close edit mode** link to see the updated

page.

Approval process

If you need to enforce some approval process for published news, you can simply set up workflow for the given site sections and all news will need to be approved by a site manager. You can find more details on workflow configuration in the [Workflow overview](#) chapter.

In this example, you have learned how to create a site section where community members can create and edit content without having access to Kentico CMS Desk.

8.50.3 Example: Editing partner profile

In this example, you will create a list of partners who will be able to edit their profile on the **My profile** page after they have signed in. This example assumes that you are using the Corporate Site sample website.

- [Create the partner document type](#)
- [Create the partner list](#)
- [Create the partner user account](#)
- [Create the partner profile document](#)
- [Create the partner profile editing page](#)
- [Test the profile editing page](#)

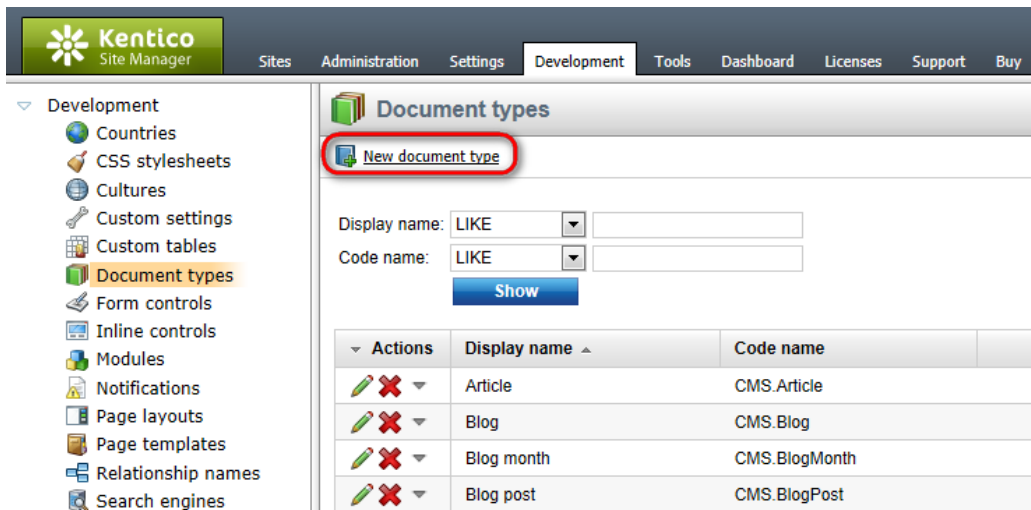

Creating the partner document type

Please note

A detailed description of how to create a new document type can be found in the [Document types and transformations -> Defining a new document type](#) topic in the Development section of the Developer's Guide.

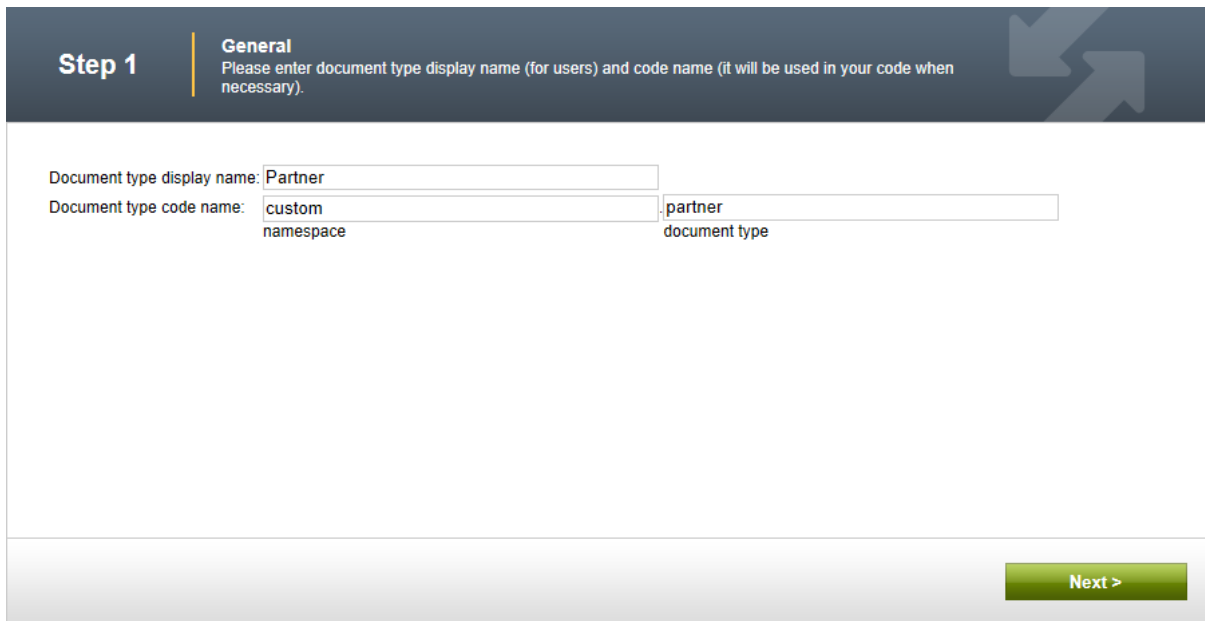

Before you create the page, it is necessary that you create a new document type **Partner**. Sign in to **Site Manager** and go to **Development -> Document types** where you need to click  **New document type**.

Step 1: General

Enter the following values and click the **Next** button.

- **Document type display name:** Partner (this name will be displayed to the users)
- **Document type code name:** custom.Partner

Please note that *custom* in the **Document type code name** field is your namespace to distinguish your document types from system types that use the *cms* namespace. You will use this value in web part properties later.

Step 2: Data type

You need to choose the name of the database table that will be used for storing partner details. You also need to enter the name of the primary key in this table. Choose the option **The document type has custom fields** and enter the following values:

- **Table name:** custom_Partner
- **Primary key name:** PartnerID

Step 2

Data type

Please choose document data type. If you choose a document type with custom attributes you will also need to supply names of the new database table and its primary key.

The document type has custom fields

Table name:

Primary key name:

Inherits fields from document type:

The document type is only a container without custom fields

[Next >](#)

Click **Next**.

Step 3: Fields

Now you need to define the columns of the table or fields. Click **New attribute** (+) to create a new field, enter the following values and click **OK**.

- **Attribute name:** PartnerName
- **Attribute type:** Text
- **Attribute size:** 100
- **Field caption:** Partner name
- **Field type:** TextBox

- **Attribute name:** PartnerProfile
- **Attribute type:** Long Text
- **Field caption:** Partner profile
- **Field type:** HTML area (Formatted Text)

When you have defined both the fields, click **Next** again.

Step 3 **Fields**

Please define custom attributes of the document type and their appearance in the editing form. You can define attributes, such as product number, product weight, press release text, etc.

PartnerID*

New attribute

Database

Column name:

Attribute type:

Attribute size:

Allow empty value:

Default value:

Display attribute in the editing form

Field appearance

Field caption:

Form control type:

Form control:

Field description:

Quick links:

- [Database](#)
- [Field appearance](#)
- [Editing control settings](#)
- [Validation](#)
- [CSS styles](#)

Next >

Step 4: Additional Settings

Now you need to choose the field that will be used as document name. Choose the *PartnerName* field option from the **Document name source** drop-down list and click **Next**.

- **Document name source:** PartnerName

Step 4 **Additional settings**

Please choose the source field that will be used as a document name. You can choose either one of the custom fields or you can choose to use document name as a separate field.

Document name source:

Next >

Step 5: Parent types

In this step, you need to select the document types under which the partner documents will be displayed. Check only the **Page (menu item)** value, which means the users will be able to create computer documents only under some page, not under article or news document in the content tree. Click the **Next** button.

Step 5

Parent types

Please select document types under which this document template can be placed.

| <input type="checkbox"/> | Document type name |
|-------------------------------------|---------------------------------|
| <input checked="" type="checkbox"/> | Page (menu item) (CMS.Menuitem) |

[Remove selected](#) [Add document types](#) ▼

[Next >](#)

Step 6: Sites

Here you need to choose which websites will use this document type. Choose your current website and click **Next**.

Step 6

Sites

Please select sites where this document type can be used:

| <input type="checkbox"/> | Site name |
|-------------------------------------|----------------|
| <input checked="" type="checkbox"/> | Corporate Site |

[Remove selected](#) [Add sites](#) ▼

[Next >](#)

Step 7: Search options

In this step, you are asked to specify how documents of this type will be indexed and displayed in the search results. For more information on these settings, please refer to the [Settings for particular object types](#) topic. Make your choice and click **Next**.

Step 7
Search options
Please set search fields for Smart search module.

Step 8: The wizard has finished

Step 8 is the last step in the process of creating the partner document type - the wizard has finished the configuration of the this document type.

Step 8
The wizard has finished

The setup has finished the following steps:

- > The new document type was created.
- > The new editing form was created.
- > The document types were added among allowed child types of the new document type.
- > The sites were selected where this document type can be used.
- > The default queries were created.
- > The default ASCX transformations were created.
- > The default permission names were created.
- > The default icon was created.
- > Document smart search specification was created.

Finish

Creating the partner list

1. Go to **CMS Desk -> Content**, choose **Examples** from the content tree, click **New** and choose to

create a new  **Page (menu item)** document. Call the page **Partner directory**, choose the **Create a blank page** option and click  **Save**.

Save Save and create another Spell check

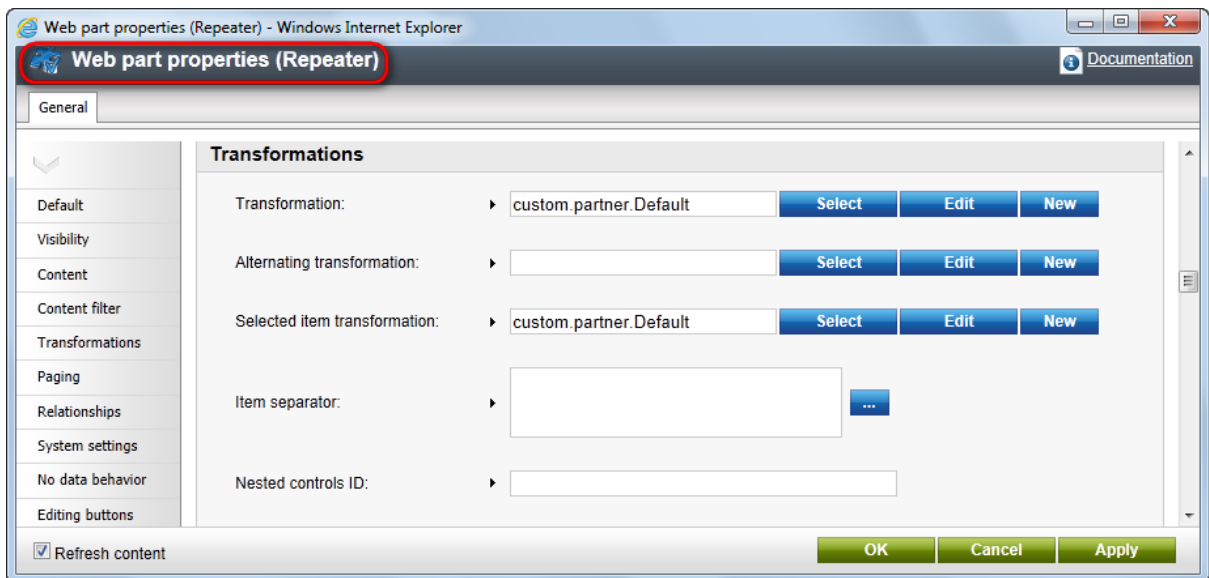

Page name: Partner directory

Use existing page template
 Use parent page template
 Create a blank page with layout
 Create a blank page

The new page will use new ad-hoc page template with an empty layout.

2. Switch to the **Design tab** of the newly created page and add the **Listings and viewers/Repeater** web part. Set the following properties:

- **ID:** repeaterPartners
- **Document types:** custom.partner
- **Transformation:** custom.Partner.Default
- **Selected item transformation:** custom.Partner.Default

Web part properties (Repeater) - Windows Internet Explorer

Web part properties (Repeater) Documentation

General

Transformations

Transformation: ▶ custom.partner.Default Select Edit New

Alternating transformation: ▶ Select Edit New

Selected item transformation: ▶ custom.partner.Default Select Edit New

Item separator: ▶ ...

Nested controls ID: ▶

Refresh content OK Cancel Apply

Please note that the default transformation generated by the system will be used. You can later modify the transformation so that it meets your design and layout requirements.

3. Click **OK**. Switch to the **Page** view and you will see an empty page now.

Creating the partner user account

1. Go to **CMS Desk -> Administration -> Users** and by clicking the  **New user** link create a new user with user name **AAAWebDesign**. Assign the user to the **CMS Basic users** role.

The screenshot shows the Kentico CMS Desk Administration interface. The 'Users' tab is active, displaying a list of users. The user 'AAAWebDesign' is highlighted with a red circle. The table below shows the details of the users.

| Actions | User name | Full name | E-mail | Nickname | Created | Enabled |
|---------|----------------------|------------------------|-------------------------------|----------|-----------------------|---------|
| | AAAWebDesign | test1 | | | 8/15/2011 12:27:29 PM | Yes |
| | administrator | Global Administrator | administrator@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | Andy | Andrew Jones | andy@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | BradS | Brad Summers | brads@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | cmsdesigner | CMS Designer | | | 8/15/2011 8:51:36 AM | Yes |
| | cmsdeskadministrator | CMS Desk Administrator | | | 8/15/2011 8:51:36 AM | Yes |
| | cmseditor | CMS Editor | | | 8/15/2011 8:51:36 AM | Yes |
| | cmsmarketingmanager | Marketing Manager | | | 8/15/2011 8:51:36 AM | Yes |
| | cmsreader | CMS Reader | | | 8/15/2011 8:51:36 AM | Yes |
| | gold | Sample Gold Partner | gold@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | LukeH | Luke Hillman | lukeh@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | public | Public Anonymous User | | | | Yes |
| | SeanG | Sean Gaines | seang@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | silver | Sample Silver Partner | silver@localhost.local | | 8/15/2011 8:51:35 AM | Yes |
| | test1 | test1 | | | 8/15/2011 10:51:54 AM | Yes |

2. For the purpose of this example, choose no (uncheck the box) in the **Is editor** field - **AAA Web Design** is a common site member without access to Kentico CMS Desk. Click **OK** to save the changes.

The screenshot shows the user profile configuration form for 'AAAWebDesign'. The 'Is editor' checkbox is highlighted with a red circle.

Creating the partner profile document

1. Go to **CMS Desk -> Content**, from the content tree, choose **/Examples/Partner directory** and click **New**. Choose to create a new **Partner** and enter the following values:

- **Partner name:** AAA Web Design Inc.
- **Partner profile:** We provide web development services.

2. Click **Save**. Go to the **Properties -> URLs** tab of the newly created document, set the **Document alias** to **AAAWebDesign** and click **Save**. You need to use the same alias as the user name since you will be using them to match the users to their user profiles. The alias path of the document will always be `/Examples/Partner-directory/<user name>`.

3. When you display the page in the **Live site** mode now, you will see a page like this:

Creating the partner profile editing page

Now you will create a page that will be available only to partners and that will allow them to edit their partner profile.

1. Go to **CMS Desk -> Content**, from the content tree, choose **/Examples** and click  **New**. Choose to create a new  **Page (menu item)**. Call the page *My profile*, choose the **Create a blank page** option and click  **Save**.

2. Switch to the **Design** tab of the newly created page and add the **Listings and viewers/Repeater** web part. It will display the current user's partner profile. Enter the following values and click **OK**.

- **ID:** repeaterPartners
- **Path:** /Examples/Partner-directory/{%UserName%}
- *this ensures that the page displays the profile that matches the current user. The {%UserName%} macro is resolved as the user name of the current site visitor.*
- **Document types:** custom.partner
- **Transformation:** custom.Partner.Default
- **Selected item transformation:** custom.Partner.Default
- **Hide if no record found:** no (unchecked)
- **No record found text:** No partner profile was found for your user account.
- **Content before:** <h1>Your Partner Profile</h1>

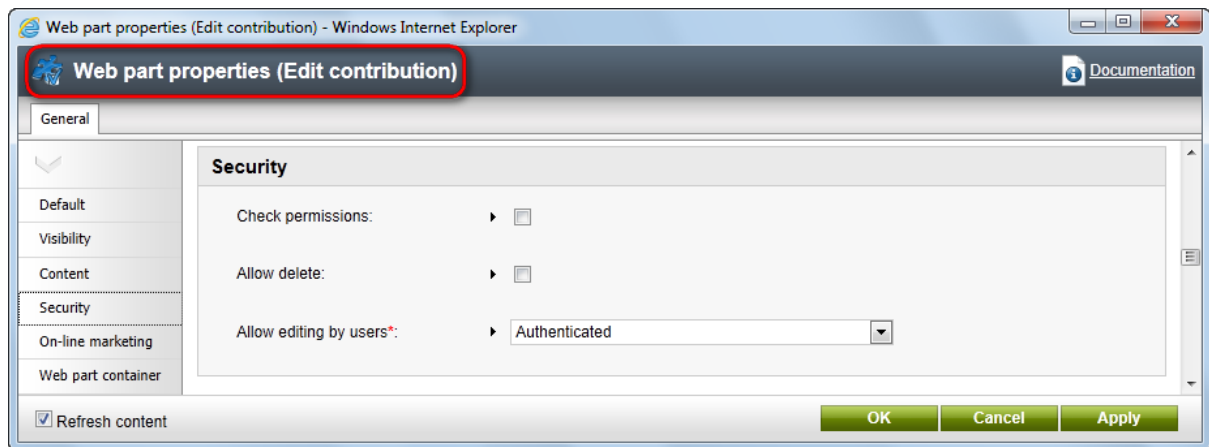

3. Add the **User contributions/Edit contribution** web part, enter the following values and click **OK**.

- **Path:** /Examples/Partner-directory/{%UserName%}
- *this ensures that the form edits the profile that matches the current user. The {%UserName%} macro is resolved as the user name of the current site visitor.*

- **Allow delete:** no (unchecked)
- *this option hides the Delete button since you do not want the partners to delete their profile accidentally.*
- **Allow editing by users:** Authenticated
- *you want to allow editing only to authenticated users; at the same time, you do not require the user to be a document owner.*

Please note that the **Edit contribution** web part is missing the **Allow insert/edit** properties.

4. As the last step, go to the **Properties -> Security** dialog, set the **Requires authentication** value to **Yes** and click **OK** - the reason is that you want to allow access to this page only to authenticated partners so that you know their user name and can display their profile.

4. Go to **Examples -> Partner directory** and you will see the updated profile.

Your Partner Profile

Partner name: AAA Web Design Inc.

Partner profile: We provide *excellent* web development services.

In this topic, you have learnt how to allow users (partners) to edit a single document that matches their user name. It was a little different in comparison to the previous example ([Example: Publishing community news](#)), since in this case, you created the document first and only then you mapped it to the user by matching the document alias path and user name. In this example, the partner was not allowed to create new documents and you did not use the document owner security option.

Hint 1: Simplifying the process of creating a new partner

In such cases, it is useful to create a custom module (see [Custom modules](#)) that will contain a custom form for creating new partners. Your code will ensure creating the user, the default partner profile and setting the document alias path and user name to the same value. You will need to use Kentico CMS to create the user account (see the [Managing users](#) API examples) and the partner profile document (see the [Creating documents](#) API examples).

Hint 2: Assigning multiple users to the same partner profile

If the user name/document alias path mapping does not fit your needs or if you need to assign multiple users to the same partner profile, you can use another option: Go to **Site Manager -> Development -> System tables -> User** and create a custom text field **PartnerProfileAliasPath**. You will use this custom field in the user profile to specify the partner profile that can be edited by the given user. Then, the **Path** property in the **Edit contribution** web part will be set to value `{%PartnerProfileAliasPath%}`. Please note that you will find your new custom field on the **Custom Fields** tab, not on the **General** tab as the default attributes.

8.50.4 Security

The User contributions (Wiki) web parts use the following properties to configure their security options:

- **Check permissions** - if you choose this option, appropriate permissions to read/modify/create/delete documents using the User contributions (Wiki) web parts need to be granted to the users. See the [Permissions](#) chapter for more details on document permissions.
- **Insert requires doc.type permission** - indicates if document type permissions are required to create a new document.
- **Allow insert/edit/delete** - indicates if the respective buttons should be displayed.

- **Allow editing by users** - you can choose between:
 - **All** - any user who comes to the page with the web part can use it to edit documents
 - **Authenticated** - any authenticated user (site member) can edit the documents; you can use this value in combination with the `NodeOwner = {%CMSContext.CurrentUser.UserID%}` value in the *WHERE* condition property for the web part to display only documents created by the current user (and therefore allow editing of these documents only to them)
 - **Document owners** - only owner of the parent document under which the user contribution documents are stored can edit them

8.50.5 User contributions and API

User contributions (Wiki) rely on standard Kentico CMS content management features. As such, they do not have a special programming interface and you need to use the document management API described in the [Content management internals](#) chapter.

8.51 Web analytics

8.51.1 Overview

The Web analytics module allows you to track and analyze metrics of your website such as visits, page views, file downloads, traffic sources and much more. Web analytics only measure activity on the live site. The statistics of the pages belonging to the Kentico CMS administration interface (CMS Desk and Site Manager) are not tracked.

You can access the web analytics interface in **CMS Desk -> Tools -> Web Analytics**. Various types of statistics are available in the tree menu, which track events that occur on your website. When you select a statistic, the page displays the corresponding data in a report.

Please read the [Web analytics reports](#) topic to find out more about individual statistics and learn about the functionality provided by the built-in reports.

Even though the module provides many statistics and tracking options out-of-the-box, you may also wish to track custom events that are unique for your website. For instructions on how to do this, please refer to the [Adding custom analytics](#) topic.

How web analytics work

When a tracked event (such as a page view, file download, etc.) occurs, the system stores a record in the application's memory. The application then periodically writes the memory records into log files in the `~/App_Data/CMSModules/WebAnalytics` folder. The names of the files use the following format:

`<event type>_<date>_<time>.log`

Disabling memory logging for analytics

The intermediate memory storage step improves the performance of the web analytics logging on high-traffic websites. The logging does not use up a significant amount of memory, but you can configure the system to directly log analytics records into physical files if you need to fully minimize the application's memory usage.

Add the following key to the `appSettings` section of the application's `web.config` file:

```
<add key="CMSWebAnalyticsUseMemoryStorage" value="false" />
```

The **Process analytics log** global [scheduled task](#) reads the content of all analytics log files every minute (or other scheduled interval) and imports the processed data into the database. You can view the status of the scheduled task and configure its settings in **Site Manager -> Administration -> Scheduled tasks**.

This data is then loaded from the database and presented in an easy to read format using web analytics reports (defined through the [Reporting](#) module).

You can manage the analytics data directly from the interface — either delete old data or generate sample data for evaluation purposes. Please see the [Managing analytics data](#) topic for further information.

Limitations

The Web analytics module only tracks content and events related to pages managed by Kentico CMS. It cannot track other content, such as html files or media files that are not served by the CMS.

Delay in the displaying of results

You may notice a delay between the time that an event occurs on the website and the time the web analytics statistics are updated. All tracked events are first stored in temporary files on the local file system and need to be processed by a scheduled task.

8.51.2 Enabling web analytics

The Web analytics module is disabled by default. To enable logging of analytics for your website:

1. Go to **Site Manager -> Settings -> On-line marketing -> Web Analytics**.
2. Check **Enable web analytics**.
3.  **Save** the settings.

The other settings in this category enable or disable tracking of individual types of statistics and events. See the [Configuration options](#) topic for details.

Disk Permissions

The Web analytics module requires your ASP.NET account to have the *Modify* permission for the `~/App_Data` folder on your disk.

See the [Disk permissions problems](#) chapter for the names of the account under various operating systems.

Selecting the logging method [Only available after applying [hotfix 7.0.17](#) or newer]

The system provides two different ways of logging web analytics:

| Processing analytics on every web request | Using JavaScript |
|--|---|
| <p>Advantages:</p> <ul style="list-style-type: none"> Provides statistics for all types of web requests. <p>Disadvantages:</p> <ul style="list-style-type: none"> Results may be skewed by non-human traffic such as web crawlers, RSS readers and other bots (typically irrelevant statistics). | <p>Advantages:</p> <ul style="list-style-type: none"> Filters out statistics generated by non-human tools such as RSS readers and web crawlers. Provides more accurate and relevant data for most public-facing websites. <p>Disadvantages:</p> <ul style="list-style-type: none"> Ignores users with browsers that do not support JavaScript or have it disabled (typically less than 1% of all visitors). If your website uses custom analytics, JavaScript logging does <i>not</i> affect their functionality. This may lead to inconsistency with the default analytics. May not work correctly on pages that run custom JavaScripts (if conflicts occur). The logging is compatible with all default Kentico CMS scripts. |

In most cases, it is recommended to use JavaScript logging for web analytics. Switching to JavaScript logging does not reduce the performance of the website.

To enable JavaScript logging:

- Go to **Site Manager -> Settings -> On-line marketing -> Web Analytics**.
- Enable the **Log via JavaScript snippet** setting.
- Save the settings.

Note: This setting also determines how the system logs on-line marketing [activities](#) related to website traffic.

8.51.3 Web analytics reports

The data logged by the web analytics module can be viewed and analyzed using reports displayed in the **CMS Desk -> Tools -> Web analytics** interface.

The reports are organized in a tree menu that can be used for navigation.

The first item in the tree is a [Dashboard](#) page, which may be personalized to display unique content for individual users. This way, users can quickly access graphs or tables containing data of the statistics that they need most frequently, view side-by-side comparisons, etc. This can be done by adding (+) the [Analytics chart viewer](#) or [Analytics table viewer](#) widgets from the **Reporting** category, and configuring their properties to display the desired graph or table from a specific report.

Reports that track the statistics and events described in the table below are included in the web analytics tree menu by default:

| Visitors | |
|------------------------|---|
| Countries | <p>This statistic shows from which countries visitors access the website.</p> <p>The countries are recognized according to the IP addresses of visitors, which may not be 100% reliable in all cases, but the overall statistics for a high number of visits should provide correct results.</p> |
| Visitors | <p>Displays the number of unique visits on the website that occurred over the specified time period. A single visit includes any number of page views or other actions performed by a specific user during one session.</p> <p>Also displayed is the ratio between the number of new and returning visitors. A visitor is considered as returning after being inactive for the amount of minutes specified in the Site Manager -> On-line marketing -> Web analytics -> Visitor idle time (minutes) setting. Visitors are recognized according to the presence of a browser cookie.</p> <p>Visitors may additionally be tracked according to their IP address. To enable this functionality, enter a value greater than 0 into the Remember visitors by IP (minutes) setting. This ensures that visitors will be remembered for the specified number of minutes even if their browser does not save cookies.</p> |
| Registered users | Displays the total amount of new users that registered on your website during the specified time period, as well as the names and IDs of individual users. |
| Search crawlers | <p>Displays the number of pages that were visited by search engine web crawlers (robots). Statistics are also provided for individual types of crawlers.</p> <p>Tracking is only done for crawlers whose user agent is specified for one of the search engines registered in the system. Please see Monitoring traffic from search engines for more information.</p> |
| Mobile devices | Displays the number of visitors who accessed the website using a mobile device. The report also provides a comparison between the number of mobile and standard visits, as well as detailed statistics for individual types of mobile devices. |
| Traffic sources | |
| All traffic sources | <p>Displays the number of page views that the website received, categorized according to the type of the traffic source. Three different types of sources are tracked:</p> <ul style="list-style-type: none"> • Direct - page views gained when the URL of one of the website's pages is entered directly into the browser (i.e. no referrer was passed) • Referring sites - page views gained through links from external websites (not including search engine result pages). • Search engines - views generated by search engines. |

| | |
|------------------|---|
| | References from the website's local pages (e.g. navigation menus) are not included in this statistic. |
| Referrals | <p>Lists the full URLs of external pages from which visitors followed links to your website. You can also see the number of page views gained from each referring URL.</p> <p>Note: After applying hotfix 7.0.25 or newer, referrals do not include search engine result pages. The system excludes all URLs that match the Domain rule of one of the search engines defined in <i>Site Manager - > Development -> Search engines</i>.</p> |
| Referring sites | <p>Displays the total amount of page views gained through links from external websites. You can view the statistics for individual website domains.</p> <p>Note: After applying hotfix 7.0.25 or newer, referring sites do not include search engines. The system excludes all websites whose URLs match the Domain rule of one of the search engines defined in <i>Site Manager - > Development -> Search engines</i>.</p> |
| Search engines | <p>Displays the amount of page views generated by visitors who found the website through a search engine, as well as the statistics of individual engines.</p> <p>See Monitoring traffic from search engines for more details.</p> |
| Search keywords | Displays which keywords were entered into search engines in order to find the website and the amount of page views generated by individual keywords. |
| Content | |
| Aggregated views | <p>This statistic tracks access to pages via links in RSS or Atom feeds created using the Syndication module. On the All tab, the total number of pages viewed this way is displayed, as well as the statistics of individual documents.</p> <p>The Multilingual tab contains the same type of data, but page views are categorized and displayed separately according to the content culture of the given pages.</p> |
| File downloads | <p>Displays the number of files downloaded by website visitors and the statistics for individual files. On the All tab, the total statistics are shown for all files regardless of their assigned content culture.</p> <p>The Multilingual tab contains the same type of data, but the number of downloads for files belonging to different content cultures is tracked and displayed separately.</p> <p>Please note that only files stored as documents in the website's content tree are tracked.</p> |
| Invalid pages | Tracks page requests that contain the website's domain name, but specify a path to a page that does not exist. The total amount of invalid |

| | |
|---|--|
| | requests logged during the specified time period can be viewed, and the paths and statistics of individual requests are also displayed. |
| On-site search keywords | Displays the total number of searches that were performed using the website's local search functionality and the keywords that were entered. |
| Page views | <p>Monitors how many times the website's pages were viewed by visitors. On the All tab, the displayed data includes the total amount of views for the entire website, and specific information for individual pages. If a page is available in multiple content cultures, the view count of all its versions is added together and tracked as a single page.</p> <p>The Multilingual tab contains the same type of data, but the views of pages that belong to different content cultures are tracked and displayed separately.</p> <p>Only pages that are served by Kentico CMS are included in the statistics.</p> |
| Top landing pages | <p>Displays which pages are the first ones viewed by visitors when they start their browsing session on the website. On the All tab, all culture versions of particular landing pages are tracked together as a single page.</p> <p>The Multilingual tab may be used to view separate statistics for individual page versions that belong to different content cultures.</p> |
| Top exit pages | <p>Keeps track of the final pages that were visited by users when their browsing session ended. On the All tab, all culture versions of particular exit pages are tracked together as a single page.</p> <p>The Multilingual tab may be used to view separate statistics for individual page versions that belong to different content cultures.</p> |
| Campaigns & conversions | |
| Campaigns | This category contains reports used to track the progress of marketing campaigns and evaluate their results. Further information can be found in the Campaigns sub-chapter. |
| Conversions | Displays the number of conversions that were performed on the entire website by users over the specified time period. The statistics of individual conversions are also included. To learn more about conversions, please see the Conversions sub-chapter. |
| Browser capabilities | |
| Browser types | This statistic shows what type of browsers are used by visitors to view the website. The name and version number of each visitor's browser is logged, for example: <i>FireFox3.6</i> |
| Please note: The statistics below can only be tracked for visitors who access a page that contains the Analytics browser capabilities web part. | |
| Flash support | Tracks if the browsers used by visitors support viewing of Flash animations and videos. |

| | |
|---------------------|---|
| Java support | Tracks if the browsers used by visitors support Java applets. |
| Operating system | This statistic logs which operating systems are used by the website's visitors. |
| Silverlight support | Tracks if the browsers used by visitors support Microsoft Silverlight. |
| Screen colors | Tracks the color depth that can be displayed in the visitors' browsers. |
| Screen resolution | Logs the screen resolution used by the website's visitors. |

Tracking browser capabilities

If you wish to log detailed browser information other than the type and version, it is necessary to use the [Web analytics -> Analytics browser capabilities](#) web part. You can choose which statistics should be tracked by configuring the properties of the web part.

This web part utilizes JavaScript to collect the necessary data, which may in some cases interfere with other scripts on the page, so it is up to the website's developers to determine where it should be located.

To provide the most accurate statistics, it is recommended to place the web part on a page that most visitors will pass through, such as the website's default page or a frequently used landing page.

The reports in the **Optimization** category are used to display the statistics of page optimization tests. Information about these sections can be found in the chapters dedicated to the [A/B testing](#) and [Multivariate testing](#) modules.

Viewing a web analytics report

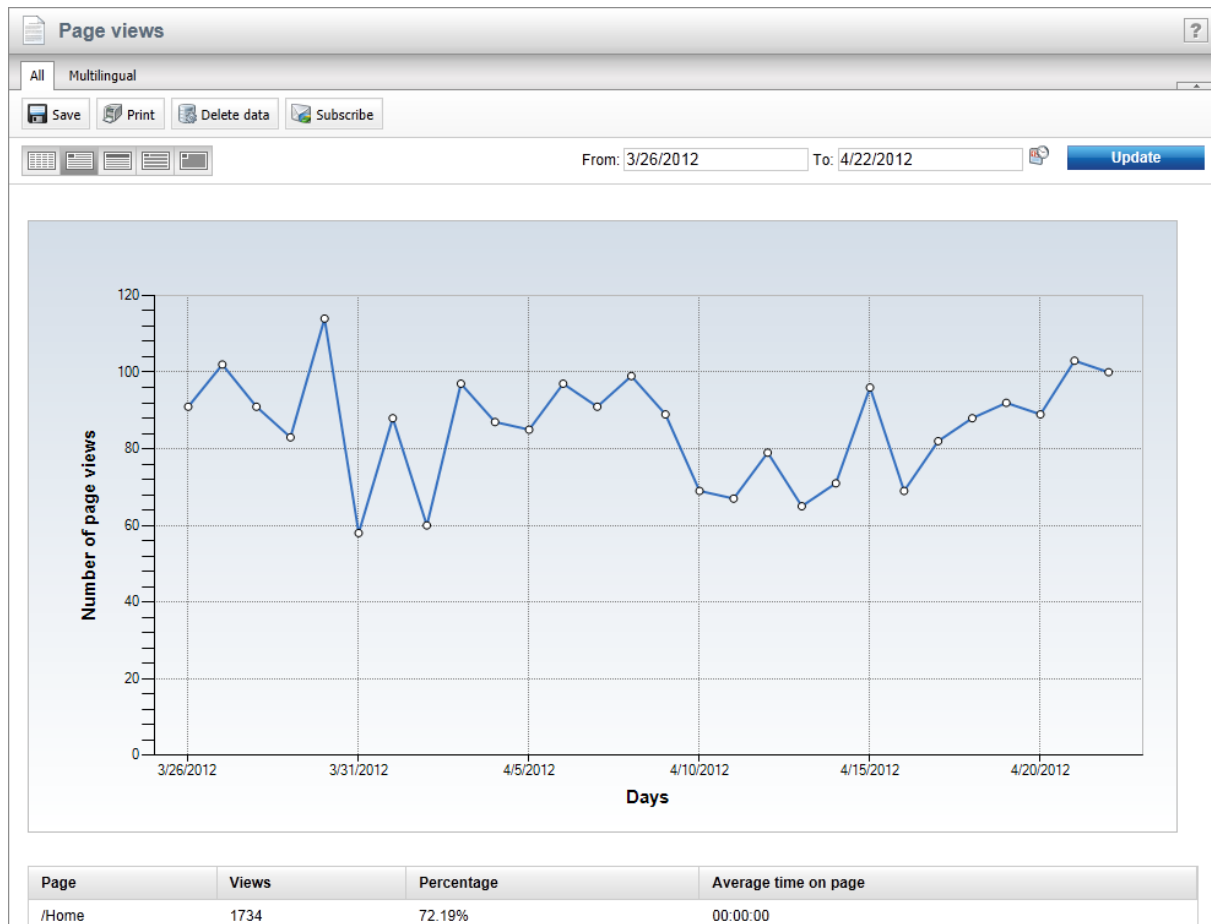

When a statistic is selected from the tree menu in the web analytics interface, its report will be displayed on the right. For most statistics, the data is organized into a graph showing the hits measured over time and a table containing detailed information for individual objects.

The **From** and **To** fields on the right can be used to enter a time period for the report. Only hits that were logged for the statistic during the specified interval will be included in the displayed data.

The following options allow you to choose which unit of time should be used in the statistic's report:

-  **Hour**
-  **Day**
-  **Week**
-  **Month**
-  **Year**

This selection determines the length of time which is represented by individual units on the horizontal axis of the report's graphs (if there are any) and the precision that can be specified in the **From** and **To** fields.

The following actions may also be performed for every report:

- **Save** - saves the report in its current state (according to the selected time interval). To view saved reports at a later time, go to *CMS Desk* -> *Tools* -> *Reporting*, select the matching report under the *Web analytics* category and switch to the *Saved reports* tab.
- **Print** - allows the report to be printed. The available options depend on the used browser.
- **Delete data** - clears all data measured for the given statistic. Please note that this permanently removes all of the statistic's hits from the database. This action is only available for users who have the *Manage data* permission for the Web analytics module. It is also possible to delete data for all statistics at once, as described in the [Managing analytics data](#) topic.
- **Subscribe** - opens a new dialog where you can [subscribe to the report](#). Subscribing allows users to periodically receive e-mails with the up-to-date content of the given report. It is also possible to subscribe to a specific reporting component (graph or table) by right clicking on it and selecting the *Subscribe to* option in the displayed context menu.

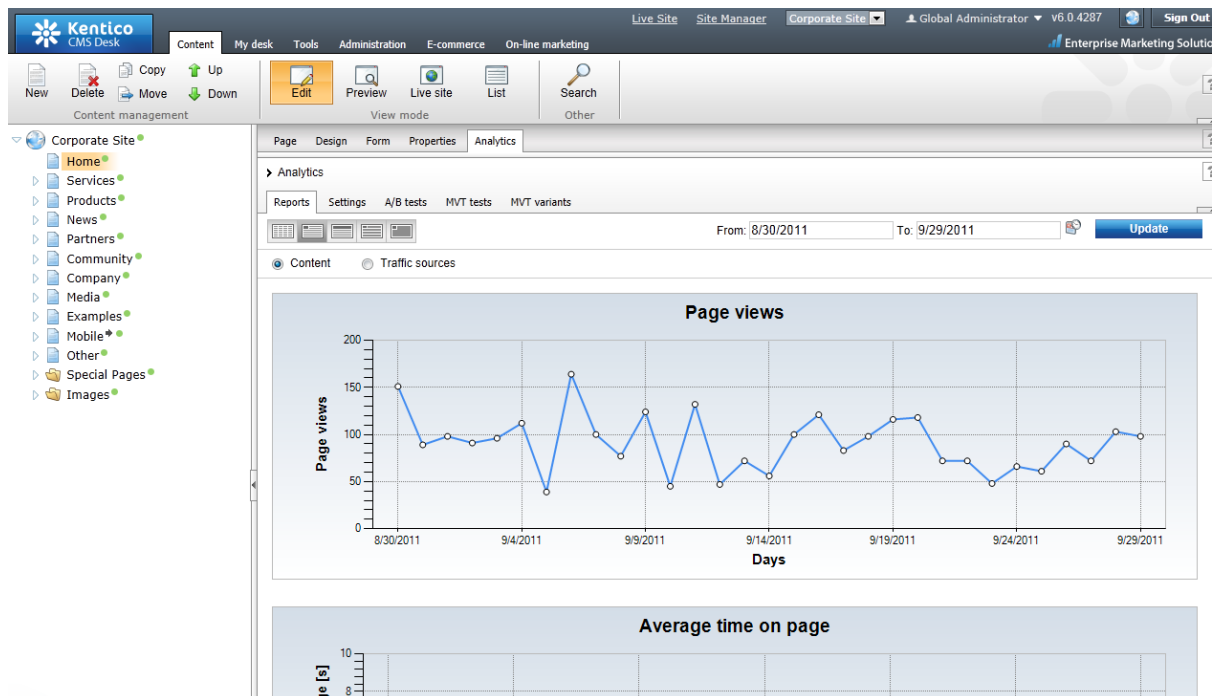

The data displayed in the reports may also be exported into external files using various formats. This can be done by right clicking on a graph or table in the given report, which will open a context menu offering the following export options:

- **Export to Excel** - exports the data displayed by the given object to an XLSX spreadsheet.
- **Export to CSV** - exports data to a CSV file.
- **Export to XML** - exports data to an XML file.

After you select an action from the menu, your browser's standard file download dialog will pop up, letting you open or save the file with the exported data just like when downloading any other type of file. For more details on the data export feature, please refer to the [Modules -> UI data export](#) chapter of this guide.

Reports for individual pages

It is also possible to view the values of web analytics statistics measured for specific website pages. To do this, go to **CMS Desk -> Content -> Edit** and select the document representing the page that you wish to examine. Then switch to the **Analytics** tab and select **Reports**.

A time interval can be specified for the reports here and their data may be exported in the same way as when using the main web analytics interface.

The reports for each page are divided into two categories:

- **Content:**

| | |
|----------------------|--|
| Page views | Shows how many times the given page was accessed by the website's visitors during the specified time interval. |
| Average time on page | Displays the average time that visitors spend viewing the given page (measured in seconds). |
| Landing page | Counts how many times the given document served as a landing page for the website's visitors. A landing page is the first page viewed when a visitor starts their browsing session on the website. |
| Exit page | Counts how many times the document was an exit page for a visitor. An exit page is defined as the last page visited by a user before their |

| | |
|--|-------------------------|
| | browsing session ended. |
|--|-------------------------|

- **Traffic sources:**

| | |
|-----------------------|---|
| Traffic sources | <p>Displays the statistics of the traffic sources that generated the document's page views. Four different types of sources are tracked:</p> <ul style="list-style-type: none"> • Direct - page views gained when the URL of the page was entered directly into the browser (i.e. no referrer was passed). • Referring local pages - views gained as a result of references (links) from other pages on the given website (e.g. through a navigation menu). • Referring sites - views gained through links from external websites (not including search engine result pages). • Search engines - views generated by visitors who found the page using a search engines. |
| Search engines | This table contains the names of the search engines that visitors used to find the given page and the amount of page views generated by each engine. |
| Search keywords | Contains the keywords that were entered into search engines in order to find the page and the page view statistics of individual keywords. |
| Referring sites | <p>Displays the domain names of external sites from which visitors were linked to the given page. You can view the statistics for individual sites.</p> <p>Note: After applying hotfix 7.0.25 or newer, referring sites do not include search engines. The system excludes all websites whose URLs match the Domain rule of one of the search engines defined in <i>Site Manager - > Development -> Search engines</i>.</p> |
| Referring local pages | Contains the alias paths of the local website's pages from which visitors were linked to the given page and the amount of views gained from each page. |
| Crawlers | Shows how many times and how recently the page was visited by search engine web crawlers (robots). Tracking is only done for crawlers whose user agent is specified for one of the search engines registered in the system. |

8.51.4 Conversions

8.51.4.1 Overview

The web analytics module provides a way to track actions that can be performed by your website's visitors and record them as *conversions*. This is typically done for desired events that somehow benefit the website, such as the registration of a new user, a product order, subscription to a newsletter or similar. Conversions are represented in the system by corresponding tracking objects, which are described in more detail in [Managing conversions](#).

Once an action is defined as a conversion, a *conversion hit* is logged whenever it occurs. Additionally, a numerical value may be stored along with each hit to indicate its importance. To learn how you can

assign conversions to individual types of actions and ensure that they are logged correctly, please refer to the [Logging actions as conversions](#) topic.

Once you start tracking conversions on the live site, you can compare the recorded statistics with the values of other web analytics metrics, such as the total amount of visitors. This allows you to evaluate the website and adjust it as necessary.

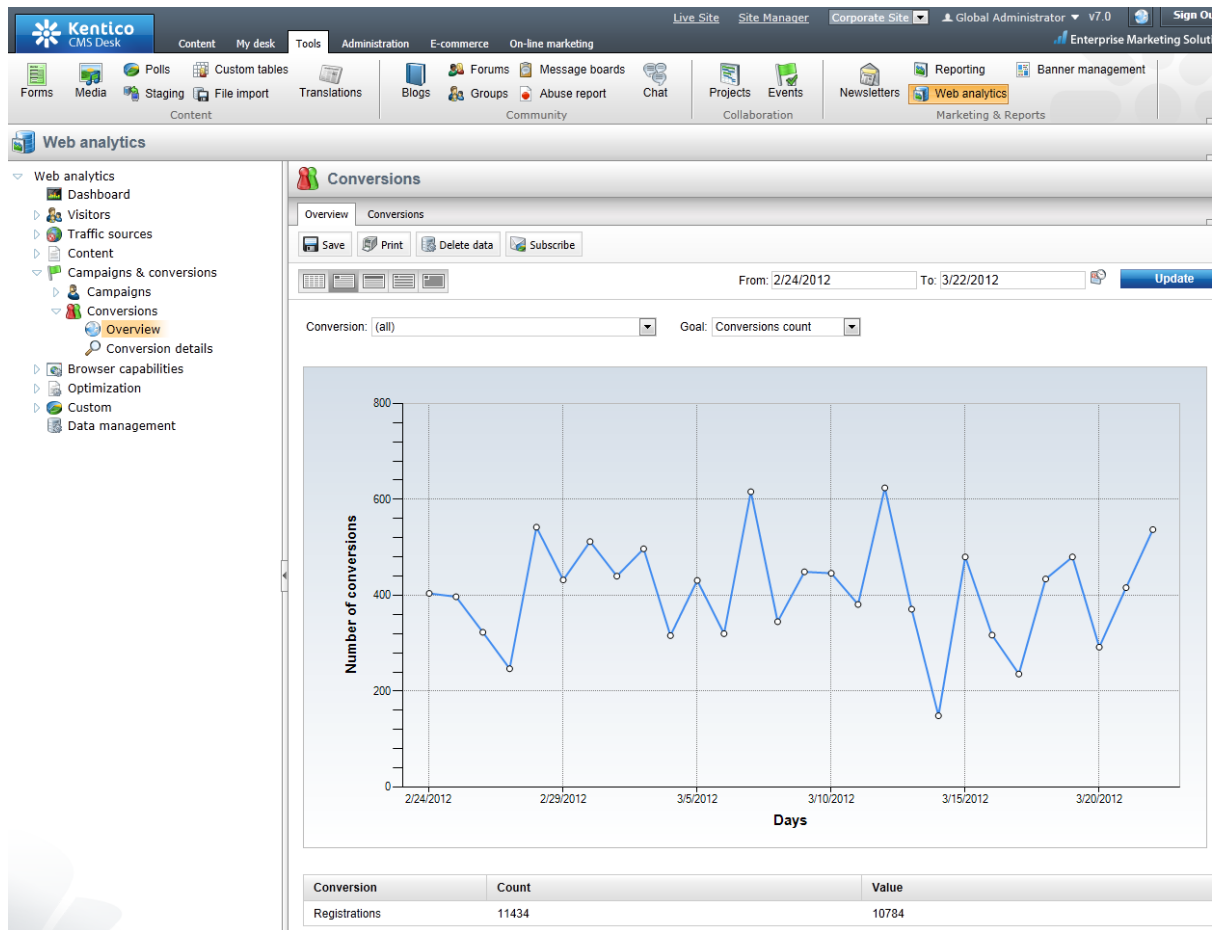

While simply tracking all conversions that occur on the website can be useful, in many cases you may also require additional information about the context in which the given actions occurred. For this reason, conversion tracking is integrated with several other web analytics and on-line marketing features. When used together with [Campaign tracking](#), conversions allow you to record actions only for visitors who arrive on the website in a specific way (e.g. as a result of a marketing campaign).

If you wish to optimize your site to increase its conversion rate (i.e. make it more user friendly to get better results), you may utilize [A/B](#) or [Multivariate](#) testing. These features allow you to accurately measure how changes made to the content or structure of your website's pages affect the behavior of users.

8.51.4.2 Managing conversions

To access the management interface dedicated to conversions, go to **CMS Desk -> Tools -> Web analytics**, expand the **Campaigns & conversions** category in the tree on the left and select **Conversions**. This section of the UI may alternatively be reached by navigating to **On-line marketing -> Conversions**.

The **Overview** contains a [web analytics report](#) displaying the conversions that were logged on the website over the specified time period.

This report only provides a general overview of the conversion statistics. Additional information about conversions that were logged under special circumstances is available in the **Conversion details** report and in the specialized reports under the **Campaigns** and **Optimization** -> **A/B tests** or **MVT tests** categories.

If you switch to the **Conversions** tab, you can view a list of all conversions defined for the current site and manage them as necessary.

The screenshot shows the 'Conversions' administration interface. It includes a 'New conversion' button and a table listing existing conversions:

| Actions | Conversion name | Count | Value |
|---------|-----------------|-------|-------|
| | Page views | 40753 | 81506 |
| | Registration | 40216 | 80432 |

To define a new conversion, click **New conversion** and fill in the following properties in the displayed dialog:

- **Conversion display name** - the name of the conversion displayed in the administration interface.

- **Conversion code name** - sets a code name that serves as a unique identifier for the conversion.
- **Conversion description** - can be used to enter text describing the conversion's purpose.

The entered data may be modified at any time by editing (✎) the given conversion object on the **General** tab.

The **Campaigns** tab allows you to configure which campaigns should track the currently edited conversion as part of their statistics. By default, campaigns log all possible conversions, so it is only necessary to assign campaigns that are configured to work with a limited set of conversions. This type of configuration is not available for A/B or multivariate tests, which automatically keep track of all conversions performed on the website.

As you can see, the objects representing conversions are very simple and do not require any advanced configuration. It is however necessary to assign the conversions to the appropriate actions to ensure that they are logged correctly. This can be done through various other parts of the Kentico CMS administration interface as described in the [Logging actions as conversions](#) topic.

8.51.4.3 Logging actions as conversions

This topic describes the possible options that may be used to ensure that the system logs specific events as conversions. When assigning a conversion through the user interface, two types of fields are provided.

The screenshot shows a 'Conversion tracking' configuration panel. It contains two main sections. The first section is labeled 'Track conversion name:' and features a dropdown menu with the text 'Product_order' selected. To the right of the dropdown are three buttons: 'Select', 'Edit', and 'New'. The second section is labeled 'Conversion value:' and features a text input field containing the number '50'.

The first is a standard conversion selector. You can either enter the *code name* of a conversion into the text box or click the **Select** button to choose from a list of conversions defined for the current site. If you enter a name that does not match any conversion in the system, a conversion with this name will automatically be added. The **New** and **Edit** buttons allow you to create a new conversion or modify the properties of the selected one directly from the given part of the user interface.

The second field is optional and provides a way to set a number that will be recorded along with the conversion when the tracked action is performed. This may be used to indicate the relative importance of the conversion, the profit generated by a single conversion hit or similar. The values are cumulative, i.e. when a conversion hit is logged, the specified value will be added to the total sum previously recorded for the conversion. You may insert a [Macro expression](#) into this field to dynamically retrieve a value from the current site context. For examples of conversion value macros, please see the sections below dedicated to individual types of actions.

Web part and widget actions

Many of the default Kentico CMS [Web parts](#) and [Widgets](#) that allow users to perform important actions come with built-in support for conversion tracking. To configure a specific web part or widget instance to log actions as conversions, open its properties dialog and enter the appropriate values into the **Track conversion name** and **Conversion value** properties.

The screenshot shows the 'Web part properties (Registration form)' dialog box. The 'Conversion tracking' section is highlighted with a red box. It contains the following fields:

- Design:** Skin ID: [text box]
- Conversion tracking:**
 - Track conversion name: [text box with value 'User_registration'] [Select] [Edit] [New]
 - Conversion value: [text box with value '10']
- Web part container:**
 - Web part container: [dropdown menu with value 'Corporate site - Light gradient box'] [Edit] [New]
 - Container title: [text box with value 'Not a member yet? Sign up now!']
 - Container CSS class: [text box]
 - Container custom content: [text box] [More options]

At the bottom, there is a 'Refresh content' checkbox and 'OK', 'Cancel', and 'Apply' buttons.

Below you can find a list of all types of actions that can be tracked as conversions through web parts:

| Action | Web part(s) |
|-------------------------|---|
| User registration | <p>In this case, the conversion will be logged when a visitor successfully completes their registration using the given web part. There are multiple web parts that allow users to register on the website:</p> <ul style="list-style-type: none"> • Registration form • Custom registration form • Facebook Connect logon and Facebook Connect required data • LinkedIn logon and LinkedIn required data • Windows LiveID and LiveID required data • OpenID logon and OpenID required data |
| Newsletter subscription | <p>Newsletter subscriptions may be tracked as conversions through the Newsletter subscription or Custom subscription form web part. This can also be done for the widget based on the web part.</p> |
| Shopping cart actions | <p>The Shopping cart web part may be used to track two types of events:</p> <ul style="list-style-type: none"> • Registration - occurs when a customer registers on the website through the shopping cart. • Order - logged when a customer successfully completes an order. <p>You can assign conversions to these actions for specific instances of</p> |

| | |
|----------------------------|--|
| | the shopping cart web part through the corresponding conversion name properties. The conversion values of these events can be configured for the entire website via the e-commerce website settings described in a dedicated section below. |
| Filling in an on-line form | A conversion can be logged when a user submits a form displayed by the On-line form web part. |
| Voting in a poll | The Poll web part may be used to log a conversion whenever a user votes in the displayed poll. |

Entering conversion value macros into web part properties

The **Conversion value** properties of web parts only support numeric (decimal) values, so it is not possible to specify a macro expression directly. However, you can enter macros via the **Edit value** dialog that can be opened by clicking the  icon next to the given property.

In the case of widgets, macros entered by users into properties are not resolved at all. If necessary, macro expressions can be pre-set as the default values of widget properties by administrators. This can be done by editing the given widget in **Site Manager -> Development -> Widgets** on the **Properties** tab.

Page views of specific documents

You can also use conversions to keep track of the amount of hits received by individual pages. To configure this behavior for a page, go to **CMS Desk -> Content -> Edit**, select the document representing the given page from the content tree and switch to its **Analytics -> Settings** tab. To assign a conversion and associated value, fill in the **Track conversion name** and **Conversion value** fields as described above.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', and 'On-line marketing'. The left sidebar shows a content tree with 'Corporate Site' expanded, containing folders like Home, Products, News, Partners, Community, Services, Company, Media, Examples, Mobile, Other, Special Pages, and Images. The main workspace is in 'Edit' mode. The 'Analytics' tab is active, showing the 'Settings' sub-tab. A 'Save' button is visible. The configuration fields are as follows:

| | | | | |
|------------------------|----------------------------------|--------|------|-----|
| Track campaign: | <input type="text"/> | Select | Edit | New |
| Track conversion name: | Product_catalog_views | Select | Edit | New |
| Conversion value: | <input type="text" value="0.5"/> | | | |

The specified conversion will be logged every time the given page is requested by the website's users.

E-commerce actions

Conversions may be configured for e-commerce actions that occur on the entire website using the settings in **Site Manager -> Settings -> E-commerce**. There are three types of events that can be tracked:

- **Registration** - occurs when a customer registers on the website through the checkout process.
- **Order** - logged when a customer successfully places a product order.
- **Add to shopping cart** - occurs when a user adds a product to a shopping cart on the website.

You can assign a different conversion and value to each of these actions through the appropriate **conversion name** and **conversion value** settings. The registration and order conversion name settings can be overridden for individual instances of the shopping cart web part through their corresponding properties.

If you wish to log the conversion value dynamically based on item prices, you may use macro expressions, for example:

Order conversion value: `{% EcommerceContext.CurrentShoppingCart.TotalPrice %}`

This macro is resolved into the total price of all items contained in the order, including tax and shipping. With this configuration, each *Order* conversion will automatically store the price of the given order as its value.

Add to shopping cart conversion value: `{% ShoppingCartItem.UnitTotalPrice %}`

With this macro as the conversion value, the *Add to shopping cart* conversion will log the price (including tax) of the specific product that was added to the shopping cart.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', 'Support', and 'Buy'. The left sidebar shows a tree view of settings categories, with 'E-commerce' selected. The main content area is titled 'E-commerce' and contains three sections: 'Pages', 'E-mails', and 'Conversion tracking'. The 'Conversion tracking' section is highlighted with a red border and contains the following settings:

| Setting | Value |
|---------------------------------------|---|
| Registration conversion name | Customer_registration |
| Registration conversion value | |
| Order conversion name | Order_completed |
| Order conversion value | {% EcommerceContext.CurrentShoppingCart.Total |
| Add to shopping cart conversion name | |
| Add to shopping cart conversion value | |

The settings described above allow you to track entire orders, but in some cases you may wish to log a separate conversion hit every time a product of a specific type is purchased. This can be done by navigating to the product list in **CMS Desk -> E-commerce -> Products** and selecting the particular product (or when editing a product document in the main content tree on the **Form** tab).

The screenshot displays the Kentico CMS interface for editing a product. The breadcrumb trail is: Products > Laptops and Tablets > HP EliteBook 8440p WJ681AW. The 'Analytics' section at the bottom is highlighted with a red border and contains the following configuration:

| Property | Value | Buttons |
|-------------------|---------------------------------------|-----------------|
| Conversion name: | Product_order | Select Edit New |
| Conversion value: | {% ShoppingCartItem.UnitTotalPrice %} | |

Here you can assign a conversion through the **Conversion name** property at the bottom of the product's editing page.

The **Conversion value** field can be used to specify an appropriate value that will be recorded for each conversion hit. In addition to numeric values, you may enter macro expressions here, for example: `{% ShoppingCartItem.UnitTotalPrice %}`. This macro allows the conversion to log the price of the given product as its value. The advantage of a macro is that it retrieves the price dynamically, including tax and any potential discounts applied by the given customer.

Please note that these properties are not available for global products, since each site has its own separate set of conversions.

You can also use the same approach to configure different conversion settings for individual product options (via **E-commerce** -> **Product options** -> **edit Category** -> **Options**).

Logging conversions using the API

If you need to track some other type of action that is not included among the options listed above, you can write your own custom code and use the API to log conversions. This allows you to monitor any type of activity performed by users on your website and view the results using the various conversion

reports available in the web analytics interface.

To log a conversion via the API, you can use code similar to the following:

[C#]

```
using CMS.WebAnalytics;
using CMS.CMSHelper;

...

string siteName = CMSContext.CurrentSiteName;
string aliasPath = CMSContext.CurrentAliasPath;

// Checks that web analytics and conversion tracking are enabled in the site's
// settings.
// Also confirms that the current IP address, alias path and URL extension are not
// excluded from web analytics tracking.
if (AnalyticsHelper.IsLoggingEnabled(siteName, aliasPath)
    && AnalyticsHelper.TrackConversionsEnabled(siteName))
{
    // Logs the conversion according to the specified parameters.
    HitLogProvider.LogConversions(siteName, CMSContext.PreferredCultureCode,
    ConversionName, 0, 1, ConversionValue);
}
```

There are several possible ways to include this type of code in your website's functionality. When tracking activity on a specific page, you may use a custom [user control](#) or [web part](#) to ensure that the code is executed as required. If you wish to log actions that may occur anywhere on the website, you may utilize [global event handlers](#).

As shown above, conversions can be logged using the **HitLogProvider** class from the **CMS.WebAnalytics** namespace, specifically the following method:

LogConversions(string siteName, string culture, string objectName, int objectId, int count, double value)

- **siteName** - sets the code name of the site for which the conversion should be logged.
- **culture** - sets the culture code under which the conversion should be logged.
- **objectName** - used to specify the code name of the conversion that should be logged.
- **objectId** - used to specify the ID of the conversion. This parameter may be set to 0 if a valid code name is passed via the *objectName*.
- **count** - sets the amount of conversion hits that should be logged. This parameter is optional and the default value (1) is used if it is not specified.
- **value** - specifies the value that will be logged for the conversion.

In addition to logging a general conversion, this method checks if the current user has passed through a page with a running [A/B](#) or [Multivariate test](#), or has arrived on the website through a [Campaign](#). If this is the case, then the conversion is also automatically logged within the appropriate context and included in the statistics of the given test or campaign.

8.51.5 Campaigns

8.51.5.1 Overview

One of the most common techniques used to bring new traffic to a website are on-line marketing campaigns. When attempting to determine if a campaign was cost-effective or when measuring its exact results, simply tracking referring sites or URLs may not always provide sufficient data.

In these cases, the campaign tracking support provided by the web analytics module may be used, which allows you to accurately monitor traffic generated by individual campaigns. This can include banners, marketing e-mails or any other method used to present links to your website. In addition to logging the amount of visits, this feature lets you keep records of any important actions performed on the website by users who arrive as a result of a campaign.

How the tracking works

There are several ways to identify visitors who come to your site through a campaign link (further details can be found in the [Managing campaigns](#) topic). When this happens, the system updates the visit statistics and stores a cookie named **Campaign** in the user's browser, which saves the name of the corresponding campaign tracking object as its value. Only one campaign may be assigned to a user at a given time and the current value is overwritten if the user returns to the site through a different campaign.

Until the cookie expires (its duration is 24 hours), any actions performed by the visitor that are defined as conversions will be logged as part of the statistics kept for the campaign. Please refer to the [Conversions](#) chapter for information about how the tracking of individual actions can be configured.

If the visitor registers on the website while the cookie is still valid, the name of the currently active campaign will be permanently stored in their user settings (administrators may view the value in **Administration -> edit (✎) user -> Settings -> Campaign**). This data field only serves to provide information about users and is not used to track activity on the website.

Campaign statistics and results can be viewed using special reports available in the web analytics interface, which are described in the [Evaluating campaigns](#) topic.

8.51.5.2 Managing campaigns

Each marketing campaign is represented in the system by a corresponding object. To configure these objects, go to **CMS Desk -> Tools -> Web analytics** and expand the **Campaigns & conversions -> Campaigns** category in the tree. Now select one of the displayed items and switch to the **Campaigns** tab on the right side of the page (alternatively, this interface may be accessed through **CMS Desk -> On-line marketing -> Campaigns**).

Here you can view the list of all campaigns defined for the current website and manage them as needed.

| Actions | Campaign name ^ | Open from | Open to | Enabled |
|---------|--------------------|----------------------|-----------------------|---------|
| | Banner Campaign Q2 | | | Yes |
| | Blog references | | | Yes |
| | Newsletters Q1 | 1/1/2012 11:20:57 AM | 3/31/2012 11:21:05 AM | No |

To create a new campaign, click **New campaign** and fill in the following properties:

- **Campaign display name** - the name of the campaign displayed in the administration interface (in campaign lists and reports).
- **Campaign name** - sets a code name that serves as a unique identifier for the campaign. It is also stored as the value of the *Campaign* browser cookie used to identify visitors who came to the website through the given campaign.
- **Campaign description** - can be used to enter a text description for the campaign in order to give information about its purpose, goals, etc.
- **Open from/to** - sets the time interval during which the campaign should be active. The *Calendar* button () can be used to select an exact date and time.
- **Enabled** - this property may be used to manually start or stop the campaign. Visitor statistics and actions will not be logged for disabled campaigns.

Click **Save**. The **General** tab of the campaign's editing interface will now be displayed, where you can modify the fields listed above at any time. Several additional properties are also available.

General Goals Conversions

Save

Campaign basic settings

Campaign display name:

Campaign name:

Campaign description:

Open from: Now

Open to: Now

Enabled:

Advanced campaign settings

Campaign impressions:

Total cost:

Campaign condition:

The **Campaign impressions** and **Total cost** values may be used to help evaluate the campaign and calculate its goals (for more information, please see [Evaluating campaigns](#)).

An important property is the **Campaign condition**, which allows you to specify a macro condition that must be fulfilled in order for visitors to be included in the campaign. Through the edit icon () you can use the [Macro condition editor](#), which provides a way to build conditions through a graphical interface.

For example: `Cookies.Campaign != "banner1"`

This sample condition checks the value of the `Campaign` cookie and prevents the edited campaign from being assigned to visitors who are already being tracked by a different campaign named **banner1**. You can write any other type of condition according to your specific requirements. For details about available macro options and syntax, please refer to the [Development -> Macro expressions](#) chapter.

If you switch to the **Conversions** tab, you can configure which [conversions](#) should be tracked by the campaign. There are two possible options:

- **All conversions will be tracked for the campaign** - if chosen, any conversion hit logged on the entire website will be included in the campaign's statistics.
- **Only the selected conversions will be tracked for the campaign** - this option allows you to limit which conversions should be tracked. Specific conversions may be assigned to the campaign by clicking the *Add conversions* button and choosing from the list in the displayed dialog.

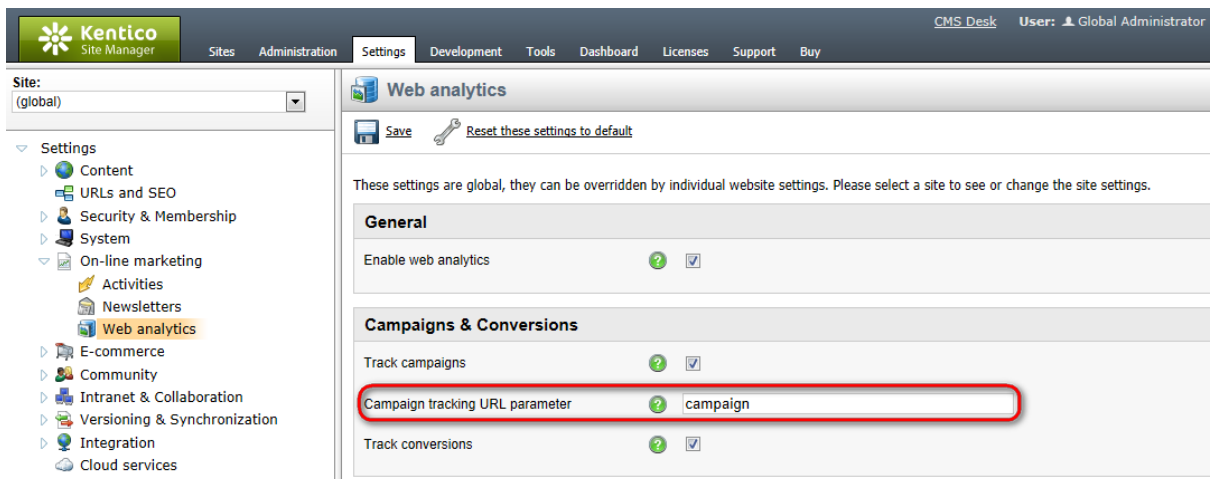

In both cases, only conversions performed by visitors who arrive on the website as a result of the given campaign will be logged.

Configuring campaign tracking

In order to correctly identify visitors who access the website through a marketing campaign and ensure that they are assigned to the appropriate campaign tracking object, you can use one of the three approaches described below.

1. URL parameter

This method utilizes a URL query string parameter to indicate that the traffic source is a campaign. All you need to do is enter the name of the parameter that you wish to use into the **Site Manager -> Settings -> On-line marketing -> Web analytics -> Campaign tracking URL parameter** setting (e.g. *campaign*).

Then, ensure that all link URLs used in the campaign's marketing materials contain this parameter, with the name of the appropriate campaign object as the value. For example:

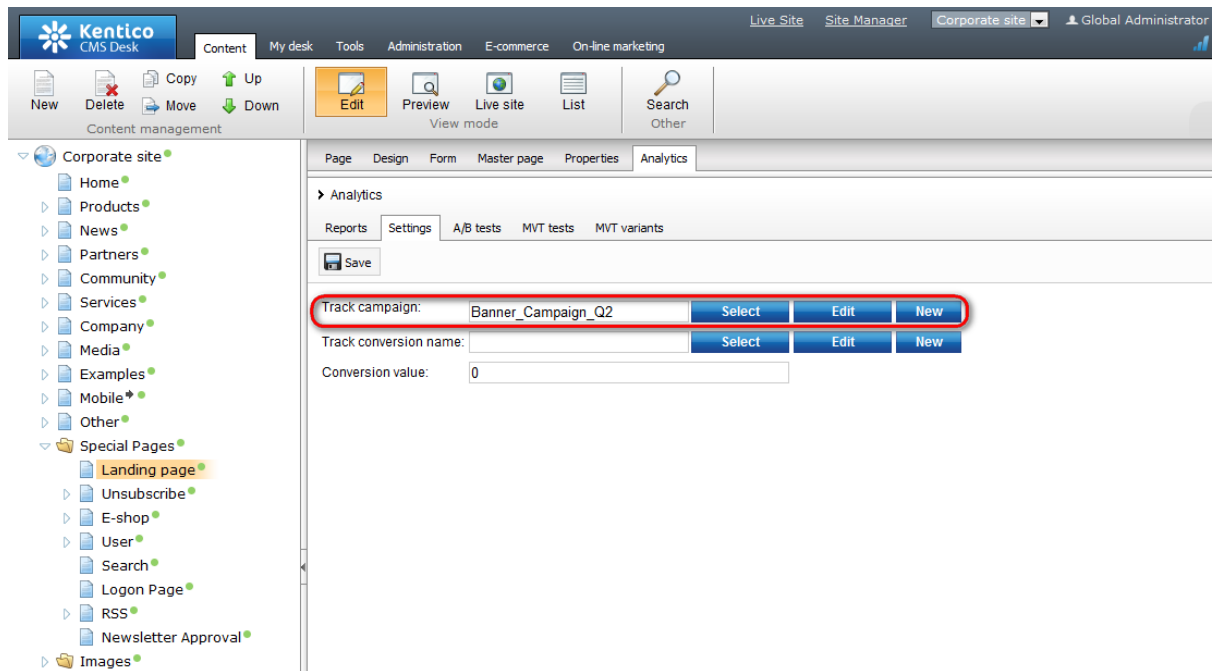

http://www.mywebsite.com/Home.aspx?campaign=banner1
http://www.mywebsite.com/News.aspx?campaign=newsletterJune

This type of campaign tracking is not limited to a specific document and works for all pages on the website.

2. Document specific campaigns

Alternatively, you can configure a document to behave as a campaign landing page. When this type of page is viewed by a user, a specified campaign will automatically be assigned. A visit will also be logged for the campaign every time the document is requested.

To enable this functionality for a page, go to **CMS Desk -> Content -> Edit**, select the given document from the content tree and switch to its **Analytics -> Settings** tab. Here, enter the name of a campaign into the **Track campaign** field. The **Select** button allows you to choose from a list of existing campaign objects available for the website. **Edit** and **New** may be used to manage campaigns directly from this dialog.

To ensure accurate campaign tracking, it is recommended to create a special page that will not be available in the website's standard navigation, since the campaign will be assigned to all users who view this page (and repeated views by the same user will also be logged as campaign visits). When using this approach, all of the campaign's links need to be directed at this special landing page.

3. Campaigns for document aliases

You can also define campaign tracking for a page's specific [document alias](#). This approach is useful if you wish for the campaign to link visitors to an easily accessible page, but want to avoid using a query string parameter. The campaign will only be assigned to users who access the document through this alias.

To add a document alias to a page, select it from the content tree in **CMS Desk** and go to **Properties -> URLs**. Here, click **Add new alias** and configure its settings in the displayed dialog. Select **Standard URL or wildcard**, enter a suitable path into the **Path or pattern** field and then specify the name of the campaign in the **Track campaign** property.

Click **OK** to create the alias. Now you can use the URL of this alias in the campaign's links, for example: <http://www.mywebsite.com/Campaigns/Home.aspx>

The campaign tracking methods are listed in the order of their priority. So if a campaign is specified for a document through **Settings -> Analytics**, but the page is accessed via a URL containing a tracking parameter, the campaign specified via the parameter will be assigned to the given visitor.

Automatic campaign creation

When a visitor comes to the website through an undefined campaign (typically specified via the tracking URL parameter), it will be ignored by default and no campaign tracking will be performed.

If you wish to change this behaviour, edit your application's web.config file and add the following key to the **/configuration/appSettings** section:

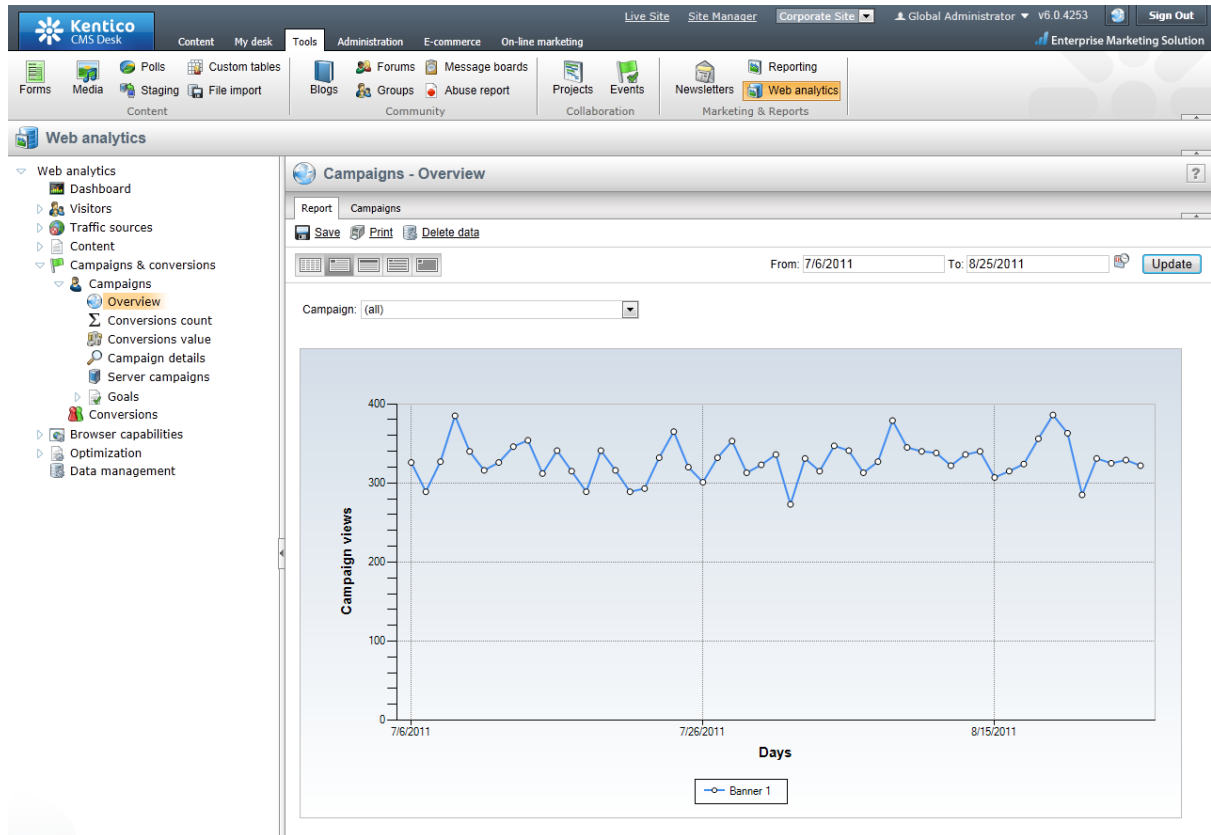

```
<add key="CMSEnableAutomaticCampaignCreate" value="true" />
```

Once this is done, unknown campaigns will automatically be added to the list of campaign objects for the given website.

Campaigns created this way will be enabled by default and active for an unlimited time interval, but they can be configured using the same approach as mentioned above at any time.

8.51.5.3 Evaluating campaigns

The statistics logged for campaigns may be viewed using various types of web analytics reports. To access these reports, go to **CMS Desk -> Tools -> Web analytics** and expand the **Campaigns & conversions -> Campaigns** category.

Campaign reports use the same basic format as other web analytics reports, so please see the [Web analytics reports](#) topic for information about the actions that can be used to specify which data should be displayed. The following types of reports are available for campaigns:

| | |
|-------------------|---|
| Overview | Displays the amount of hits that the website received as a result of the selected campaign(s). It contains a line chart that shows the number of visits recorded over time and a table with the total amount of page views generated by the given campaigns during the entire time period. |
| Conversions count | Displays the number of conversion hits that were performed by users who arrived on the website through the selected campaign.

This report includes two types of charts, one that shows the progress of the amount of conversion hits recorded during the specified time period and another with detailed statistics for individual units of time according to the selected report type (hours, days, months etc.). |
| Conversions value | Displays the sum of the conversion values generated by users who arrived on the website through the selected campaign. |

| | |
|------------------|---|
| | This report includes two types of charts, one that shows the progress of the conversion values recorded during the specified time period and another with detailed statistics for individual units of time according to the selected report type. |
| Campaign details | <p>Displays the values of the following campaign metrics:</p> <ul style="list-style-type: none"> • Visits - the amount of hits that the website received as a result of the given campaign. • Conversions - the number of conversions that were performed by users who arrived on the site through the campaign. • Conversions rate - the percentage of visitors that performed a conversion. This can be higher than 100% if the average visitor generated more than one conversion. • Conversions value - the total sum of the values recorded for all of the campaign's conversions. • Conversions value per visit - the average conversion value contributed by the campaign's visitors. • Total cost - shows the total cost that was specified for the given campaign. • ROI - the rate of investment, calculated as the sum of the campaign's conversion values divided by the total cost. This statistic is accurate only if your conversion values are set to reflect the income generated by the matching conversions. <p>You can either choose to view all campaigns defined for the website and compare their values, or select a specific campaign and analyze the statistics logged for individual types of conversions.</p> |
| Server campaigns | May be used to compare the results of campaigns created for different sites in the system. You can choose to display the <i>Views</i> , <i>Conversion count</i> or <i>Conversion value</i> statistics for the campaigns belonging under the selected site. |

Campaign goals

In addition to the data provided by the reports listed above, you can optionally specify goals that should be achieved by each campaign and then compare them with the actual results.

To enter a campaign's goals, select any of the reports, switch to the **Campaigns** tab, and edit (✎) the given campaign. On the **General** tab, the following two properties are available among the advanced settings:

- **Campaign impressions** - this field can be used to specify how many people were targeted by the given marketing campaign. For example, if you sent marketing e-mails containing a link to the website to ten thousand people, the amount of impressions would be 10000.
- **Total cost** - allows you to manually enter the total cost of the given marketing campaign. This can be used to determine whether the campaign was a success and when calculating the campaign's goals.

Now switch to the **Goals** tab, where you can configure the following types of target values for the campaign:

- **Number of visitors** - sets how many visitors should be brought to the website by the campaign. It can either be specified directly as an *Absolute* number, or as a percentage of the campaign's *Impressions* according to the value set on the *General* tab.
- **Number of conversions** - specifies the expected amount of conversions performed by users who visit the website as a result of the campaign. It can either be specified directly as an *Absolute* number, or as a percentage of the campaign's *Impressions*.
- **Total value of conversions** - sets a target number for the sum of all conversion values logged as a result of the campaign. It can either be specified directly as an *Absolute* number, or as a percentage of the campaign's *Total cost*.
- **Value per visitor** - this indicator allows you to specify the average conversion value that should be generated by a single campaign visitor. It is calculated as the campaign's *Total value of conversions* divided by its *Number of visitors*. The value can either be specified directly as an *Absolute* number, or as a percentage of the campaign's *Cost per visitor* (i.e. the *Total cost* divided by the *Number of Visitors*).

Campaigns - Overview

Report Campaigns

› Campaigns › Banner campaign

General Goals Conversions

Save

| | Red flag | Goal | |
|-----------------------------|---------------------------------|----------------------------------|--|
| Number of visitors: | <input type="text" value="15"/> | <input type="text" value="50"/> | <input type="radio"/> Absolute <input checked="" type="radio"/> Percentage of impressions |
| Number of conversions: | <input type="text" value="10"/> | <input type="text" value="25"/> | <input type="radio"/> Absolute <input checked="" type="radio"/> Percentage of impressions |
| Total value of conversions: | <input type="text" value="30"/> | <input type="text" value="200"/> | <input type="radio"/> Absolute <input checked="" type="radio"/> Percentage of total cost |
| Value per visitor: | <input type="text" value="5"/> | <input type="text" value="20"/> | <input checked="" type="radio"/> Absolute <input type="radio"/> Percentage of cost per visitor |

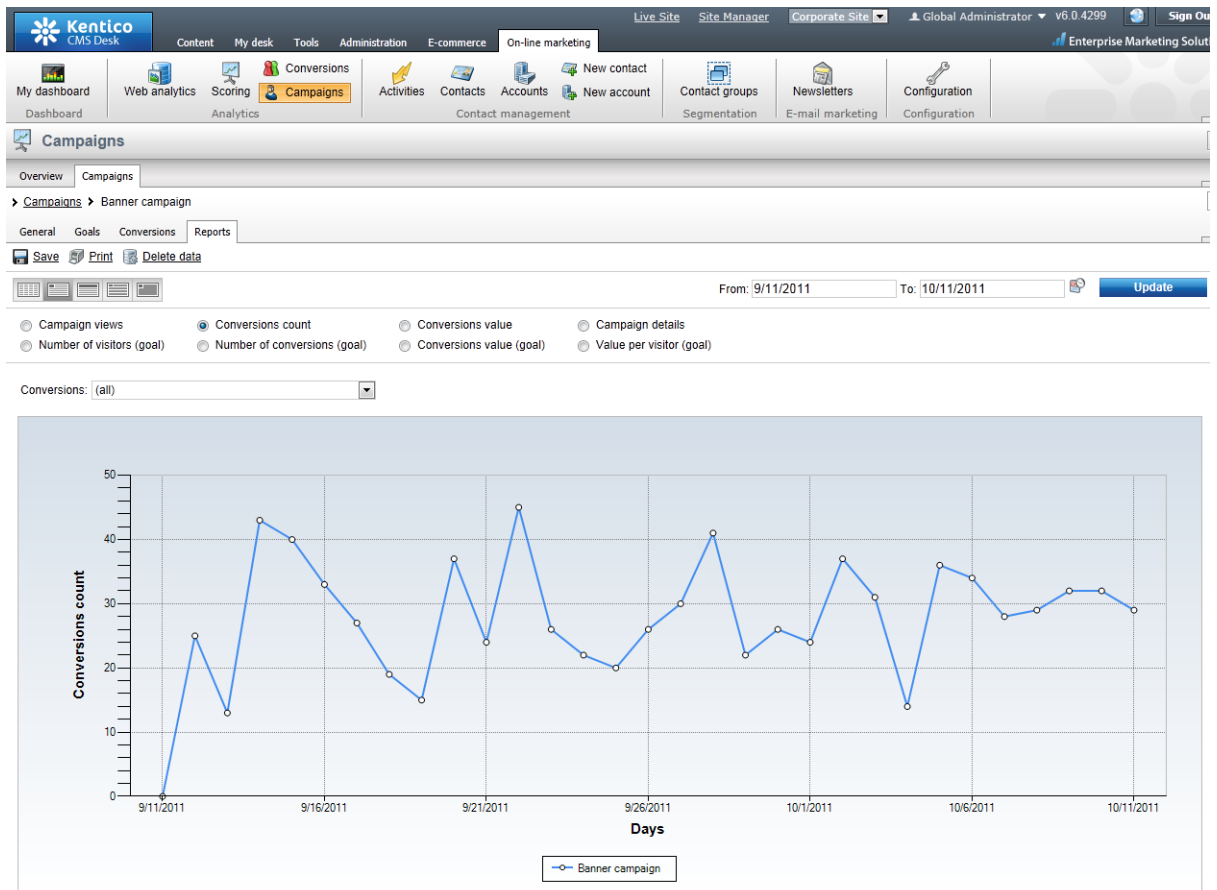

Each goal may have two values. The **Red flag** may be used to set a number that must be reached in order for the campaign to be at least partially successful (campaigns below this value are considered to have failed). The **Goal** value sets a target that should ideally be achieved by the campaign. The progress that individual campaigns make towards their goals can then be followed using the corresponding reports under the **Goals** sub-category in the web analytics tree.

The red flag and goal values configured for the selected statistic are displayed in the reports as red and green lines, so you can easily see the current status of the specified campaign.

Reports for individual campaigns

Any of the reports described above may also be viewed when editing a campaign in **CMS Desk -> On-line marketing -> Campaigns** on the **Reports** tab. You can choose a specific report via the radio buttons at the top of the page.

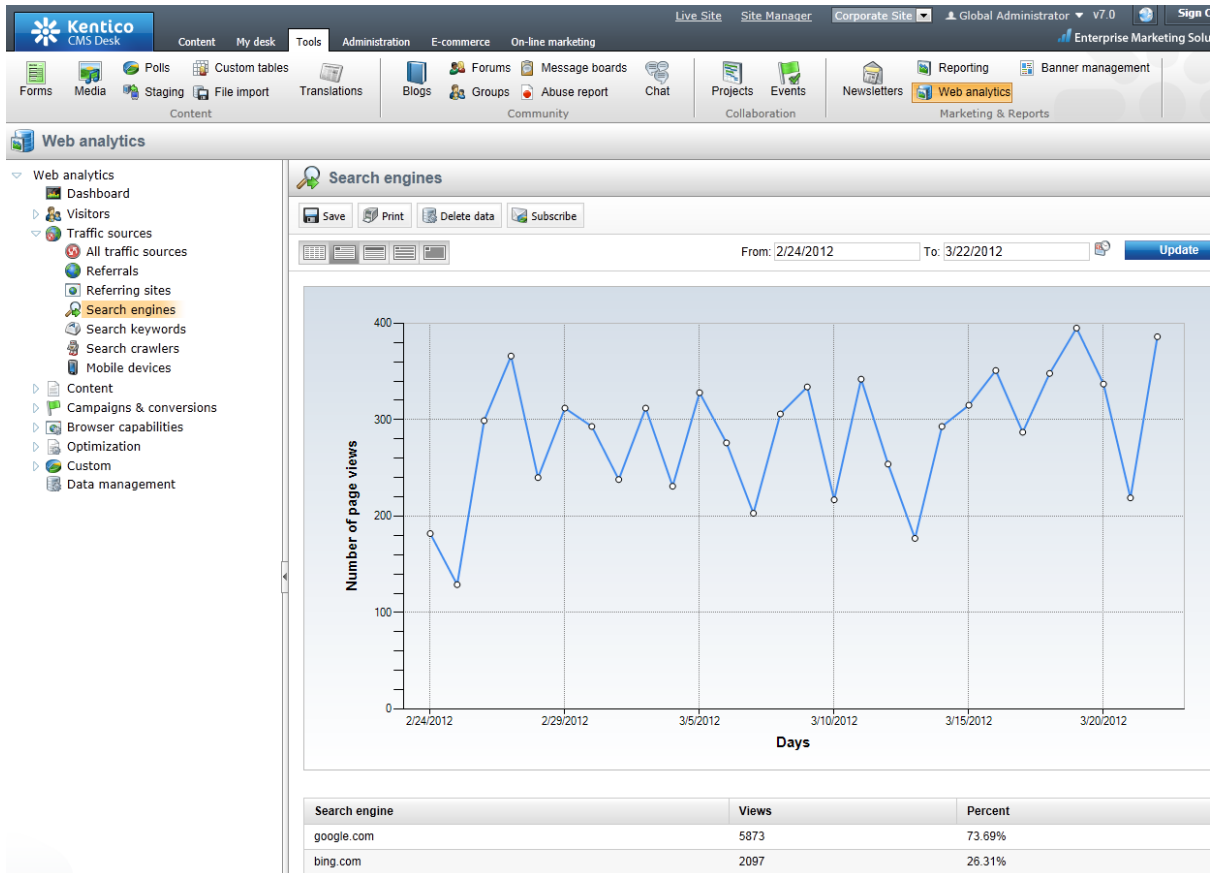

Only the data logged for the given campaign is displayed here.

8.51.6 Monitoring traffic from search engines

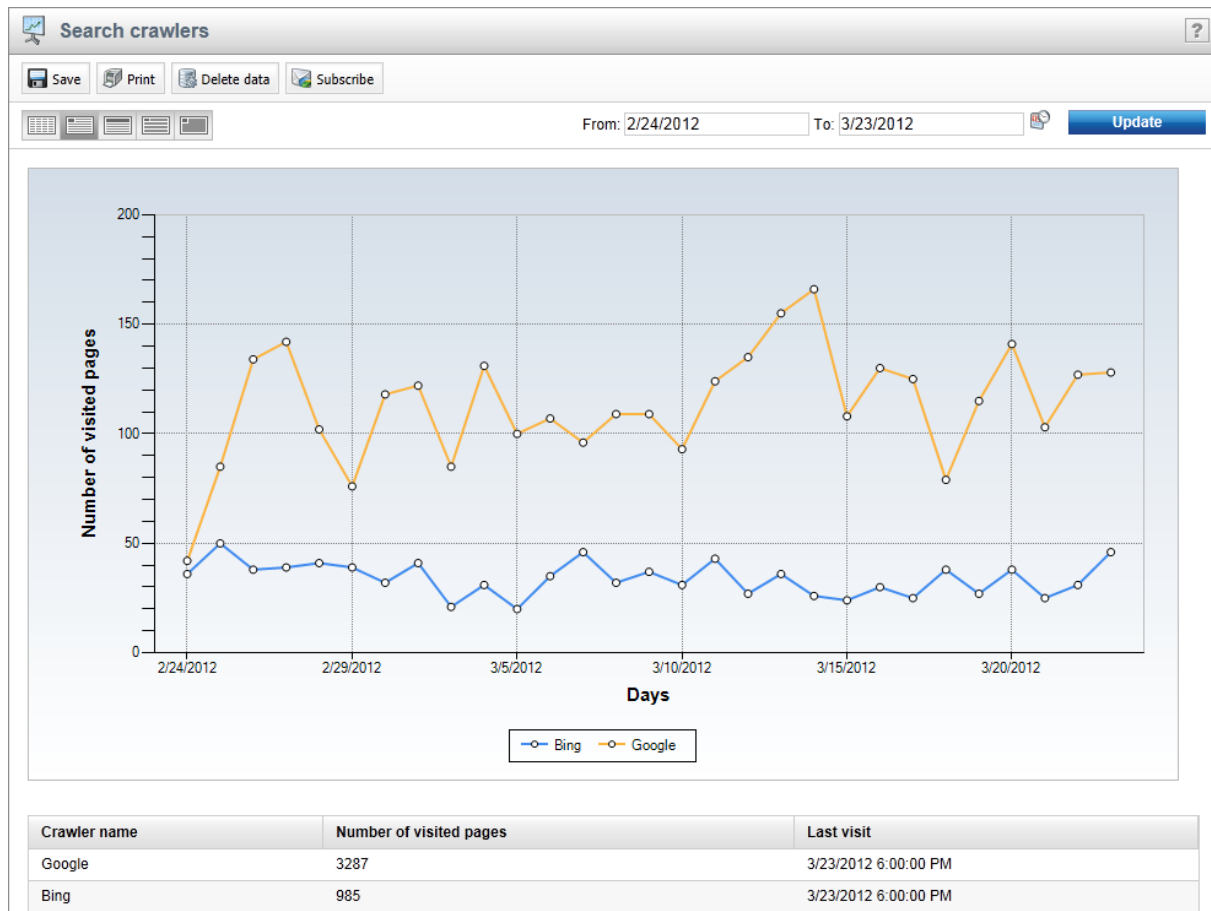

Search engine tracking allows you to monitor the amount of page views received from visitors who found the website using a search engine. Since search engines are the most common type of referring websites, they are tracked separately and with additional details.

The report containing this data can be accessed through the web analytics tree menu in **Traffic sources** -> **Search engines**. As shown below, it contains a graph displaying the total amount of page views generated by search engine traffic and a breakdown of the statistics for individual search engines.

Additionally, it is possible to view the exact keywords that were entered into the search engines using the **Search keywords** report (also located under the **Traffic sources** category).

Before they can provide search results that link users to your website, search engines need to index the site using web crawlers (robots). The web analytics module is also capable of tracking the activity of these crawlers on your website's pages, and the results can be reviewed in the **Search crawlers** report.

The data provided in this report can be useful when performing [Search engine optimization](#) of your website. These statistics can also be checked for specific pages by selecting the corresponding document in the content tree of CMS Desk and viewing its **Traffic sources** reports on the **Analytics -> Reports** tab.

Managing search engines

In order to correctly log incoming traffic from search engines, objects representing individual engines must be defined in the system. This can be done in **Site Manager -> Development -> Search engines**. By default, the list contains some of the most commonly used search engines, but any additional ones that you wish to track must be added manually.

When creating or editing (✎) a search engine object, the following properties can be specified:

- **Display name** - sets the name of the search engine used in the administration and web analytics interface.
- **Code name** - may be used to set a unique identifier for the search engine. You can leave the default (*automatic*) option to have the system generate an appropriate code name.
- **Domain rule** - this string is used to identify whether website traffic originates from the given search engine. In order to work correctly, this string must always be present in the engine's URL, for example *google.* for the Google search engine.
- **Keyword parameter** - specifies the name of the query string parameter that the given search engine uses to store the keywords entered when a search request is submitted. This is necessary so that

the system can log which search keywords visitors used to find the website.

- **Crawler agent** - sets the user agent that will be used to identify which web crawlers (robots) belong to this search engine. Examples of common crawler agents are *Googlebot* for Google, or *msnbot* for Bing. This property is optional and it is recommended to specify the crawler agent only for major search engines, or those that are relevant to your website.

The screenshot shows the Kentico Site Manager interface. The top navigation bar includes 'Sites', 'Administration', 'Settings', 'Development', 'Tools', 'Dashboard', 'Licenses', and 'Support'. The left sidebar lists various development options, with 'Search engines' highlighted. The main content area is titled 'Search engine properties' and shows the configuration for a search engine named 'Google'. The configuration includes a 'Save' button and the following fields:

- Display name: Google
- Code name: Google
- Domain rule: google.
- Keyword parameter: q
- Crawler agent: googlebot

If the site is accessed from an external website, the system parses the URL of the page that generated the request. First, the URL is checked for the presence of a valid **Domain rule** that matches the value specified for a search engine object. Then the query string of the URL is searched for the parameter defined in the corresponding **Keyword parameter** property to confirm that the referring link was actually generated by search results, not by a banner or other type of link. This allows the system to accurately track user traffic that is gained from search engine results.

Whenever a page is accessed (indexed) by a web robot with a user agent matching the **Crawler agent** property of one of the search engines registered in the system, a hit is logged in the **Search crawlers** web analytics statistic.

8.51.7 Adding custom web analytics

The system allows you to track custom events as web analytics and display the results in reports. The following example logs a basic button click event, but you can use the same approach to implement tracking for any type of event on your website.

Logging the event

This example logs the event through a user control:

1. Open your Kentico CMS web project in Visual Studio.
2. Create a **New folder** under the root named according to the code name of your site, e.g. *CorporateSite* (if doesn't already exist).
 - o This location ensures that the control will be exported along with your website if it is deployed to a different server.
3. Right-click the folder and select **Add New Item**. Create a **Web User Control** named *AnalyticsButton.ascx*.
4. Add the following code to the control:

```
<asp:Button id="btnLog" runat="server" Text="Add analytics hit"
onclick="btnLog_Click" />
```

This inserts a standard Button control, which will be used to add hits to the custom statistic.

5. Switch to the code behind file of the control and modify it according to the following:

Note: The name of the class will be different according to the code name of your site.

[C#]

```
using CMS.WebAnalytics;
using CMS.CMSHelper;

public partial class CorporateSite_AnalyticsButton : System.Web.UI.UserControl
{
    // Handler for the button's click event
    protected void btnLog_Click(object sender, EventArgs e)
    {
        // Checks if web analytics are enabled in the settings
        if (AnalyticsHelper.AnalyticsEnabled(CMSContext.CurrentSiteName))
        {
            // Adds a hit to a custom statistic
            HitLogProvider.LogHit("buttonclicked", CMSContext.CurrentSiteName,
            null, CMSContext.CurrentUser.UserName, 0);
        }
    }
}
```

You can log custom events for web analytics via the API using the **HitLogProvider** class from the **CMS.WebAnalytics** namespace, specifically the following method:

```
LogHit(string codeName, string siteName, string culture, string objectName, int objectId, int count,
double value)
```

- **codeName** - determines the code name of the custom statistic, *buttonclicked* in the case of this example. This name is also used in the code names of related reports.
- **siteName** - specifies the code name of the site for which the event is logged.
- **culture** - specifies the culture code under which the system logs the event.
- **objectName / objectId** - specifies the context in which the hit was logged. You can use the name or ID of an object. For example, when logging page views, you could store the alias path and document ID of the given page. In the example, the name of the user who clicked the button is logged as the related object.
- **count** - sets the amount of hits added to the statistic. This parameter is optional and the default value (1) is used if not specified.
- **value** - specifies a special value for the hit. This parameter is optional and can be used to assign weight to the hit according to some conditions. The value of a statistic is cumulative, which means that each hit adds to the total value logged for the given analytics record (specified by the **objectName** and **objectId**).

6. **Save** the user control's files.

When a user clicks the button, the API creates an analytics log. Once the system processes the log, the results containing the given user's name and the amount of clicks are stored in the database, where they can be used by the web analytics module.

Note *[Only applies after installing [hotfix 7.0.17](#) or newer]*

Custom analytics do not automatically use [JavaScript logging](#). If your website has JavaScript logging enabled, you may need to leverage JavaScript in the code to keep your custom statistics consistent with the default web analytics.

Integrating custom analytics into the website

Now you need to publish the user control on your website (this example uses the sample Corporate site).

1. Open the Corporate site in CMS Desk in **Content -> Edit** mode.
2. Select the **Home** document from the content tree and switch to the **Design** tab.
3. Add (+) the **User control** web part to the *Main zone* zone.
4. Enter `~/CorporateSite/AnalyticsButton.ascx` into the web part's **User control virtual path** property.
 - The page now displays the custom button.
5. View the live site version of the **Home** page and click the **Add analytics log** button several times to add hits to the custom statistic. Try doing this while logged in under different user accounts.

There are also other ways to add custom web analytics functionality to the pages of your website. For example:

- You can implement the control as a [custom web part](#), add it to your pages and configure it through

the portal engine as necessary.

- If you are using the [ASPX page template](#) development model for your website, you can integrate the analytics logging code and any required interface elements directly into your page templates.

Using the Analytics custom statistics web part

If you wish to log a simple event when visitors access a specific page, you can do so without having to write any code using the [Analytics custom statistics](#) web part.

Once this web part is placed on a page, it automatically adds a hit to a custom statistic when the given page is viewed. You can specify the details of the statistic, such as its code name, the name of the related object or the hit value using the web part's properties. The web part automatically loads the site name and culture from the context of the page.

Creating reports for statistics

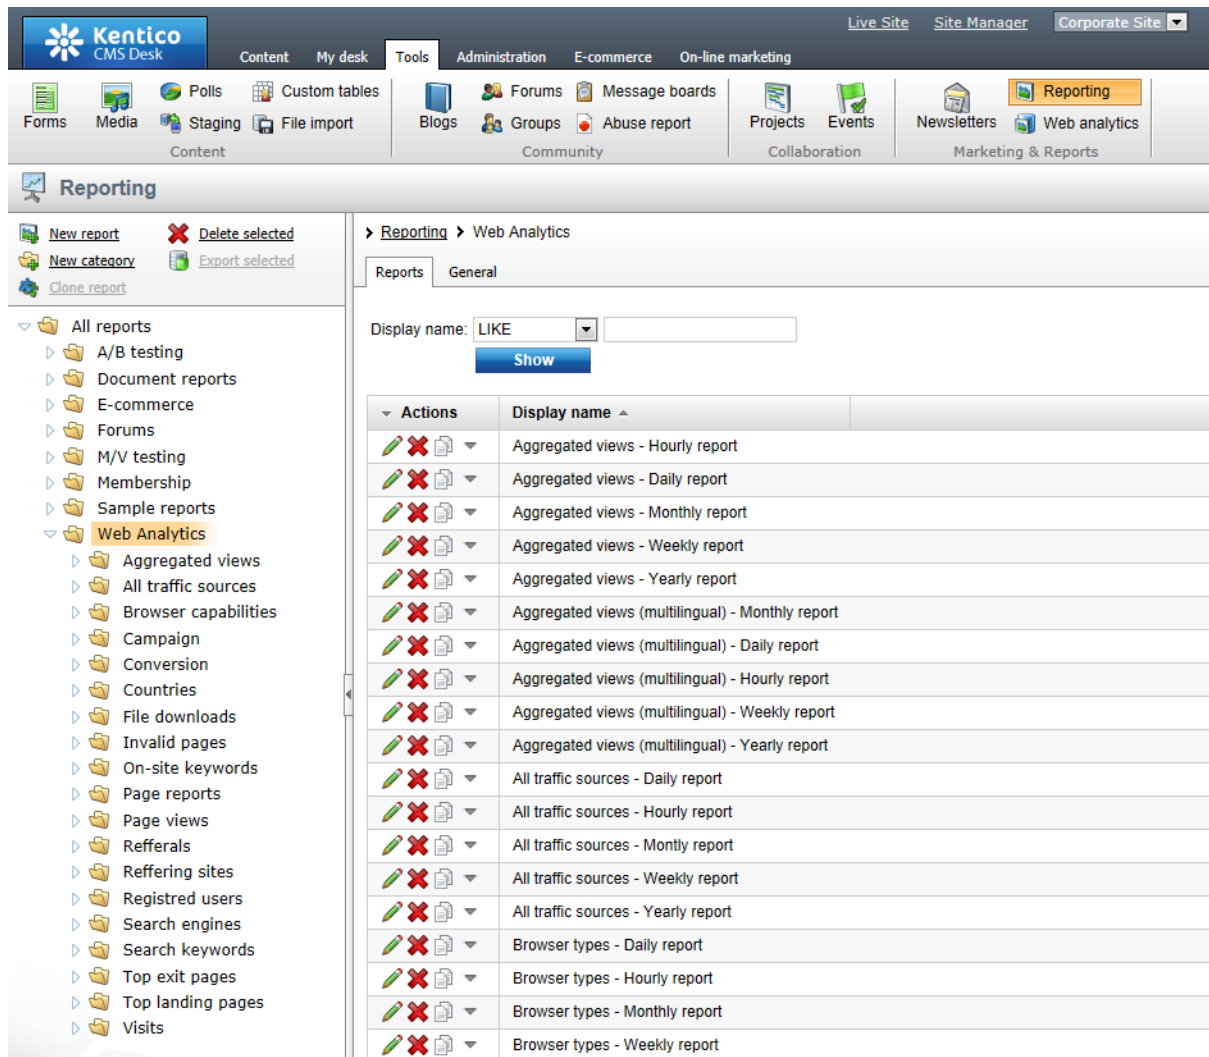

Before users can view the statistics of the button click event in **CMS Desk -> Tools -> Web Analytics**, you need to create reports for displaying the data of the custom statistic.

1. Go to **CMS Desk -> Tools -> Reporting** and expand the **Web Analytics** category in the tree on the left. The sub-categories contain reports used by the default statistics such as page views, traffic sources, campaigns, etc. Most statistics have five types of reports: hourly, daily, weekly, monthly and yearly.

The code names of the reports have to use a specific format:

- <statistic code name>.hourreport
- <statistic code name>.dayreport
- <statistic code name>.weekreport
- <statistic code name>.monthreport
- <statistic code name>.yearreport

In our example, the code name of the custom statistic is **buttonclicked**, as defined above in the code of the user control.

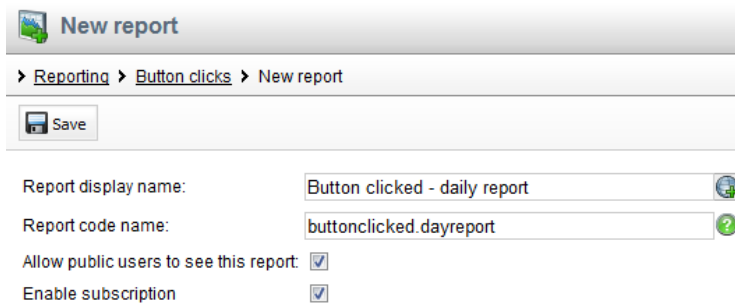

2. Add a **New category** under **Web Analytics** and enter the following names for it:

- **Category display name:** Button clicks
- **Category code name:** ButtonClicks

Click **Save**.

3. Now we will create a daily report for the new statistic. Click **New report** and enter the following values:

- **Report display name:** Button clicked - daily report
- **Report code name:** buttonclicked.dayreport

New report

> Reporting > Button clicks > New report

Save

Report display name: Button clicked - daily report

Report code name: buttonclicked.dayreport

Allow public users to see this report:

Enable subscription:

Click  **Save**.

4. Switch to the **Parameters** tab of the new report and use the **New attribute** (+) button to create three essential parameters which will be used internally by the web analytics module. Click  **Save field** for every parameter before moving on to the next one:

- **Column name:** FromDate
- **Attribute type:** Date and Time
- **Display attribute in the editing form:** disabled

- **Column name:** ToDate
- **Attribute type:** Date and Time
- **Display attribute in the editing form:** disabled

The two parameters above define a time interval used to limit which data of the statistic should be loaded. Only hits that occurred during the specified interval will be displayed in the report. The values of these parameters can be set by users when viewing the data of the statistic in the web analytics interface.

- **Column name:** CodeName
- **Attribute type:** Text
- **Attribute size:** 20
- **Default value:** buttonclicked (the code name of the displayed statistic in general)
- **Display attribute in the editing form:** disabled

This parameter is simply used to identify from which statistic the data should be loaded. Its value is usually not modified if the report is dedicated to a single statistic (like the one in this example).

Reporting > Button clicks > Button clicked - daily report

View General Parameters Saved reports

FromDate*
ToDate*
CodeName*

Save field

The changes were saved.

Database

Column name: CodeName

Attribute type: Text

Attribute size: 20

Allow empty value:

Default value: buttonclicked

Display attribute in the editing form

5. Go to the **General** tab and click the **New** button in the **Tables** section below the layout editor to create a report table. Fill in its properties as shown below:

- **Display name:** Table
- **Code name:** Table_ButtonClicked_Day
- **Enable export:** true (checked)
- **Query:**

```
SET @FromDate = dbo.Func_Analytics_DateTrim(@FromDate, 'day');
SET @ToDate = dbo.Func_Analytics_EndDateTrim(@ToDate, 'day');

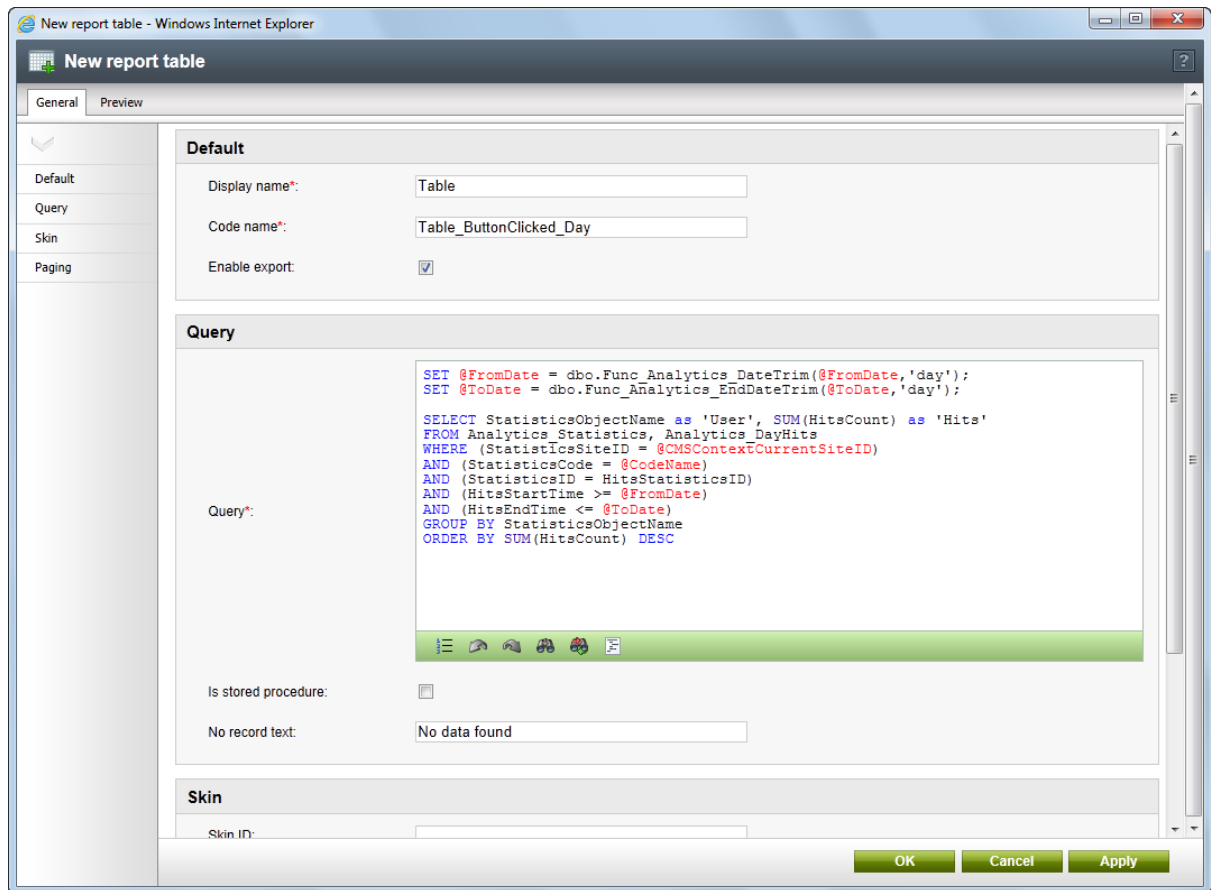

SELECT StatisticsObjectName as 'User', SUM(HitsCount) as 'Hits'
FROM Analytics_Statistics, Analytics_DayHits
WHERE (StatisticsSiteID = @CMSContextCurrentSiteID)
AND (StatisticsCode = @CodeName)
AND (StatisticsID = HitsStatisticsID)
AND (HitsStartTime >= @FromDate)
AND (HitsEndTime <= @ToDate)
GROUP BY StatisticsObjectName
ORDER BY SUM(HitsCount) DESC
```

Trimming the values of the FromDate and ToDate parameters

The SET statements included in the query are necessary to ensure that the specified time interval includes the first and last units of time (e.g. the exact days entered entered into the **From** and **To** fields of a daily report).

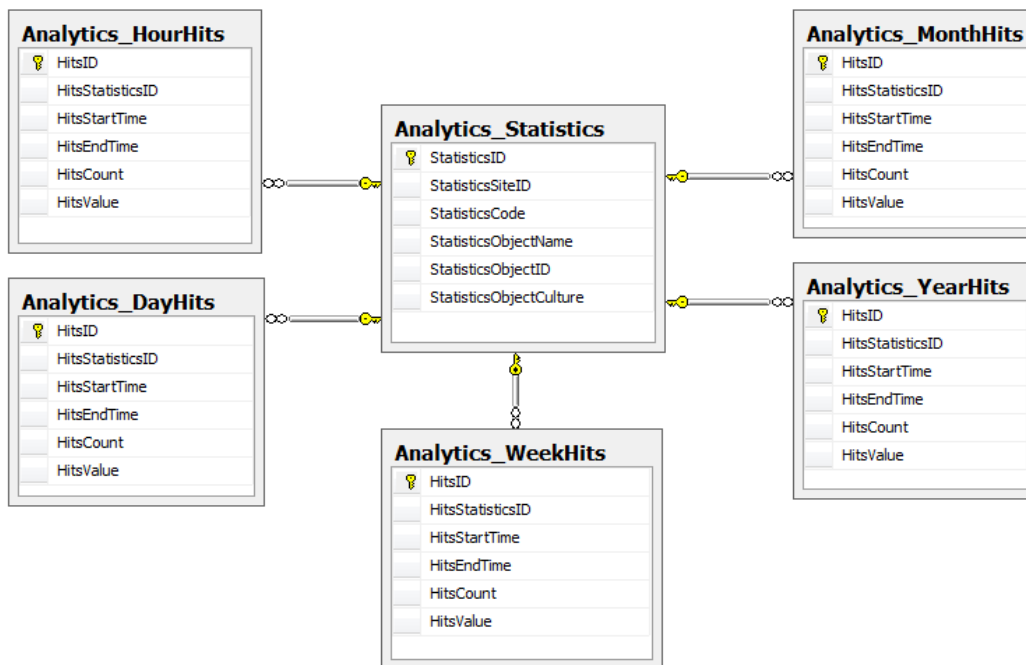

The second parameter of the trimming functions must match the time unit of the given report. The options are: *'hour'*, *'day'*, *'week'*, *'month'*, *'year'*.

There are six important database tables used by the web analytics module to keep track of statistics and their values. The *Analytics_Statistics* table stores records that represent the statistics of a tracked event within a certain context, i.e. related to a specific object, site and culture.

Five other tables are used to store the exact number of hits for the statistics in the *Analytics_Statistics* table (*Analytics_HourHits*, *Analytics_DayHits*, *Analytics_WeekHits*, *Analytics_MonthHits* and *Analytics_YearHits*). When a hit for a tracked statistic occurs, it is logged into all of these tables. The difference between them is in the unit of time used to separate hits into individual records. For example, a record in the *Analytics_HoursHits* table would contain the number of hits that were logged for a given statistic during one hour, while a single record in *Analytics_MonthHits* would count all hits that occurred over an entire month.

The diagram below represents the basic database structure used to store statistics and their hits:

Since the new report is a daily report, the data of the table is retrieved from the *Analytics_DayHits* table, together with the *Analytics_Statistics* table.

Click **OK** to create the table.

6. To complete the daily report, use the **Insert** button in the **Tables** section to add a macro representing the table into the layout of the report and click **Save**.

In a real-world scenario, the report would usually also contain a graph to display the data. Please refer to the [Modules -> Reporting](#) chapter to learn more about graphs and other reporting options.

You can create the reports for the remaining time intervals using the same approach. The only differences should be in the names of the reports and tables, and the code of the queries, where you need to load data from the appropriate tables — *Analytics_YearHits* in the yearly report, *Analytics_MonthHits* in the monthly report, etc. You can make this process easier by using the **Clone report** action from the menu above the report tree. Simply create copies of the daily report and then make the necessary adjustments.

Setting the user interface title for custom statistics

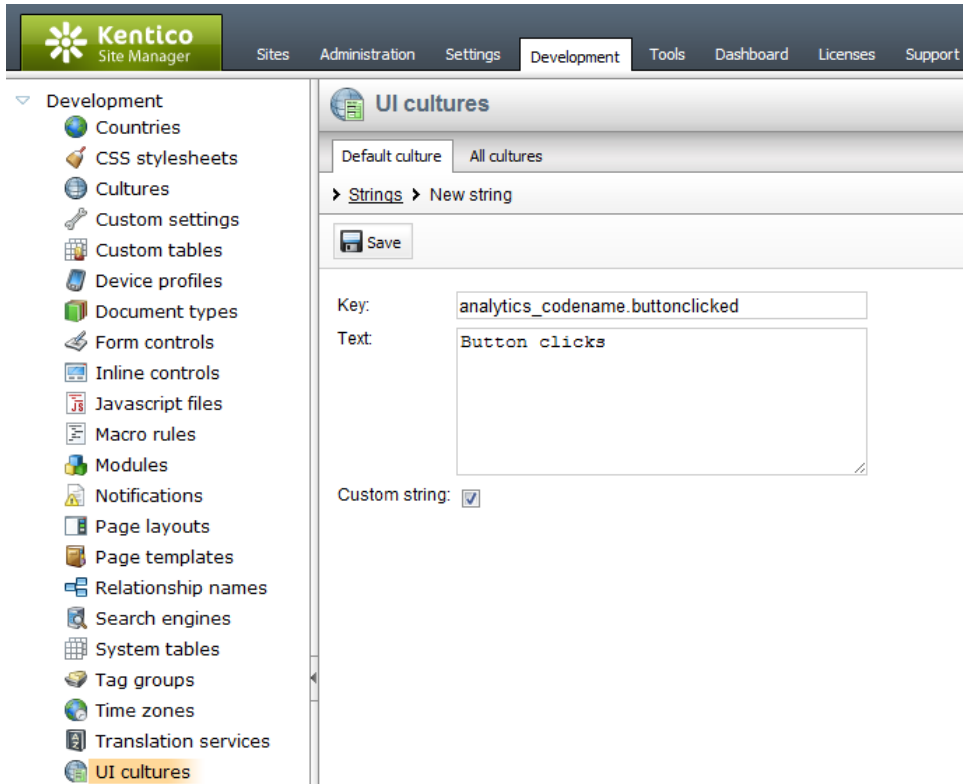

To ensure that the user interface displays an appropriate title for your custom statistic, you need to create a resource string:

1. Go to **Site Manager -> Development -> UI cultures**.

2. Click **New string** and enter the values below:

- **Key:** *analytics_codename.buttonclicked*; in general, the key of the string must always be in format *analytics_codename.<statistic code name>*.
- **Text:** *Button clicks*; you may enter any required text.

- If you are using a multilingual UI, you can enter translations of the string for specific cultures via the *All cultures* tab.
- **Custom string:** yes (checked)

3. Click  **Save**.

The system uses the string as the title for the matching statistic.

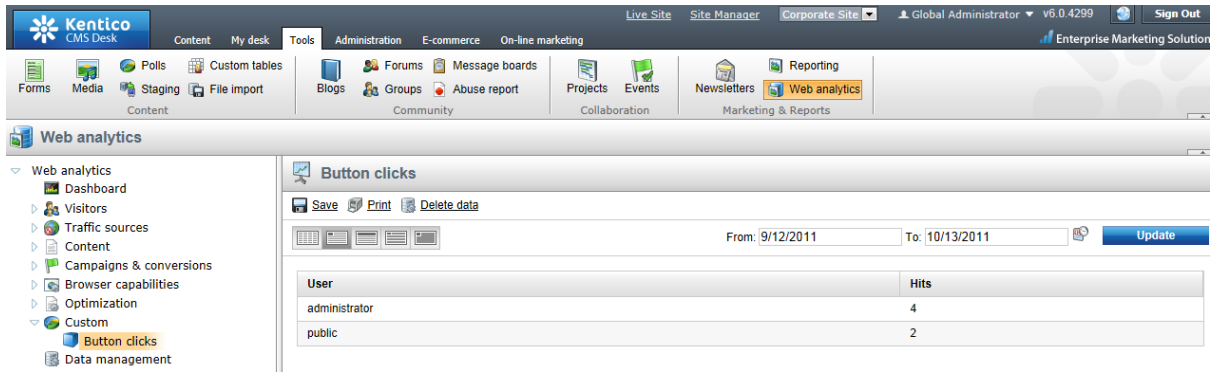

Adding icons for custom statistics

You can add a custom icon for your new statistic:

1. Open the `\App_Themes\Default\Images\` folder in your Kentico CMS project's directory.
2. Extract the **CMSSModules** folder from the **Images.zip** archive and place it into the `~/App_Themes/Default/Images/` directory.
3. Add your icon image file into the `CMSSModules\CMS_WebAnalytics` folder.
 - Name the image file in format **<statistic code name>.<extension>** (for example `buttonclicked.png` in this scenario).
 - If there are any period characters ('.') in the code name, you can replace them with an underscore ('_') to create a valid file name.

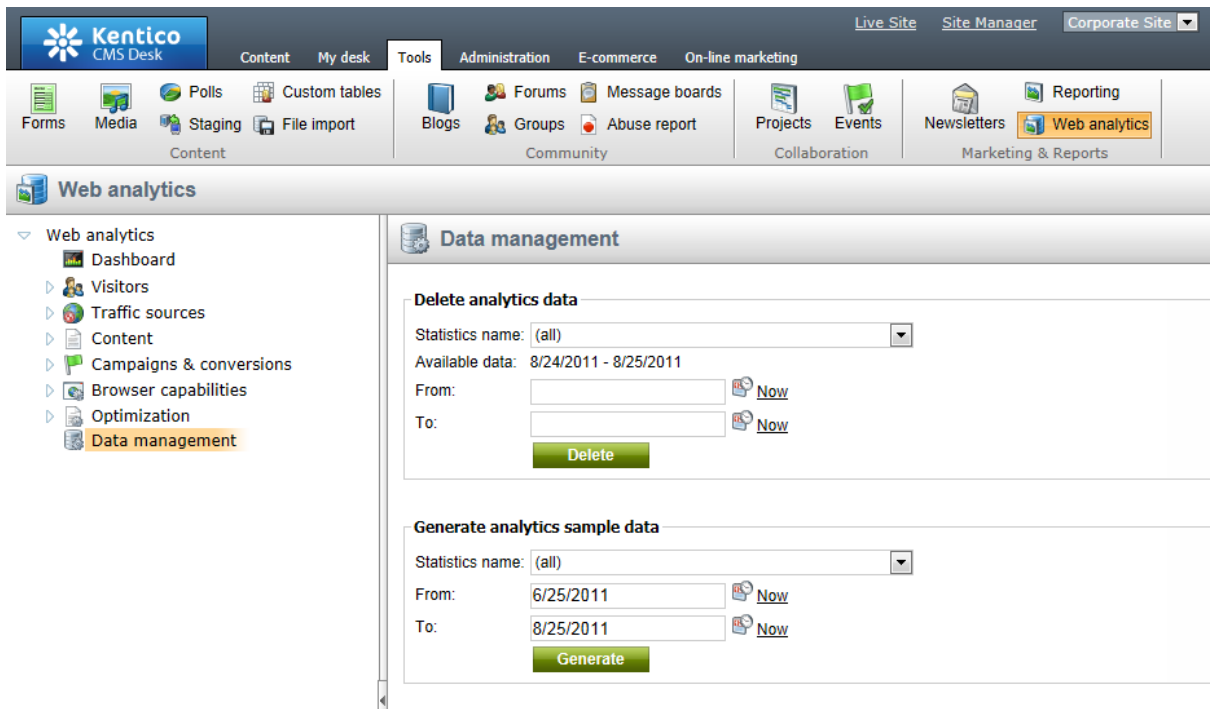

Result

Once there are some hits logged in the database for a custom statistic, the system automatically displays the statistic under the **Custom** category of the tree in **CMS Desk -> Tools -> Web Analytics**. The reports of the sample statistic show the number of hits logged for the tracked button click event.

8.51.8 Managing analytics data

It is possible to manually manage the data used to store how many hits are logged for individual web analytics statistics. To do this, access the **CMS Desk -> Tools -> Web analytics** interface and select the **Data management** item from the tree menu. By default, this UI element is only available for global administrators.

Data security

Performing the actions available in this section will permanently modify the analytics records of the website. Only use them if you are sure that doing so will not delete or overwrite valuable statistical data.

For security reasons, the actions can only be performed by users who have the **Manage data** permission for the Web analytics module.

Delete analytics data

When running a site with web analytics enabled, the amount of data that is stored may grow quite large over time, particularly when tracking many types of events or on high-traffic websites. The **Delete analytics data** action can be used to remove hits that were logged for the selected statistic during the time period specified in the **From** and **To** fields. You can either choose a specific statistic or clear all analytics data for the given time interval by selecting the *(all)* option from the **Statistics name** drop-down list.

Generate analytics sample data

This action logs randomly generated sample data for the selected statistics, which can be used to simulate hits measured over the given time period. The specific statistic and time interval may be configured the same way as when deleting data.

The purpose of this function is to allow testing or evaluation of the web analytics module and the various types of statistics that it provides, since a certain amount of time and traffic would otherwise be required to naturally log a realistic amount of data for the website.

Important!

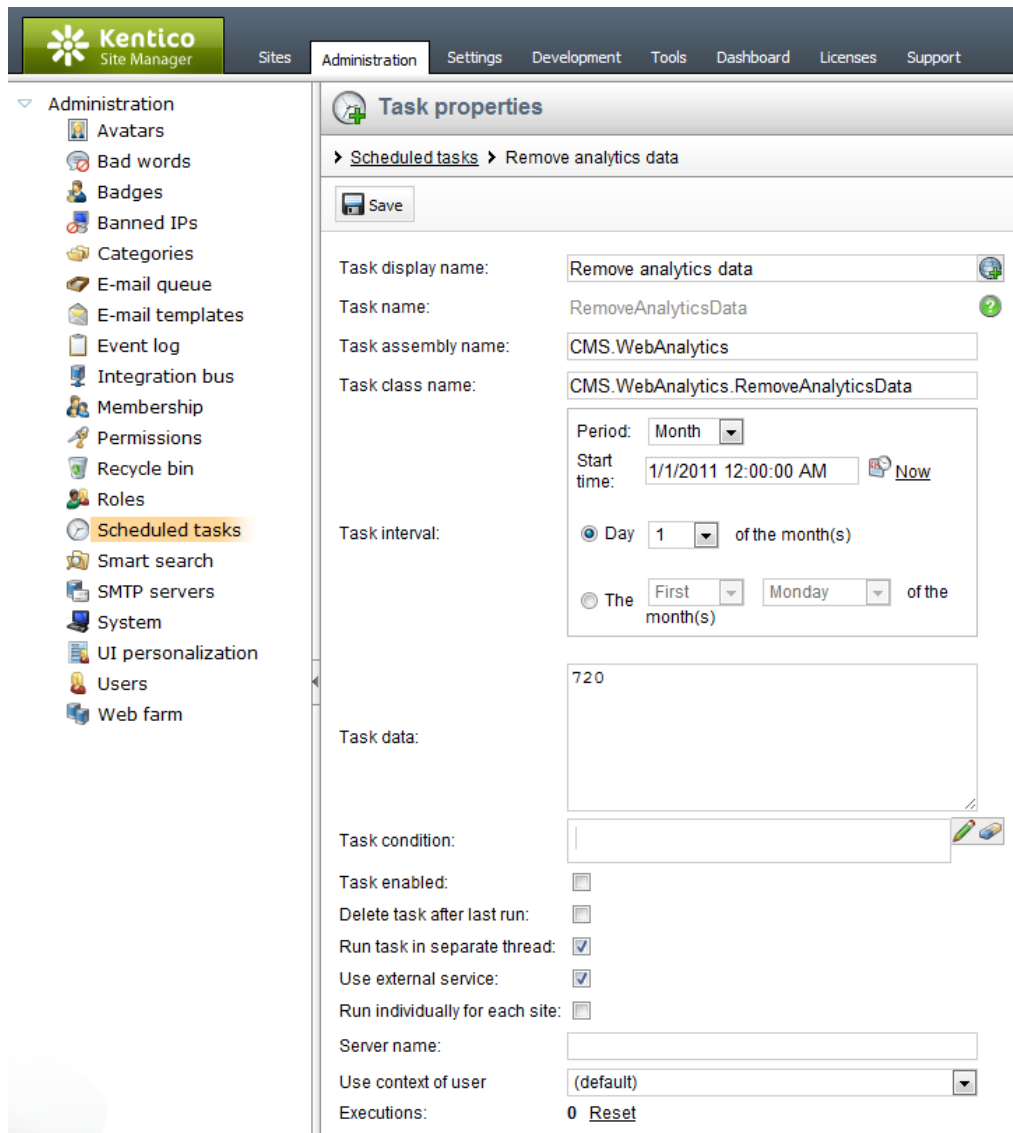

The data generation process is a highly resource-intensive operation, since it must create a very large amount of records in multiple database tables.

For this reason, it is necessary to set a reasonably short interval to prevent time out issues. This depends on the performance of the server used to host the site, but it is recommended to avoid generating more than six months of data in a single operation.

Automatic data cleanup

It is also possible to configure the system to automatically delete old web analytics data that is no longer needed. There is a global scheduled task available for this purpose called **Remove analytics data**. By default this task is disabled to prevent unwanted deletion of data.

To enable automatic data removal for web analytics, go to **Site Manager -> Administration -> Scheduled tasks**, edit (✎) the mentioned task and check its **Task enabled** field.

You can configure how often the task should be executed using the **Task interval** settings. To specify how old data must be before the task is allowed to remove it, enter a number into the **Task data** field. This number indicates age in days, so the default value of 720 sets the task to delete only data that is approximately two years old. It is recommended to configure this task carefully to avoid losing valuable data.

8.51.9 Configuration options

You can configure the functionality of the web analytics module in **Site Manager -> Settings -> On-line marketing -> Web analytics**. The settings here allow you to enable or disable tracking of various types of events and specify other related configuration options.

Note: The system checks the values of the settings at the moment that tracked events occur. Changes do not affect previously logged data, only future events.

General

| | |
|------------------------------------|---|
| Enable web analytics | Enables or disables the entire web analytics module. If this setting is disabled, the system does not track any of the statistics listed below. |
| Log via JavaScript snippet | <p>By default, the system logs analytics directly on each request. If you enable this setting, the analytics are logged via JavaScript.</p> <p>JavaScript logging ignores all browsers and devices that do not support JavaScript or have it disabled. This filters out non-human tools such as RSS readers and web crawlers from future analytics statistics.</p> <p>Switching to JavaScript logging does not affect the performance of the website.</p> |
| Campaigns & Conversions | |
| Track campaigns | Indicates if campaign tracking should be enabled. |
| Campaign tracking URL parameter | Sets the name of the URL query string parameter which is used to indicate that the site was accessed as a result of a campaign. The value of the parameter stores the code name of the given campaign. |
| Track conversions | Indicates if tracking of conversions should be enabled. This includes both general conversions and those logged within a certain special context, such as for A/B or Multivariate tests , or as a result of a Campaign . |
| Views & Downloads | |
| Track file downloads | If enabled, the system tracks which files were downloaded by website visitors. Please note that only files stored as documents in the website's content tree are tracked. |
| Track invalid pages | Indicates if invalid page requests should be tracked. Invalid requests are those that contain the website's domain name, but specify a path to a page that does not exist. |
| Track page views | Indicates if the system should track how many times the website's pages were viewed by visitors. Only pages that are served by Kentico CMS are included in the statistics. |
| Track aggregated views | If enabled, access to pages via links contained in RSS or Atom feeds (created using the Syndication module) are tracked. |
| Track landing pages | Indicates if the system should track which pages are the first ones viewed by visitors when they start their browsing session on the website. |
| Track exit pages | If enabled, the system logs the final pages that were visited by users when their browsing session ended. |
| Track average time on page | If enabled, the average time that users spend on pages is tracked. |
| Visitors | |
| Track browser types | Indicates if the browser types and versions used by the website's visitors is tracked. |
| Track visits | Indicates if site visits should be tracked. A single visit includes any |

| | |
|-----------------------------------|--|
| | <p>number of page views or other actions performed by a specific user during one session.</p> <p>First time users are logged as new visits. After a specified time period of inactivity, known users are logged as returning visits. Visitors are recognized using a browser cookie.</p> |
| Visitor idle time (minutes) | <p>Determines how long (in minutes) a visitor must be inactive before their presence on the website is logged as a returning visit.</p> <p>The default value is 1380 (23 hours). You can adjust this setting depending on how often visitors usually return to your site. For example, to track how frequently your site's visitors return over the course of a single day, you could set the value to 60 minutes or less.</p> |
| Remember visitors by IP (minutes) | <p>If the entered value is higher than 0, the IP addresses of the website's visitors are stored in the memory for the specified number of minutes.</p> <p>You may use this setting in cases where there are problems identifying visitors using the standard approach, e.g. if many of your visitors have cookies disabled in their browser.</p> |
| Track countries | <p>If enabled, the countries from which visitors access the website is tracked.</p> <p>The countries are recognized according to the IP addresses of visitors, which may not be 100% reliable in all cases, but the overall statistics for a high number of visits should provide correct results.</p> |
| Track registered users | Enables tracking of user registrations. |
| Track search crawlers | Indicates whether the activity of search engine web crawlers (robots) should be monitored. This type of tracking is performed even if the Exclude search engines setting is enabled. |
| Track mobile devices | If enabled, the system tracks whether visitors access the website using mobile devices. |
| Excluded | |
| Exclude search engines | If enabled, hits generated by search engine robots (crawlers) are not included in tracking statistics. This does not affect the <i>Search crawlers</i> statistic. |
| Excluded file extensions | Sets which file types should not be tracked as part of the File downloads statistics. The file types are specified using a list of extensions separated by semicolons (;), for example: <i>.jpg;.gif</i>
Please note that it's necessary to include the period in the extension name. |
| Excluded URLs | Can be used to exclude websites or their sections from all types of web analytics tracking. To exclude a page and all underlying pages, enter its URL (or document alias). You can specify multiple URLs (or site sections) separated by a semicolon (;). |
| Excluded IP addresses | Hits generated by the client IP addresses listed here are not included in |

| | |
|--------------------------------------|--|
| | <p>web analytics tracking. If multiple addresses are entered, they must be separated by semicolons (;). The asterisk (*) wildcard can be used as a substitute for any number in an IP address, substituting for all values from 0 to 255.</p> <p>This can be used to exclude the IP addresses of the website's administrators or other special users so that they do not influence tracking results.</p> |
| Traffic sources | |
| Track search engines | Indicates if traffic from search engines should be tracked. |
| Track search keywords | Indicates if the keywords that were entered into search engines in order to find the website should be logged. |
| Track on-site keywords | Indicates if the keywords that were used in the website's local search functionality should be logged. |
| Track referring local pages | If enabled, the system tracks which links visitors use to navigate within the website (i.e. menus or other types of links present on the site's pages). |
| Track referring pages by direct link | If enabled, the system tracks how many times website's pages are accessed directly through a URL entered into the browser. |
| Track referring sites | Indicates if the system should log the total amount of page views gained through links from external websites and the statistics for individual website domains. |
| Track referrals | Indicates if the system should log the full URLs of external pages from which visitors were linked to the website and the number of resulting page views. |

8.51.10 Security

You can configure security options for the various types of actions provided by the web analytics module in **Site Manager/CMS Desk -> Administration -> Permissions**. Choose to display the *Module* permission type and then select *Web analytics*.

The following permissions can be given to the listed roles:

- **Read** - allows members of the specified roles to view web analytics reports and other parts of the *CMS Desk -> Tools -> Web analytics* interface. It is also required to access the analytics reports anywhere else in the UI, e.g. in *CMS Desk -> Content -> Analytics -> Reports*.
- **Save reports** - allows members of the specified roles to save web analytics reports. The saved reports can be viewed using the *CMS Desk -> Tools -> Reporting* interface.
- **Manage data** - allows members of the specified roles to manage the data logged for various statistics (i.e. delete or generate sample data for statistics).
- **Manage campaigns** - allows members of the specified roles to create or delete campaign tracking objects and edit their properties, including goals.
- **Manage conversions** - allows members of the specified roles to create or delete conversions and edit their properties.

| Permissions | | | | | |
|------------------------------|-------------------------------------|--|-------------------------------------|--------------------------|--------------------------|
| Site: | Corporate site | | | | |
| Permissions for: | Module | Web analytics | | | |
| Report for user: | (none) | <input type="checkbox"/> Show only this user's roles | | | |
| Role | Read | Save reports | Manage data | Manage campaigns | Manage conversions |
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Editors | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Readers | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> | <input type="checkbox"/> |

8.51.11 Web analytics internals and API

8.51.11.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Web analytics module.

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.51.11.2 Database tables

There are six important database tables used by the web analytics module to keep track of statistics and their values. The **Analytics_Statistics** table stores records that represent the statistics of a tracked event within a certain context, i.e. related to a specific object, site and culture.

Five other tables are used to store the exact number of hits for the statistics in the **Analytics_Statistics** table:

- **Analytics_HourHits**
- **Analytics_DayHits**
- **Analytics_WeekHits**
- **Analytics_MonthHits**
- **Analytics_YearHits**

When a hit for a tracked statistic occurs, it is logged into all of these tables. The difference between them is in the unit of time used to separate hits into individual records. For example, a record in the **Analytics_HourHits** table would contain the number of hits that were logged for a given statistic during one hour, while a single record in **Analytics_MonthHits** would count all hits that occurred over an entire month.

The **Analytics_ExitPages** table is used to temporarily store exit page candidates for the *Top exit pages* statistic. The latest candidate recorded for a visitor when their session expires is then stored as the final exit page.

Additionally, the tables listed below are used to store campaign and conversion tracking objects:

- **Analytics_Campaign** - contains records representing campaigns and their settings.
- **Analytics_Conversion** - contains records representing conversions.
- **Analytics_ConversionCampaign** - stores relationships between campaigns and conversions. Each entry in this table indicates that a conversion should be included in the statistics of a certain campaign. Only campaigns that are restricted to a limited set of conversions have these relationships.

Campaign and conversion statistic storage

The data logged for campaigns and conversions is stored like all other web analytics

statistics. The main records are kept in the **Analytics_Statistics** table and the corresponding amount of hits for individual units of time are saved in the appropriate **Hits** table.

Page view statistics for campaigns always use the *campaign* **StatisticsCode** with the name of the given campaign stored in the **StatisticsObjectName** column.

The following code names are used for conversion statistics:

- **conversion** - general statistic used to store the overall conversion records. This statistic is always logged when a conversion is performed on the website.
- **camconversion;<campaign name>** - logged when a conversion is performed by a user associated with the particular campaign.
- **abconversion;<A/B test code name>;<Variant code name>** - logged when a conversion is performed by a user who viewed the given page variant of an A/B test.
- **mvtconversion;<MVT test code name>;<Combination name>** - logged when a conversion is performed by a user who viewed the given content combination on a page with a defined multivariate test.

All types of conversions use the **StatisticsObjectName** column to store the code name of the logged conversion.

8.51.11.3 API classes

If you are not familiar with the database table data management by Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The classes of the web analytics module can be found in the **CMS.WebAnalytics** namespace.

Analytics_Statistics table API:

- **StatisticsInfo** - represents the statistics of a certain event within a specific context.
- **StatisticsInfoProvider** - provides management functionality for statistic records.

Analytics_<time interval>Hits table API:

- **HitsInfo** - represents the hits of a statistic during a specific time interval.
- **HitsInfoProvider** - provides management functionality for statistic hits.

Analytics_Campaign table API:

- **CampaignInfo** - represents one campaign tracking object.
- **CampaignInfoProvider** - provides management functionality for campaigns.

Analytics_Conversion table API:

- **ConversionInfo** - represents one conversion tracking object.
- **ConversionInfoProvider** - provides management functionality for conversions.

Analytics_ConversionCampaign table API:

- **ConversionCampaignInfo** - represents a relationship between a campaign and a conversion.
- **ConversionCampaignInfoProvider** - provides management functionality for campaign-conversion relationships.

Other classes:

- **AnalyticsHelper** - provides general web analytics functionality and data.
- **HitLogProvider** - contains methods used to create the analytics log files for statistics.
- **HitLogProcessor** - this class implements the scheduled task used to periodically process the analytics log, which transfers the information to the database.

8.52 WebDAV integration

8.52.1 Overview

WebDAV stands for *Web-based Distributed Authoring and Versioning*. It is a set of extensions to the HTTP protocol which allows users to collaboratively edit and manage files on remote web servers. Detailed information, specifications and documentation related to this technology can be found on its official website: <http://www.webdav.org/>. Other valuable information is located on its Wikipedia page: <http://en.wikipedia.org/wiki/WebDAV>.

WebDAV integration in Kentico CMS enables users to open, edit and save [files stored in the CMS](#) in a client application installed on their local computer (e.g. *Microsoft Office Word, Excel, PowerPoint, MS Paint*, etc.). The advantage of this approach is that no local copy of the edited file needs to be created and uploaded back to the server manually after editing. Saving the document in the client application updates the file on the server automatically. This provides a much more straightforward process of editing attached documents, especially for non-experienced or non-technical end users.

The [Requirements and limitations](#) topic gives you an overview of which software and configuration is required for WebDAV integration to be functional both on the server- and the client-side. The [Configuration for WebDAV](#) topic explains how a website needs to be installed and configured in order to meet these requirements. Finally, [WebDAV-related settings](#) need to be adjusted in the CMS.

Once you have met all pre-requisites and performed the required configuration, you can use WebDAV in two modes:

- [Edit mode](#) - this mode represents integration of WebDAV editing in Kentico CMS user interface. Using this feature, files uploaded in the CMS can be opened for WebDAV editing by clicking the **Edit in client application** () icon.
- [Browse mode](#) - this mode enables you to map a network drive in your operating system. Content of the network drive reflects the content of your website and you can edit website files just as if they were stored on a local drive.

To learn details about WebDAV editing in each of the two modes, click the name of the mode above to get redirected to its sub-chapter. Both modes also fully integrate with [workflow and versioning](#) support in Kentico CMS. To learn more about system behavior specifics in this case, please proceed to the [Integration with workflow and versioning](#) topic.

8.52.2 Requirements and limitations

The following requirements must be met on the server- and the client-side in order for WebDAV integration to be functional in Kentico CMS:

Server-side requirements

- **Windows authentication** must be enabled in IIS and the CMS must be configured to use this type of authentication.
- If you are using an older version of IIS than 7.0, the Kentico CMS website must be **installed in the root** of the server. This is necessary because Microsoft Office submits configuration requests to the site root and requires the server to respond properly. If the website is not installed to the root, Microsoft Office will open its associated documents as read-only.
- If you are using IIS 7.0 or higher, the website needn't be installed in the root - it can also be installed in a virtual directory.
- [IIS WebDAV](#) is not compatible with Kentico CMS WebDAV integration. If you have WebDAV enabled in your IIS, Kentico CMS WebDAV integration will not be functional.

The [Configuration for WebDAV](#) topic explains how the required configuration can be achieved.

Client-side requirements

- WebDAV can be used only in **Internet Explorer 6 or higher**. No other web browsers are currently supported.
- **Client applications with WebDAV support** for a particular file types need to be installed on the client machine. E.g. *Microsoft Office 2003* or higher or *Paint* and *Notepad* in *Windows 7* support editing of associated file types using WebDAV.
- **Matching (x86) or (x64) versions** of both *Internet Explorer* and *Microsoft Office* must be installed. In other words, to be able to open documents using WebDAV in *Internet Explorer (x86)*, *Microsoft Office (x86)* must be installed on the client computer. For *Internet Explorer (x64)*, you need to have *Microsoft Office (x64)* installed.
- The **WebClient** service needs to be installed and running in order for WebDav clients to be able to connect to the server. For more information on how to install and run the service on different versions of Windows, visit the [Installing and running WebClient service topic](#).

Editable file size limit

By default, WebDAV editing is only functional with files smaller than 50 MB.

In case that a user needed to edit larger files using WebDAV, they would need to go to `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\WebClient\Parameters` in their Windows registry and adjust the `FileSizeLimitInBytes` key to the required value.

Forbidden characters in file names

WebDAV does not support uploading and editing of files whose names contain the following characters: `%`, `&`, `+`. Uploading and editing of such files using WebDAV may result in unwanted behavior and is not recommended.

8.52.3 Configuration for WebDAV

The following steps need to be taken in order to install a Kentico CMS website with WebDAV support enabled. The beginning of the procedure is different for IIS 7.0 or higher and the previous versions of IIS.

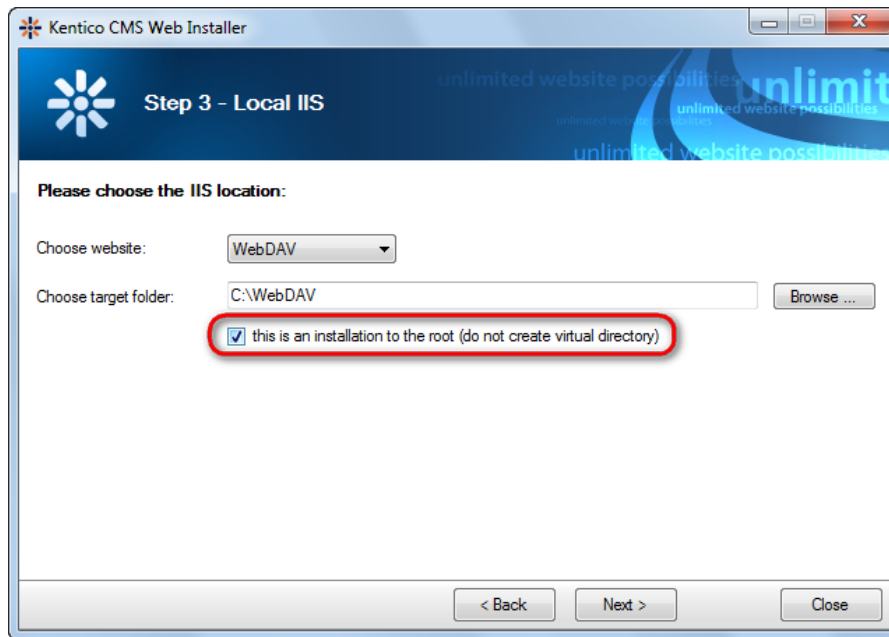

Step 1 on IIS versions prior to 7.0

Before you start, it is necessary to have a website created in the IIS root (i.e. not in a virtual directory). The website should have *Windows authentication* enabled in IIS.

1. Launch [Kentico Web Installer](#). In step 2, choose **I want to use local IIS server**. In step 3, use the following configuration:

- **Choose web site**: choose the website that you have prepared in the IIS root
- **Choose target folder**: enter the path to the website's physical folder
- **This is an installation to the root (do not create virtual directory)**: enabled

Click **Next** and proceed through the rest of the wizard.

When using IIS versions older than 7.0, it is also necessary to correctly map the **aspnet_isapi.dll** file in IIS. The process of performing this configuration is described below.

Configuration for IIS 5 and earlier versions

Open the IIS Management console, right-click on your Kentico application in the tree and select **Properties**. On the **Home Directory** tab, click **Configuration** and then **Add** to create a new application extension mapping. Enter the following details into the dialog:

- **Executable:** <Windows install directory>\Microsoft.NET\Framework\<.Net framework version>\aspnet_isapi.dll
- **Extension:** .*
- **Verbs:** All Verbs
- **Check that file exists:** disabled

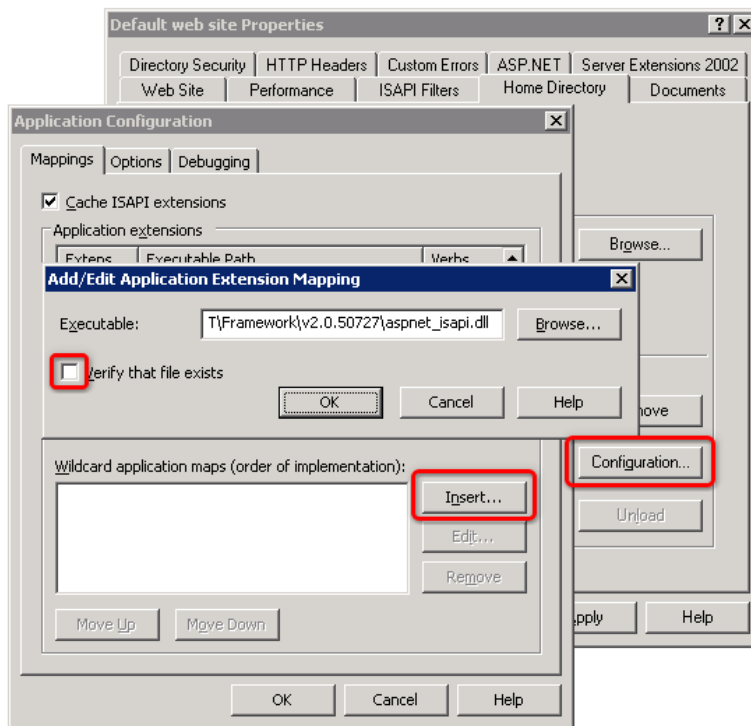

Click **OK** and return to the main management console. Now right-click the website under which your application is stored and select **Properties**. Switch to the **Home directory** tab, ensure that the **Read** box is checked and set the **Execute permissions** field to *Scripts only*.

Configuration for IIS 6

Open the IIS 6 Management console, right-click on your Kentico application in the tree and select **Properties**. On the **Home Directory** tab, click **Configuration** and then **Insert** to add a new wildcard application map. Enter the following details into the dialog:

- **Executable:** <Windows install directory>\Microsoft.NET\Framework\<.Net framework version>\aspnet_isapi.dll
- **Verify that file exists:** disabled

Click **OK** and return to the main management console. Now right-click the website under which your application is stored and select **Properties**. Switch to the **Home directory** tab, ensure that the **Read** box is checked and set the **Execute permissions** field to *Scripts only*.

Step 1 on IIS 7.0 or higher

On IIS 7.0 or higher, you do not need to have the website created in the IIS root - it can also be installed in a virtual directory.

1. Launch [Kentico Web Installer](#) and proceed through the steps with configuration according to your needs.

If you wish to run the website using an application pool set for *Classic* managed pipeline mode, please ensure that your **web.config** file contains the two **Isapi** extension handlers highlighted below once the **Web installer** finishes.

The handlers should be defined as follows on .NET 3.5:

```

...
<!-- WebDAV location BEGIN -->
<location path="cms/files">
  <system.web>
    <httpHandlers>
      <clear />
      <add verb="*" path="*" type="CMS.WebDAV.WebDAVHandler, CMS.WebDAV" />
    </httpHandlers>
    <httpRuntime executionTimeout="2400" maxRequestLength="2097151" />
  </system.web>

```

```

<system.webServer>
  <handlers>
    <clear />
    <add name="aspnet_isapi 32-bit" path="*" verb="*" modules="IsapiModule"
      scriptProcessor="%windir%\Microsoft.NET\Framework\v2.0.50727
      \aspnet_isapi.dll" resourceType="Unspecified" requireAccess="Script"
      precondition="classicMode, runtimeVersionv2.0, bitness32" />
    <add name="aspnet_isapi 64-bit" path="*" verb="*" modules="IsapiModule"
      scriptProcessor="%windir%\Microsoft.NET\Framework64\v2.0.50727
      \aspnet_isapi.dll" resourceType="Unspecified" requireAccess="Script"
      precondition="classicMode, runtimeVersionv2.0, bitness64" />
    <add name="CMSWebDAVHandler" path="*" verb="*"
      type="CMS.WebDAV.WebDAVHandler, CMS.WebDAV" />
  </handlers>
  <security>
    <requestFiltering>
      <requestLimits maxAllowedContentLength="2147483648" />
    </requestFiltering>
  </security>
</system.webServer>
</location>
<!-- WebDAV location END -->
...

```

On .NET 4.0, the handlers should be defined the following way:

```

...
<!-- WebDAV location BEGIN -->
<location path="cms/files">
  <system.web>
    <httpHandlers>
      <clear />
      <add verb="*" path="*" type="CMS.WebDAV.WebDAVHandler, CMS.WebDAV" />
    </httpHandlers>
    <httpRuntime executionTimeout="2400" maxRequestLength="2097151" />
  </system.web>
  <system.webServer>
    <handlers>
      <clear />
      <add name="aspnet_isapi 32-bit" path="*" verb="*" modules="IsapiModule"
        scriptProcessor="%windir%\Microsoft.NET\Framework\v4.0.30319
        \aspnet_isapi.dll" resourceType="Unspecified" requireAccess="Script"
        precondition="classicMode, runtimeVersionv4.0, bitness32" />
      <add name="aspnet_isapi 64-bit" path="*" verb="*" modules="IsapiModule"
        scriptProcessor="%windir%\Microsoft.NET\Framework64\v4.0.30319
        \aspnet_isapi.dll" resourceType="Unspecified" requireAccess="Script"
        precondition="classicMode, runtimeVersionv4.0, bitness64" />
      <add name="CMSWebDAVHandler" path="*" verb="*"
        type="CMS.WebDAV.WebDAVHandler, CMS.WebDAV" />
    </handlers>
    <security>
      <requestFiltering>
        <requestLimits maxAllowedContentLength="2147483648" />
      </requestFiltering>
    </security>
  </system.webServer>
</location>
<!-- WebDAV location END -->
...

```

```
</system.webServer>
</location>
<!-- WebDAV location END -->
...
```

If necessary, adjust the path in the **scriptProcessor** attributes of the handlers according to your current .NET framework version.

The rest of the configuration - common for all IIS versions

2. When the web installation is complete and the appropriate configurations have been made according to your IIS version and application pool mode, open the website using the link in the last step of the **Web installer**. When you access the URL, **Kentico CMS Database Setup** will be displayed. Follow the wizard as described in [Installation and deployment -> Installation procedure -> Database setup](#).
3. After finishing the Database Setup, go to **Site Manager -> Settings -> Integration -> WebDAV** and configure the settings as described in the [Settings](#) topic.
4. The last step is to enable **Windows authentication** for your website. Please follow the instructions in [Development -> Membership -> Authentication -> Windows authentication -> Configuring Windows authentication](#).

With all these steps performed, WebDAV editing should be possible. Please refer to the [Editing files using WebDAV](#) topic to learn more about the editing possibilities.

8.52.4 Settings

Settings related to WebDAV integration can be found in **Site Manager -> Settings -> Integration -> WebDAV**. The following settings are available:

- **Enable WebDAV support** - this options enables/disables WebDAV in both Edit mode and Browse mode.
- **Supported file extensions** - list of file extensions that should be editable using WebDAV Edit mode. The **Edit in client application** () icon is only displayed next to documents with this extension. Enter extensions with or without the leading dots, separated by semicolons; e.g. *.docx; .xlsx; .pptx; .jpg; .jpeg*. An appropriate client application with WebDAV support must be installed on the client machine for each listed extension in order for WebDAV editing of these files to be possible.

8.52.5 Integration with workflow and versioning

WebDAV editing fully integrates with [workflow and versioning](#). The following text explains behavior specifics of the system when editing [attachments](#) or [files in file fields](#) of documents to which workflow and versioning is applied. The behavior is explained separately for each of the two supported WebDAV modes.

Edit mode

When there is a workflow defined for a document, the same rules apply when editing its file fields or attachments using WebDAV Edit mode as when editing the document's content. When its file fields or attachments are edited using WebDAV Edit mode, a new version of the document is created, check-in/check-out is performed etc., based on settings of the workflow applied to the document.

Browse mode

In Browse mode, documents under workflow or their attachments can only be edited by users that are allowed to edit the document in the current workflow step. Please note that because WebDAV only works with [Windows Authentication](#), the account used to log on to Windows needs to be imported as a user account in Kentico CMS. If you allow editing in a workflow step to roles where the CMS user is member, Browse mode editing for the Windows account will be allowed. If a user tries to open a document in a workflow step that they can't approve, the document is opened as read-only.

When a document under workflow with check-out/check-in enabled is opened in Browse mode, it is checked out automatically. A checked out document can only be edited by the user who checked it out, other users can only open it as read-only. When it is saved and closed, automatic check-in is performed so that the document can be edited by other users again.

8.52.6 Edit mode

8.52.6.1 Edit mode overview

WebDAV Edit mode integrates WebDAV editing into the user interface of Kentico CMS. With Edit mode enabled, the **Edit in client application** () icon is displayed next to files throughout the CMS. Clicking the icon opens the respective file for editing in a client application.

WebDAV Edit mode is integrated in various sections throughout the whole UI. The following topics will give you an overview of these sections:

- [Editing files using WebDAV](#) - explains the general process of WebDAV editing in a simple example, showing how to edit [document attachments](#) and files stored in a [file field](#) of a document (typically the *CMS.File* document type).
- [Editing metafiles using WebDAV](#) - explains WebDAV editing of metafiles (e.g. [E-commerce](#) product images, [web part](#) teaser images, etc.).
- [Integration with WYSIWYG editor dialogs](#) - explains how to use WebDAV editing in dialogs of the [WYSIWYG editor](#).
- [Integration with Media libraries](#) - explains how to use WebDAV editing in the administration interface of the [Media libraries](#) module.

WebDAV editing has also been integrated into the following built-in modules to provide the functionality even to live site users:

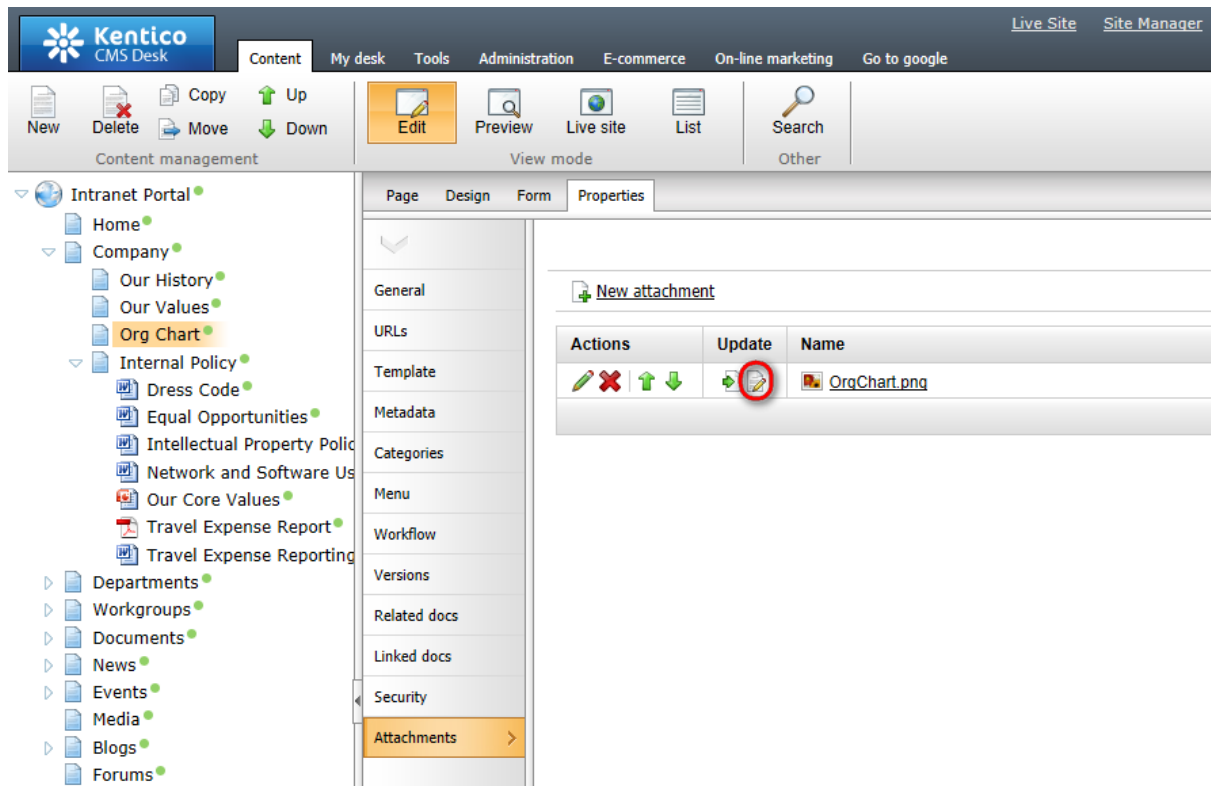

- [Integration with Document library](#) - explains how live site users can edit documents stored by means of the [Document library](#) module.
- [Integration with User contributions](#) - explains how live site users can edit files uploaded as part of documents submitted via the [User contributions](#) module.

In case that you want to learn more about WebDAV Browse mode, the other WebDAV editing mode supported by Kentico CMS, please proceed to the [Browse mode overview](#) topic in the following sub-chapter.

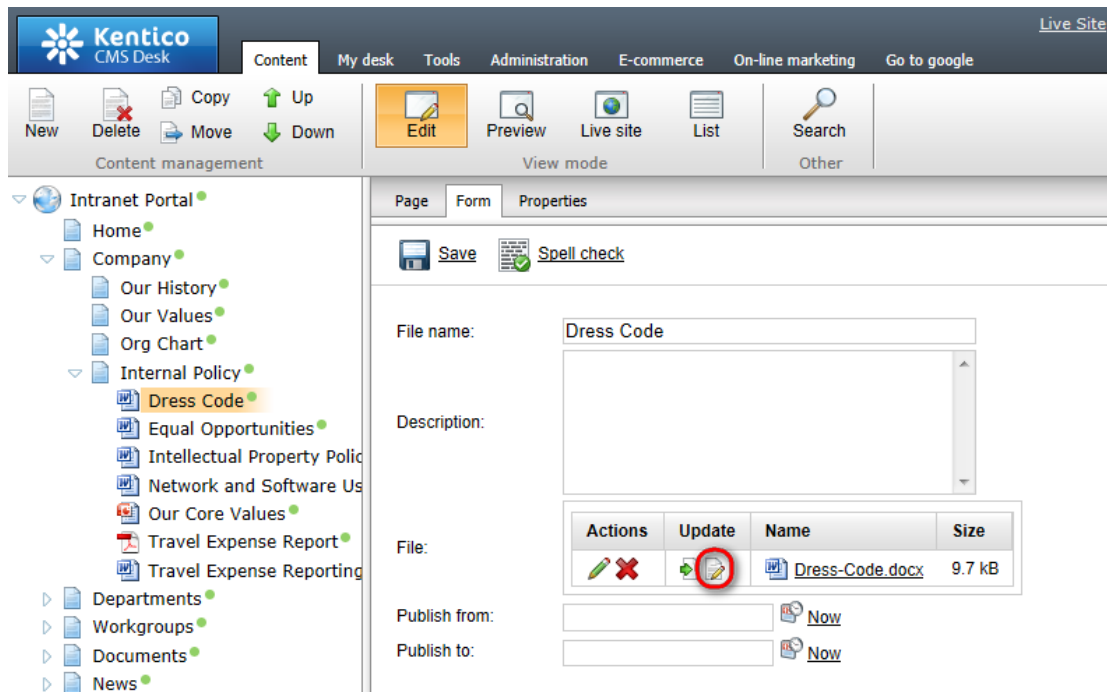

8.52.6.2 Editing files using WebDAV

After configuring your server as described in [Configuration for WebDAV](#), users who meet the client-side requirements listed in the [Requirements](#) topic may start editing [document attachments](#) or documents using the [File field](#) (e.g. *CMS.File* document type) using WebDAV.

1. WebDAV editing of document attachments is possible in **CMS Desk -> Content -> Edit**, after selecting a document in the content tree and switching to its **Properties -> Attachments** tab. The **Edit in client application** () icon should be displayed next to each attachment whose extension is included in **Site Manager -> Settings -> Integration -> WebDAV -> Supported file extensions**.

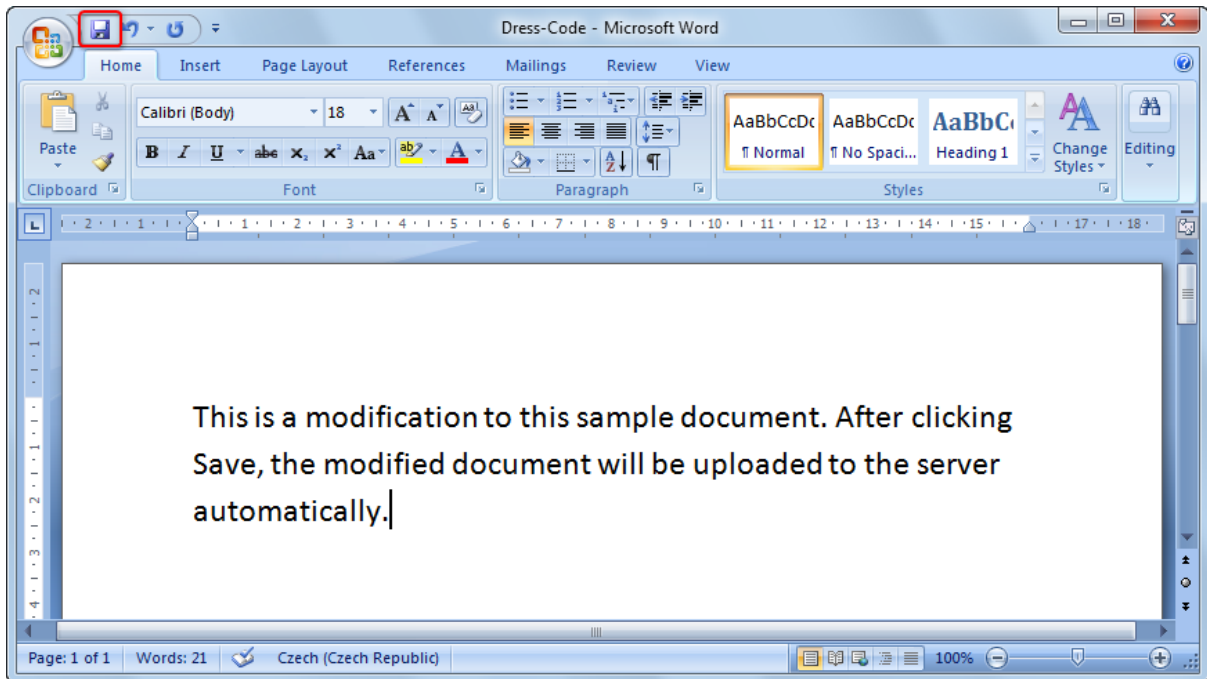

2. The same **Edit in client application** (📄✎) icon is displayed on the **Form** tab of documents using the **File field** (e.g. *CMS.File* document type) where a file with a supported extension is uploaded.

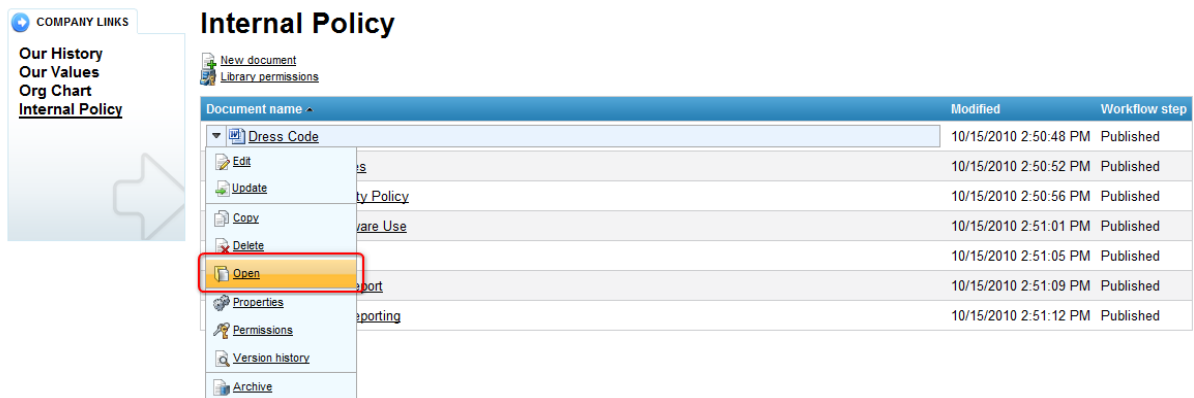

3. Clicking the icon opens the document in a client application associated with the particular file extension (e.g. *.docx* documents are opened in MS Office Word). Try editing the opened file and save

your changes using the **Save** button.

4. Now close the client application and try to open the document again, either from the UI or from the live site.

5. You should see that the file that you modified has been saved to the server and the version that you have just opened contains the modifications you made to it in the previous step.

You have learned how document attachments or documents using the File field can be edited using a client application when WebDAV integration is enabled. Editing of any other file types in any other client application (e.g. *Microsoft Office Excel*, *PowerPoint*, *Paint*, etc.) can be performed exactly the same way - all you need to do is click the **Edit in client application** (📄) icon, edit the file and save it in the client application. Transfer of the updated file to the server is handled by the CMS automatically.

Required permissions

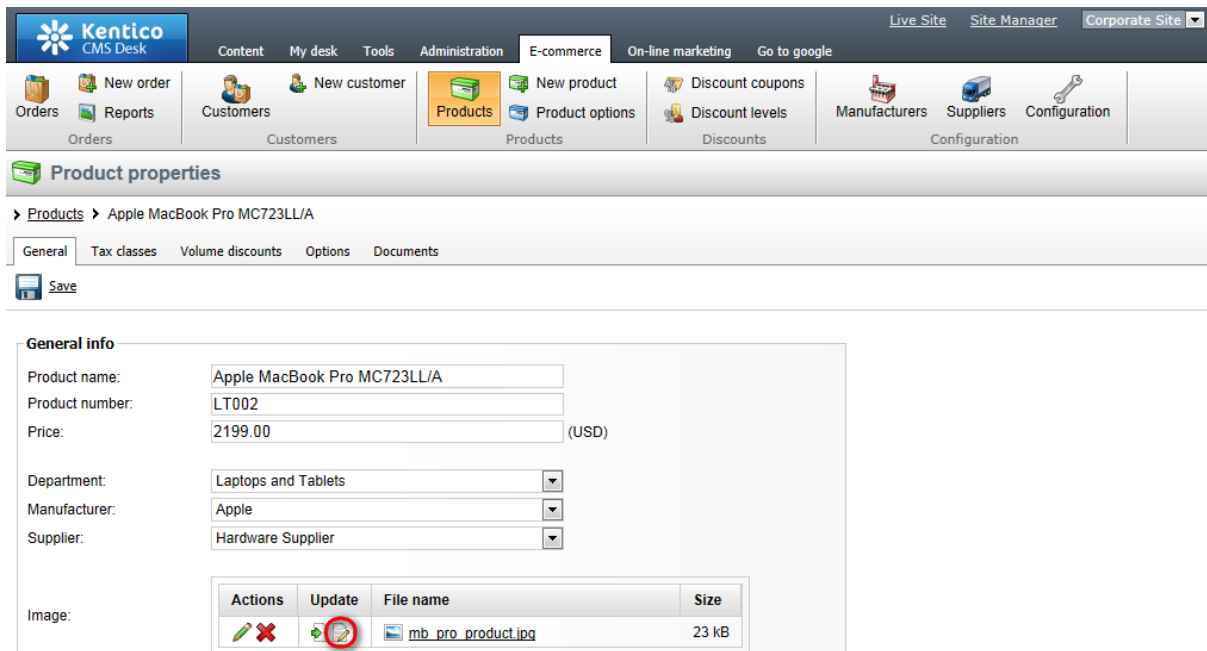

For the **Edit in client application** (📄) icon to be enabled, the **Modify** permission for the current document must be granted to the current user (or one of their roles) on one of the three levels described in [Development -> Membership -> Permissions -> Document permissions](#).

8.52.6.3 Editing metafiles using WebDAV

Metafiles in Kentico CMS are files stored together with system objects. Typical examples of metafiles are:

- [E-commerce](#) product images
- [web part](#) thumbnails
- [widget](#) thumbnails
- [page template](#) thumbnails
- etc.

All these files can be edited using WebDAV Edit mode — in the respective fields, you can find the **Edit in client application** (📄) icon, just as highlighted in the screenshot below. Clicking the icon opens the document for editing in a client application (if there is an application for the particular file type installed on the client machine and if the application supports WebDAV).

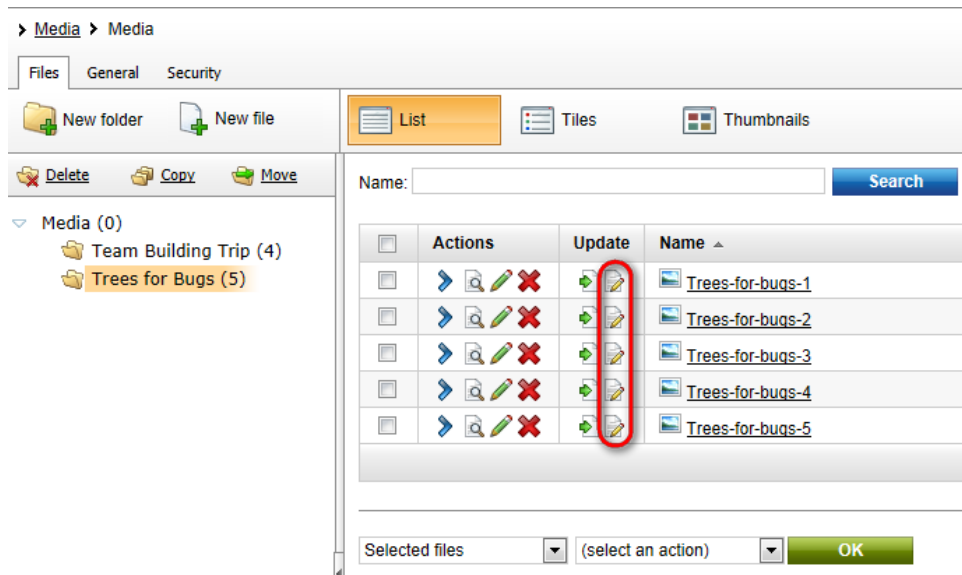

Required permissions

The following metafiles can be edited by site editors with appropriate module permissions:

| Metafile | Permissions matrix | Required permissions |
|---|-----------------------|--|
| Forms metafiles | Module -> Forms | Read form, Edit form |
| E-commerce invoice | Module -> E-commerce | Read configuration, Modify configuration |
| E-commerce product images | Module -> E-commerce | Read products, Modify products |
| Newsletters (issue attachments) | Module -> Newsletters | Read, Author newsletter issues |
| Newsletters (issue template attachments) | Module -> Newsletters | Read, Manage templates |
| Reports (General tab -> Attachments) | Module -> Reporting | Read, Modify |
| All other metafiles can only be edited by global administrators. | | |

8.52.6.4 Integration with Media libraries

[Media library](#) files can be edited using WebDAV as well. In the libraries, the **Edit in client application** () icon is displayed next to files with the supported file extensions (see [Settings](#) for more details). Clicking the icon opens the document for editing in a client application (if there is an application for the particular file type installed on the client machine and if the application supports WebDAV).

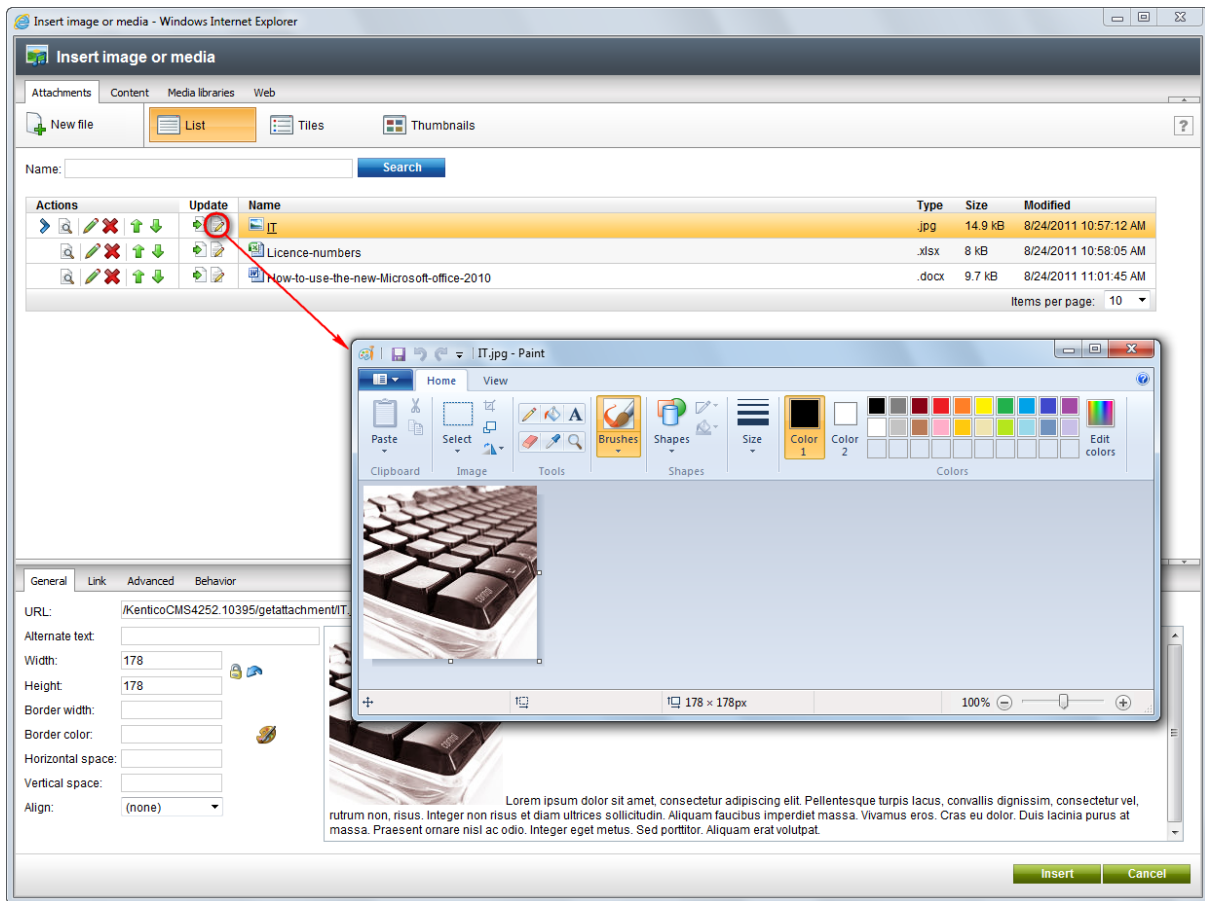

Required permissions

For the action to be available, the user must either have the **Manage** permission for the **Media libraries** module, or the **Modify file** permission in security configuration of a particular media library. See [Modules -> Media libraries -> Security -> Media library permissions](#) for more details.

8.52.6.5 Integration with WYSIWYG editor dialogs

WebDAV editing is also integrated in the [Insert/Edit image or media](#) and [Insert/Edit link](#) dialogs of the [WYSIWYG editor](#). In these dialogs, the **Edit in client application** (icon) is displayed on the **Attachments**, **Content** and **Media libraries** tabs, next to files with the supported file extensions (see [Settings](#) for more details).

Required permissions

For the icon to be displayed on the **Attachments** tab, the **Modify** permission for the current document needs to be granted to the current user. On the **Content** tab, the icon is displayed only with documents for which the **Modify** permission is granted to the current user. Please refer to [Development -> Membership -> Permissions -> Document permissions](#) for more details on the three-level document permissions hierarchy in Kentico CMS.

For the action to be available on the **Media libraries** tab, the user must either have the **Manage** permission for the **Media libraries** module, or the **Modify file** permission in security configuration of a particular media library. See [Modules -> Media libraries -> Security -> Media library permissions](#) for more details.

8.52.6.6 Integration with User contributions

WebDAV editing is integrated into the [User contributions](#) module, which brings WebDAV editing to the live site. If a document type used for user contributions contains a field of the **File** or **Document attachment** type, the **Edit in client application** (📄) icon is displayed with files uploaded into these fields. Clicking the icon opens the document for editing in a client application (if there is an application for the particular file type installed on the client machine and if the application supports WebDAV).

Required permissions

For the icon to be displayed in the **Contribution list** or **Edit contribution** web parts, the **Check permissions** property of the web part needs to be enabled and the current user must have appropriate permissions to edit the document, as described in [Modules -> User contributions -> Security](#). When using the [Groups module](#) versions of the web parts, the icon is displayed either under the same conditions as described above or when the current user is the administrator of the respective group.

8.52.6.7 Integration with Document library

Files stored in a [Document library](#) can also be edited in a client application using WebDAV directly on the live site. There is the  **Edit** action available in their drop-down menu, as can be seen in the screenshot below. Clicking the icon opens the document for editing in a client application (if there is an application for the particular file type installed on the client machine and if the application supports WebDAV).

Required permissions

For this action to be enabled, the document must have one of the supported extensions (see [Settings](#) for more details) and the **Modify** permission for the particular document must be granted to the current user. Please refer to [Modules -> Document library -> Security](#) for more details on permissions in document libraries.

8.52.7 Browse mode

8.52.7.1 Browse mode overview

WebDAV Browse mode enables you to **map a network drive** in your operating system that represents the content of your website. [Files stored by the website](#) can be found on the drive, letting you **open, edit and save** the files in a client application just as if they were stored on your local drive.

For to start using WebDAV Browse mode, you need to meet all [requirements](#) and performed the necessary [configuration](#). After that, you only need to map the network drive in the operating system. The [Mapping a WebDAV network drive](#) topic explains two approaches how this can be achieved. When the network drive is mapped, you can start editing website files right away.

The network drive contains the following folders:

- [attachments](#) - contains [document attachments](#) and files stored in documents' [file fields](#). They can be found in folders resembling the website's content tree structure.
- [content](#) - contains [CMS.File documents](#) stored in folders resembling the website's content tree structure.
- [media](#) - contains a folder for each [media library](#) on the website, while each folder contains the actual content of the respective library.
- [groups](#) - contains a folder for each [group](#) defined on the site, while each group folder contains the three folders mentioned above, containing only those attachments, content and media that belong to the particular group.

The **media** and **groups** folders may not be present, depending on if the [Media libraries](#) and [Groups](#) modules are installed. Click a folder name above in order to get more information about how files are stored in it. To get a quick overview of how Browse mode editing actually works, you may refer to the [Example of Browse mode editing](#) topic.

8.52.7.2 Mapping a WebDAV network drive

Once you have Kentico CMS installed and configured as described in the [Configuration for WebDAV](#) topic, you only need to map a network drive in your operation system that will be pointing to the web server. There are two ways how this can be done:

1. Mapping the network drive in Windows command line

1. Open Windows command line (press **[window]+R**, type `cmd` and click **OK**).
2. Enter the following command:

```
net use x: http://<your_domain>/cms/files
```

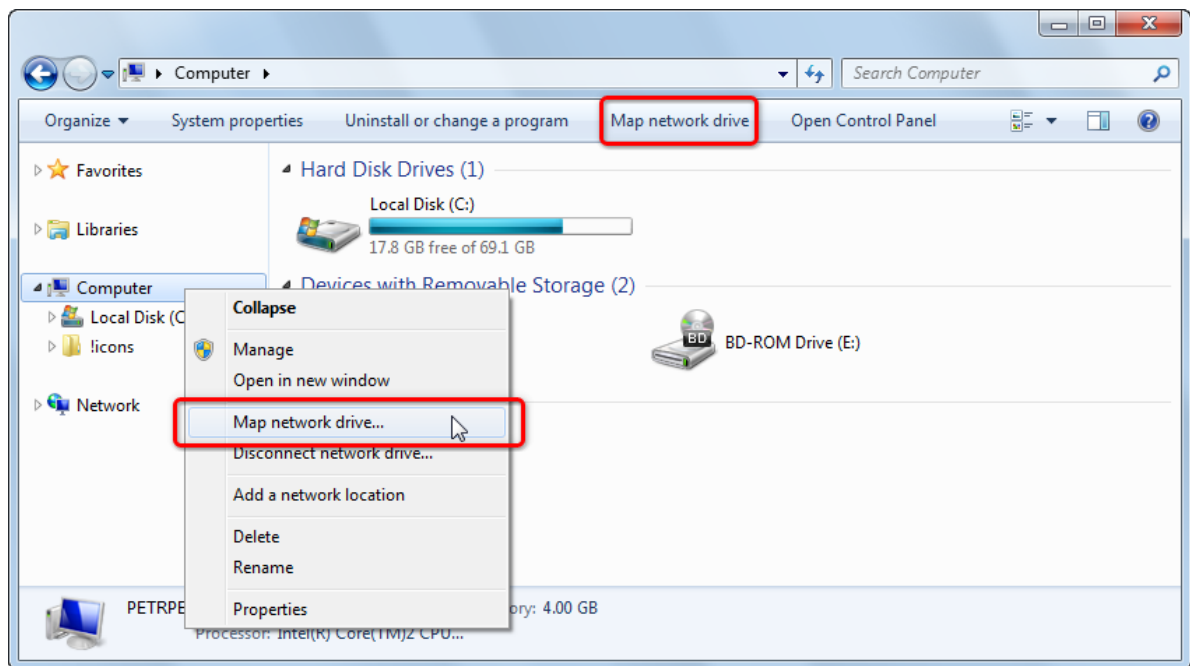

The `x:` part of the command determines which letter will be used for identification of the network drive in your system. Instead of `x`, you can use any letter that is not used for another drive yet.

The `<your_domain>` part of the command needs to be replaced with the domain name of your website. So, for example, if your website is running on `http://www.example.com`, you would need to enter `net use x: http://www.example.com/cms/files`. Similarly for `http://localhost/KenticoCMS`, you would need to enter `net use x: http://localhost/KenticoCMS/cms/files`.

2. Mapping the network drive in Windows UI

The following procedure is demonstrated on Windows 7. In other versions of Windows, it may be slightly different, while its principles and the entered values remain the same.

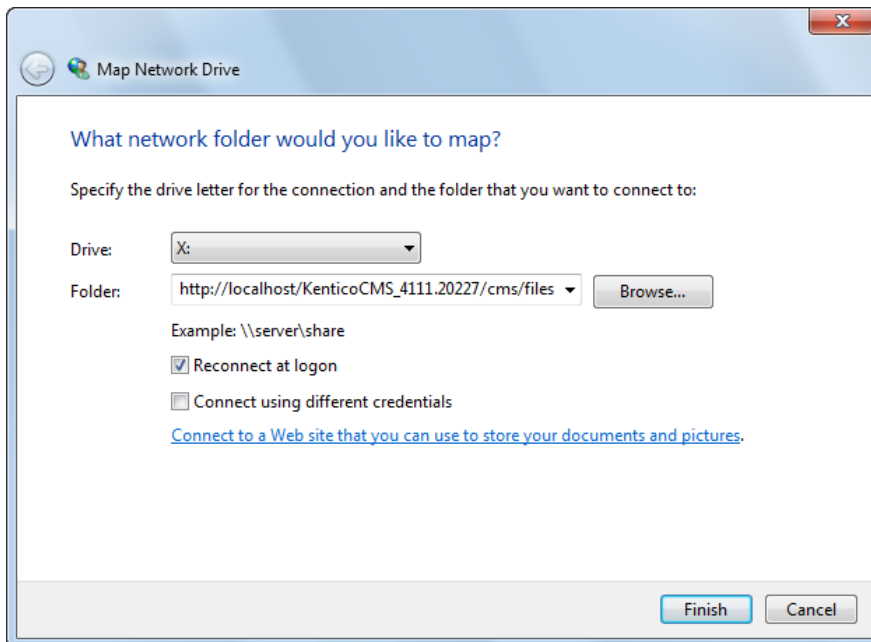

1. Open **Windows Explorer** and select **Computer** in the left menu. Right-click it and select **Map network drive**. Alternatively, the **Map network drive** action can be executed from the top menu, as highlighted in the screenshot below.

2. In the **Map Network Drive** dialog, adjust the following values:

- **Drive** - select the letter that will be assigned to the network drive in Windows.
- **Folder** - enter a URL in format *http://<your_domain>/cms/files* where the *<your_domain>* part should be replaced with the domain name of your website.
- **Reconnect at logon** - leave this option enabled if you want the drive to be connected next time you start Windows.
- **Connect using different credentials** - use this option in case that you want to use a different user account than your current Windows account. In such case, you will be asked to enter logon credentials after clicking **Finish**.

Click **Finish** and wait until the network drive gets connected.

Mapping a network place on Windows XP/Server 2003/Vista

When you experience problems while mapping a network drive on Windows XP, Windows Server 2003 or Windows Vista, you can map a network place instead:

1. Open the **Start** menu, right-click **My Computer** (or **Computer** on Vista) and choose **Map Network Drive** from the context menu.
2. In the dialog which pops up, click the link saying *Sign up for online storage or connect to a network server* (on Vista, the link says *Connect to a Web site that you can use to store your documents and pictures*). This will open the **Add Network Place Wizard**.
3. In the first step, click **Next**. In the second step, choose **Choose another network location** and click **Next**. In the third step, enter the URL in the *http://<your_domain>/cms/files* format and click **Next**.
4. In the fourth step, enter a name that will be used for the network location (e.g. *MyNetworkPlace*) and click **Next**. In the final step, click **Finish**.

Once finished, the network place should be mapped and content of the WebDAV network drive should be accessible through it. Please note that in this case, the content will not be accessible under a drive letter (e.g. X:\), but under the name of the network place specified in step 4 of the wizard (e.g. \\MyNetworkPlace).

Accessing the network drive

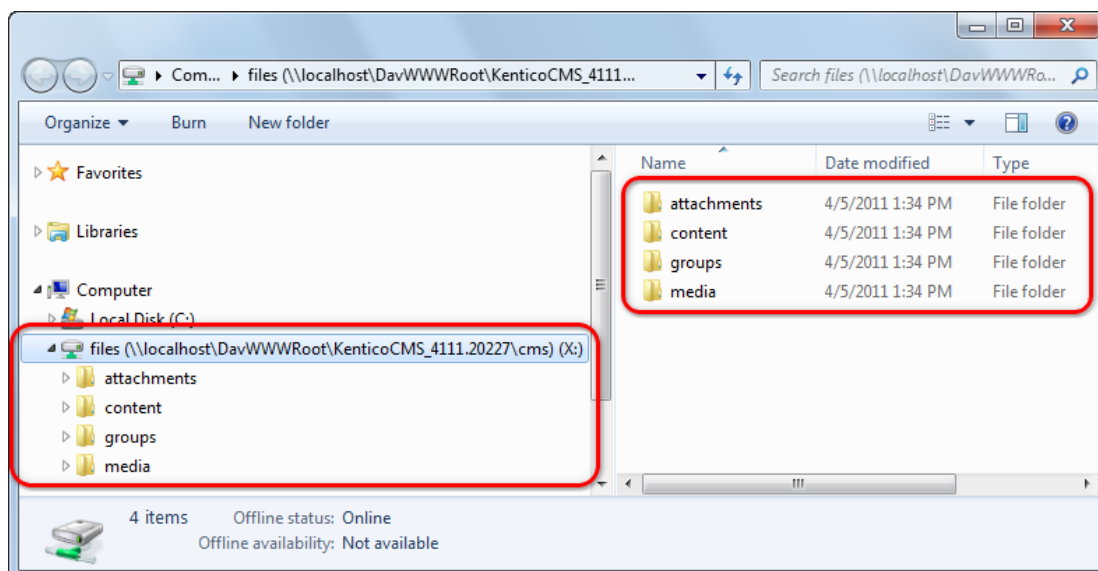

Once you have the network drive connected, it is recommended to check that you can access it. Open

Windows Explorer or any other file manager that you are using. The drive should be available among other drives in your system, under the letter that you assigned to it when you mapped it.

If you open the drive, you should see that it contains four folders. Each of them contains different types of files stored by your website:

- [attachments](#) - contains [document attachments](#) and files stored in documents' [file fields](#). They can be found in folders resembling the website's content tree structure.
- [content](#) - contains [CMS.File documents](#) stored in folders resembling the website's content tree structure.
- [media](#) - contains a folder for each [media library](#) on the website, while each folder contains the actual content of the respective library.
- [groups](#) - contains a folder for each [group](#) defined on the site, while each group folder contains the three folders mentioned above, containing only those attachments, content and media that belong to the particular group.

Click a folder name above to learn more about content of the respective folder.

Unusually long response time

If you are experience unusually long delays when opening a WebDAV drive, copying files to or from it or switching between different WebDAV drives, please make sure you have the **Automatically detect settings** option disabled in **Internet Explorer -> Tools -> Internet Options -> Connections -> LAN Settings**.

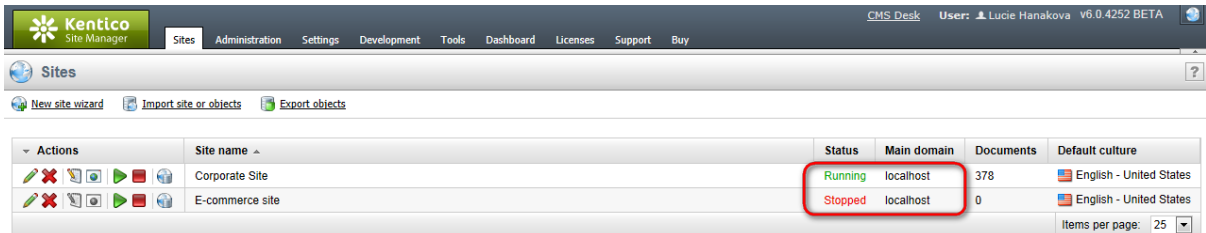

See the following article for more details: <http://support.microsoft.com/kb/2445570>

Multiple websites using the same domain

In a typical scenario, each website running in Kentico CMS uses a different domain. Therefore, the URL

of the mapped network drive would be different for each site, letting you map a drive separately for each website.

However, if you have multiple websites using the same domain (typically *localhost* in a development environment), only one of these websites can be running at a time while all others are stopped. In this case, the network drive always displays content of the site that is currently running.

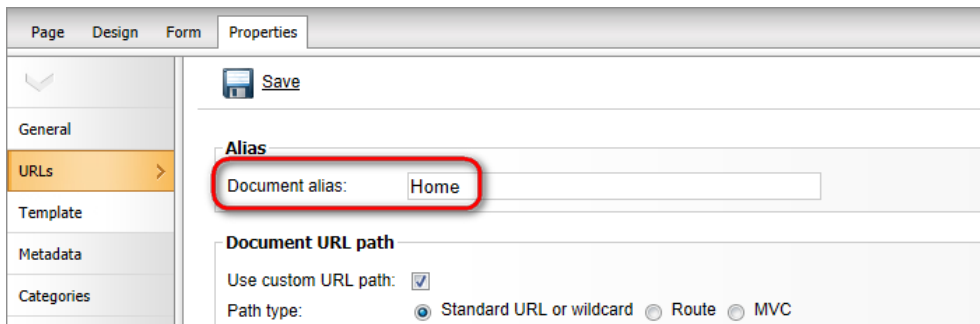

| Actions | Site name | Status | Main domain | Documents | Default culture |
|---------|-----------------|---------|-------------|-----------|-------------------------|
| | Corporate Site | Running | localhost | 378 | English - United States |
| | E-commerce site | Stopped | localhost | 0 | English - United States |

8.52.7.3 Attachments

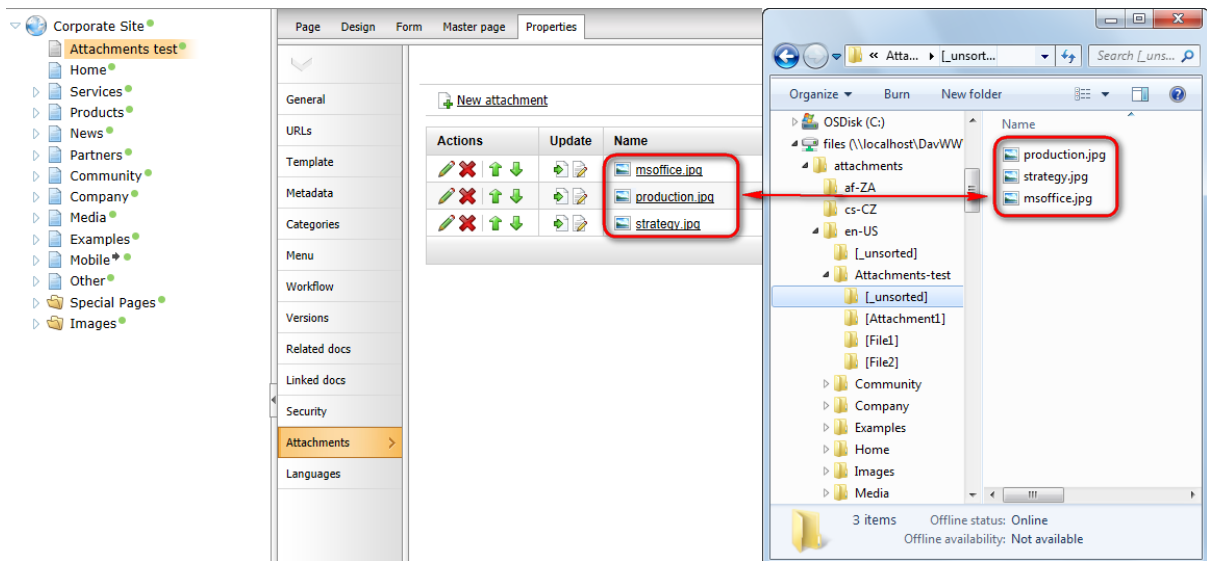

The **attachments** folder in the root of your WebDAV network drive contains [document attachments](#) of all documents in the website's content tree. Under the **attachments** folder, there is one folder for each culture used for the website (1. in the screenshot below). Under each of the folders, you can find one folder for each document in the content tree in the particular language version (2. in the screenshot below).

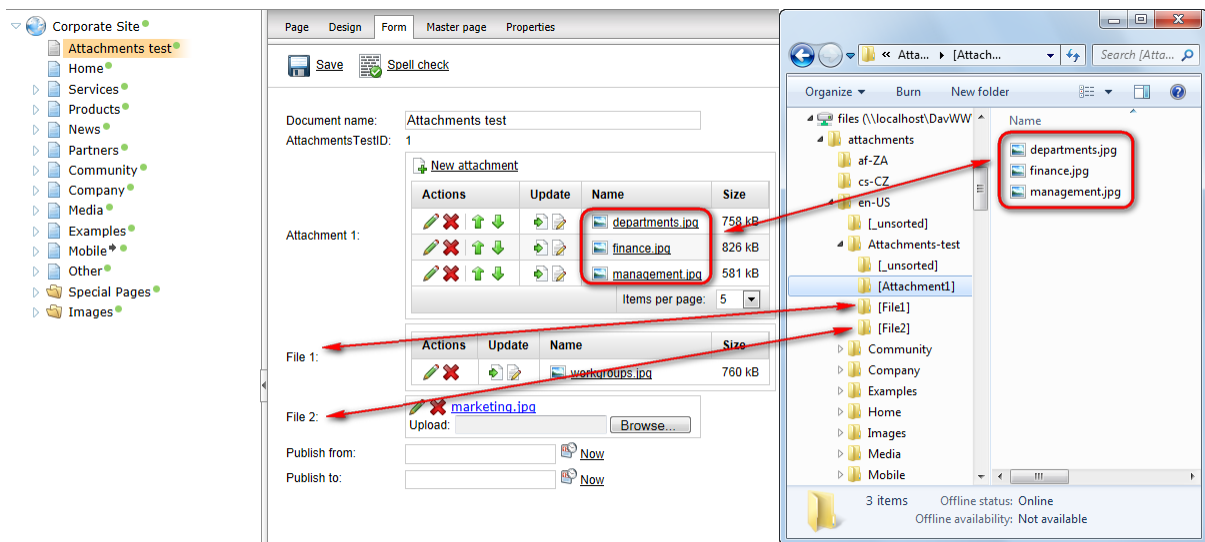

Please note that **folder names reflect node aliases** of particular documents, **not their document names**. This is necessary for unique identification of documents in URLs. Node aliases of documents can be viewed and modified on the **Properties -> URLs** tab, in the **Document alias** field.

The **[_unsorted]** folder does not represent any document in the content tree. It is present under each folder representing a document and contains its [unsorted attachments](#). In the root, this folder contains unsorted attachments of the content tree root. Unsorted attachments are the ones that are added to documents on the **Properties -> Attachments** tab.

If you expand a folder representing a document that has some [grouped attachment fields](#) or [file fields](#), you should see a folder for each of the fields. The folder has the same name as the respective field's DB column, wrapped in square brackets like **[MyAttachmentField]**. Under it, you can find all files uploaded into the field.

Possible actions and required permissions

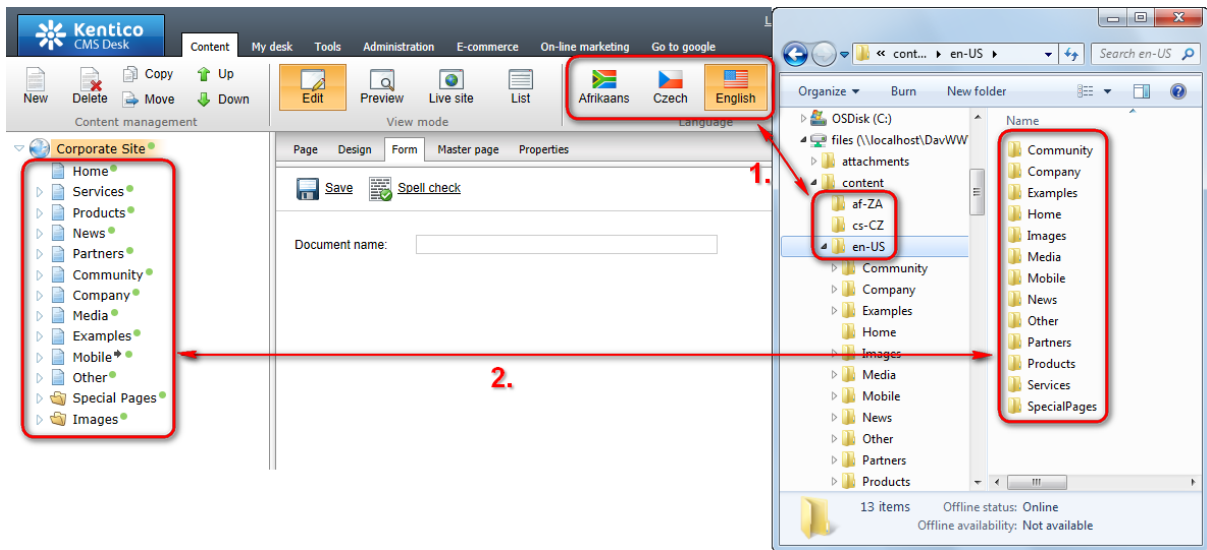

The following [document permissions](#) need to be granted to users (their roles) in order to perform respective actions with document attachments:

| Action | Required permission |
|---|---|
| Browse folder structure | Browse tree |
| Display attachments & open them in read-only mode | Read |
| Upload attachments | Modify, while the file must have one of the extensions defined in the <i>Allowed extensions</i> value for the respective field, or globally in <i>Site Manager -> Settings -> System -> Files -> Upload extensions</i> in case that the field is configured to inherit from settings. |
| Edit attachments | Modify |
| Delete unsorted attachments | Modify |
| Delete grouped attachments | Modify, while the <i>Allow empty value</i> option must be enabled for the respective field. |

Please note that because WebDAV only works with [Windows Authentication](#), the account used to log on to Windows needs to be imported as a user account in Kentico CMS. If you grant permissions to roles where the CMS user is member, Browse mode editing for the Windows account will be allowed.

8.52.7.4 Content

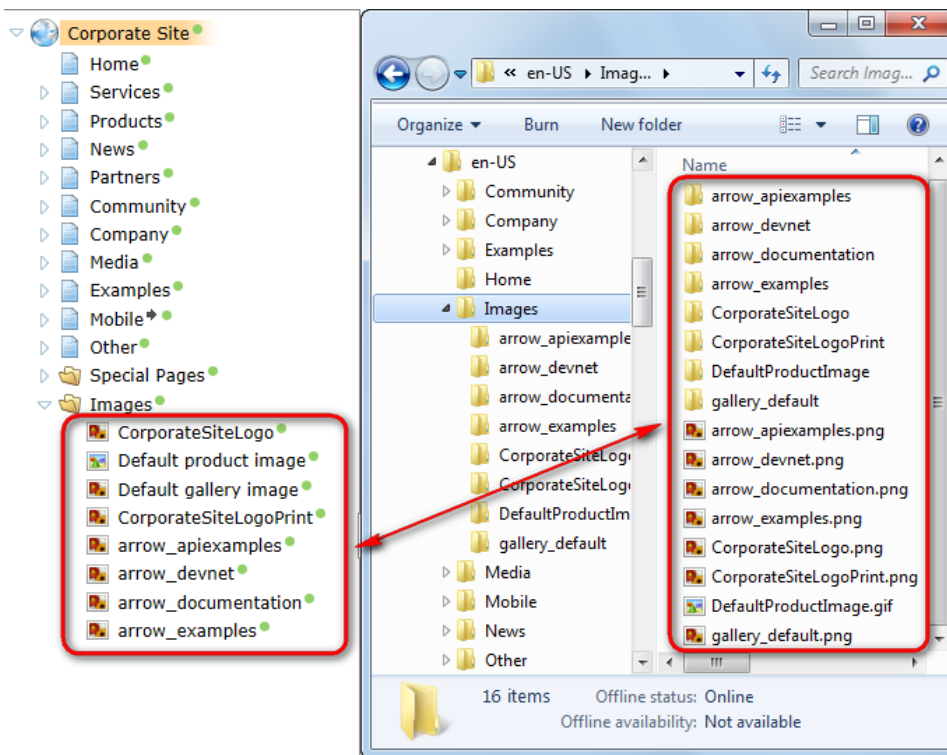

The **content** folder contains documents of the **CMS.File** document type (see [Content management -> File management](#) for more details). Under the **content** folder, there is one folder for each culture used for the website (1. in the screenshot below). Under each of the folders, you can find a folder for each document in the content tree in the particular language version (2. in the screenshot below).

Please note that **folder names reflect node aliases** of particular documents, **not their document names**. This is necessary for unique identification of documents in URLs. Node aliases of documents can be viewed and modified on the **Properties -> URLs** tab, in the **Document alias** field.

While standard documents are represented by a folder, *CMS.File* documents are here both as a folder and as a file. The file represents the actual physical file stored in the document's file field. The folder is here for the case that the *CMS.File* document had some child documents, as those would be located under it in this case (as the *Services_webdevelop* document under the *CompanyLogo* document in the screenshot below).

Possible actions and required permissions

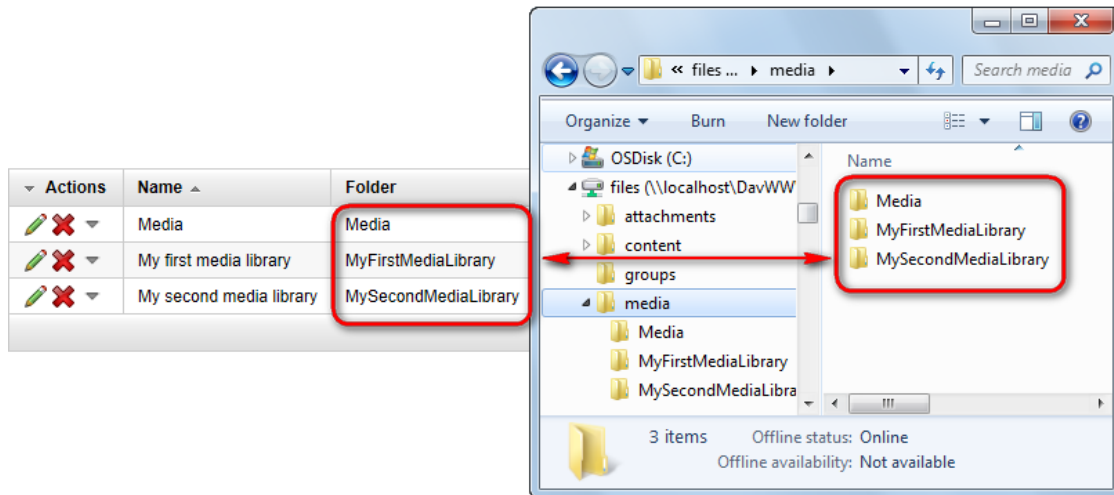

The following [document permissions](#) need to be granted to users (their roles) in order to perform respective actions with *CMS.File* documents:

| Action | Required permission |
|-------------------------------|---|
| Open a file in read-only mode | Read |
| Upload a file | Create, while the file must have one of the extensions defined in the <i>Allowed extensions</i> value for the <i>FileAttachment</i> field of the <i>CMS.File</i> document type, or globally in <i>Site Manager -> Settings -> System -> Files -> Upload extensions</i> in case that the field is configured to inherit from settings. |
| Edit a file | Modify |
| Delete a file | Delete, while the <i>Allow empty value</i> option must also be enabled for the <i>FileAttachment</i> field of the <i>CMS.File</i> document type. Deleted files are moved to the recycle bin (in the CMS, not in Windows). |

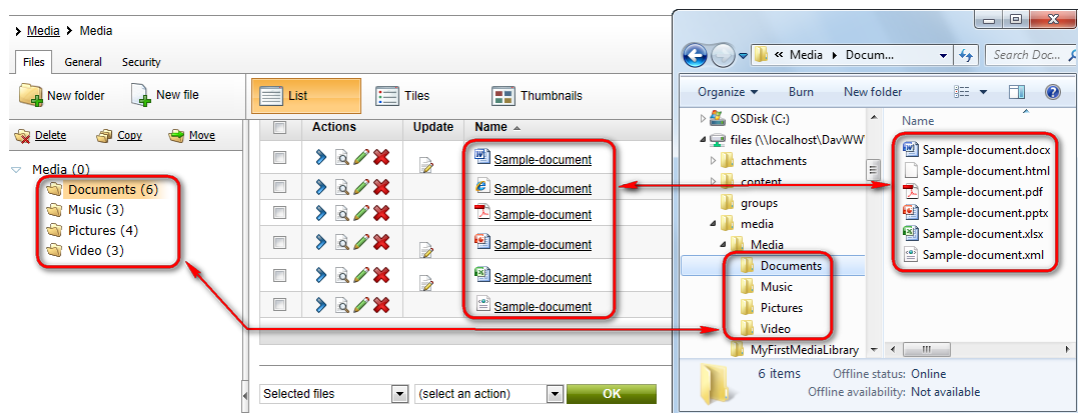

Please note that because WebDAV only works with [Windows Authentication](#), the account used to log on to Windows needs to be imported as a user account in Kentico CMS. If you grant permissions to roles where the CMS user is member, Browse mode editing for the Windows account will be allowed.

8.52.7.5 Media

The **media** folder contains a folder for each [media library](#) on the website. The name of each folder is the same as the **Folder name** value entered when creating the respective media library.

Under each of the folders mentioned above, structure of the particular library is reflected the same way as in the CMS — files and folders are displayed in the same structure as in the actual library.

Possible actions and required permissions

Appropriate permissions need to be granted to users (their roles), either globally for the **Media libraries** module or separately for each particular library. Permissions required for individual actions are listed in the table in [Modules -> Media libraries -> Security -> Media library permissions](#), while only the **Files** and **Folders** action groups are relevant for WebDAV Browse mode.

Please note that because WebDAV only works with [Windows Authentication](#), the account used to log on to Windows needs to be imported as a user account in Kentico CMS. If you grant permissions to roles where the CMS user is member, Browse mode editing for the Windows account will be allowed.

8.52.7.6 Groups

The **groups** folder contains a sub-folder for each [group](#) on the website.

Under each group folder, you can find three folders: [attachments](#), **pages** (similar behavior as the [content](#) folder in the network drive root) and [media](#). The content and behavior of these folders is identical to the three folders of the same name that are located in the WebDAV network drive root. Click the folder names above to get redirected to pages dedicated to their descriptions. The following text will describe the main differences applied in this section.

Group pages attachments

The **attachments** folder contains a sub-folder for each website culture. Under each culture, you can find folders representing pages in the group pages location (configurable in **Site Manager -> Settings -> Community -> Group pages location**) that belong to the respective group.

In the screenshot below, you can see that the **en-US** folder actually represents the *en-US* version of the **African_travellers** document. The **[_unsorted]** folder contains [unsorted attachments](#) of the

African_travellers document, while the **[MenuItemTeaserImage]** folder represents the **Menu item teaser image file field** of the **African_travellers** document. The same applies to the documents under it.

Group pages content

The **content** folder also contains a sub-folder for each website culture. Similarly to the content folder in the WebDAV network drive root, these folders are used to provide WebDAV editing of *CMS.File* documents. The only difference is that only documents belonging to the group found in the group pages location (configurable in **Site Manager -> Settings -> Community -> Group pages location**) can be found in each culture folder.

In the following screenshot, you can see the **msoffice.jpg** file in the content tree under the **Pages** document, as well as in **Windows Explorer** under the **Pages** folder. It is there twice. Once as a file, which represents the actual **.jpg** file uploaded in the document's file field, and as a folder, for the case that it had some child documents that would then be located under it.

Group media libraries

The **media** folder contains one folder for each media library of the respective group. Under the folder, the structure of the media library is reflected identically to the structure shown by the CMS — folders represent folders inside the library, while files represent the actual files stored in them.

Possible actions and required permissions

Only group administrators, community administrators or global administrators are allowed to browse the **groups** folder. Only those groups where the user is an administrator are displayed to them as a folder under the **groups** folder (community and global administrators are able to see all group folders). Therefore, only files of the appropriate groups can be edited by them.

Please note that permission requirements described in the [Attachments](#), [Content](#) and [Media](#) topics apply in the respective folders in the network drive root. Therefore, users who do not belong to those mentioned in the previous paragraph can still get to the group files via these folders if they have the

required permissions.

8.52.7.7 Example of Browse mode editing

The following example demonstrates how website file management using WebDAV Browse mode actually works. The sample Intranet Portal website is used for the purpose of the example.

Before trying this example on your machine, please make sure that your system meets all [requirements](#), that it is configured as described in the [Configuration for WebDAV](#) topic, that you have [WebDAV settings](#) adjusted properly and that you have [mapped a WebDAV network drive](#).

Editing a CMS.File document

1. Go to **CMS Desk** and expand the **Company/Internal Policy** node in the content tree. From the documents under it, select **Dress Code** and switch to its **Form** tab. As it is a *CMS.File* document, you can see that it has a **Dress-Code.docx** file uploaded in its File field.

The screenshot shows the Kentico CMS Desk interface. The top navigation bar includes 'Content', 'My desk', 'Tools', 'Administration', 'E-commerce', 'On-line marketing', and 'Go to google'. The left sidebar shows a content tree with 'Intranet Portal' expanded to 'Company' and then 'Internal Policy', where 'Dress Code' is selected. The main area shows the 'Form' tab for the 'Dress Code' document. The 'File' field contains a table with the following data:

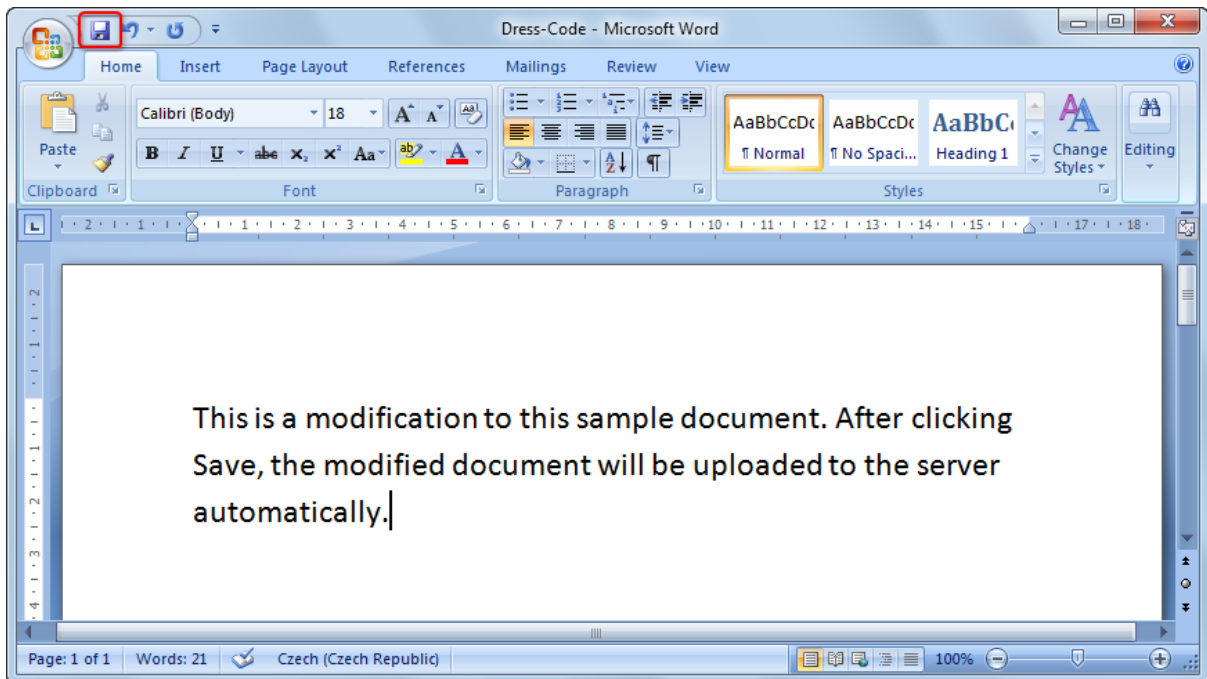

| Actions | Update | Name | Size |
|---|---|---|--------|
|   |  |  Dress-Code.docx | 9.7 kB |

The 'Actions' column for the 'Dress-Code.docx' entry is circled in red. Below the table, there are 'Publish from:' and 'Publish to:' fields, both with a 'Now' button.

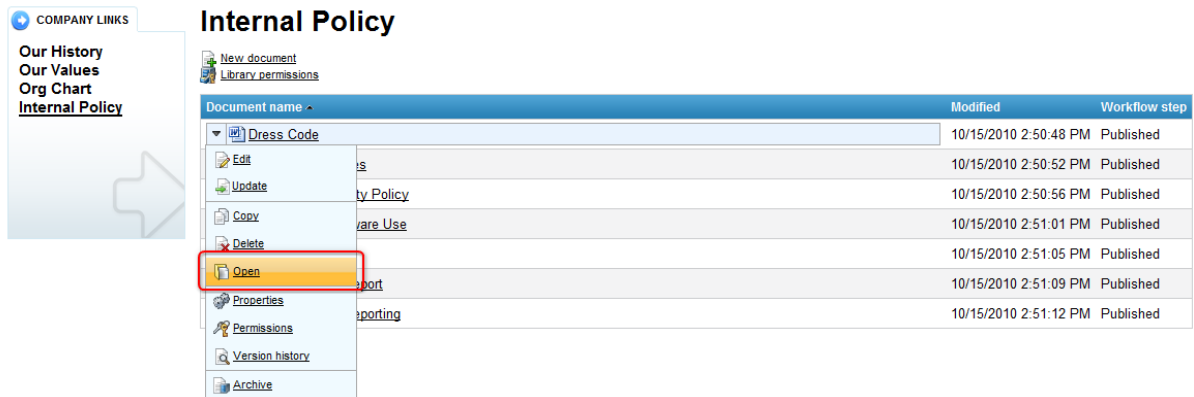

2. Let's take a look at the document on our network drive. Open **Windows Explorer** or any other file manager that you prefer. Open the WebDAV network drive and browse to *content\<your culture>\Company\Internal-Policy*. As you can see in the screenshot below, the **Dress-Code** document is represented twice in the folder — first as the **Dress-Code** folder and second as the **Dress-Code.docx** file. The folder represents the document in the content tree and would contain unsorted attachments if the document had some. The file represents the **Dress-Code.docx** file uploaded in the document's File field. Open the **Dress-Code.docx** file to see how it can be edited.

3. The **Dress-Code.docx** file gets opened in a client application (typically in Microsoft Office Word). Try editing the opened file and save your changes using the **Save** button.

4. When you have your modifications saved, try opening the file either from the UI or from the live site.

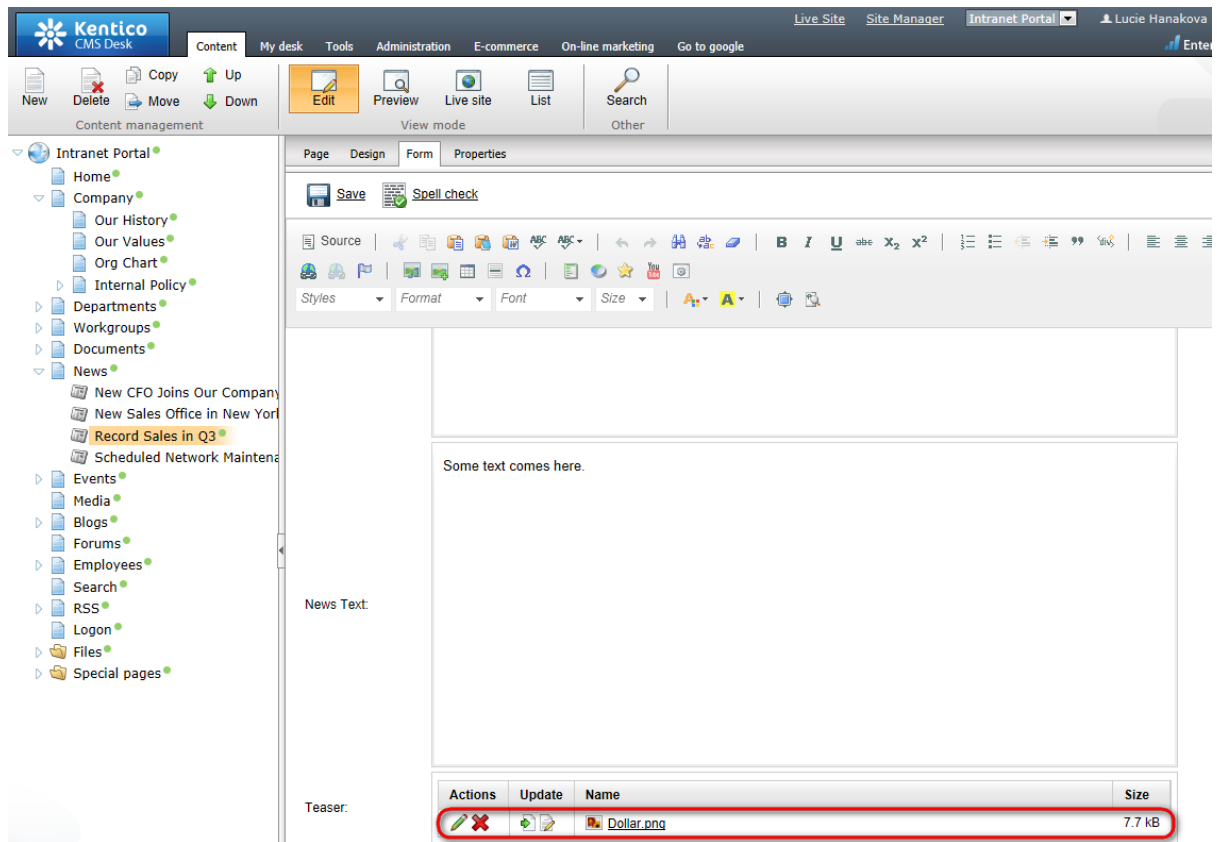

5. You should see that the opened file contains the modifications that you made to it.

Updating a file in a File field

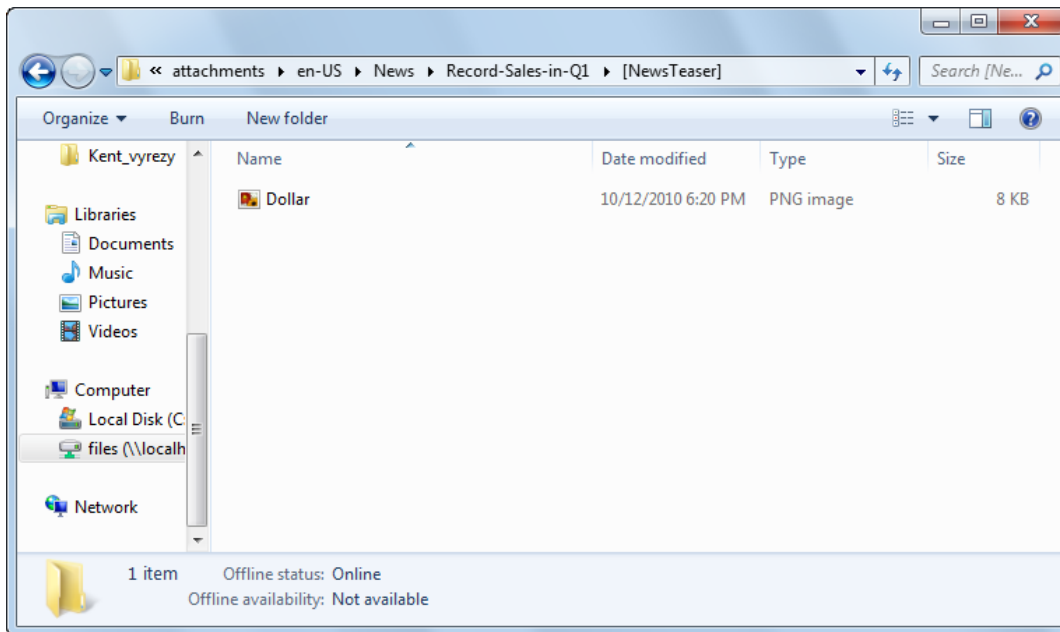

6. Next, we will try out how file uploaded in File fields can be replaced with other files. For this purpose, go back to **CMS Desk** and choose the **News/Record Sales in Q3** document in the content tree. On its **Form** tab, you can see a file uploaded in the **Teaser** File field.

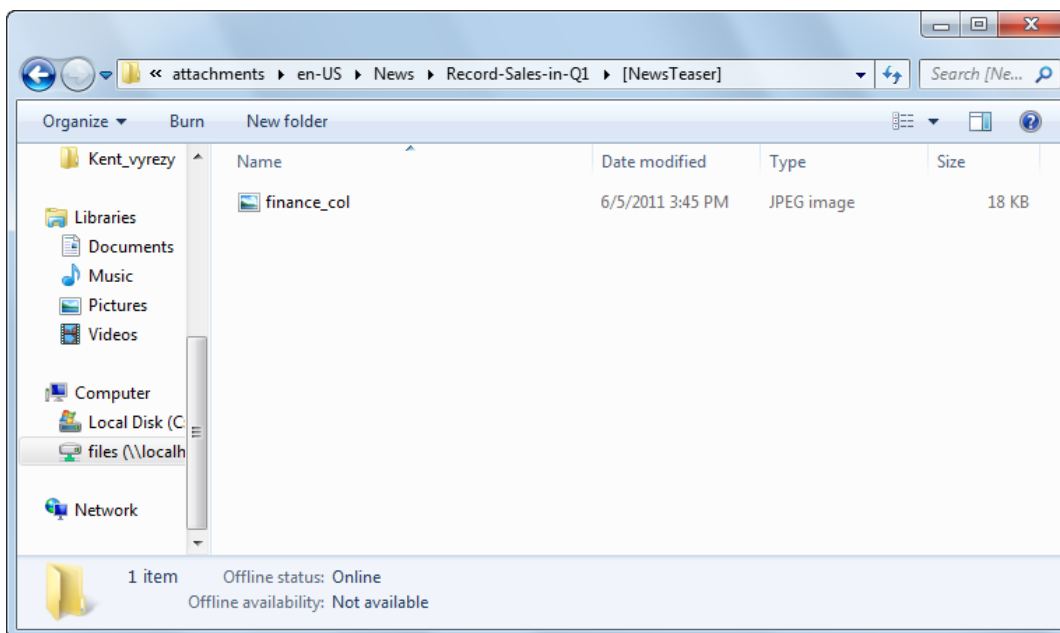

7. This file is displayed in the summary of the News item on the live site.

8. Open the WebDAV network drive and navigate to `attachments\en-US\News\Record-Sales-in-Q3\News Teaser`. You should see that the original **Dollar.png** file in the folder.

8. Try copying another image file into the folder. If you refresh the content of the folder (press F5) after a few seconds, you should see that the original file disappeared. This means that the original file in the File field has been replaced with the newly uploaded one.

9. The newly uploaded file should now also be visible in the UI ...

| Actions | Update | Name | Size |
|---|---|---|--------|
|   |   |  finance_col.jpg | 2.3 kB |

10. ... and on the live site.

Record Sales in Q3 | 10/12/2010

The third quarter was the best quarter in our history! We grew the sales by 70% year-to-year. Thanks to everybody to their hard work.

8.52.7.8 Browse mode limitations and specifics

The following text lists specific behavior of the system when WebDAV Browse mode is used. These specifics are by design and can't be influenced or solved by a workaround.

Maximal path length

The maximal path length in Windows file systems is 250 characters. Therefore, if you have deep indentation in your content tree, folders and files that would have the path to them longer than 250 characters are not displayed on the network drive.

Windows cache delays

As explained in step 5 of the [Example of Browse mode editing](#) topic, you may experience delays when updating files in grouped attachment fields or file fields. The original file will be present along with the new one for about 1 minute. If you refresh displayed content of the folder after the interval, the file should disappear.

The same problems may be experienced when deleting a file without appropriate permissions. The file will not actually be deleted, but it will not appear in the folder for the 1 minute interval until Windows cache is refreshed.

Zero file-length limitations

It is not possible to upload or create [document attachments](#) and [files using the file field](#) based on files that have zero file length. On attempt to do so, the following behavior can be expected by-design:

When uploading a zero-length file under the **attachments** folder, a temporary attachment is created. It is not visible in the UI or on the network drive. If you try to upload a file to the same folder, an error message saying that the file already exists will be displayed (asking you if you want to overwrite it).

When uploading a zero-length file under the **content** folder, a standard *CMS.File* document is created, while it only has a temporary attachment in the file field. The document can be seen both in the UI (as a document in the content tree) and on the network drive (as a folder which can't be deleted using Browse mode). The temporary attachment can't be seen in either of the two. If you try to upload a file to the same folder, an error message saying that the file already exists will be displayed (asking you if you want to overwrite it).

Please note that in [WebDAV Edit mode](#), uploading of zero-length files is possible without any problems or limitations.

8.53 Web farm synchronization

8.53.1 Overview

Native web farm support in Kentico CMS provides the following features:

- It synchronizes the changes made to the site settings or content on one of the servers to all the other servers.
- It synchronizes the files uploaded to the site to all other servers. This is used only if you store the uploaded files on the disk or on both disk and in the database.

The following image shows the structure of the web farm and how the synchronization works:

If you change some settings or upload a file using server 192.168.1.2, the other servers do not know about it in a standard scenario. However, if you're using the **Web farm synchronization** module, it automatically creates a new synchronization task in the database and notifies the other servers so that they process their synchronization task. To learn more about how the synchronization works, refer to the [Synchronization mechanisms](#) topic.

To learn how to add web farm servers into the system and configure them, please see the [Defining web farm servers](#) topic.

Developers can write custom tasks to be used by this module. The [Creating custom web farm synchronization tasks](#) topic contains more information.

The [Web farm synchronization internals and API](#) sub-chapter provides information about the database

tables and classes used by the module and examples of how web farm synchronization can be managed using the API.

Using Kentico CMS on a web farm without the Web farm synchronization module

You can use Kentico CMS on a web farm even if you do not use the web farm synchronization module, especially if you do not store uploaded files in the file system. Then, the only limitation is that if you change the settings or page content on one of the servers, the other servers may keep using the old version of the settings in their memory/cache until the web application is restarted or cache content expires.

Please note: The web farm support **doesn't replace any load-balancing or web farm management tools**.

SSL in a web farm environment

If you use an SSL offload device or accelerator as part of your web farm, you may encounter problems with a redirection loop if your website is configured to require SSL for the administration interface or on specific pages.

For this type of scenario, it is necessary to add some custom code to your website, as described in the [SSL \(HTTPS\) support](#) topic in the **Membership, permissions and security** -> **Security** chapter of this guide.

8.53.2 Synchronization mechanisms

This topic describes the process of propagating changes in a web farm.

When you make changes to content on a server, those changes get logged into the database as a web farm task. The server then notifies other servers, which retrieve the task data from the database and make appropriate changes in their file system or memory. There are two ways servers can get notified about changes in the web farm.

URL notifications

Every Kentico CMS instance contains a page that a web farm server can send requests to when it generates one or more web farm tasks. The other web farm servers don't get involved in the process until they are notified about the changes. When this happens, each server fetches its tasks and processes them accordingly.

This is the default behavior in instances not running on Windows Azure.

Database notifications

In this approach, a column in the **CMS_WebFarmServer** database table is used. The column contains a time stamp, which indicates the time of the last change made on a server. On the application side, a

routine runs in a separate thread which continuously polls the database to find out whether a time stamp changed.

To enable this mechanism, add the following key to your web.config file. You don't need this key if your application runs on Windows Azure, as this mechanism is used on Azure by default.

```
<add key="CMSWebFarmUseDBUpdater" value="true" />
```

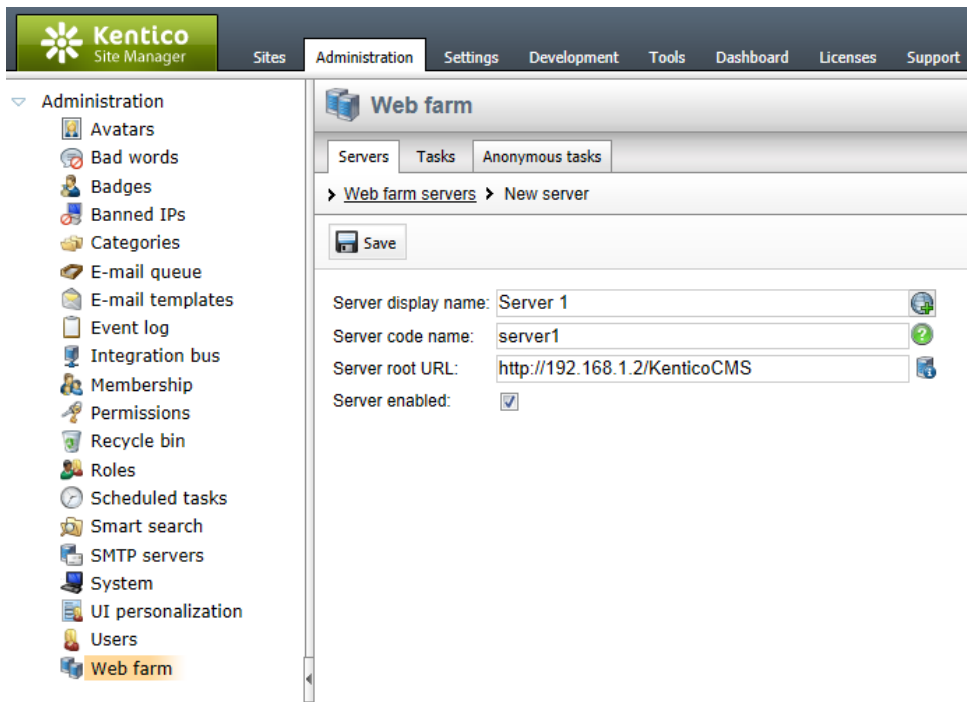

8.53.3 Defining web farm servers

You need to enter the **internal** URLs of all your servers into the system so that the web farm synchronization module knows which servers should be synchronized.

To add a server to the web farm:

1. Go to **Site Manager -> Administration -> Web farm**.
2. Click  **New server**.
3. Fill in the following fields:
 - **Server display name** - a descriptive name for the server displayed in the administration interface.
 - **Server code name** - a unique code name of the server that will be used in the server's configuration file.
 - **Server root URL** - the URL of the root of the website on the server, such as *http://192.168.1.2/KenticoCMS*. You can check the availability of the server by clicking *Check server availability* ().
 - **Server enabled** - this checkbox may be used to manually enable or disable web farm synchronization for the server.
4. Click  **Save** to register the server.

Repeat the process for every server in your web farm.

You also need to update the web.config file on each server and add the **CMSWebFarmServerName** key into the *appSettings* section:

```
<add key="CMSWebFarmServerName" value="<servername>" />
```

Where *<servername>* is the **code name** that the system created for the server (or the code name that you manually entered). Every server must contain only one such key with its own name.

After you have defined your web farm servers, you need to enable the web farm module itself in the settings:

1. Navigate to **Site Manager -> Settings -> Versioning & Synchronization -> Web farm**.
2. Turn on **Enable web farm**.
3. Click **Save**.

You can perform additional low-level settings of web farm synchronization by adding the keys listed in [Web farm synchronization settings](#) into the */configuration/appSettings* section of your web.config file.

Web farm license keys

Please be sure to enter an appropriate license key for the internal URLs of the web farm servers.

For example, if you use the web farm for domain name **example.com** and access the servers internally through URLs like:

- http://192.168.1.2
- http://192.168.1.3
- ...

Enter separate license keys for **example.com**, **192.168.1.2** and **192.168.1.3** in **Site Manager -> Licenses**. You only need to add the licenses on one server and restart the other instances using **Site Manager -> Administration -> System -> Restart application**.

Configuring servers for synchronizing macros

The system uses signatures to ensure the security of [macro expressions](#). Macro signatures contain the user name of the macro's author and a hash of the given expression.

The hash function used to create the signatures appends a [salt](#) to the input. To ensure that macro expressions work correctly in a web farm environment, you need to configure all servers to use the same hash salt:

- Add the **CMSHashStringSalt** key to the *appSettings* section of the web.config file on all web farm servers. You can use any string as the value, but the salt should be random and at least 16 characters long. For example, a randomly generated [GUID](#) is a strong salt:

```
<add key="CMSHashStringSalt" value="e68b9ad6-a461-4707-8e3e-ece73f03dd02" />
```

The best option is to set the hash salt value before you start creating content for your website. Changing the salt causes all current hash values to become invalid. To fix existing macro expressions in the system after changing the hash salt, you need to re-sign the macros. See [Macro security](#) for more information.

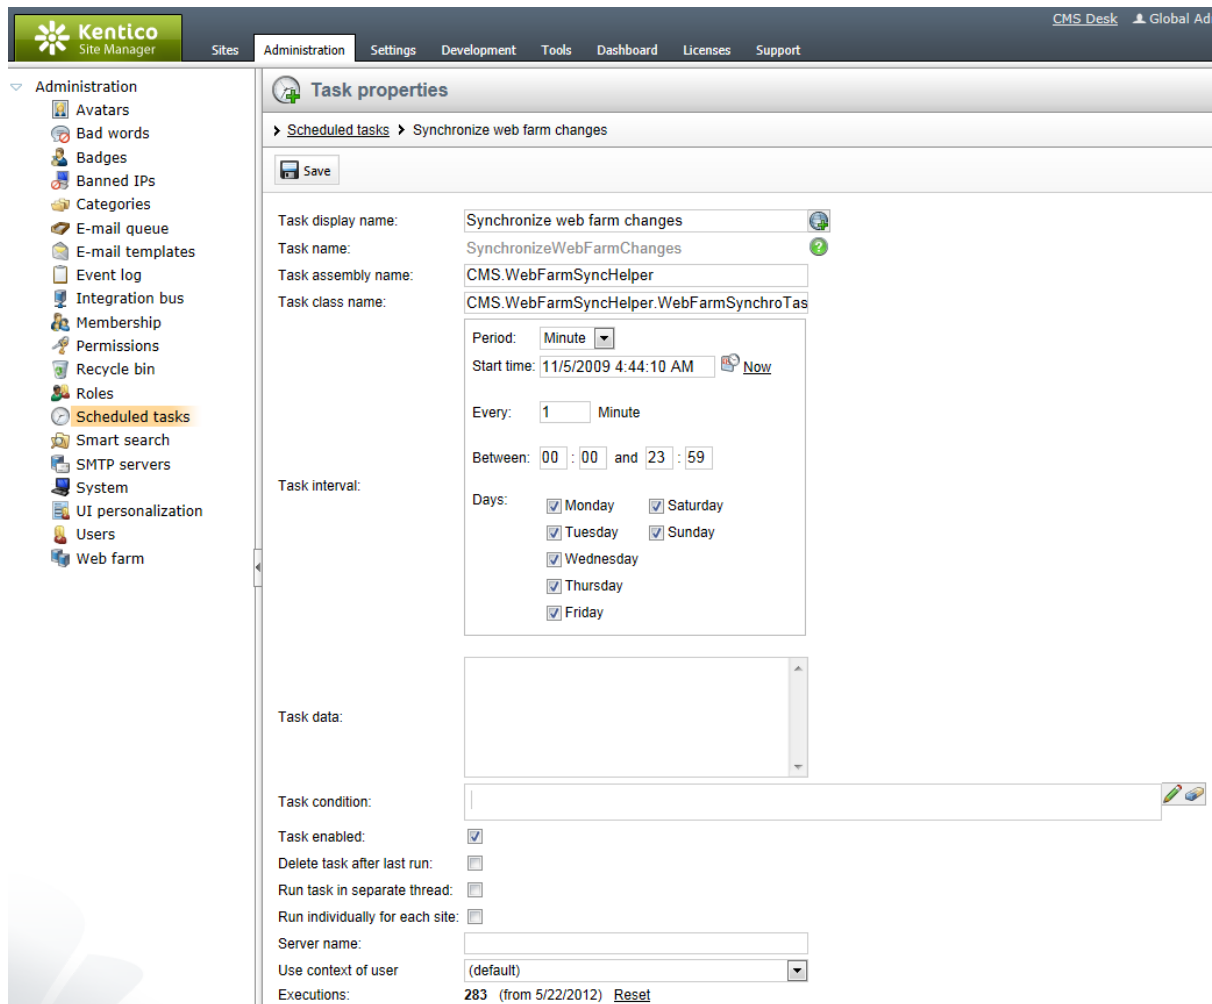

Setting the server synchronization interval

By default, web farm servers are updated with changes made on other servers once per request. Synchronizing this frequently may be impractical for high-traffic websites. To change the synchronization interval, set the value of the **CMSWebFarmUpdateWithinRequest** web.config key to false:

```
<add key="CMSWebFarmUpdateWithinRequest" value="false" />
```

and use the **Synchronize web farm changes** [scheduled task](#) instead, which has a configurable execution interval:

1. Go to **Site Manager -> Administration -> Scheduled tasks**.
2. Select (*global*) in the **Site** selector at the top of the page.
3. Edit (✎) the **Synchronize web farm changes** task.
4. Set an appropriate **Task interval**.
5. Check the **Task enabled** box.
6. Click  **Save**.

You also need to create the task for each server in the web farm. To create the tasks quickly:

Note: All web farm servers that you wish to use need to be registered in the system before performing the following steps.

1. Return to the list of scheduled tasks.
2. Click **New task**.
3. Fill in the same properties as those of the **Synchronize web farm changes** task (the **Task name** must be different)
4. Check **Create tasks for all web farm servers** below the **Server name** property.
5. Click **Save** to complete the process.

Your web farm now synchronizes according to the interval of the scheduled tasks.

Monitoring web farm synchronization tasks

If synchronization doesn't work as expected, you can check the **Tasks** tab of the web farm administration interface. Here, you can view information about all synchronization tasks that are currently active (waiting to be processed).

You can filter the tasks using the **Server** drop-down list according to the server to which they are assigned, or select **(all servers)** to show all synchronization tasks in the entire web farm.

Click **Run tasks** to manually execute tasks, regardless of how the synchronization interval is currently configured.

You can remove all listed tasks using the **Clear task list** button, or individual tasks via the **Delete** (✘) action. Clearing the list is not necessary if the web farm is working correctly — the system automatically removes successfully processed tasks.

| Actions | Server | Type | Created | Machine name | Text data | Error |

A similar user interface can be found on the **Anonymous tasks** tab. This tab displays a list of currently active (waiting to be processed) anonymous synchronization tasks. These tasks are logged by external applications (e.g. Windows services) to ensure that changes made by the external application are reflected in the web application cache. Tasks are logged as anonymous only if the application is NOT configured to run in a web farm. If it is configured to run in a web farm, these tasks are logged as standard synchronization tasks on the **Tasks** tab.

Creating web farm servers automatically

An alternative way of defining web farm servers is letting the system create them automatically on application start. You need to have web farm enabled via a setting or a web.config key on all the servers. Then add the following key

```
<add key="CMSWebFarmGenerateServers" value="true" />
```

or turn on the following setting: **Versioning & Synchronization -> Web farm -> Generate servers dynamically**.

All servers with enabled web farm support will add themselves into the list of servers in Administration -> Web farm when the application starts. If a server doesn't have a server name defined in the web.config, it uses its machine name.

8.53.4 Creating custom web farm synchronization tasks

You can write custom tasks to be executed by web farm servers. This is done by adding the code of your tasks into the **App_Code** folder of your web project (or **Old_App_Code** if you installed Kentico CMS as a web application).

The following example shows how to create a custom synchronization task that logs information events into the event log of all servers in the web farm:

1. Open your web project in Visual Studio, expand the **App_Code** folder and add a new class into it called **WebFarmTaskLoader.cs**.

2. Add the following references:

[C#]

```
using CMS.SettingsProvider;
using CMS.EventLog;
using CMS.WebFarmSyncHelper;
```

3. Delete the default class declaration and its content. Instead extend the **CMSModuleLoader** partial class and define a new attribute for it as shown below:

[C#]

```
[WebFarmTaskLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Module registration
    /// </summary>
    private class WebFarmTaskLoaderAttribute : CMSLoaderAttribute
    {
        ...
    }
}
```

4. Enter the following code into the **WebFarmTaskLoaderAttribute** class:

[C#]

```
/// <summary>
/// Called automatically when the application starts
/// </summary>
public override void Init()
{
    // Hook the custom task event
    WebSyncHelper.OnProcessCustomTask += new WebSyncHelper.TaskHandler
(WebSyncHelper_OnProcessCustomTask);
}
```

```
static void WebSyncHelper_OnProcessCustomTask(WebFarmTaskTypeEnum taskType, string
target, string data, int taskId)
{
    // Log execution
    EventLogProvider ev = new EventLogProvider();
    ev.LogEvent("I", DateTime.Now, "CustomTask", "Execute", null, data);
}
```

The override of the **Init()** method is called automatically when the application starts. The code assigns a handler for the **OnProcessCustomTask** event, which is then used to log a record with *Execute* as its *event code* into the website's event log.

5. Repeat the steps above for all web servers in the web farm, so that the *Execute* event is logged for each one. **Build** their projects if they are installed as a web application.

6. Select one web farm server and expand the **Init()** method according to the following:

[C#]

```
/// <summary>
/// Called automatically when the application starts
/// </summary>
public override void Init()
{
    // Hook the custom task event
    WebSyncHelper.OnProcessCustomTask += new WebSyncHelper.TaskHandler
(WebSyncHelper_OnProcessCustomTask);

    string data = "Task from " + WebSyncHelperClass.ServerName;

    // Add your actions for the custom synchronization task
    if (WebSyncHelperClass.CreateTask(WebFarmTaskTypeEnum.Custom, "MyTask", data,
null))
    {
        // Log creation
        EventLogProvider ev = new EventLogProvider();
        ev.LogEvent("I", DateTime.Now, "CustomTask", "Create", null, data);
    }
}
```

This ensures that the custom task is created when the selected server is started and if successful, an event with *Create* as its event code will be logged for the given server.

7. Finally, save the changes (**Build** the project if you installed it as a web application). You can see the results by checking the event log for all web farm servers at **Site Manager -> Administration -> Event log**.

8.53.5 Web farm synchronization internals and API

8.53.5.1 Overview

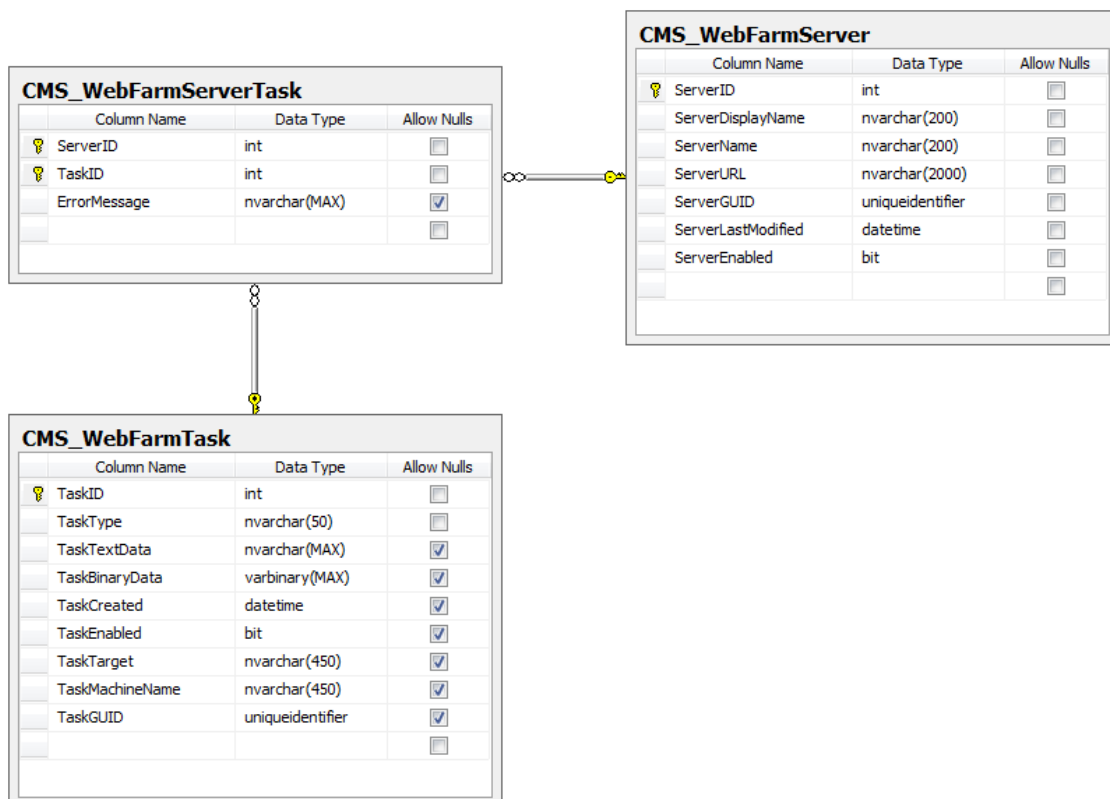

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in the Web farm synchronization module. You will also see the most common [API examples](#).

Further API-related information and examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all members of the module's classes, please refer to [Kentico CMS API Reference](#), which is a part of your Kentico CMS installation and can be accessed through the programs folder in the Windows Start menu.

8.53.5.2 Database tables

The following database tables are used to store information for the web farm module:

- **CMS_WebFarmServer** - contains records representing web farm servers.
- **CMS_WebFarmTask** - stores web farm synchronization tasks.
- **CMS_WebFarmServerTask** - stores relationships between web farm servers and synchronization tasks. Each entry indicates that a task should be processed by a server. Successfully completed tasks are automatically deleted from the table.

8.53.5.3 API classes

If you are not familiar with database table data management through Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

**Please note**

The main classes of the web farm module can be found in the **CMS.WebFarmSync** namespace.

CMS_WebFarmServer table API:

- **WebFarmServerInfo** - represents one web farm server.
- **WebFarmServerInfoProvider** - provides management functionality for web farm servers.

CMS_WebFarmTask table API:

- **WebFarmTaskInfo** - represents one web farm synchronization task.
- **WebFarmTaskInfoProvider** - provides management functionality for synchronization tasks.

Other classes:

- **CMS.SettingsProvider.WebSyncHelperClass** - allows the creation of synchronization tasks and the management of general web farm settings.
- **CMS.WebFarmSyncHelper.WebSyncHelper** - provides functionality for processing web farm synchronization tasks.

8.53.5.4 API examples

8.53.5.4.1 Overview

These topics show examples of how the API of the Web farm module can be used:

- [Managing web farm servers](#)
- [Managing synchronization tasks](#)

**Please note**

All API examples can be simulated on your Kentico CMS website through the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please refer to **<web project folder>\CMSAPIExamples\Code\Administration\WebFarm\Default.aspx.cs**.

The web farm API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.WebFarmSync;
```

```
using CMS.WebFarmSyncHelper;  
using CMS.SettingsProvider;
```

8.53.5.4.2 Managing web farm servers

The following example creates a web farm server.

```
private void CreateWebFarmServer()  
{  
    // Create new web farm server object  
    WebFarmServerInfo newServer = new WebFarmServerInfo();  
  
    // Set the properties  
    newServer.ServerDisplayName = "My new server";  
    newServer.ServerName = "MyNewServer";  
    newServer.ServerEnabled = true;  
    newServer.ServerURL = "http://localhost/KenticoCMS";  
  
    // Save the web farm server  
    WebFarmServerInfoProvider.SetWebFarmServerInfo(newServer);  
}
```

The following example gets and updates a web farm server.

```
private bool GetAndUpdateWebFarmServer()  
{  
    // Get the web farm server  
    WebFarmServerInfo updateServer =  
    WebFarmServerInfoProvider.GetWebFarmServerInfo("MyNewServer");  
    if (updateServer != null)  
    {  
        // Update the properties  
        updateServer.ServerDisplayName = updateServer.ServerDisplayName.ToLower();  
  
        // Save the changes  
        WebFarmServerInfoProvider.SetWebFarmServerInfo(updateServer);  
  
        return true;  
    }  
  
    return false;  
}
```

The following example gets and bulk updates web farm servers.

```
private bool GetAndBulkUpdateWebFarmServers()  
{  
    // Get the data
```

```
DataSet servers = WebFarmServerInfoProvider.GetAllEnabledServers();
if (!DataHelper.DataSourceIsEmpty(servers))
{
    // Loop through the individual items
    foreach (DataRow serverDr in servers.Tables[0].Rows)
    {
        // Create object from DataRow
        WebFarmServerInfo modifyServer = new WebFarmServerInfo(serverDr);

        // Update the properties
        modifyServer.ServerDisplayName =
modifyServer.ServerDisplayName.ToUpper();

        // Save the changes
        WebFarmServerInfoProvider.SetWebFarmServerInfo(modifyServer);
    }

    return true;
}

return false;
}
```

The following example deletes a web farm server.

```
private bool DeleteWebFarmServer()
{
    // Get the web farm server
    WebFarmServerInfo deleteServer =
WebFarmServerInfoProvider.GetWebFarmServerInfo("MyNewServer");

    // Delete the web farm server
    WebFarmServerInfoProvider.DeleteWebFarmServerInfo(deleteServer);

    return (deleteServer != null);
}
```

8.53.5.4.3 Managing synchronization tasks

The following example creates a web farm synchronization task.

```
private void CreateTask()
{
    // Set the properties
    string taskTarget = "";
    string taskTextData = "MyWebFarmTask";
    byte[] taskBinaryData = null;
    WebFarmTaskTypeEnum webfarmTaskType = WebFarmTaskTypeEnum.ClearHashtables;

    // Create the web farm task
```

```
WebSyncHelperClass.CreateTask(webfarmTaskType, taskTarget, taskTextData,
taskBinaryData);
}
```

The following example runs all tasks assigned to the current server (the one specified in the web.config file).

```
private void RunMyTasks()
{
    WebSyncHelper.ProcessMyTasks();
}
```

8.54 Website optimization

8.54.1 Overview

Making improvements on a website can be a difficult process, since it is often not possible to know ahead of time whether a change will have a positive effect, or which modification out of several options will bring the best results. A possible solution for these issues is optimization testing of pages.

Optimization testing allows you to create different versions of a page (or specific parts of a page) and evaluate them according to the behavior of the website's visitors. This way you can confirm which changes are actually beneficial and use the content that works best for the users who visit your website. The entire process is completely transparent for the site's visitors and does not require them to give any feedback manually. Testing is typically done for key sections of the website that receive the most traffic, such as the default home page (landing page).

There are two different techniques that you can use to optimize pages in Kentico CMS:

- [A/B testing](#) - divides incoming traffic between two or more different variants of a page. Each variant is defined as a separate document in the content tree. Results are tracked for each page variant as a whole, meaning that the combined effect of all changes made to the given page is measured.
- [Multivariate testing \(MVT\)](#) - allows you to make multiple modifications to the content of a single page and monitor the effect that specific changes have on the behavior of visitors.

Each type of testing has its advantages and disadvantages and is intended for different scenarios. A/B testing is usually more straightforward and easier to set up and use. It is most suitable for situations where you need to test a single variable element or a full redesign that changes the entire appearance of a page. In cases where you need to evaluate multiple variables on a single page or monitor the effect of individual modifications with a greater degree of detail, multivariate testing is the better option. Because MVT usually involves more tested variants, it may require more time (or site traffic) than A/B testing to get meaningful results.

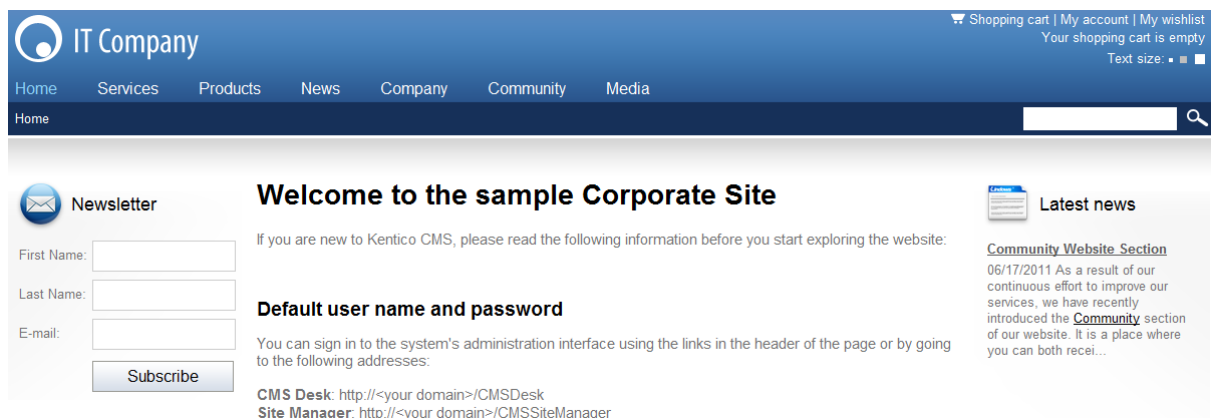

For both types of optimization testing, results are measured by tracking the activity of users after they access the tested page and view one of the different content versions. Actions that are desired from visitors are represented in the system as **Conversions**. Typical examples of conversions are product orders, registrations, newsletter subscriptions, views of special pages etc. When a user performs the specific action tracked by a conversion, it is referred to as a **Conversion hit**. To learn more about conversions and how they can be implemented on your website, please read the [Modules -> Web analytics -> Conversions](#) chapter.

8.54.2 A/B testing

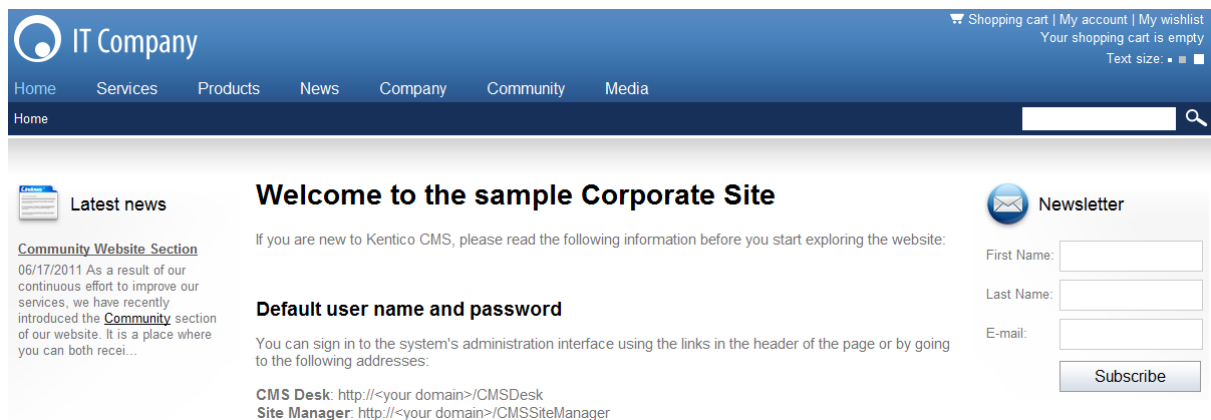

8.54.2.1 A/B testing overview

A/B testing is an on-line marketing technique used to optimize the pages of a website according to the reactions of visitors. This is achieved by creating one or more modified versions of a given page and running them all at the same time during a designated testing period. The system then divides traffic between individual page versions and tracks how the changes affect the user experience and activity of visitors.

The following images show two versions of a sample home page — the original and an alternative page with the position of the left and right content columns reversed.

Some visitors will be assigned to the second version and will see the following when they view the home page:

There are no limitations placed on the modifications that can be made to different page options. They may include anything from subtle changes to using a completely different page.

In Kentico CMS, the basic objects that provide this functionality are **A/B tests**, which can be created for specific website pages. The page options defined for a test are called **Page variants**. Each variant is linked to a document in the content tree of the website that can be designed and configured using the standard web development process. Usually, the **Original page** for which the test was created will be included as one of the variants, so that potential improvements can be compared with the baseline

statistics (those of the unmodified page).

For a practical scenario, imagine that you have an e-commerce page on your website where visitors can purchase products and you wish to fine-tune it to be more user friendly in order to increase the amount of sales. By utilizing A/B testing, you can create multiple versions of this page with any type of modifications such as a slightly altered layout, graphical design or text content. These alternative pages will then serve as variants of the A/B test. While the test is running, it will automatically display different page variants to different visitors and keep track of all product purchases as conversions. When the test is completed after a certain amount of time, you can evaluate which page variant encouraged more users to make purchases on the website and set the most successful one as the permanent page.

Please see the [Creating an A/B test](#) topic for detailed information about how an A/B test can be defined for a page. The data gathered by A/B tests is displayed using reports that allow you to view and analyze several types of conversion metrics, as described in [Analyzing A/B test results](#).

With A/B testing, results are tracked for entire page variants, which means that the measured statistics reflect the combined effect of all changes made to each variant. If you wish to monitor how individual page modifications affect the behaviour visitors, you may use [Multivariate testing](#), which is another website optimization feature provided by Kentico CMS.

How it works

When visitors navigate to a page that has a running A/B test defined, one of the page variants configured for the given test will be displayed to them. The variant is chosen randomly for every user. With a large enough visit sample size, each page variant should receive roughly the same amount of traffic during the course of the test.

A persistent cookie is stored in the visitor's browser, used to identify which variant was assigned by the given A/B test. The name of the cookie uses the following format: *CMSAB<A/B test code name>*. It saves the code name of the assigned page variant as its value. This cookie expires either within 30 days after the last visit on the tested page, or on the date when the test is configured to end.

Any conversions performed on the website by users who have passed through an A/B test page will be logged under the assigned page variant, which is taken from the value of the A/B testing cookie. The logging of conversion hits is provided by the [Web analytics](#) module. In addition to monitoring conversions, the cookie also ensures that returning visitors are always shown the page variant that was previously assigned to them, which helps avoid confusion by maintaining a consistent appearance of the tested page.

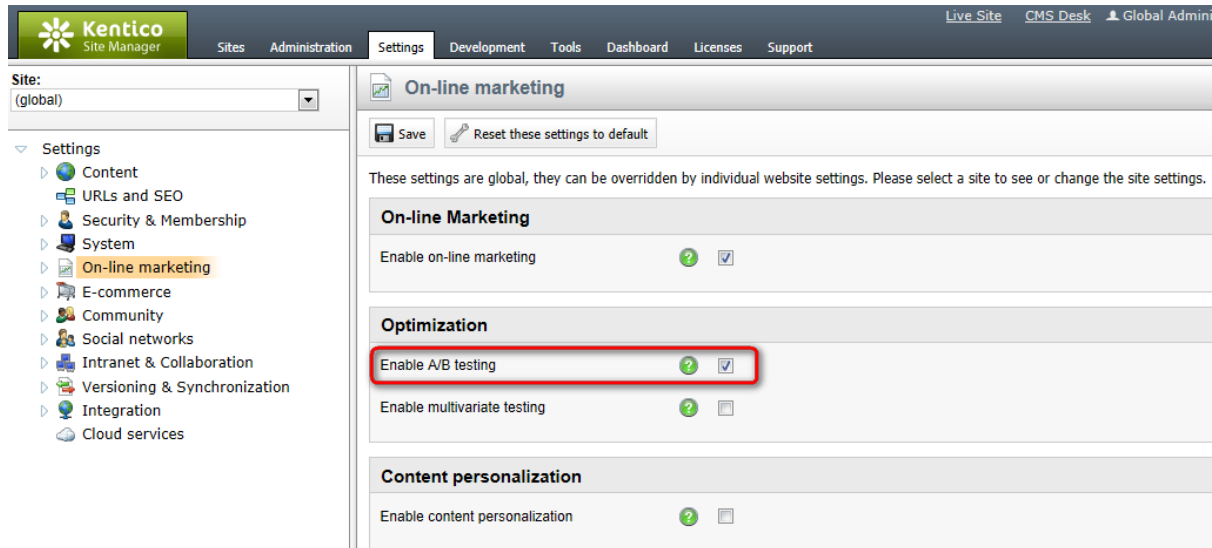

It is possible to run multiple A/B tests concurrently for different pages on the same website. Conversions will be logged for all tests defined for pages visited by a given user, according to the cookies present in the browser.

8.54.2.2 Creating an A/B test

The sections below describe the tasks that must be performed to successfully set up an A/B test on your website.

Enabling A/B testing

Before you can start creating A/B tests for pages, it is first necessary to enable the module by going to **Site Manager -> Settings -> On-line marketing** and checking the **Enable A/B testing** field.

Since web analytics are used to log conversion statistics for individual page variants, the **Enable web analytics** and **Track conversions** fields must also be enabled in the **On-line marketing -> Web analytics** sub-category of the settings. All other requirements for the correct functioning of the Web analytics module also need to be fulfilled, so please refer to [Modules -> Web analytics](#) if you encounter any problems with conversion tracking while performing an A/B test.

Defining an A/B test for a page

To start optimizing a page on your website via A/B testing, create and configure an *A/B test* object for it. To do this, open **CMS Desk**, select the appropriate document from the content tree and switch to its **Analytics -> A/B tests** tab. Here you can find a list of all A/B tests assigned to the currently selected document and manage them as required.

Click **New test** and fill in the A/B test's properties according to the information in the table below:

| | |
|------------------------------|---|
| Display name | The name of the A/B test displayed in the administration interface. |
| Code name | Sets a code name that serves as an identifier for the test. It is also used in the name of the browser cookie used to store which of the test's page variants was assigned to a visitor. |
| Test description | Can be used to enter a text description for the test in order to give information about its purpose, goals, etc. |
| Test culture | Used to select which culture version(s) of the document should be included in the test. |
| Target number of conversions | Sets the number of conversion hits that must be logged to complete the test. Once this number is reached, the A/B test will automatically stop working and switch to the Finished status.

If the total option is selected, then the number will be |

| | |
|--------------|---|
| | <p>compared with the total sum of the conversion hits logged for all test page variants. If any variant is chosen, then the test will be concluded when the specified number is reached by one variant (the one with the most conversion hits).</p> <p>Leaving this property empty or setting it to 0 means that there will be no conversion hit limit for the test.</p> |
| Test from/to | Sets the time interval during which the test should occur. The Calendar button (📅) can be used to select the exact date and time. |
| Test enabled | This property may be used to manually start or stop the test. |
| Status | <p>Displays the current status of the A/B test. The following statuses are possible:</p> <ul style="list-style-type: none">• Disabled - indicates that the test is not active. The original tested page will always be displayed to visitors and conversions will not be logged for the test's variants.• Not running - indicates that the test is not active yet. Used when the test is enabled, but the <i>Test from</i> date is still in the future.• Running - indicates that the test is currently active.• Finished - this status is automatically assigned after the <i>Test to</i> date passes or when the <i>Current number of conversions</i> reaches the <i>Target number of conversions</i>. Tests with this status are no longer active. <p>Each page may have only one A/B test running at a given time. It is however possible to have multiple finished or inactive (disabled) tests assigned to a page, which can be used to archive data from previous tests or when preparing future tests. Different culture versions of a page may each have a different test running at the same time.</p> |

Click **OK** when everything is configured. The test will now be assigned to the document.

Managing A/B tests through the Web analytics interface

If you wish to manage all tests assigned to different pages from a single location, go to **CMS Desk -> Tools (or On-line marketing) -> Web analytics**. Then expand the **Optimization -> A/B tests** category, select any of the contained items (reports) and switch to the **A/B tests** tab.

Here, all A/B tests defined on the current website and their page variants may be managed in the same way as described for individual documents. The only difference is that the **Original page** property is additionally available when editing a test, which can be used to assign tests to specific pages.

Adding page variants to an A/B test

Test variants are created the same way as any other pages, since each variant is represented by a separate document in the website's content tree and can be managed in **CMS Desk -> Content**. Because of this, you can utilize all page configuration and design options provided by Kentico CMS. Please refer to the [Development -> Web development overview](#) chapter if you require basic information about page development.

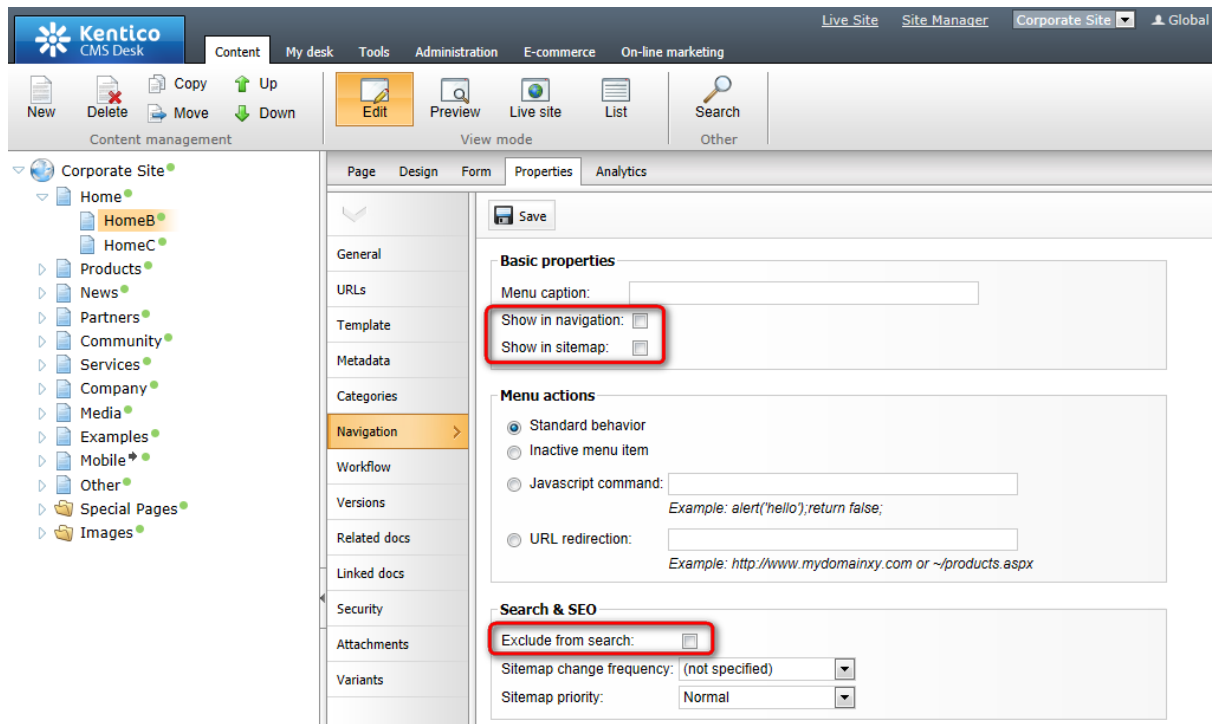

Usually, the page variants of an A/B test will all use the same basic concept, but have one key difference that sets them apart from the original page, such as:

- The position of an important page element.
- A different color scheme intended to highlight a part of the page.
- Alternative text content of headings or descriptions that could potentially be more interesting for visitors.

These are only basic examples of ideas that can be tested by individual variants. You can implement any other type of modifications according to your specific requirements.

You may also leverage existing functionality to help present all variants defined for an A/B test as a single page. The following two properties are available on the **Properties -> Navigation** tab when editing any document:

- **Show in navigation** - indicates if the page variant should be displayed by navigation controls and web parts (i.e. in the website's menus).
- **Show in site map** - indicates if the page variant should be included in the website's [Google Sitemap](#) and displayed by the [Site map](#) web part.

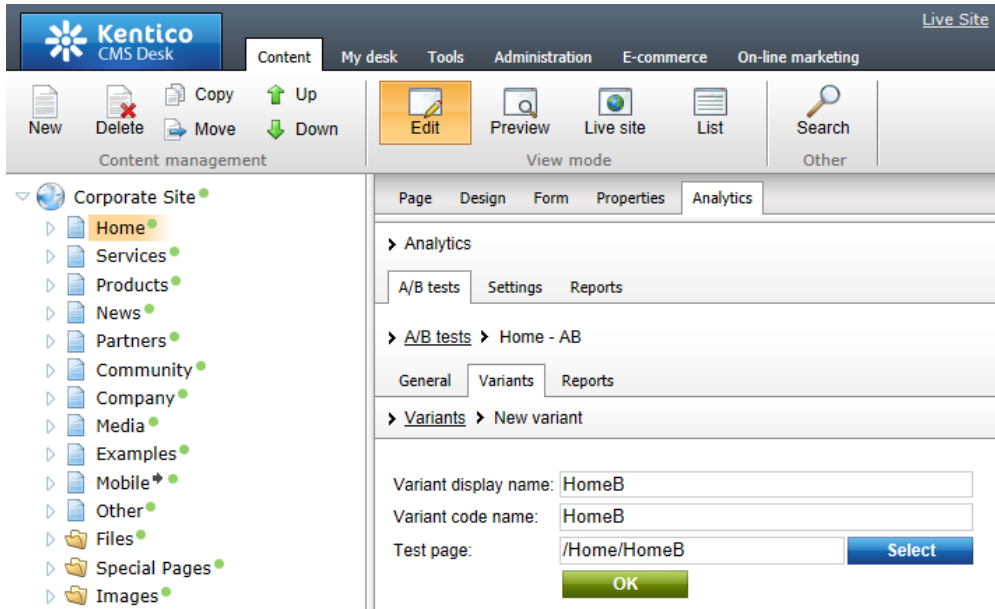

In most cases, it is recommended to have these properties disabled for page variants in order to prevent users from encountering multiple pages with nearly identical content. The appropriate variant will automatically be displayed to users when they view the test's original page, so standard navigation is not necessary.

Additionally, the **Exclude from search** flag can be enabled for page variants under the **Search & SEO** section. This will ensure that the given variant will not be returned in the results of searches performed on the website.

Once the modified versions of the original document are added to the content tree, they must be registered as variants of the given A/B test. To do this, select the original document, go to **Analytics ->**

A/B tests, edit (✎) the test and switch to its **Variants** tab. Click  **New variant** and enter the following properties:

- **Variant display name** - the name of the variant displayed in the administration interface.
- **Variant code name** - sets a code name that serves as an identifier for the page variant. It is also used as the value of the A/B testing cookie stored for visitors assigned to this variant.
- **Test page** - must contain the path of the associated page (document). When users assigned to the variant access the original page of the given A/B test, they will see the page specified here instead. The *Select* button may be used to choose an existing page from the website's content tree.

Repeat this process for all documents that should be included as possible page options for the A/B test. The original document is automatically added as a variant when the A/B test is created, and highlighted in the list by a yellow background.

| Actions | Variant name | Test page | Conversions |
|---------|-------------------|-------------|-------------|
| | Home - AB variant | /Home | 0 |
| | HomeB | /Home/HomeB | 0 |
| | HomeC | /Home/HomeC | 0 |

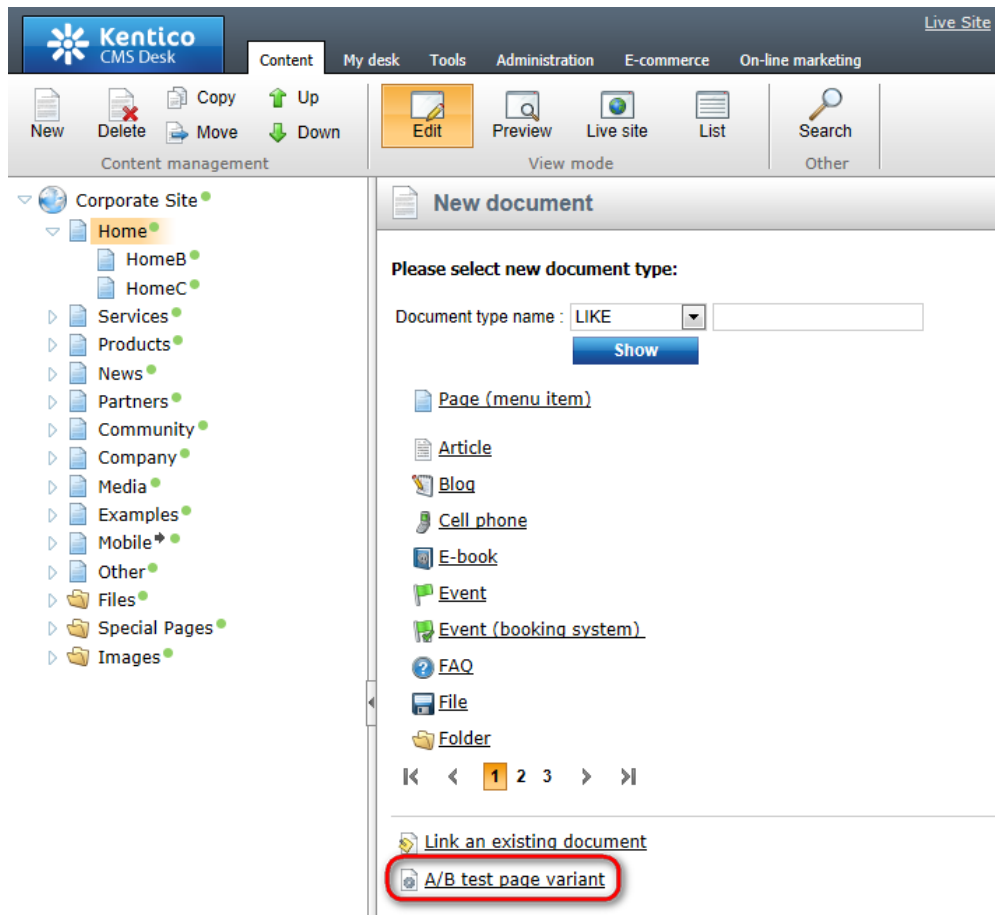

Important!

When editing a running A/B test, it is necessary to always keep the variant **Test page** paths up-to-date and ensure that the target documents actually exist in the content tree. Otherwise visitors may encounter a *Page not found* error if the path of their variant is not valid.

To preserve conversion statistics, variants remain in the system even if their associated document is deleted.

It is possible to save time when defining page variants by using an action that combines the two steps described above. Simply select the A/B test's original page in **CMS Desk -> Content** and click the **New** button in the menu above the content tree. Instead of selecting a document type, choose the **A/B test page variant** option below the list.

This can also be done by right-clicking the document in the content tree and selecting the **New -> A/B test page variant** item from the context menu. A dialog with the following options will be opened:

- **Document name** - sets the name of the new document that will be associated with the page variant.
- **Save under location** - sets the path of the document under which the page variant will be placed. The *Select* button may be used to choose a parent page directly.
- **Assign to A/B test** - selects the A/B test to which the variant will be added.
- **Show in navigation, Show in site map, Exclude from search** - these options may be used to directly set the corresponding properties of the new document. The default values will hide the page variant from all standard website navigation.

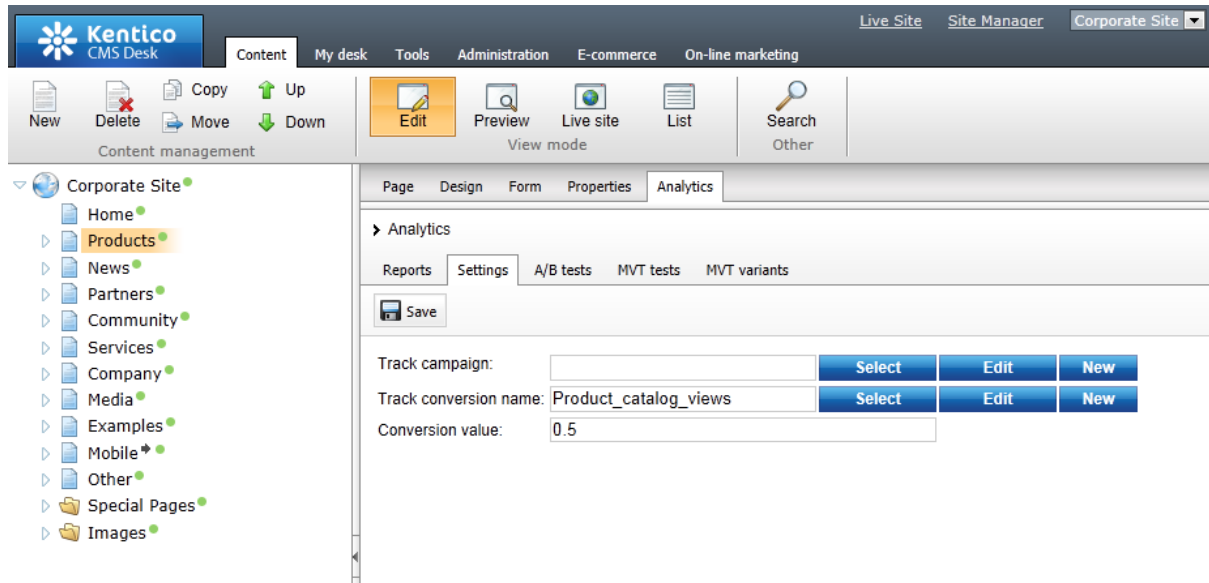

Fill in these properties accordingly and click **Save** to confirm the entered data. This will create a copy of the selected document and automatically add it as a page variant of the specified A/B test. Now you can implement the required modifications that will distinguish the variant from the original page. Please keep in mind that this copy will use the same page template as the original document, so the template must be *Cloned as ad-hoc* on the document's **Properties -> Template** tab if you wish to make any changes to the design or layout of the page.

Configuring conversions

Conversions allow you to track the behaviour and actions of the website's visitors, so they must be used in order to get A/B testing results. They work on a site-wide level and are not assigned to A/B tests in any way. All that needs to be done is define conversion objects and link them with the actions that you

wish to log for the test.

There are many ways to specify that an action should be logged as a conversion. For example, to have the system log a conversion hit whenever a specific page is viewed by a user, select the given document from the content tree in **CMS Desk** and switch to its **Analytics -> Settings** tab. Use the **Track conversion name** property to either create a conversion via the **New** button, or **Select** an existing one.

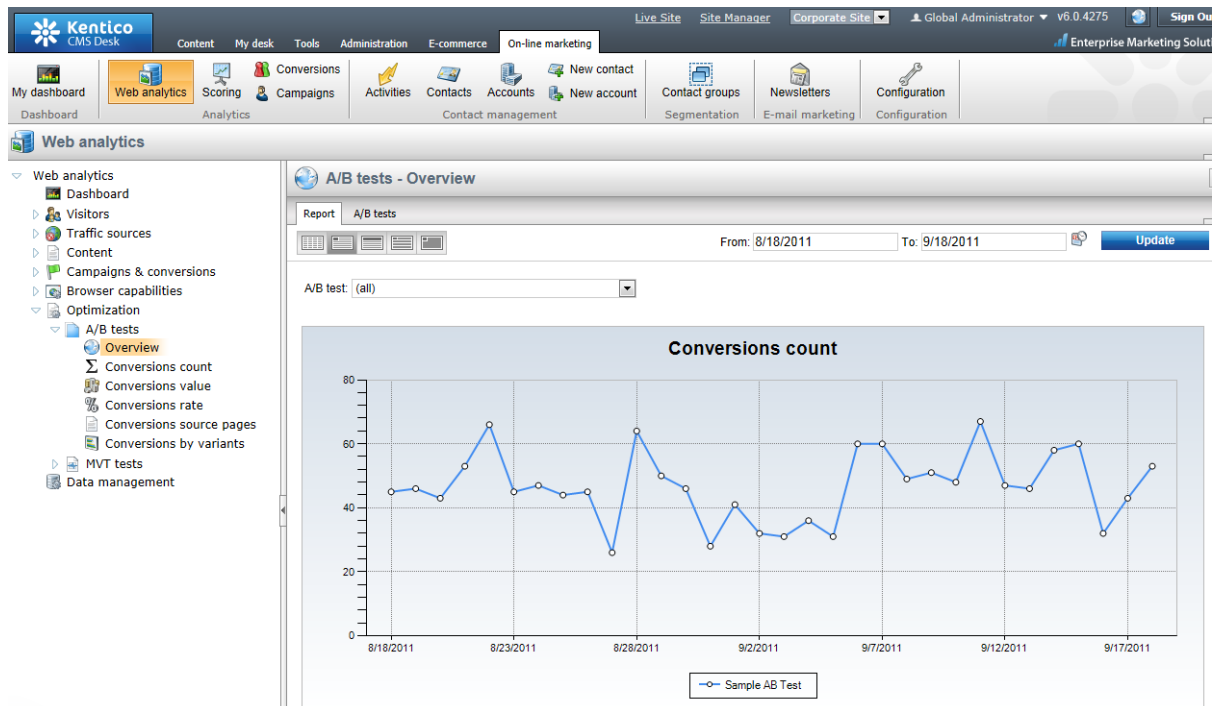

Additionally, many web parts and widgets that allow users to perform important actions (e.g. registration) also have the **Track conversion name** property, which can be used to specify a conversion in the same way. Further details about conversion management may be found in the [Modules -> Web analytics -> Conversions](#) chapter.

When an action designated as a conversion is performed anywhere on the website, the system checks if the given user has passed through a page with an A/B test (according to the presence of a cookie). If this is the case, the conversion hit will be logged for the page variant assigned to the user.

Once the A/B test starts running on the live website, you can monitor the conversion statistics for individual page variants using pre-defined reports, as described in the [Analyzing A/B test results](#) topic.

8.54.2.3 Analyzing A/B test results

The data gathered during the course of A/B testing may be viewed in reports that display various types of conversion metrics. To access the main interface containing these reports, go to **CMS Desk -> On-line marketing -> Web analytics** and expand the **Optimization -> A/B tests** category.

When viewing a report, the **From** and **To** fields on the right can be used to enter a time period. Only conversion hits that were logged for the selected **A/B test** during the specified interval will be included in the data.

The following options allow you to choose which unit of time should be used in the report:

-  **Hour**
-  **Day**
-  **Week**
-  **Month**
-  **Year**

This selection determines the length of time which is represented by individual units in the report's graphs and the precision that can be specified in the **From** and **To** fields.

The **Conversions** drop-down list may be used to select which conversion's statistics should be displayed. Please note that the system logs *all* conversion hits generated by visitors who have passed through a page where an A/B test is running. If there are many conversions defined on your website, only those that can somehow be affected by the differences in the A/B test's page variants will contain relevant data.

Data in the reports is represented by two possible types of graphs. The line charts show the progress of a certain conversion statistic over time and display combined data for all of the A/B test's variants. The bar graphs contain details for individual units of time according to the selected report type (hours, days, months etc.). You may also view the conversion data in a table located between the graphs. Each row in the table shows the data logged for a specific page variant, both for the time period currently displayed by the report and the entire duration of the test.

The following reports are available for A/B testing:

| | |
|--------------------------|--|
| Overview | This report can be used to view the progress of the primary metrics measured for the site's A/B tests from a single location. |
| Conversions count | <p>Displays the number of conversion hits logged for the selected A/B test during the specified time interval.</p> <p>In the bar graph, the number of conversion hits is divided into categories that represent individual page variants. This allows you to compare the A/B test's variants and determine which one generated the most conversions (in absolute terms).</p> |
| Conversions value | <p>Displays the sum of the conversion values logged for the selected A/B test during the specified time interval.</p> <p>In the bar graph, the conversion values are divided into categories that represent individual page variants, which allows you to determine which variant generated the highest total conversion value. This way you can easily evaluate an A/B test's variants when using weighted conversions that have a different level of importance.</p> |
| Conversions rate | <p>Used to indicate how many visitors who access the tested page perform a conversion. The conversion rate is calculated as the amount of logged conversion hits divided by the total number of visitors on the variants of the tested page.</p> <p>If you select the <i>(all)</i> option from the Conversions drop-down list, then the rate will be measured for all possible conversions, i.e. as the percentage of visitors who generated at least one conversion hit of any type.</p> <p>The conversion rate in the bar graph is displayed for individual page variants. This allows you to compare the A/B test's variants and determine which one encouraged the highest share of its visitors to perform a conversion.</p> |
| Conversions source pages | <p>Displays hit statistics for individual conversions that were logged as part of the selected A/B test during the specified time interval.</p> <p>The data logged for the chosen conversion is categorized according to the page variants defined for the given A/B test. This allows you to easily determine which variant generated the most conversion hits of the selected type.</p> |
| Conversions by variants | <p>Displays details of the number of hits logged for each conversion by individual page variants defined for the selected A/B test. You can select the variant that you wish to evaluate from the Variants drop-down list.</p> <p>The hits logged for the chosen variant are divided into categories that match individual conversions. This allows you to easily measure which conversions are performed most commonly by visitors assigned to the selected page variant.</p> |

Reports for individual A/B tests

These reports can also be viewed when editing the original page of an A/B test in **CMS Desk -> Content -> Edit -> Analytics -> A/B testing -> Reports**.

The same options are available as described for the web analytics interface, but statistics are only displayed for the currently edited A/B test.

The following actions may also be performed for the reports:

-  **Save** - saves the report in its current state (according to the selected time interval). To view saved reports at a later time, go to *CMS Desk -> Tools -> Reporting*, select the matching report under the *A/B testing* category and switch to the *Saved reports* tab. This action is only available for users who have the *Save reports* permission for the *Web analytics* module.
-  **Print** - allows the report to be printed. The available options depend on the used browser.
-  **Delete data** - can be used to clear all conversion hits logged during the specified time period for the selected A/B test. Please note that this permanently removes the data from the database. This action is only available for users who have the *Manage data* permission for the *Web analytics* module.
-  **Subscribe** - opens a new dialog where you can subscribe to the report. Subscribing allows you to periodically receive e-mails with the up-to-date content of the given report. It is also possible to subscribe to a specific reporting component (graph or table) by right clicking on it and selecting the *Subscribe to* option in the displayed context menu.

The data displayed in the reports can be exported into external files using various formats. This can be done by right clicking on a specific graph, which opens a context menu offering the following export options:

-  **Export to Excel** - exports the data displayed by the given object to an XLSX spreadsheet.
-  **Export to CSV** - exports data to a CSV file.
-  **Export to XML** - exports data to an XML file.

After you select an action from the menu, your browser's standard file download dialog will pop up, letting you open or save the file with the exported data just like when downloading any other type of file. For more details on the data export feature, please refer to the [Modules -> UI data export](#) chapter.

8.54.3 Multivariate testing

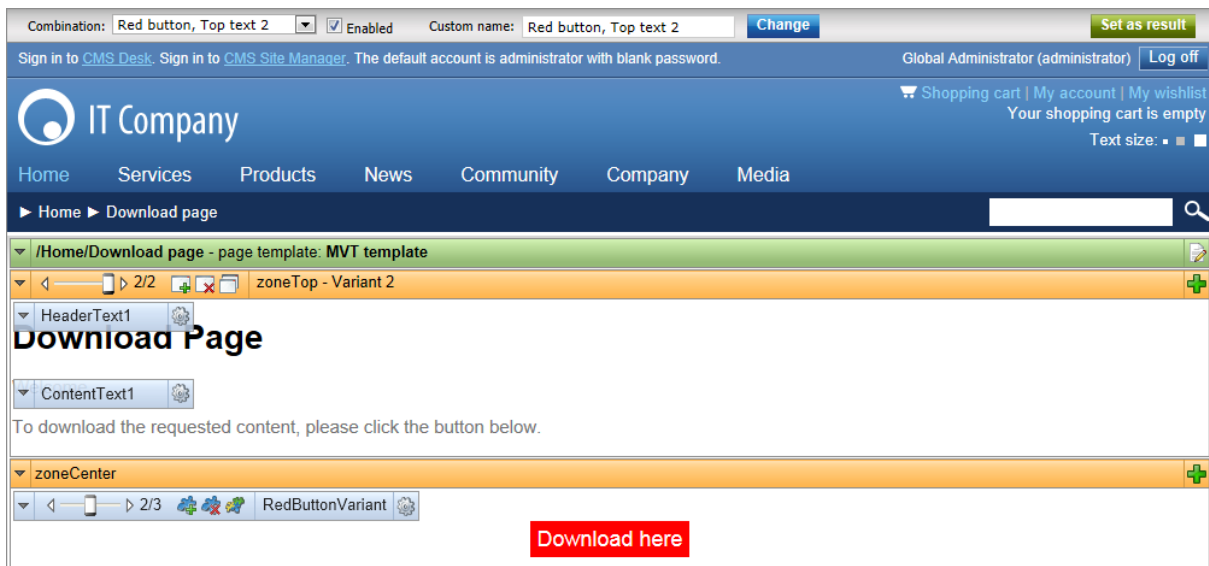

8.54.3.1 Multivariate testing overview

Multivariate testing (MVT) provides a way to optimize a website's pages based on the behaviour of its visitors. It allows you to define any number of elements on a page as variables and create different versions for each one. Once the test is started, users who view the page will see one of the possible versions of its content and their subsequent activity will then be tracked to determine which modifications produce the best results.

The basic objects used to manage this functionality are **MVT tests**, which can be created for specific documents (pages) on the website. You can implement the changes that you wish to test by creating **Variants** of the standard design objects that make up the content of the given page. This includes [Web parts](#), entire web part zones and [Widgets](#) in the page's editor zones.

Testing is not done for individual variants, but rather for **Combinations** of the variants on the page. Because scenarios with multiple object variables can lead to a very large amount of possible combinations, you can limit the scope of the test by disabling those that you are not considering as options. The default page is also available as a combination, so you can compare potential improvements with the baseline statistics (those of the page with its original, unmodified content).

The image below shows how a page with a defined multivariate test could look in the design interface. There are two different versions of the top zone's content and three possible variants of the web part that displays the download button in the bottom zone. That makes six total combinations of the page's content which can be included in the MVT test.

To learn how you can define an MVT test for a page and create different testing variants of its content, please see the [Creating an MVT test](#) topic. The data gathered by MVT tests can be viewed in various reports that allow you to analyze several types of conversion metrics, as described in [Analyzing MVT test results](#).

With multivariate testing, results are tracked for specific combinations of the variants defined on a single page, which represent individual modifications. If you wish to monitor the aggregate effect of all changes made to an entire page as a single variable, you may use [A/B testing](#), which is another optimization feature provided by Kentico CMS.

How it works

When a visitor navigates to a page that has a running MVT test on the live site, one of the enabled content combinations will be displayed. The combination is chosen randomly for every user. With a large enough visit sample size, each active combination should receive roughly the same amount of traffic during the course of the test.

A persistent cookie is stored in the visitor's browser, used to identify which combination was assigned to the user by the given MVT test. The name of the cookie uses the following format: *CMSMVT<MVT test code name>*. It saves the name of the assigned combination as its value. This cookie expires either within 30 days after the last visit on the tested page, or on the date when the test is configured to end.

Any conversions performed on the website by users who have passed through a page where an MVT

test is running will be logged for the given test under the assigned combination, which is taken from the value of the MVT testing cookie. The logging of conversion hits is provided by the [Web analytics](#) module. In addition to monitoring conversions, the cookie also ensures that returning visitors are always shown the same content combination that was previously assigned to them, which helps avoid confusion by maintaining a consistent appearance of the tested page.

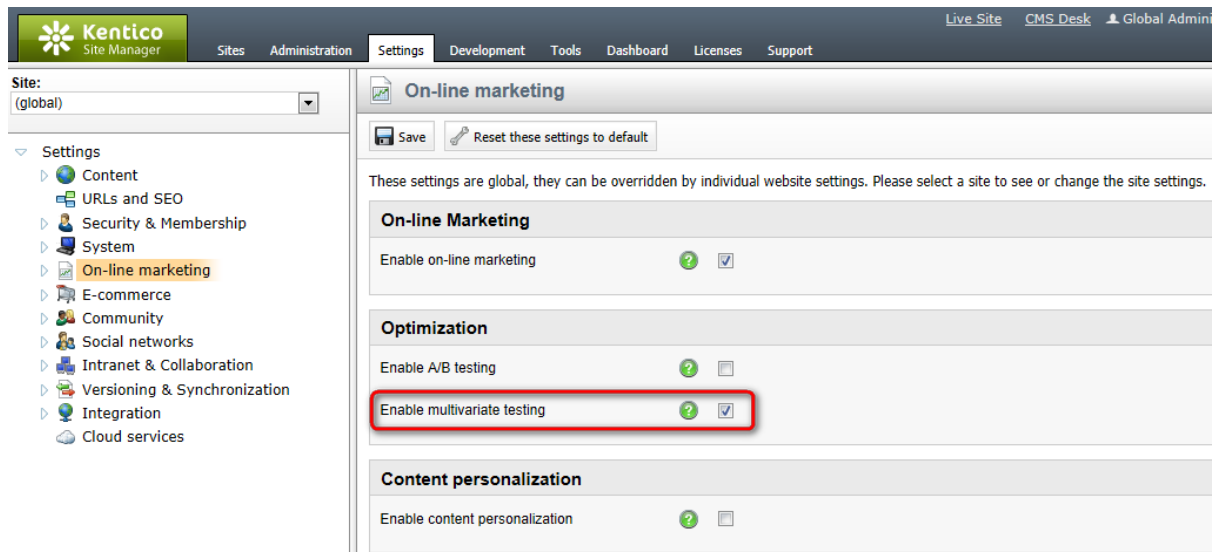

It is possible to run multiple MVT tests concurrently for different pages on the same website. Conversions will be logged for all tests defined on the pages visited by a given user, according to the cookies present in the browser.

8.54.3.2 Creating an MVT test

The sections below describe the tasks that must be performed to successfully set up a multivariate test on your website.

Enabling multivariate testing

Before you can start creating MVT tests for pages, it is first necessary to enable the module by going to **Site Manager -> Settings -> On-line marketing** and checking the **Enable multivariate testing** field.

The screenshot shows the Kentico CMS 7.0 Site Manager interface. The top navigation bar includes 'Live Site', 'CMS Desk', and 'Global Admin'. The main menu on the left lists various settings categories, with 'On-line marketing' selected. The main content area displays the 'On-line marketing' settings for the 'global' site. The 'Enable multivariate testing' checkbox is checked and highlighted with a red box. Other settings include 'Enable on-line marketing' (checked), 'Enable A/B testing' (unchecked), and 'Enable content personalization' (unchecked).

Since web analytics are used to log conversion statistics for individual versions of tested pages, the **Enable web analytics** and **Track conversions** fields must also be enabled in the **On-line marketing -> Web analytics** sub-category of the settings. All other requirements for the correct functioning of the Web analytics module also need to be fulfilled, so please refer to [Modules -> Web analytics](#) if you encounter any problems with conversion tracking while performing an MVT test.

Defining an MVT test

To start optimizing a page on your website via multivariate testing, create and configure an *MVT test* object for it. To do this, open **CMS Desk**, select the appropriate document from the content tree and switch to its **Analytics -> MVT tests** tab. Here you can find a list of all MVT tests assigned to the currently selected document and manage them as required.

Click  **New MVT test** and fill in the test's properties according to the information in the table below:

| | |
|------------------------------|--|
| Display name | The name of the MVT test displayed in the administration interface. |
| Test code name | Sets a code name that serves as an identifier for the test. It is also used in the name of the browser cookie used to store which of the test's variant combinations was assigned to a visitor. |
| Description | Can be used to enter a text description for the test in order to give information about its purpose, goals, etc. |
| Culture | Used to select which culture version(s) of the document should be included in the test. |
| Target number of conversions | <p>Sets the number of conversion hits that must be logged to complete the test. Once this number is reached, the MVT test will automatically stop working and switch to the Finished status.</p> <p>If the total option is selected, then the number will be compared with the total amount of conversion hits logged for all of the test's combinations. If any combination is chosen, then the test will be concluded when the specified number is reached by one combination (the one with the most conversion hits).</p> <p>Leaving this property empty or setting it to 0 means that there will be no conversion hit limit for the test.</p> |
| Test from/to | Sets the time interval during which the test should occur. The Calendar button () can be used to select the exact date and time. |
| Enabled | This property may be used to manually start or stop the test. |
| Status | <p>Displays the current status of the MVT test. The following statuses are possible:</p> <ul style="list-style-type: none"> • Disabled - indicates that the test is not active. The default content of the tested page will always be displayed to visitors and conversions will not be logged for the test's combinations. • Not running - indicates that the test is not active. Used when the test is enabled, but the <i>Test from</i> date is still in the future. • Running - indicates that the test is currently active. • Finished - this status is automatically assigned after the <i>Test to</i> date passes or when the <i>Current number of conversions</i> reaches the <i>Target number of conversions</i>. Tests with this status are no longer active. <p>Each page may have only one MVT test running at a given time. It is however possible to have multiple finished or</p> |

disabled tests assigned to a page, which can be used to archive data from previous tests or when preparing future tests. Different culture versions of a page may each have a different test running at the same time.

Click **OK** to confirm the configuration and the test will be assigned to the document.

Managing MVT tests through the Web analytics interface

If you wish to manage all tests assigned to different pages from a single location, go to **CMS Desk -> Tools (or On-line marketing) -> Web analytics**. Then expand the **Optimization -> MVT tests** category, select one of the contained items (reports) and switch to the **MVT tests** tab.

Here, all MVT tests defined on the current website may be managed in the same way as described for individual documents. The only difference is that the **Page** property is additionally available when editing a test, which can be used to assign tests to specific pages.

Creating testing variants on the page

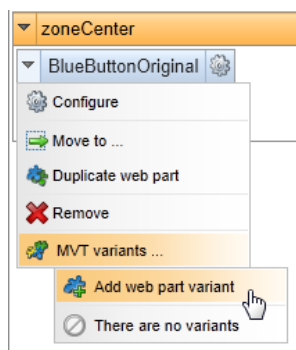

Once a page contains an MVT test, you can start creating the content options that you wish to evaluate. This is done by defining variants for the elements that make up the content of the page. It is possible to

use the following objects as variables:

- **Web parts** - each variant is another instance of the original web part. A variant's properties may be configured differently and an alternative [Web part layout](#) can be specified.
- **Web part zones** - in this case, variants are added as entire web part zones. Each zone variant may contain any type or number of child web parts as required. The basic properties of the zone may also be set differently. When a new variant is added to a zone, the content of the original is automatically copied into it, so you do not have to rebuild the zone from scratch if you only need to make small modifications. Please note that creating variants for individual web parts inside zone variants is not supported.
- **Editor widgets** - like with web parts, each variant is a widget of the same type as the original that provides the option to set different values for its properties.

If you are not familiar with the basics of page development in Kentico CMS, it is recommended to read through the [Development -> Web parts](#) and [Widgets](#) chapters of this guide before you continue.

To add an MVT variant to a web part or zone, open the page on the **Design** tab, expand the context menu of the given object by right clicking its header (or through the ▼ icon), hover over the **MVT variants** option and select **Add <object type> variant** from the second level of the menu.

Then, fill in the following properties in the displayed dialog:

- **Display name** - the name used in lists of MVT variants in the administration interface.
- **Code name** - sets a code name that serves as an identifier of the variant.
- **Description** - can be used to enter a text description of the variant.
- **Enabled** - indicates if the variant should be considered as a possible testing option. If you disable an MVT variant, all testing combinations that include this variant will also be disabled.

After you enter and confirm these basic values for the new variant, a configuration dialog will be opened, just like when creating a standard web part or widget. Here, you can set up the available properties (according to the type of the given object) so that the variant generates the content that you wish to test. By default, the values set for the original will be loaded into the properties, so you only have to change the parts of the configuration that are unique for the given variant.

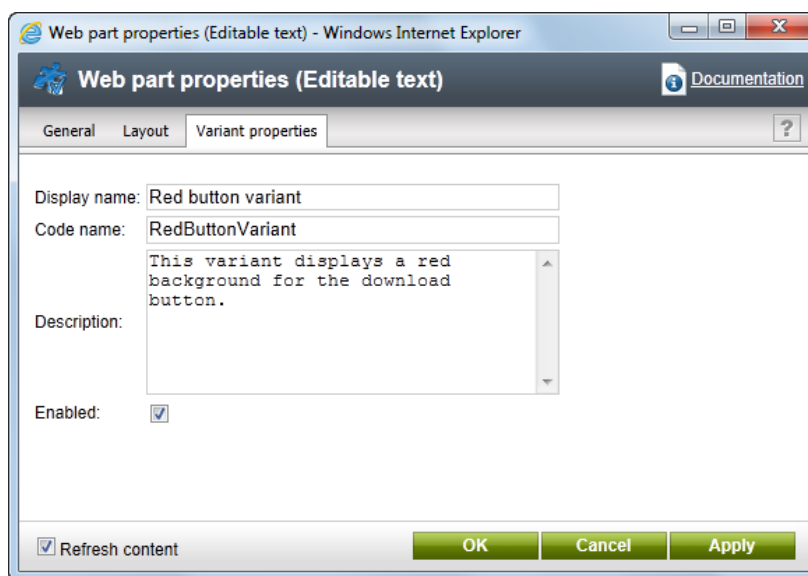

Each object for which you create testing variants will have a slider available in its header as shown below:

This slider can be used to switch between individual variants as needed (including the original). The content specified by the current selection on the page's variant sliders will be displayed in CMS Desk on the **Design** and **Page** tabs, and in **Preview** mode. You can also switch between different versions of the page's content by using the combination panel, which is described in the next section below.

If you wish to view the content of variants while cycling through the slider on the **Design** tab, make sure that the **Display web part content** checkbox on the right side of the **Edit** mode header is checked. To make orientation easier, it is recommended to assign an appropriate **title** property for each web part or zone variant, so that you can identify which one you are working with straight from the header text.

The buttons on the right of the slider allow you to add new variants (🔍), remove the currently selected one (🗑️) or open a list (📄) of all variants that the given object currently has. At any time, you can **Configure** (⚙️) the properties of the variant currently chosen on the slider.

When editing a variant like this, you can access the properties that affect the content on the **General** tab. The specific settings related to the testing functionality of the specific variant (the same options that were offered when creating a new variant) can be changed on the additional **Variant properties** tab.

In the case of editor widgets, multivariate testing variants are handled using a very similar approach. The only difference is that editing is done on the **Page** tab of **CMS Desk** and the slider and actions for variant management are located on the pop-up menu of individual widgets.

You can access a list of all multivariate testing variants defined on a given document (page), by selecting it from the content tree in **CMS Desk -> Content -> Edit** and going to **Analytics -> MVT variants**. The variants of all three object types are included here, and they can be removed or edited as necessary.

There are some general rules that apply to all MVT variants:

- If you delete an object from the page, any variants that it might have will be removed along with it.
- Variants are not linked to a specific MVT test. Instead, they are either stored on the [page template](#) used by the given document (in the case of web parts and zones) or bound to the document itself (editor widget variants). This means that existing variants may be used by other MVT tests performed on the given page at another time. Also keep this in mind if you wish to [Export](#) a multivariate testing scenario to another website. Variants will be transferred along with documents and page templates, not MVT test objects.

Multivariate testing and Content personalization

Please note that it is not possible to create multivariate testing variants of web parts, zones or widgets that already have variants defined for [Content personalization](#).

Setting up testing combinations

Individual testing scenarios are represented by combinations of the MVT variants created on the page. By default, all possible combinations of the page's content will be included in a multivariate test, but you may perform some additional configuration to fine-tune your test as required.

Combinations can be managed for documents that have an MVT test defined via a panel located at the top of the page editing interface in CMS Desk. This panel is available on both the **Page** and **Design** tabs, and in **Preview** mode.

You can choose any of the available combinations through the **Combination** selector. Doing so will cause the page to display the content defined by the variants that make up the given combination. The selection made through the combination panel is linked with the positions set on the MVT sliders of variable objects on the page. If you switch to a different variant through an object's slider, the current combination will also change accordingly and vice versa.

Pages where there are several variants for multiple objects will have a large amount of possible combinations. For this reason, it is recommended to carefully choose which combinations should be included in the page's MVT test. You can include or exclude a combination by toggling the **Enabled** checkbox located on the panel next to the selector. There is a close relationship between the status of a combination and its variants. If an individual variant is disabled through its properties, all combinations that include it will also be disabled. If a disabled combination is enabled at a later point, all of its variants will be enabled automatically if needed.

A good way to evaluate potential combinations is to check them in the **Preview** mode of CMS Desk, and disable those where the variants clash visually, have conflicting logic or are otherwise incompatible.

We recommend leaving the *Default page* combination enabled, so you can compare any improvements with the baseline statistics of the original page.

Another best practice is to set a descriptive custom name for each active combination, so that you can easily differentiate between combinations in the editing interface and identify them in the test's result reports. To do this, simply select a combination through the panel, enter the appropriate text into the **Custom name** field and click the **Change** button. The default names assigned to new combinations are composed of a number indicating their order, followed by a list of the display names of all variants that are included in the given combination.

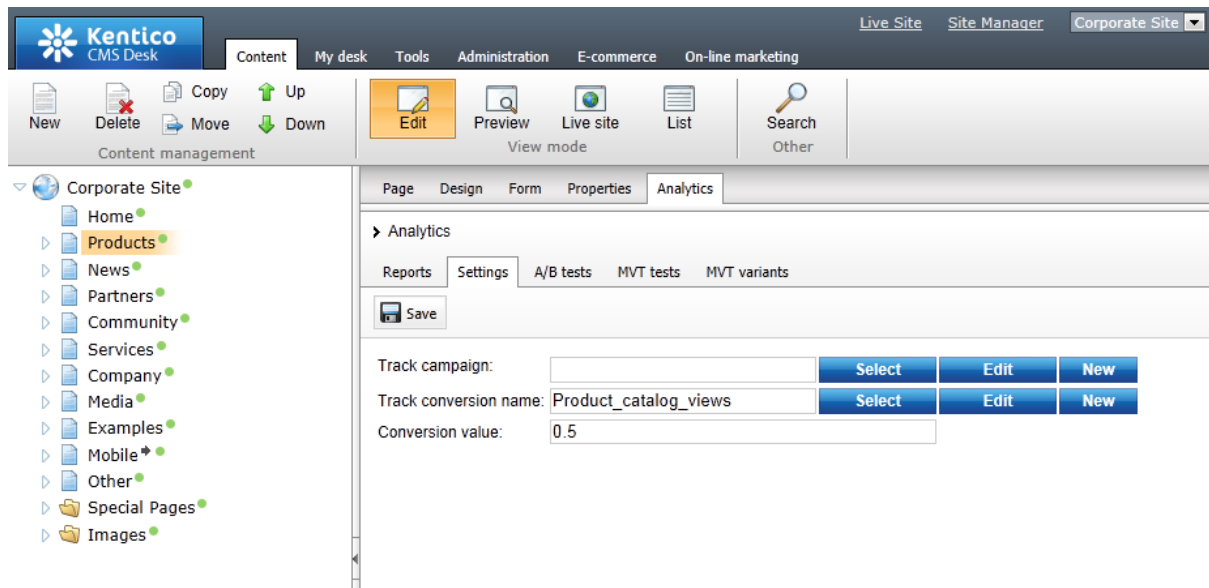

Once the page's variants and combinations are all configured as needed, you can enable your MVT test on the **Analytics -> MVT tests** tab of the document. Making further modifications on the page while an MVT test is running is not recommended, since this may affect the accuracy and relevance of the measured statistics. A warning will be displayed below the combination panel on pages where a test is running.

The **Set as result** action should only be used after the conclusion of the test, once you have analyzed the logged conversion data and identified the combination that provides the best results. The action allows you to easily set the winning combination as the permanent content of the page. Simply select the given combination via the combination panel, then click the button and confirm the action. This will replace the original web parts, zones and widgets with the variants included in the currently selected combination and remove all other MVT variants from the page.

Configuring conversions

Conversions allow you to track the behaviour and actions of the website's visitors, so they must be used in order to get MVT testing results. They work on a site-wide level and are not assigned to MVT tests in any way. All that needs to be done is define conversion objects and link them with the actions that you wish to log for the test.

There are many ways to specify that an action should be logged as a conversion. For example, to have the system log a conversion hit whenever a specific page is viewed by a user, select the given document from the content tree in **CMS Desk** and switch to its **Analytics -> Settings** tab. Use the **Track conversion name** property to either create a conversion via the **New** button, or **Select** an existing one.

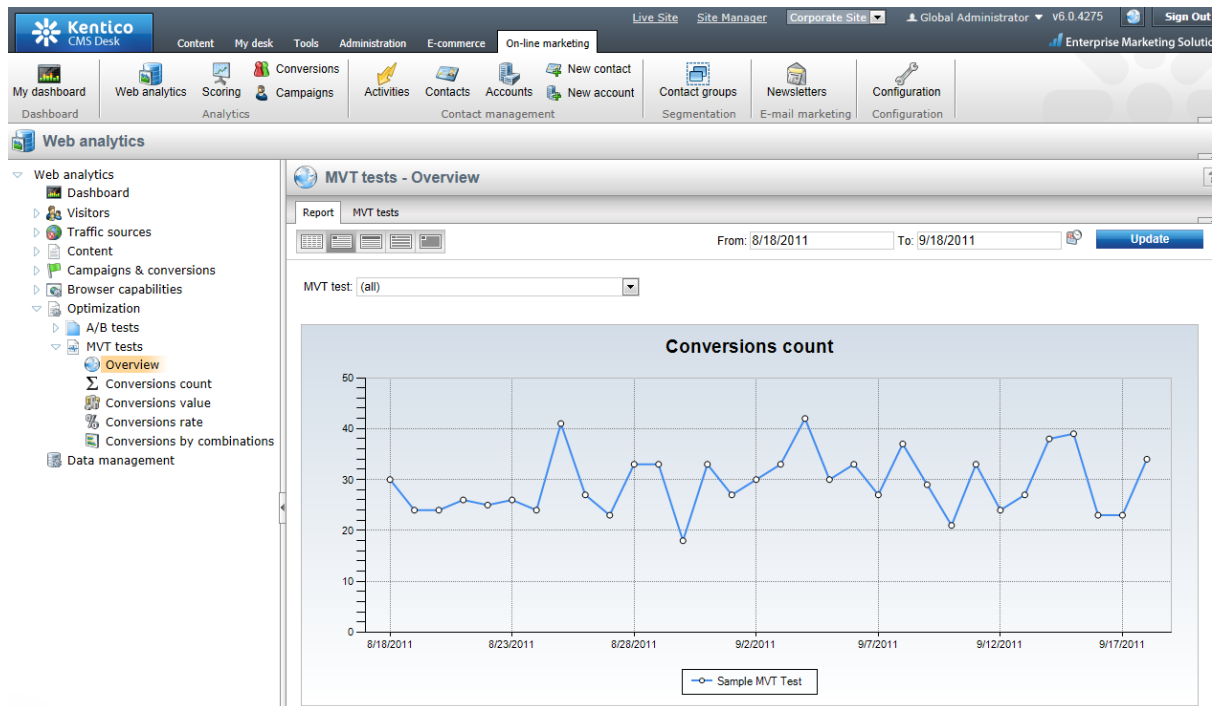

Additionally, many web parts and widgets that allow users to perform important actions (e.g. registration) also have the **Track conversion name** property, which can be used to specify a conversion in the same way. Further details about conversion management may be found in the [Modules -> Web analytics -> Conversions](#) chapter.

When an action designated as a conversion is performed anywhere on the website, the system checks if the given user has passed through a page with a running MVT test (according to the presence of a cookie). If this is the case, the conversion hit will be logged for the content combination that was assigned to the user.

Once you enable the MVT test and it starts running on the live site, the conversion statistics for individual combinations can be monitored using pre-defined reports, as described in the [Analyzing MVT test results](#) topic.

8.54.3.3 Analyzing MVT test results

The data gathered during the course of MVT testing may be viewed in reports that display various types of conversion metrics. To access the main interface containing these reports, go to **CMS Desk -> On-line marketing -> Web analytics** and expand the **Optimization -> MVT tests** category.

When viewing a report, the **From** and **To** fields on the right can be used to enter a time period. Only conversion hits that were logged for the selected **MVT test** during the specified interval will be included in the data.

The following options allow you to choose which unit of time should be used in the report:

-  **Hour**
-  **Day**
-  **Week**
-  **Month**
-  **Year**

This selection determines the length of time which is represented by individual units in the report's graphs and the precision that can be specified in the **From** and **To** fields.

The **Conversions** drop-down list may be used to select which conversion's statistics should be displayed. Please note that the system logs *all* conversion hits generated by visitors who have passed through a page where an MVT test is running. If there are many conversions defined on your website, only those that can somehow be affected by the differences between the tested content combinations will have relevant data.

Data in the reports is represented by two possible types of graphs. The line charts show the progress of a certain conversion statistic over time and display combined data for all of the tested combinations. The bar graphs contain details for individual units of time according to the selected report type (hours, days, months etc.). You may also view the conversion data in a table located between the graphs. Each row in the table shows the data logged for a specific combination, both for the time period currently displayed by the report and the entire duration of the test.

The following reports are available for MVT testing:

| | |
|-----------------------------|--|
| Overview | This report can be used to view the progress of the primary metrics measured for the site's MVT tests from a single location. |
| Conversions count | <p>Displays the number of conversion hits logged for the selected MVT test during the specified time interval.</p> <p>In the bar graph, the number of conversion hits is divided into categories that represent individual content combinations. This allows you to compare the tested combinations and determine which one generated the most conversions (in absolute terms).</p> |
| Conversions value | <p>Displays the sum of the conversion values logged for the selected MVT test during the specified time interval.</p> <p>In the bar graph, the conversion values are divided into categories that represent individual content combinations, which allows you to determine which one generated the highest total conversion value. This way you can easily evaluate the results of the MVT test when using weighted conversions that have a different level of importance.</p> |
| Conversions rate | <p>Used to indicate how many visitors who access the tested page perform a conversion. The conversion rate is calculated as the amount of logged conversion hits divided by the total number of visitors on the given page.</p> <p>If you select the <i>(all)</i> option from the Conversions drop-down list, then the rate will be measured for all possible conversions, i.e. as the percentage of visitors who generated at least one conversion hit of any type.</p> <p>The conversion rate in the bar graph is displayed for individual content combinations. This allows you to compare the tested combinations and determine which one encouraged the highest share of its visitors to perform a conversion.</p> |
| Conversions by combinations | <p>Displays details about the number of conversion hits logged for individual content combinations defined on the page associated with the selected MVT test.</p> <p>You can select the combination that you wish to evaluate from the Combinations drop-down list. If the MVT test is used for multiple culture versions of the page, you can also specify the culture.</p> <p>The hits logged for the chosen combination are divided into categories that match individual conversions. This allows you to easily measure which conversions are performed most commonly by visitors assigned to the selected content combination.</p> |

Reports for individual MVT tests

These reports can also be viewed when working with the tested page in **CMS Desk -> Content -> Edit** by editing the given MVT test in **Analytics -> MVT tests** and switching

to its **Reports** tab.

The same options are available as described for the web analytics interface, but statistics are only displayed for the currently edited MVT test.

The following actions may also be performed for the reports:

-  **Save** - saves the report in its current state (according to the selected time interval). To view saved reports at a later time, go to *CMS Desk* -> *Tools* -> *Reporting*, select the matching report under the *MV testing* category and switch to the *Saved reports* tab. This action is only available for users who have the *Save reports* permission for the *Web analytics* module.
-  **Print** - allows the report to be printed. The available options depend on the used browser.
-  **Delete data** - can be used to clear all conversion hits logged during the specified time period for the selected MVT test. Please note that this permanently removes the data from the database. This action is only available for users who have the *Manage data* permission for the *Web analytics* module.
-  **Subscribe** - opens a new dialog where you can subscribe to the report. Subscribing allows you to periodically receive e-mails with the up-to-date content of the given report. It is also possible to subscribe to a specific reporting component (graph or table) by right clicking on it and selecting the *Subscribe to* option in the displayed context menu.

The data displayed in the reports can be exported into external files using various formats. This can be done by right clicking on a specific graph, which will open a context menu offering the following export options:

-  **Export to Excel** - exports the data displayed by the given object to an XLSX spreadsheet.
-  **Export to CSV** - exports data to a CSV file.
-  **Export to XML** - exports data to an XML file.

After you select an action from the menu, your browser's standard file download dialog will pop up, letting you open or save the file with the exported data just like when downloading any other type of file. For more details on the data export feature, please refer to the [Modules -> UI data export](#) chapter.

8.54.4 Security

Permissions from several different modules are required to perform A/B or MVT testing actions on the website. These permissions can be set by going to **CMS Site Manager** (or **CMS Desk**) -> **Administration** -> **Permissions**.

To configure the basic security options for optimization testing, select the *A/B testing* or *MVT testing* module respectively. The following two permissions can be assigned for either one of the modules:

- **Read** - allows members of the selected roles to view all parts of the A/B or MVT testing management interface and the corresponding reports.
- **Manage** - allows members of the selected roles to create, edit and delete tests and manage their variants. In this case of A/B testing, this means page variants. For MVT testing, this affects management of object (web part, zone or widget) variants on pages that have a test defined.

 **Permissions**

Site: Corporate site

Permissions for: Module A/B testing

Report for user: (none) Show only this user's roles

| Role | Read | Manage |
|------------------------------|-------------------------------------|-------------------------------------|
| Authenticated users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Basic users | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Community administrators | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Designers | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Desk Administrators | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| CMS Editors | <input type="checkbox"/> | <input type="checkbox"/> |
| CMS Readers | <input checked="" type="checkbox"/> | <input type="checkbox"/> |
| Everyone | <input type="checkbox"/> | <input type="checkbox"/> |

Additionally, permissions for the *Web analytics* module are required to access A/B or MVT testing reports in the web analytics interface and in **CMS Desk -> Content -> Analytics -> A/B tests / MVT tests -> Reports**. The following are available:

- **Read** - allows members of the specified roles to access the web analytics interface and view its reports (including those for A/B and MVT testing).
- **Save reports** - allows members of the specified roles to archive the reports via the  Save action.
- **Manage data** - allows members of the specified roles to delete the conversion statistics logged for tests. This is done through the  *Delete data* action available for reports.

Editing A/B testing page variant documents

Because every page variant is represented by a document in the content tree, the standard document permissions apply.

All permissions that can be configured for the *Content* module are checked, such as for creating, modifying or deleting documents. Also, the **Design web site** permission for the *Design* module is needed to edit page variants on the **Design** tab of **CMS Desk**.

Managing MVT object variants

The **Design web site** permission for the *Design* module is also needed for users to be able to manage the variants of web parts and zones on the **Design** tab of **CMS Desk**.

To work with variants of editor widgets on the **Page** tab, the **Modify** permission for the *Content* module is required. Also, the security settings defined for specific widgets are checked, as described in [Development -> Widgets -> Security](#).

8.55 Modules internals and API

8.55.1 Overview

In this chapter, you will learn which [database tables](#) and [API classes](#) are used in Modules. You will also see the most common [API examples](#).

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to [Kentico CMS API Reference](#).

8.55.2 Database tables

The following database tables are used in Modules:

- **CMS_Resource** - contains records representing modules.
- **CMS_ResourceSite** - contains relationships between modules and sites indicating that particular modules are available for a particular site.
- **CMS_Permission** - contains records representing modules permissions.
- **CMS_RolePermission** - contains relationships between roles and permissions indicating that a particular role is granted with particular permissions.
- **CMS_UIElement** - contains records representing modules UI elements.
- **CMS_RoleUIElement** - contains relationships between roles and UI elements indicating that a particular role is granted with particular UI elements.

8.55.3 API classes

If you are not familiar with the database table data management by Info and Provider classes, we strongly recommend that you refer to the [Database table API](#) topic first.

Please note

The Modules classes use the **CMS.SiteProvider** namespace.

CMS_Resource table API:

- **CMSResourceInfo** - represents one module.
- **CMSResourceInfoProvider** - provides management of modules.

CMS_ResourceSite table API:

- **CMSResourceSiteInfo** - represents relationship between one module and one site expressing that the particular module is available for the particular site.
- **CMSResourceSiteInfoProvider** - provides management of relationships between modules and sites.

CMS_Permission table API:

- **CMSPermissionInfo** - represents one module permission.
- **CMSPermissionInfoProvider** - provides management of module permissions.

CMS_RolePermission table API:

- **CMSRolePermissionInfo** - represents relationship between one role and one permission expressing that the particular role is granted with the particular permission.
- **CMSRolePermissionInfoProvider** - provides management of relationships between roles and permissions.

CMS_UIElement table API:

- **CMSUIElementInfo** - represents one module UI element.
- **CMSUIElementInfoProvider** - provides management of module UI elements.

CMS_RoleUIElement table API:

- **CMSRoleUIElementInfo** - represents relationship between one role and one UI element expressing that the particular role is granted with the particular UI element.
- **CMSRoleUIElementInfoProvider** - provides management of relationships between roles and UI elements.

8.55.4 API examples

8.55.4.1 Overview

These topics show examples of how the Modules API can be used:

- [Managing modules](#)
- [Managing permissions](#)
- [Managing UI elements](#)

Please note

All API examples can be simulated in the API examples user interface; please refer to the [API examples](#) chapter for more details.

If you would like to check the code of the examples, please [install CMS API examples](#) and refer to **<web project folder>\CMSAPIExamples\Code\Development\Modules\Default.aspx.cs**.

The Modules API examples use the following namespaces:

```
using System;
using System.Data;

using CMS.GlobalHelper;
using CMS.UIControls;
using CMS.CMSHelper;
using CMS.SiteProvider;
```

8.55.4.2 Managing modules

The following example creates a module.

```
private bool CreateModule()
{
    // Create new module object
    ResourceInfo newModule = new ResourceInfo();

    // Set the properties
    newModule.ResourceDisplayName = "My new module";
    newModule.ResourceName = "MyNewModule";

    // Save the module
    ResourceInfoProvider.SetResourceInfo(newModule);

    return true;
}
```

The following example gets and updates a module.

```
private bool GetAndUpdateModule()
{
    // Get the module
    ResourceInfo updateModule = ResourceInfoProvider.GetResourceInfo
("MyNewModule");
    if (updateModule != null)
    {
        // Update the properties
        updateModule.ResourceDisplayName =
```

```
updateModule.ResourceDisplayName.ToLower();

    // Save the changes
    ResourceInfoProvider.SetResourceInfo(updateModule);

    return true;
}

return false;
}
```

The following example gets and bulk updates modules.

```
private bool GetAndBulkUpdateModules()
{
    // Prepare the parameters
    string where = "ResourceName LIKE N'MyNewModule%'";

    // Get the data
    DataSet modules = ResourceInfoProvider.GetResources(where, null);
    if (!DataHelper.DataSourceIsEmpty(modules))
    {
        // Loop through the individual items
        foreach (DataRow moduleDr in modules.Tables[0].Rows)
        {
            // Create object from DataRow
            ResourceInfo modifyModule = new ResourceInfo(moduleDr);

            // Update the properties
            modifyModule.ResourceDisplayName =
            modifyModule.ResourceDisplayName.ToUpper();

            // Save the changes
            ResourceInfoProvider.SetResourceInfo(modifyModule);
        }

        return true;
    }

    return false;
}
```

The following example adds a module to site.

```
private bool AddModuleToSite()
{
    /// Get the module
    ResourceInfo module = ResourceInfoProvider.GetResourceInfo("MyNewModule");
    if (module != null)
    {
```

```
int moduleId = module.ResourceId;
int siteId = CMSContext.CurrentSiteID;

// Save the binding
ResourceSiteInfoProvider.AddResourceToSite(moduleId, siteId);

return true;
}

return false;
}
```

The following example gets and bulk updates site modules.

```
private bool GetAndBulkUpdateSiteModules()
{
    int siteId = CMSContext.CurrentSiteID;
    string where = "ResourceName LIKE N'MyNewModule%'";

    // Get the data
    DataSet modules = ResourceInfoProvider.GetResources(where, null, 0, null,
siteId);
    if (!DataHelper.DataSourceIsEmpty(modules))
    {
        // Loop through the individual items
        foreach (DataRow moduleDr in modules.Tables[0].Rows)
        {
            // Create object from DataRow
            ResourceInfo modifyModule = new ResourceInfo(moduleDr);

            // Update the properties
            modifyModule.ResourceDisplayName =
modifyModule.ResourceDisplayName.ToLower();

            // Save the changes
            ResourceInfoProvider.SetResourceInfo(modifyModule);
        }

        return true;
    }

    return false;
}
```

The following example removes a module from site.

```
private bool RemoveModuleFromSite()
{
    // Get the module
    ResourceInfo removeModule = ResourceInfoProvider.GetResourceInfo
```

```
("MyNewModule");
    if (removeModule != null)
    {
        int siteId = CMSContext.CurrentSiteID;

        // Get the binding
        ResourceSiteInfo moduleSite = ResourceSiteInfoProvider.GetResourceSiteInfo(
removeModule.ResourceId, siteId);

        // Delete the binding
        ResourceSiteInfoProvider.DeleteResourceSiteInfo(moduleSite);

        return true;
    }

    return false;
}
```

The following example deletes a module.

```
private bool DeleteModule()
{
    // Get the module
    ResourceInfo deleteModule = ResourceInfoProvider.GetResourceInfo(
("MyNewModule"));

    // Delete the module
    ResourceInfoProvider.DeleteResourceInfo(deleteModule);

    return (deleteModule != null);
}
```

8.55.4.3 Managing permissions

The following example creates a permission.

```
private bool CreatePermission()
{
    // Get the resource
    ResourceInfo module = ResourceInfoProvider.GetResourceInfo("MyNewModule");
    if (module != null)
    {
        // Create new permission object
        PermissionNameInfo newPermission = new PermissionNameInfo();

        // Set the properties
        newPermission.PermissionDisplayName = "My new permission";
        newPermission.PermissionName = "MyNewPermission";
        newPermission.ResourceId = module.ResourceId;
    }
}
```

```
        // Save the permission
        PermissionNameInfoProvider.SetPermissionInfo(newPermission);

        return true;
    }

    return false;
}
```

The following example gets and updates a permission.

```
private bool GetAndUpdatePermission()
{
    // Get the permission
    PermissionNameInfo updatePermission =
    PermissionNameInfoProvider.GetPermissionNameInfo("MyNewPermission", "MyNewModule",
    null);
    if (updatePermission != null)
    {
        // Update the properties
        updatePermission.PermissionDisplayName =
        updatePermission.PermissionDisplayName.ToLower();

        // Save the changes
        PermissionNameInfoProvider.SetPermissionInfo(updatePermission);

        return true;
    }

    return false;
}
```

The following example gets and bulk updates permissions.

```
private bool GetAndBulkUpdatePermissions()
{
    // Prepare the parameters
    string where = "PermissionName LIKE N'MyNewPermission%'";

    // Get the data
    DataSet permissions = PermissionNameInfoProvider.GetPermissionNames(where,
    null, 0, null);
    if (!DataHelper.DataSourceIsEmpty(permissions))
    {
        // Loop through the individual items
        foreach (DataRow permissionDr in permissions.Tables[0].Rows)
        {
            // Create object from DataRow
            PermissionNameInfo modifyPermission = new PermissionNameInfo
            (permissionDr);
        }
    }
}
```

```
        // Update the properties
        modifyPermission.PermissionDisplayName =
modifyPermission.PermissionDisplayName.ToUpper();

        // Save the changes
        PermissionNameInfoProvider.SetPermissionInfo(modifyPermission);
    }

    return true;
}

return false;
}
```

The following example adds a permission to role.

```
private bool AddPermissionToRole()
{
    // Get the permission
    PermissionNameInfo permission =
PermissionNameInfoProvider.GetPermissionNameInfo("MyNewPermission", "MyNewModule",
null);

    // Get the role
    RoleInfo role = RoleInfoProvider.GetRoleInfo("cmsdeskadmin",
CMSContext.CurrentSiteID);

    if ((permission != null) && (role != null))
    {
        // Create new role permission object
        RolePermissionInfo newRolePermission = new RolePermissionInfo();

        // Set the properties
        newRolePermission.PermissionID = permission.PermissionID;
        newRolePermission.RoleID = role.RoleID;

        // Add permission to role
        RolePermissionInfoProvider.SetRolePermissionInfo(newRolePermission);

        return true;
    }

    return false;
}
```

The following example removes a permission from role.

```
private bool RemovePermissionFromRole()
{
```

```
// Get the permission
PermissionNameInfo permission =
PermissionNameInfoProvider.GetPermissionNameInfo("MyNewPermission", "MyNewModule",
null);

// Get the role
RoleInfo role = RoleInfoProvider.GetRoleInfo("cmsdeskadmin",
CMSContext.CurrentSiteID);

if ((permission != null) && (role != null))
{
    // Get the role permission
    RolePermissionInfo deleteRolePermission =
RolePermissionInfoProvider.GetRolePermissionInfo(role.RoleID,
permission.PermissionId);

    // Remove permission from role
    RolePermissionInfoProvider.DeleteRolePermissionInfo(deleteRolePermission);

    return true;
}

return false;
}
```

The following example deletes a permission.

```
private bool DeletePermission()
{
    // Get the permission
    PermissionNameInfo deletePermission =
PermissionNameInfoProvider.GetPermissionNameInfo("MyNewPermission", "MyNewModule",
null);

    // Delete the permission
    PermissionNameInfoProvider.DeletePermissionInfo(deletePermission);

    return (deletePermission != null);
}
```

8.55.4.4 Managing UI elements

The following example creates a UI element.

```
private bool CreateUIElement()
{
    // Get the module
    ResourceInfo module = ResourceInfoProvider.GetResourceInfo("MyNewModule");
    if (module != null)
    {
```

```

        // Get the parent UI element
        UIElementInfo rootElement = UIElementInfoProvider.GetRootUIElementInfo
(module.ResourceId);
        if (rootElement == null)
        {
            // Create root UI element
            rootElement = new UIElementInfo();
            rootElement.ElementResourceID = module.ResourceId;
            rootElement.ElementDisplayName = module.ResourceDisplayName;
            rootElement.ElementName = module.ResourceName.ToLower().Replace(".",
"");

            rootElement.ElementIsCustom = false;

            // Save root UI element
            UIElementInfoProvider.SetUIElementInfo(rootElement);
        }

        // Create new UI element object
        UIElementInfo newElement = new UIElementInfo();

        // Set the properties
        newElement.ElementDisplayName = "My new element";
        newElement.ElementName = "MyNewElement";
        newElement.ElementResourceID = module.ResourceId;
        newElement.ElementIsCustom = true;
        newElement.ElementParentID = rootElement.ElementID;

        // Save the UI element
        UIElementInfoProvider.SetUIElementInfo(newElement);

        return true;
    }

    return false;
}

```

The following example gets and updates a UI element.

```

private bool GetAndUpdateUIElement()
{
    // Get the UI element
    UIElementInfo updateElement = UIElementInfoProvider.GetUIElementInfo
("MyNewModule", "MyNewElement");
    if (updateElement != null)
    {
        // Update the properties
        updateElement.ElementDisplayName =
updateElement.ElementDisplayName.ToLower();

        // Save the changes
        UIElementInfoProvider.SetUIElementInfo(updateElement);
    }
}

```

```
        return true;
    }

    return false;
}
```

The following example gets and bulk updates UI elements.

```
private bool GetAndBulkUpdateUIElements()
{
    // Prepare the parameters
    string where = "ElementName LIKE N'MyNewElement%'";

    // Get the data
    DataSet elements = UIElementInfoProvider.GetUIElements(where, null);
    if (!DataHelper.DataSourceIsEmpty(elements))
    {
        // Loop through the individual items
        foreach (DataRow elementDr in elements.Tables[0].Rows)
        {
            // Create object from DataRow
            UIElementInfo modifyElement = new UIElementInfo(elementDr);

            // Update the properties
            modifyElement.ElementDisplayName =
            modifyElement.ElementDisplayName.ToUpper();

            // Save the changes
            UIElementInfoProvider.SetUIElementInfo(modifyElement);
        }

        return true;
    }

    return false;
}
```

The following example adds a UI element to role.

```
private bool AddUIElementToRole()
{
    // Get the role
    RoleInfo role = RoleInfoProvider.GetRoleInfo("cmsdeskadmin",
    CMSContext.CurrentSiteID);

    // Get the UI element
    UIElementInfo element = UIElementInfoProvider.GetUIElementInfo("MyNewModule",
    "MyNewElement");

    if ((role != null) && (element != null))
```

```
{
    // Create new role UI element object
    RoleUIElementInfo newRoleElement = new RoleUIElementInfo();

    // Set the properties
    newRoleElement.RoleID = role.RoleID;
    newRoleElement.ElementID = element.ElementID;

    // Save the role UI element
    RoleUIElementInfoProvider.SetRoleUIElementInfo(newRoleElement);

    return true;
}

return false;
}
```

The following example removes a UI element from role.

```
private bool RemoveUIElementFromRole()
{
    // Get the role
    RoleInfo role = RoleInfoProvider.GetRoleInfo("cmsdeskadmin",
CMSContext.CurrentSiteID);

    // Get the UI element
    UIElementInfo element = UIElementInfoProvider.GetUIElementInfo("MyNewModule",
"MyNewElement");

    if ((role != null) && (element != null))
    {
        // Get the role UI element
        RoleUIElementInfo deleteElement =
RoleUIElementInfoProvider.GetRoleUIElementInfo(role.RoleID, element.ElementID);

        // Delete the role UI element
        RoleUIElementInfoProvider.DeleteRoleUIElementInfo(deleteElement);

        return (deleteElement != null);
    }

    return false;
}
```

The following example deletes a UI element.

```
private bool DeleteUIElement()
{
    // Get the UI element
    UIElementInfo deleteElement = UIElementInfoProvider.GetUIElementInfo
```

```
("MyNewModule", "MyNewElement");  
  
    // Delete the UI element  
    UIElementInfoProvider.DeleteUIElementInfo(deleteElement);  
  
    return (deleteElement != null);  
}
```

External utilities

9 External utilities

9.1 Kentico AD Import Utility

9.1.1 Overview

Introduction

Kentico Active Directory Import Utility is a standalone Windows application which allows importing of users and groups (roles) from Active Directory (AD) into Kentico CMS and assigning users to roles depending on AD settings. The application also provides the possibility of updating already imported users and roles so that their properties are the same as in the current AD.

What can it do?

- Import users from AD into Kentico CMS.
- Import roles (groups) from AD into Kentico CMS.
- Assign users to appropriate roles based on AD settings.
- Update already imported users and roles according to current AD.

What can't it do?

- Import from multiple ADs or domains at once.
- Import the tree structure of roles, since Kentico CMS does not support hierarchical roles.
- Since there is no hierarchy in the CMS roles, import cannot keep the tree structure of AD groups.

Terminology

- **Import profile** – XML file with import settings; this file can be created using the wizard mode, or even written manually; it is necessary to have an import profile prepared when you want to use the console mode of the tool
- **SAM Account Name** - logon name used to support clients and servers on older versions of the operating system, such as Windows NT 4.0, Windows 95, Windows 98, and LAN Manager.
- **UPN (User Principal Name)** - Internet-style login name for a user. It is based on the RFC 822 standard. The UPN is shorter than the distinguished name and easier to remember. By convention, the name should map to the user's e-mail name. The value set for this attribute is equal to the length of the user's ID and the domain name. (Sample UPN: username@subdomain.domain.tld)
- **Role or Group** - these two terms have an almost identical meaning, while "group" is used in AD terminology and "role" in Kentico CMS

Requirements

- **Kentico CMS 5.0** or higher
- **Ultimate edition** or any edition with the **Advanced package**

Launching the utility

There are two ways how the utility can be launched. You will typically use the AD import wizard, which is described in the [Using the wizard](#) chapter. If you want to schedule AD import to be performed on a

regular basis, you may utilize the second option - launching AD import from the command line. This approach is described in the [AD import from command line](#) chapter.

9.1.2 Using the wizard

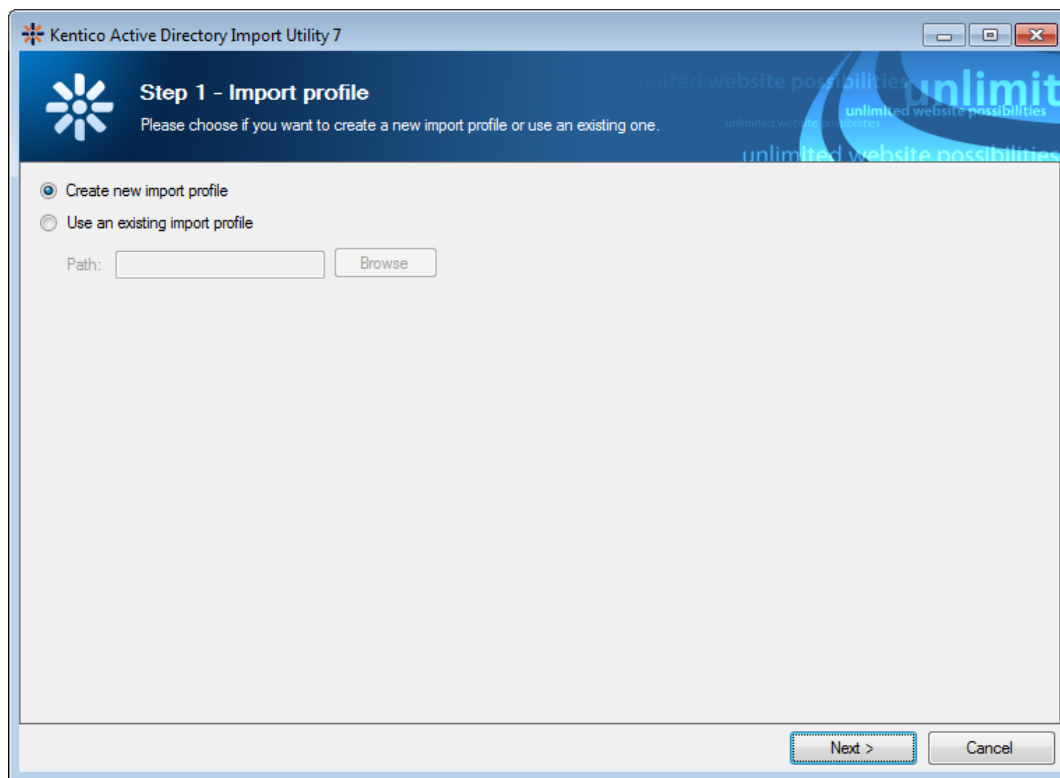

The AD Import Utility wizard can be executed either from **Start menu -> All programs -> Kentico CMS <version number> -> Kentico CMS Utilities**, or by launching the **ADImport.exe** file located in **<Kentico CMS installation folder>\Bin** (typically *c:\Program Files (x86)\KenticoCMS\<version number>\Bin*).

The following text describes particular steps of the wizard:

Step 1 – Import profile settings

In the first step, you need to choose if you want to create a new import profile or use an existing XML profile. If you select an existing profile, values will be pre-filled in the following steps based on the profile settings.

Step 2 – Kentico CMS DB Setup

In the second step, specify the target database of the CMS where the users and roles will be imported:

- **SQL Server name or IP address** - name or IP address of the server where the target database is stored.
- **Database name** - name of the target database.
- **Use integrated Windows authentication** - choose this option if you want to log on to the server using Windows authentication.
- **Use SQL Server account** - choose this option if you want to log on to the server using credentials filled in the fields below.

It is a good idea to test the specified connection using the **Test connection** button before proceeding to the next step.

The screenshot shows a Windows-style dialog box titled "Kentico Active Directory Import Utility 7". The main heading is "Step 2 - Choose Kentico CMS database" with the instruction "Please enter the database connection details." Below this, there are several input fields and options:

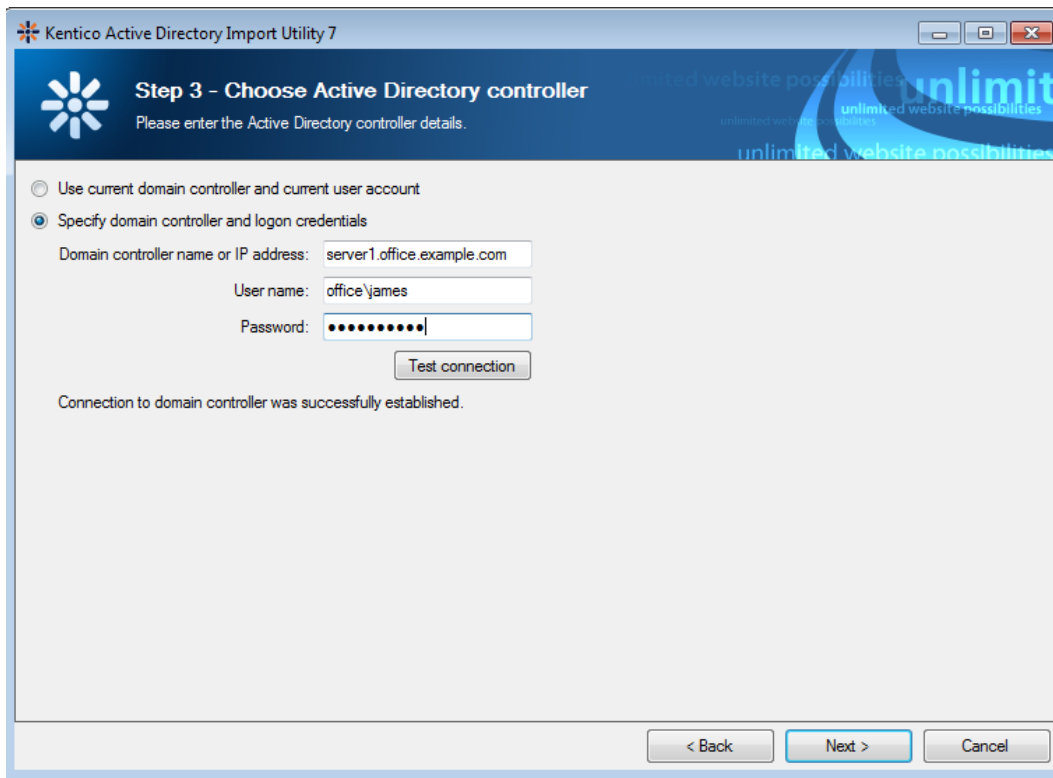

- "SQL Server name or IP address:" with a dropdown menu showing "SQL1".
- Two radio buttons for authentication: "Use integrated Windows authentication" (unselected) and "Use SQL Server account" (selected).
- Under "Use SQL Server account", there are text boxes for "User name:" (containing "admin") and "Password:" (containing seven dots).
- An "Establish connection" button is located below the password field.
- "Database name:" with a dropdown menu showing "KenticoCMS7".
- A status message at the bottom of the form area: "Connection to SQL Server was successfully established."
- At the bottom of the dialog, there are three buttons: "< Back", "Next >" (highlighted in blue), and "Cancel".

Step 3 – Active directory connection

In the third step, specify the source AD's domain controller. You have two options:

- **Use current user account** - uses the domain where the current user belongs.
- **Specify domain controller and logon credentials** - if you choose this option, you can enter the logon details manually into the fields below.

Here again, it is recommended to test the specified connection using the **Test connection** button.

Step 4 – Import settings

In this step, you can adjust some general settings of the import process:

- **Import users/groups** - determines which users or groups (roles) will be pre-selected in Step 6, you have the following options:
 - **All** - all users or groups will be pre-selected.
 - **Only selected** - when using an existing import profile, selection stored in the profile will be used. Otherwise, nothing will be pre-selected.
 - **Only selected and new** - same as above, while new users and groups will be selected as well.
- **Update user and role data** - if enabled, properties of users and roles already imported from the AD will be updated in the CMS based on the current values in AD.
- **Update user membership in roles** - if enabled, membership of users imported from the AD will be updated in the CMS based on the current membership settings in AD.
- **Import new users only from selected roles** - if enabled, only those new users who belong to at least one role (group) selected in Step 6 or 8 of the wizard will be imported. Please note that enabling this option may override previous selection of users to be imported.
- **Delete users and roles that were deleted in the Active directory** - if enabled, users who were previously imported from the Active Directory but were deleted on the source server since then will be deleted in the CMS.
- **Log import process to file** - if enabled, you can specify a file where the import log will be stored.
- **Select sites** - choose the sites to which the imported users and roles will be assigned.

Please note

If you do not choose any site in this step, the rest of the wizard will leave out steps related to the import of roles (groups). This happens because it is currently not possible to import roles from AD into Kentico CMS as global objects and they must be assigned to a specific site.

The screenshot shows the 'Step 4 - Import settings' dialog box. The title bar reads 'Kentico Active Directory Import Utility 7'. The main heading is 'Step 4 - Import settings' with the instruction 'Please adjust the settings of the import process.' Below this, there are radio buttons for 'Import users' (All users, Only selected, Update selected and import new users) and 'Import groups' (All groups, Only selected, Update selected and import new groups). There are several checked checkboxes: 'Update user and role data', 'Update user membership in roles', 'Delete users and roles that were deleted in the Active Directory', and 'Log import process to file'. An unchecked checkbox is 'Import new users only from selected roles'. A text box shows the path 'C:\Program Files (x86)\KenticoCMS\Adel' with a 'Browse' button. At the bottom, there is a 'Select sites:' section with a table:

| Import | Site |
|-------------------------------------|----------------|
| <input checked="" type="checkbox"/> | Corporate site |

At the bottom of the dialog are buttons for '< Back', 'Next >', and 'Cancel'.

Step 5 – Import properties

In this step, you are asked to define user name and role name format and to bind AD user properties to CMS user properties. The following options can be defined:

- **User name format** - choose one of the three possible formats:
 - Domain\SAM (e.g. intranet\joe)
 - SAM account name (e.g. joe)
 - UPN (joe@intranet.mycompany.com)
- **Configure user as CMS editor** - turn on to enable the *Is editor* option for newly imported users. This option is located in *Administration -> Users -> user edit -> General*.
- **Target/Source** - you can choose which attributes from AD (Source) will be mapped to particular attributes of the *CMS_User* role.
- **Show all attributes** - turn on to enable all the attributes, including custom attributes, from your AD schema to be selected as *Source*. Note that you can import attributes of any data type, however, their values are always imported to *Target* as string.
- **Role display name format** - choose one of the two possible formats:

- Domain\SAM (intranet\DB Admins)
- SAM (DB Admins)
- **Role code name format** - choose one of the following formats:
 - Domain\SAM (intranet\DB Admins)
 - SAM (DB Admins)
 - Guid (16-byte number)
- **Import description** - indicates if role description should be imported from the AD.

Step 5 - Field mapping
Please choose the user name and role name format and specify mapping of user fields.

Users

User name format:

Configure new users as CMS editors: Show all attributes

| Target | Source |
|-----------------|--------------------------|
| Email | E-mail address (mail) |
| FirstName | First name (givenName) |
| FullName | (None) |
| LastName | Last name (sn) |
| MiddleName | Middle name (middleName) |
| UserAvatarType | (None) |
| UserCampaign | (None) |
| UserCustomData | (None) |
| UserDescription | (None) |

Roles

Role display name format:

Role code name format:

Import description:

< Back Next > Cancel

Step 6 – Select users & groups to be imported

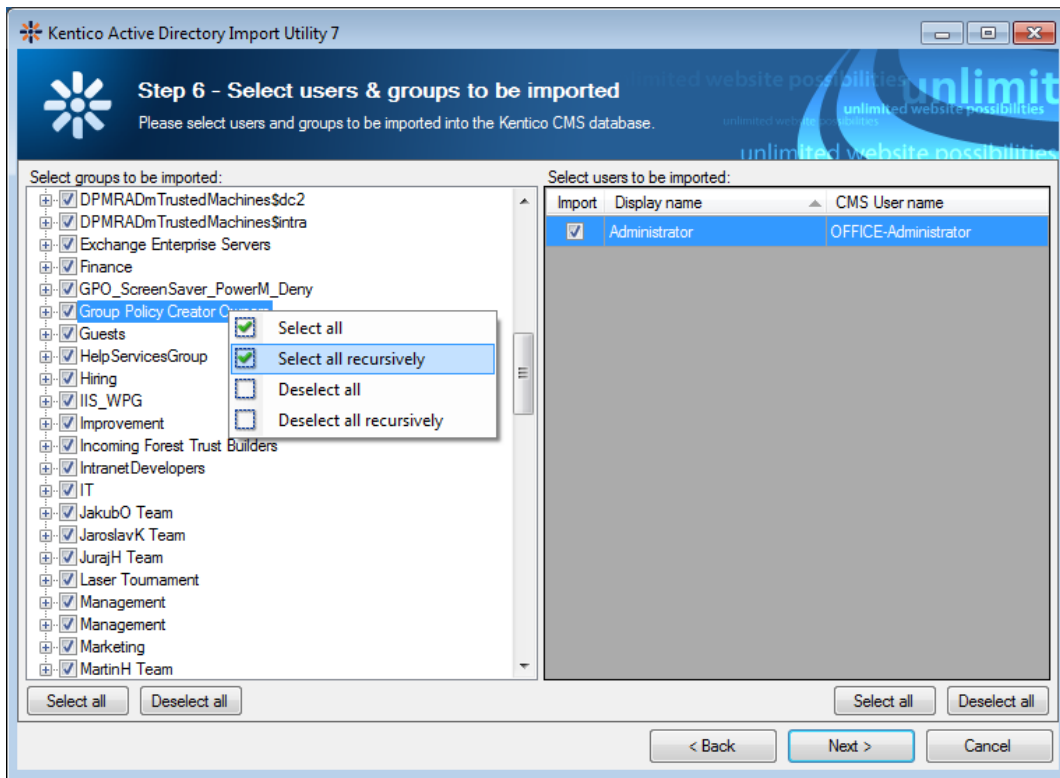

In the sixth step, you can select which roles and users will be imported. It will be possible to adjust the settings made here in the following two steps.

On the left, you can see all groups (roles) found on the source server. If you select a group, its members are displayed in the list on the right. You can define which users and roles will be imported using the appropriate check-boxes.

By right-clicking a group, you can display a context menu with the following actions:

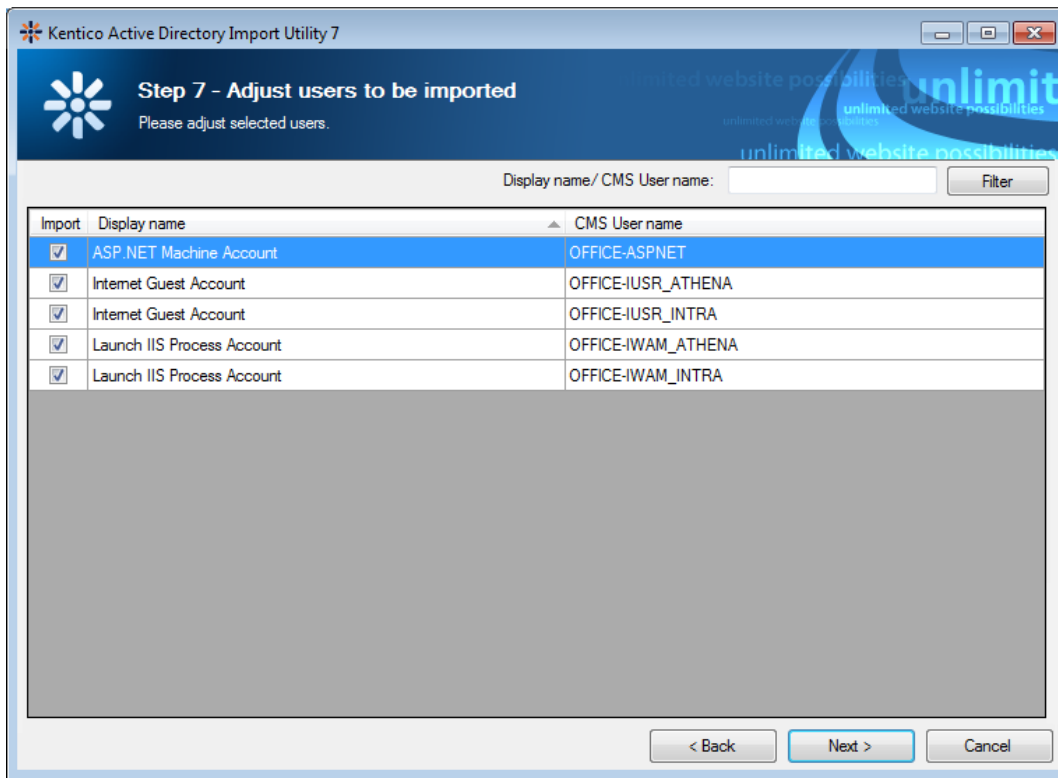

- **Select all** - selects all child groups directly under the selected group.
- **Select all recursively** - selects all child groups under the selected group until the last level.
- **Deselect all** - selects all groups directly under the selected group.
- **Deselect all recursively** - selects all group under the selected group until the last level.

All users in a role or all roles can be selected or deselected in one click using the **Select all** and **Deselect all** buttons.

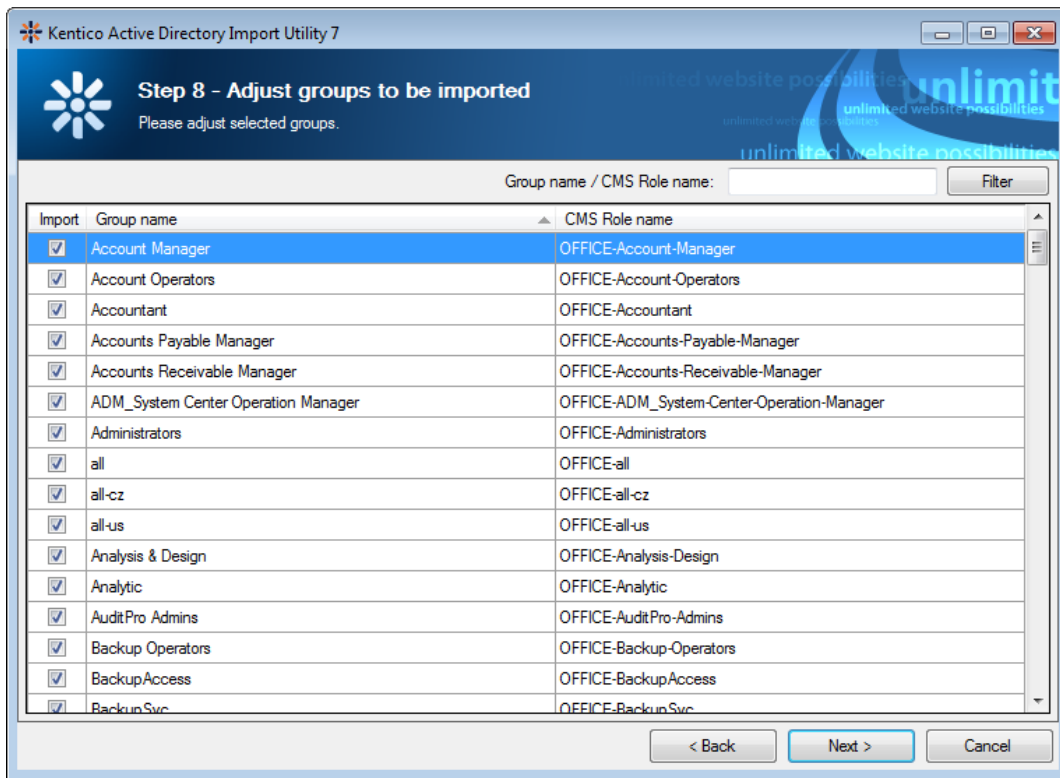

Step 7 – Adjust users to be imported

In this step, you can adjust the users to be imported. Users are selected based on settings made in the previous step, while you can adjust the selection using the check-boxes. You can also filter the listed users by *Display name* and *User name* using the filter above the list.

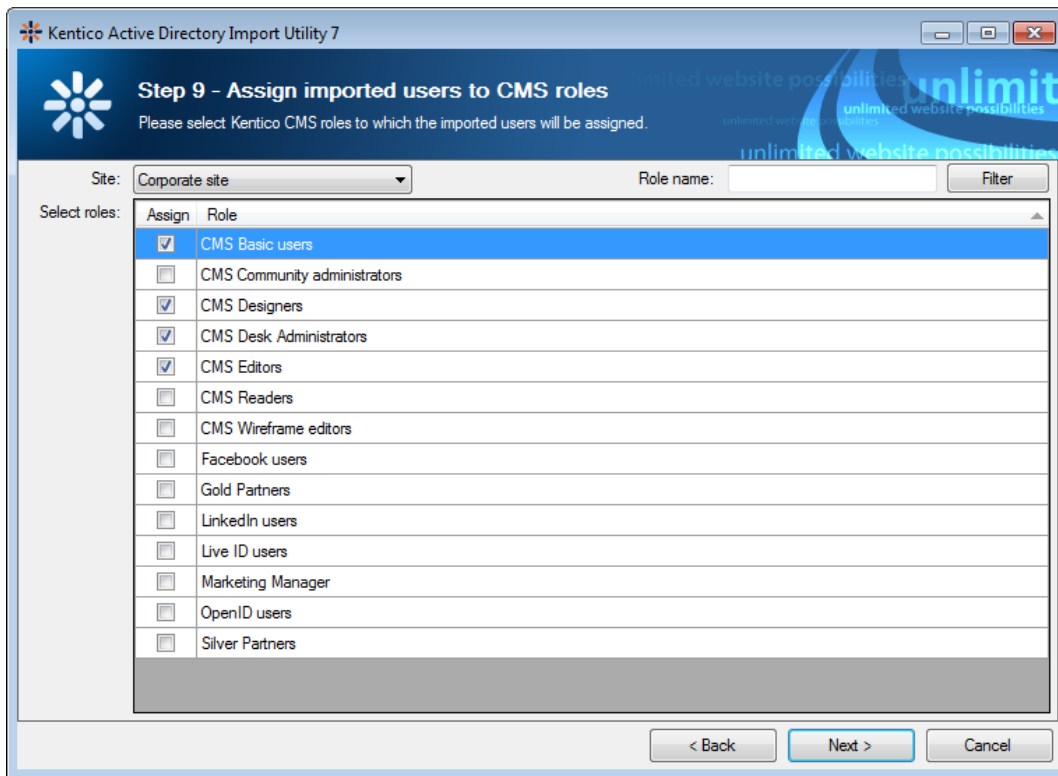

Step 8 – Adjust groups to be imported

This step is similar to the previous one, while groups (roles) to be imported can be adjusted here using the check-boxes. Listed groups can be filtered by *Group name* using the filter above the list.

Step 9 – Assign to CMS roles

In the sixth step, you can select roles to which the imported users will be assigned. If you are importing to multiple sites, you first need to choose the site whose roles should be displayed using the **Site** drop-down.

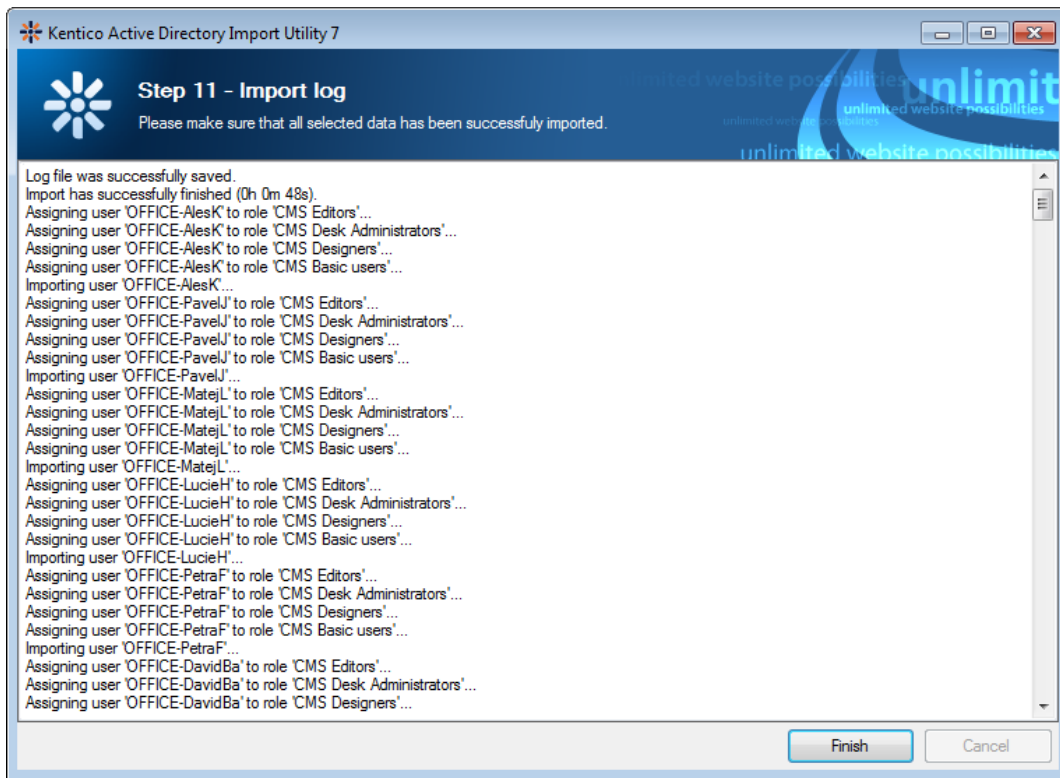

Step 10 - Finalize

Now you have your import profile configured. You can execute it immediately, save it into a file or perform both of these actions, depending on which of the **Import now** and **Save import profile to file** check-boxes is enabled.

Step 11 – Import log

The last step displays an import log, showing the progress of the import process. When the import finishes, you can close the wizard using the **Finish** button.

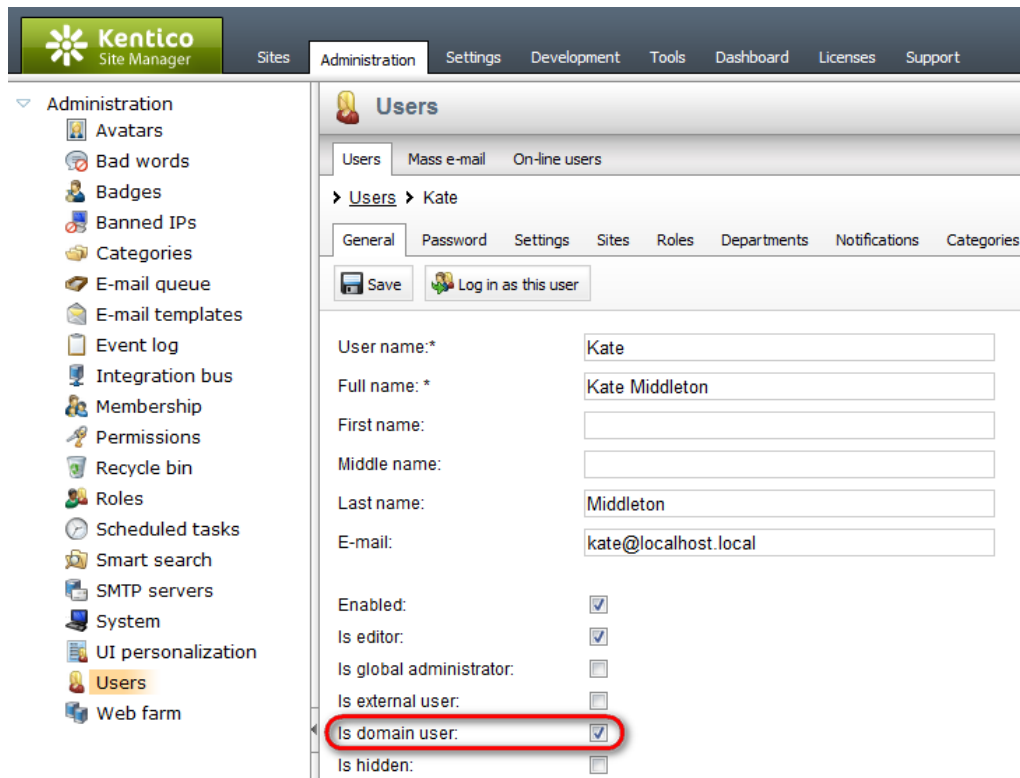

9.1.3 How to recognize imported users and roles

In the CMS, you can recognize users imported from AD by the **Is domain user** check-box on a user's **General** tab, as you can see in the screenshot below.

When editing roles, you can see the **Is domain role** check-box, which has the same meaning for roles.

These check-boxes reflect the values of the following Boolean fields in the database tables:

- **CMS_User** -> **UserIsDomain**
- **CMS_Role** -> **RoleIsDomain**

9.1.4 AD import from command line

Apart from the wizard described in the [Using the wizard](#) chapter, the AD Import Utility can also be launched from windows command line. It is achievable by executing the **ADImport.exe** file located in **<Kentico CMS installation folder>\Bin** (typically *C:\Program Files (x86)\KenticoCMS\<version number>\Bin*) using a special syntax.

You can launch the utility with the **-h** parameter, which displays help on using the utility from the command line:

```
ADImport -h
```

To perform the actual import, you need to have an import profile created via the wizard. With the import profile prepared, you need to execute the utility using the **ADImport /profile <profile file name>** syntax. When specifying the profile file name, an absolute or a relative path can be used. Please make sure that you use proper quotation when entering an absolute path containing special characters (e.g. blank spaces).

```
ADImport /profile my_profile.xml
ADImport /profile "C:\Temp\AD Import\my_profile.xml"
```

After executing the command, users or groups from Active Directory will be imported to your Kentico CMS instance based on settings contained in the specified import profile.

9.2 Kentico Import Toolkit

9.2.1 Overview

Kentico Import Toolkit is an external utility which enables import of data from external sources into Kentico CMS. As a source of data, you can use:

- **MS SQL database**
- **XML file**
- **CSV file**
- **XLSX file**

Data from these sources can be imported as:

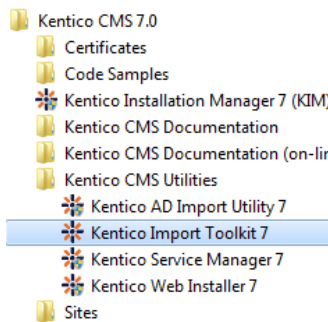

- **Documents**
- **Document attachments**
- **Objects**
- **Object attachments (metafiles)**
- **Custom table items**
- **On-line form items**
- **Resource strings**

To learn how to use the tool, proceed to the [Initial steps](#) topic and follow the step-by-step guide through the topics that follow.

9.2.2 Initial steps

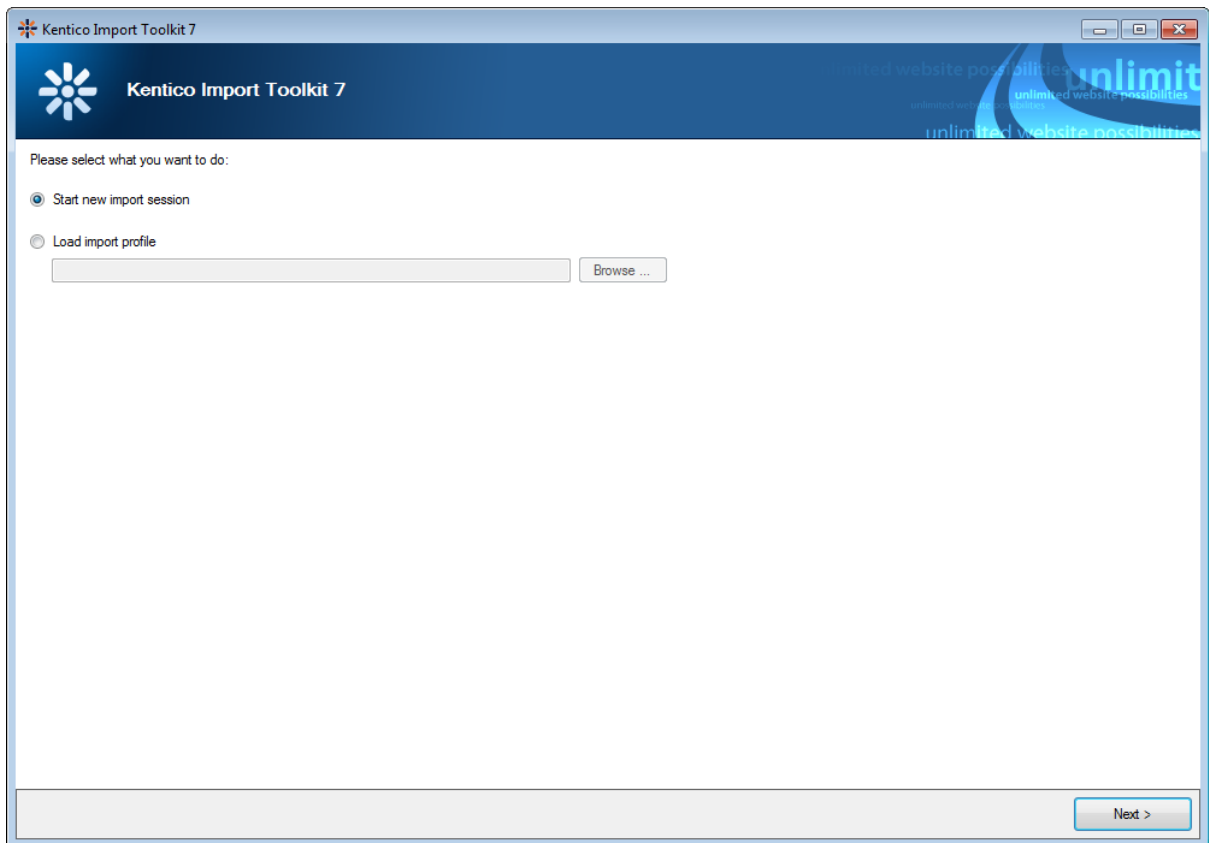

This topic describes the initial steps of the Kentico Import Toolkit wizard.

1. You can launch Kentico Import Toolkit from the Windows Start menu. In the Kentico CMS program group, open the Kentico CMS Utilities folder and choose **Kentico Import Toolkit**.

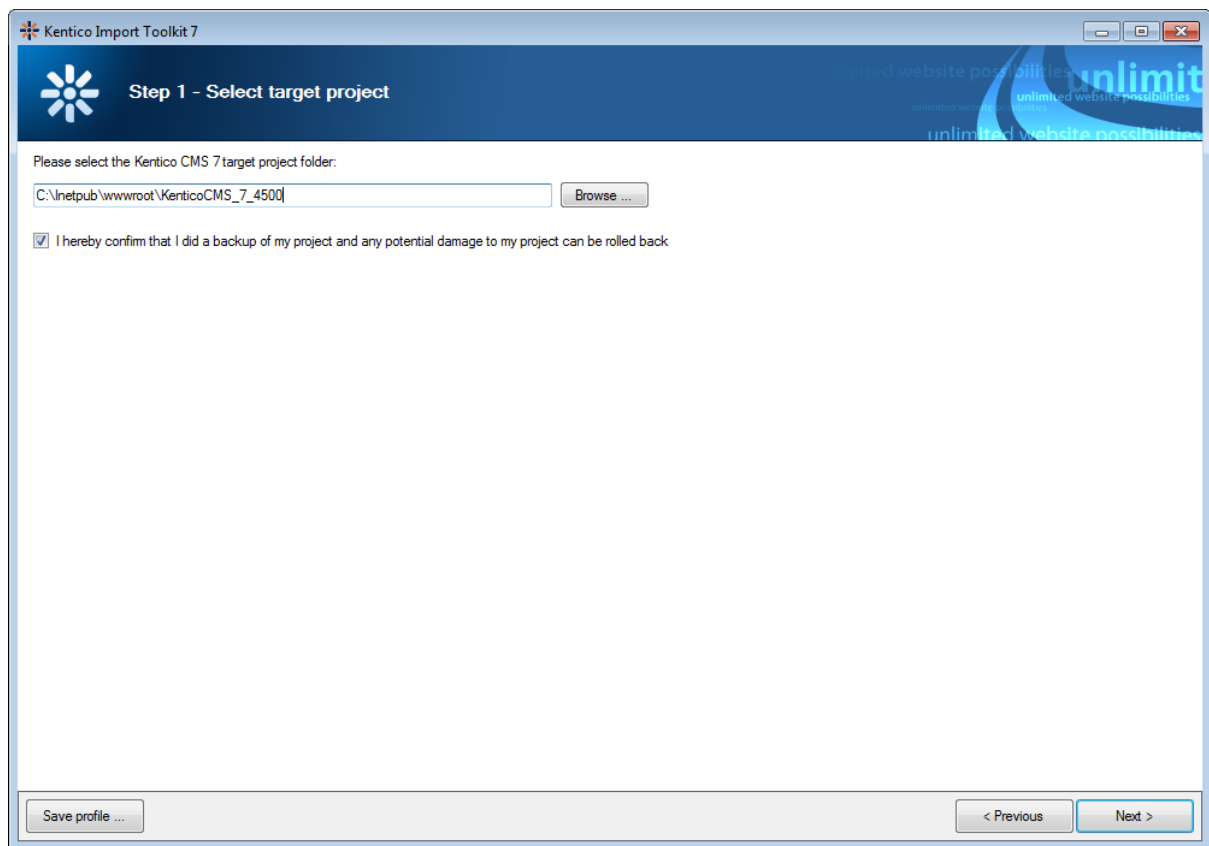

2. On the initial screen of the wizard, you can choose from the following options:

- **Start new import session** - starts a new import session where you can configure all the options of the import. In each of the configuration steps, you can click the *Save profile* button to save all the configuration done until that point. The configuration is saved as an *.iprofile* file in a destination of your choice.
- **Load import profile** - By selecting the *Load import profile* option, you can load an *.iprofile* file that you created when *importing a new session*. All the configuration you have done prior to saving the configuration file will be pre-filled automatically.

Click **Next** to proceed when selected.

3. In **Step 1**, choose the root folder of the project into which you want to import your data. Either enter the path manually, or click **Browse** and search for the folder within your file system structure. In order to proceed, you also need to turn the check-box below the field on. By doing this, you confirm that you have performed a backup of your project so that you can roll back any potential damage caused by the import.

Click **Next** to proceed to the following step.

4. In **Step 2**, select the data type that will be used to store the imported data in Kentico CMS. You can make the selection by clicking the **Select data type to import** drop-down list and the optional drop-down lists below it:

- **Custom table items** - imports the data into a custom table selected in the *Import to custom table* drop-down list.
- **On-line form items** - imports the data as [Form](#) records of the on-line form selected in the *Import to on-line form* drop-down list.
- **Objects** - imports the data as Kentico CMS objects of a type selected in the *Import as* radio buttons. Three options are offered:
 - *Typical objects* - offers a set of typically used objects.
 - *All data objects* - includes all data objects except for many to many relationship objects.
 - *Many to many relationships* - provides a selection of objects with many to many relationship such as *contact list*, *group permissions* and *workflow step roles*.

Additionally, you can reduce the selection of *objects* offered in the drop-down lists by adding optional keys to the **ImportToolkit.exe.config** file. You can find the configuration file in **<Kentico CMS installation folder>\Bin** (typically *C:\Program Files (x86)\KenticoCMS\<version number>\Bin*). The keys accept object *ClassNames*, separated by semicolons, as their values. You can find *ClassNames*, e.g. in the *CMS_Class* table of your Kentico CMS database.

Using the following key you can restrict the selection offered in the *Typical objects* drop-down list to *Product*, *Manufacturer* and *Supplier* only.

```
<add key="TypicalObjectTypes" value="CMS.Product;COM.Manufacturer;  
COM.Supplier" />
```

By adding the following key, you can modify the selection of the *All data objects* drop-down list to contain only *Newsletter*, *Newsletter subscriber* and *Newsletter issue*.

```
<add key="AllObjectTypes" value="Newsletter.Newsletter;  
Newsletter.Subscriber;Newsletter.Issue" />
```

You can limit the selection offered in the *Many to many relationships* drop-down list to *Workflow user*, *Workflow step* and *Workflow step user* with the following key.

```
<add key="MNRelationshipTypes" value="CMS.WorkflowUser;CMS.WorkflowStep;  
CMS.WorkflowStepUser" />
```

- **Object attachments (metafiles)** - imports the data as metafiles of Kentico CMS objects. The *Attach to object type* drop-down list offers a selection of object types to which the metafiles will be attached.

By adding the following key to the Import toolkit's configuration file, you can restrict the selection of the *Attach to object type* drop-down list to *Newsletter issue* and *Newsletter email template* only.

```
<add key="MetafileObjectTypes" value="Newsletter.Issue;  
Newsletter.EmailTemplate" />
```

- **Documents** - imports the data as documents of the type selected in the *Import as* drop-down list. If you enable the *Automatically publish documents under workflow* option, imported documents will be automatically published when a [workflow](#) applies to them. By enabling the *Import as products* option, only product document types will be offered in the *Import as* drop-down list and [E-commerce](#) products will be created together with the product documents.
- **Document attachments** - imports the data as attachments of a document specified in Step 6 of the wizard.
- **Resource strings** - imports the data as resource strings into a culture selected in the *Import as* drop-down list.

With data types that can be site-related, the **Import data to site** drop-down list is displayed. Using this drop-down list, you can select a site to which the imported objects should be assigned. Where applicable, you can also choose (**global objects**) from the drop-down list to import the data as global objects not bound to a specific website.

Using the **Import options** radio buttons, you can determine the tool's behavior when it detects that some of the imported data already exists in Kentico CMS. Existing objects can either be detected automatically (based on code name or GUID), or by a WHERE condition specified in Step 6 of the wizard.

- **Always insert as new objects/documents** - all imported data will be inserted as new objects/documents, even if some of the data exists in Kentico CMS.

- **Import new and overwrite existing objects/documents** - all imported data will be inserted. Objects that already exist in Kentico CMS will be overwritten by the newly imported equivalents. This option must be selected if you wish to import new culture versions of an existing document (node).
- **Skip existing objects/documents** - existing objects/documents will be skipped and only new ones will be imported.

Kentico Import Toolkit 7

Step 2 - Select object type to import

Select data type to import:
Custom table items

Import data to site:
(global objects)

Import to custom table:
Sample table

Import options:
 Always insert as new objects
 Import new and overwrite existing objects
 Skip existing objects

Save profile ...

< Previous Next >

Once selected, click **Next** to proceed to the following step.

5. In **Step 3**, specify the source of the imported data. Using the radio buttons, you can choose to import from:

- [MS SQL database](#) - imports data from a specified MS SQL database.
 - **Server** - name of the database server containing the source database.
 - **Database name** - name of the source database.
 - **Use integrated Windows authentication** - the current user's Windows account will be used to log on to the database server.
 - **Use SQL server authentication** - logon credentials filled into the *Username* and *Password* fields below will be used to log on to the database server.
- [XML file](#) - imports data from an XML file specified in the field below.
- [CSV file](#) - imports data from a CSV file specified in the field below.
- [XLSX file](#) - imports data from an Excel spreadsheet specified in the field below.

Kentico Import Toolkit 7

Step 3 - Select source of the data

Get the source data from:

MS SQL database:

Server:

Database name:

Use integrated Windows authentication

Use SQL server authentication:

Username:

Password:

XML file CSV file XLSX file

Once selected, click **Next** to proceed to the following step.

The rest of the wizard differs depending on the selected source of data. Click the links above to learn more about the following step once you select the respective source of data.

9.2.3 Data selection from MS SQL database

This topic contains information about the part of Kentico Import Toolkit wizard specific for import from an MS SQL database. The preceding steps of the wizard are explained in the [Initial steps](#) topic.

6. In **Step 4**, you can choose from the following options:

- **Table** - imports data from the table selected in the drop-down list. You can filter the imported data using a WHERE condition and sort them using an ORDER BY expression entered into the respective fields.
- **View** - imports data from the view selected in the drop-down list. You can filter the data you want imported using a WHERE condition and sort them using an ORDER BY expression entered into the respective fields.
- **SQL query** - imports data retrieved by a custom SQL query entered into the text area.

Kentico Import Toolkit 7

Step 4 - Data selection

Please select the data source:

Table: Categories Where: CategoryID <= 7 Order by: CategoryID DESC

View: Alphabetical list of products

SQL query:

Save profile ... < Previous Next >

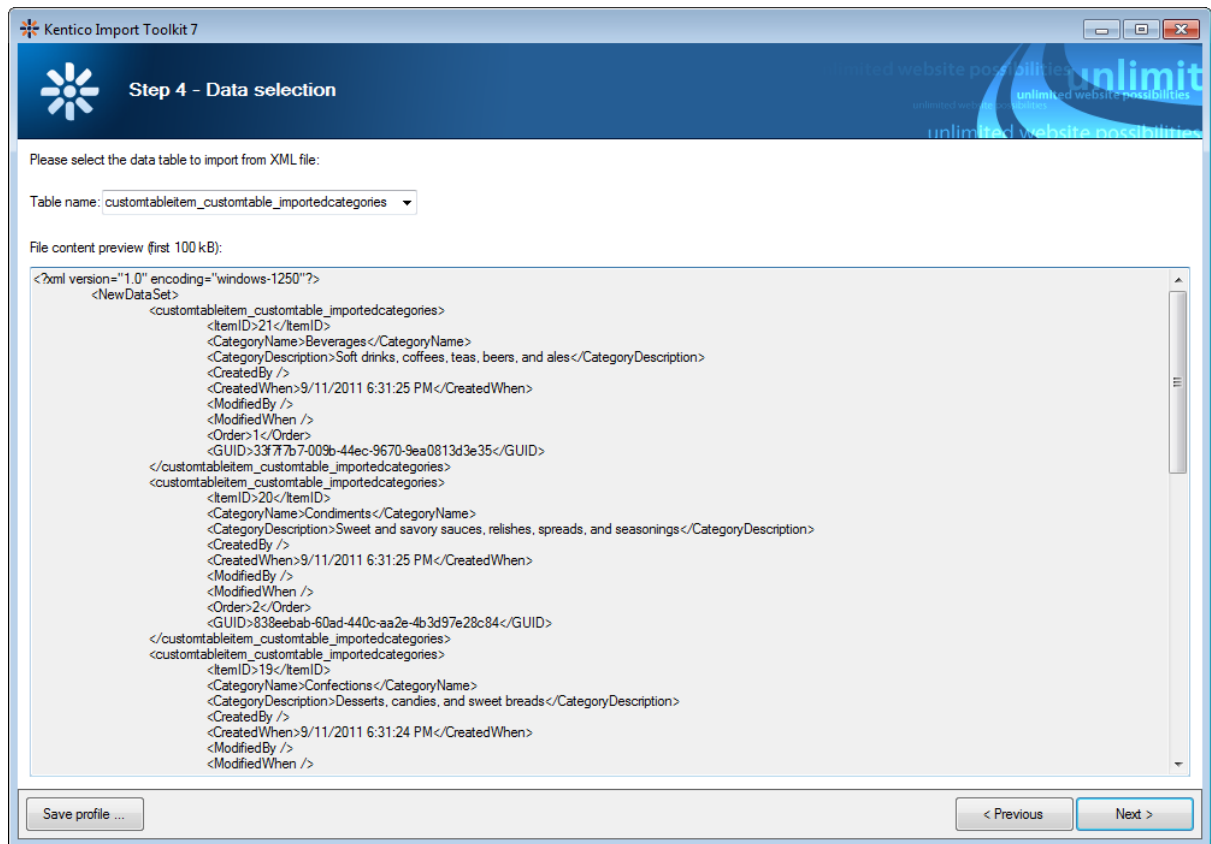

When specified, click **Next** to proceed to the following step.

For the rest of the wizard, which is common for all the imported data sources, see the [Final steps](#) topic.

9.2.4 Data selection from XML file

This topic contains information about the part of Kentico Import Toolkit wizard specific for import from an XML file. The preceding steps of the wizard are explained in the [initial steps](#) topic.

6. In **Step 4**, use the **Table name** drop-down list to select which elements of the source XML file represent individual records to be imported. All its sub-elements will then be taken as individual data columns of the imported records.

Once selected, click **Next** to proceed to the following step.

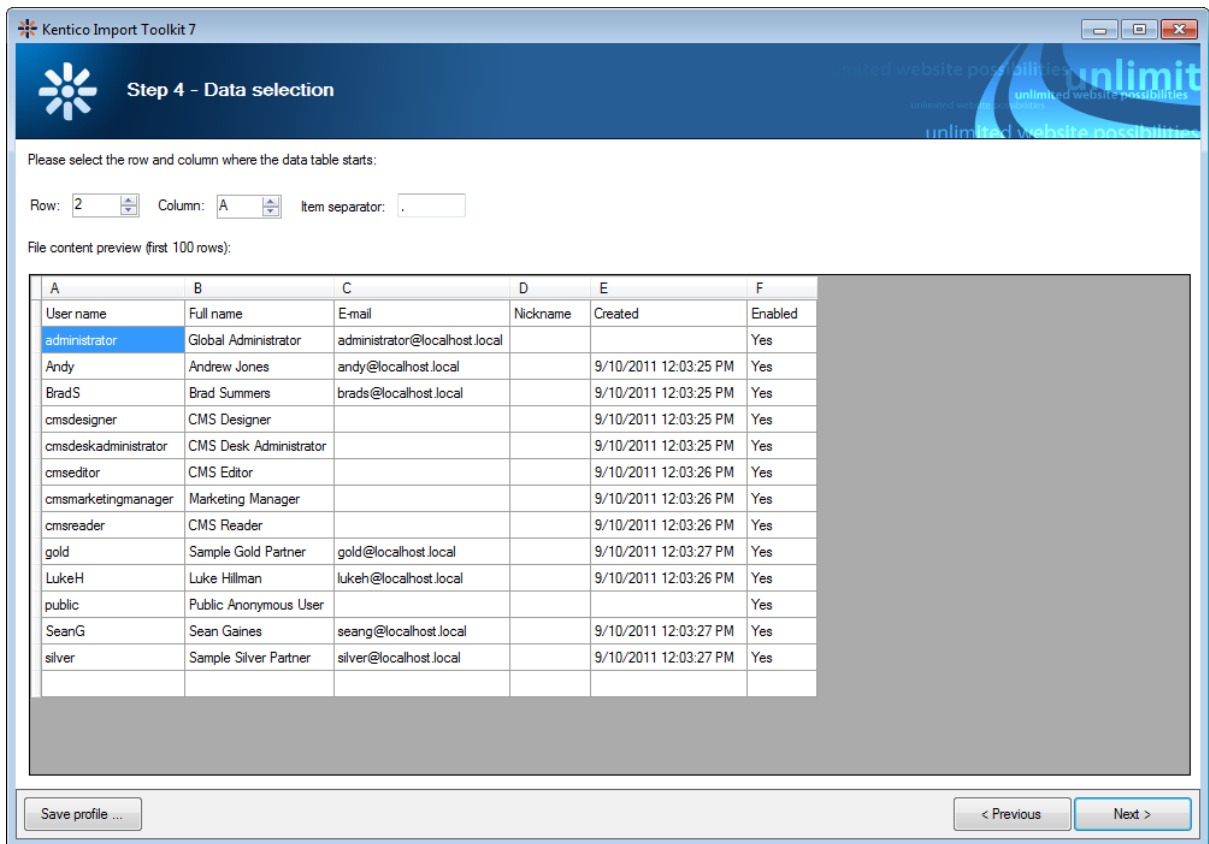

For the rest of the wizard, which is common for all the imported data sources, see the [Final steps](#) topic.

9.2.5 Data selection from CSV or XLSX file

This topic contains information about the part of Kentico Import Toolkit wizard specific for import from CSV or XLSX files. The preceding steps of the wizard are explained in the [Initial steps](#) topic.

6. In **Step 4**, choose which row and column of the file will be taken as the beginning of the data grid. This is useful for excluding non-data rows and columns (typically heading rows) from the imported data. The selection can either be done by specifying the row and column in the **Row** and **Column** fields above the grid, or simply by clicking the respective cell in the grid.

When importing from a CSV file, the **Item separator** field is displayed next to the two fields mentioned above. Here, specify which character is used in the source CSV file as a separator between values in individual rows. A comma is used most typically, but you may come across CSV files that use different item separators, e.g., semicolons.

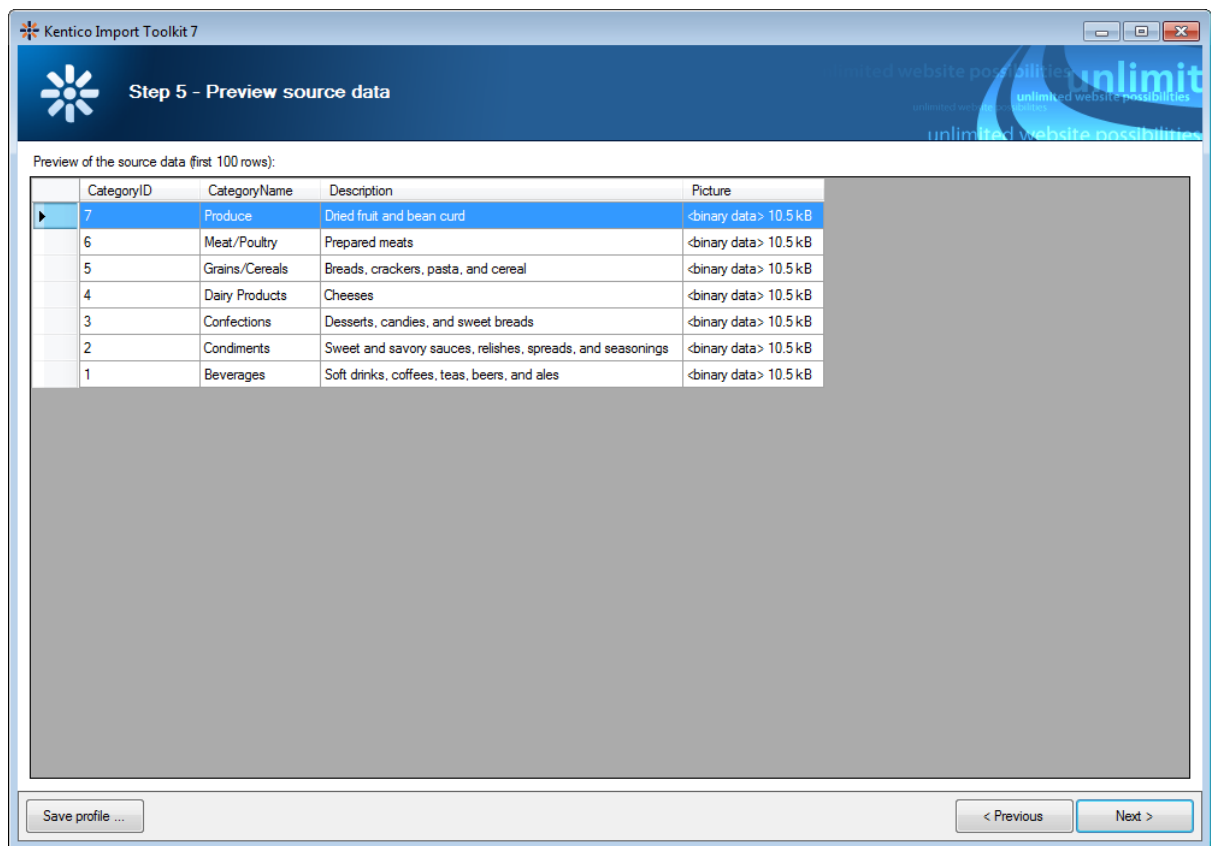

When selected, click **Next** to proceed to the following step.

For the rest of the wizard, which is common for all the imported data sources, see the [Final steps](#) topic.

9.2.6 Final steps

In this topic, you will find information on the final steps of the Kentico Import Toolkit wizard. To learn about the preceding steps, refer to the [Initial steps](#) topic and the topics about data selection for import from an [MS SQL database](#), [XML file](#) or [CSV and XLSX files](#).

7. In **Step 5**, you can see a preview of the data to be imported. This step is only informative and you can use it to check if you specified the source data correctly in the previous steps.

Click **Next** to proceed to the next step.

8. In **Step 6**, perform mapping of source fields to target fields. The utility automatically recognizes fields that appear to be equivalent, so if names of the fields or at least their suffixes match, most of the fields should be mapped automatically. You then only need to check and fine-tune the mappings. If you want to return to the default mappings after adjusting them, click **Reset to default mappings** above the grid.

The mappings grid contains the following columns:

- **Target field** - field of the target object/document into which the data should be imported. If you turn on the **Show advanced columns** check-box above the grid, additional columns that you typically wouldn't use as an import target are offered as well.
- **Required** - indicates if the target field is required.
- **Source field or expression** - source field from which data will be imported into the target field. You can use the following expressions in the text to get the values dynamically:
 - **=macroexpression** - evaluates the specified [macro expression](#) using the source data and uses its result in the value. For example, `={%ItemText%} - {%ItemOrder%}`.
 - **#<source>query** - executes a query against the source database and uses the result in the field. For example, `#<source>SELECT TOP 1 UserID FROM CMS_User WHERE UserName ='{%SourceUserName%}'`.
 - **#<target>query** - executes a query against the target database and uses the result in the field. For example, `#<target>SELECT TOP 1 ...`
 - **#<file>** - you can specify a file using a URL or a disk path. Binary data of the file will be used as the value of the target field.
- **Default value** - value that is used if the source field does not contain any value (or when its value is NULL).

- **FK mapping file** - you can specify an *.fkmap* file from a previous export session which converts an ID field to a new field mapped in the previous session. See the following text for more details.

If you selected to skip or overwrite existing objects in Step 2 of the wizard, you can specify a WHERE condition in the field below the list. Based on this, the existing objects to be skipped or overwritten will be identified.

When importing the data as documents, you can see an extra field below the grid. Use the field to specify the path or NodeID of the document under which you want to create the imported documents. When importing the data as document attachments, there is also an extra field below the grid. In this case, you need to specify the path to the document to which you want to attach the imported attachments.

Importing new culture versions of an existing document

If you wish to use the import toolkit to add language versions to an existing node in the content tree, you also need to specify the appropriate NodeID using the extra field. This can be done through the following expression:

```
#<target>SELECT TOP 1 NodeID FROM View_CMS_Tree_Joined WHERE  
NodeAliasPath = '{%NodeAliasPath%}'
```

As described for the **Source field or expression** fields above, the *#<target>* query is used to select the NodeID of the document that should be updated from the target database.

The *{%NodeAliasPath%}* macro is resolved into the alias path of your document versions in the source data. Because all language versions of the same document share the same alias path, this allows you to find the appropriate NodeID in the target database.

Please note that the **Import new and overwrite existing documents** option must be selected in step 2 of the wizard in order for this to work correctly.

You can also enable the **Save the old ID to new ID mappings to file** check-box. This enables you to save mappings of source ID columns to target ID columns into an *.fkmap* file that can be used during another session in the FK mapping file column above. The following example explains the use of the file:

- You have a list of questions and a list of answers, where each answer is bound to a question with a foreign key.
- You want to import both lists and preserve their bindings.
- First, import the questions and save the ID mapping to a *questions.fkmap* file.
- Then import the answers and use the *questions.fkmap* file in the FK mapping file column of the field that contains the foreign key.

Kentico Import Toolkit 7

Step 6 - Column mappings

Please select how the source columns map to the destination columns: [Reset to default mappings](#) [Show advanced columns](#)

| Target field | Required | Source field or expression | Default value | FK mapping file |
|---------------------|-------------------------------------|----------------------------|---------------|-----------------|
| ItemID | <input checked="" type="checkbox"/> | CategoryID | | |
| ItemOrder | <input type="checkbox"/> | CategoryID | | |
| CategoryName | <input checked="" type="checkbox"/> | CategoryName | | |
| CategoryDescription | <input checked="" type="checkbox"/> | Description | | |

WHERE condition to find existing items based on source data. If empty, they are found automatically by GUID or code name of the object:

Save the old ID to new ID mappings to file:

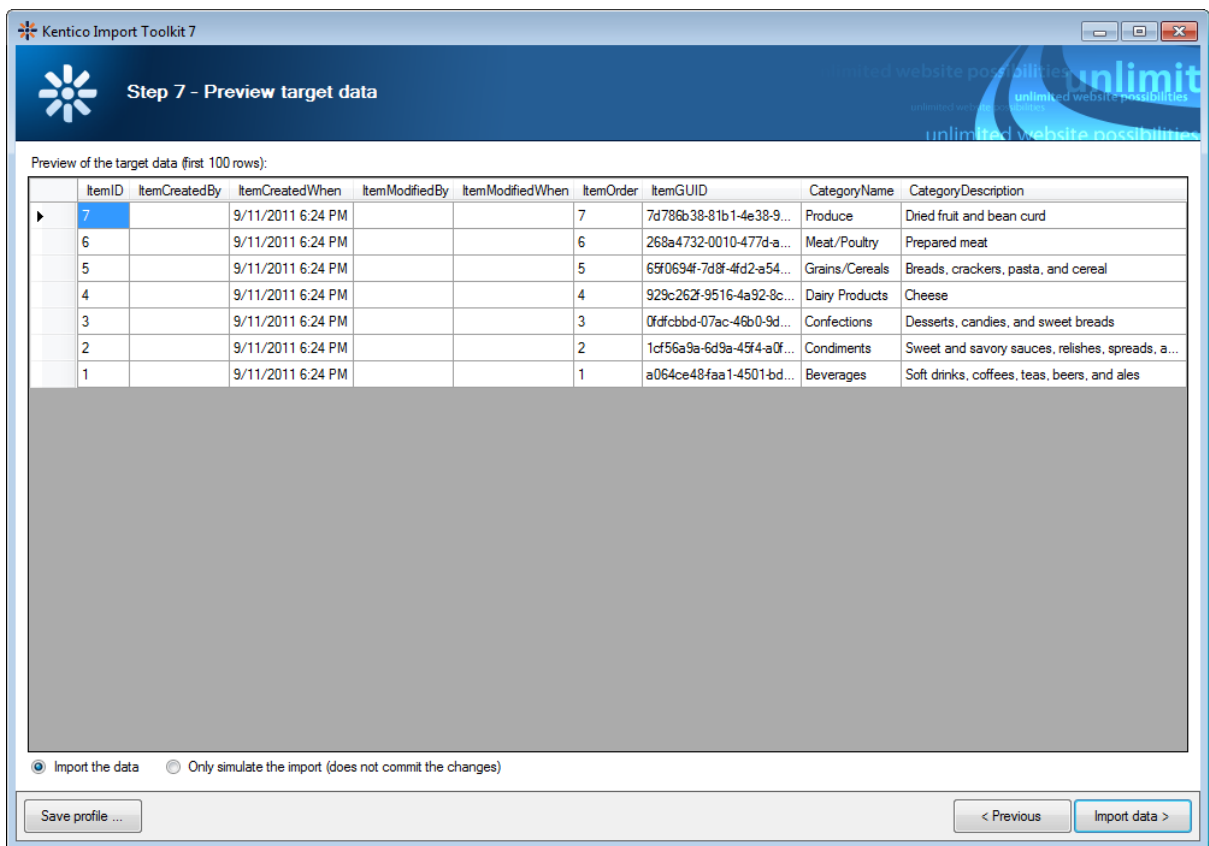

customtable_ImportedCategories.fkmap [Browse ...](#)

[Save profile ...](#) [< Previous](#) [Next >](#)

Once you have the mappings specified, click **Next** to proceed to the following step.

9. In **Step 7**, you can see a preview of the data as it will look when imported to the target. Before proceeding, you can choose how you want the data to be imported:

- **Import the data** - imports the specified data into Kentico CMS.
- **Only simulate the import (does not commit the changes)** - performs the import to validate that the data is correct, but does not commit the changes to the database.

Kentico Import Toolkit 7

Step 7 - Preview target data

Preview of the target data (first 100 rows):

| ItemID | ItemCreatedBy | ItemCreatedWhen | ItemModifiedBy | ItemModifiedWhen | ItemOrder | ItemGUID | CategoryName | CategoryDescription |
|--------|---------------|-------------------|----------------|------------------|-----------|---------------------------|----------------|--|
| 7 | | 9/11/2011 6:24 PM | | | 7 | 7d786b38-81b1-4e38-9... | Produce | Dried fruit and bean curd |
| 6 | | 9/11/2011 6:24 PM | | | 6 | 268a4732-0010-477d-a... | Meat/Poultry | Prepared meat |
| 5 | | 9/11/2011 6:24 PM | | | 5 | 65f0694f-7d8f-4fd2-a54... | Grains/Cereals | Breads, crackers, pasta, and cereal |
| 4 | | 9/11/2011 6:24 PM | | | 4 | 929c262f-9516-4a92-8c... | Dairy Products | Cheese |
| 3 | | 9/11/2011 6:24 PM | | | 3 | 0fdfcbbd-07ac-46b0-9d... | Confections | Desserts, candies, and sweet breads |
| 2 | | 9/11/2011 6:24 PM | | | 2 | 1cf56a9a-6d9a-45f4-a0f... | Condiments | Sweet and savory sauces, relishes, spreads, a... |
| 1 | | 9/11/2011 6:24 PM | | | 1 | a064ce48-faa1-4501-bd... | Beverages | Soft drinks, coffees, teas, beers, and ales |

Import the data Only simulate the import (does not commit the changes)

Save profile ... < Previous Import data >

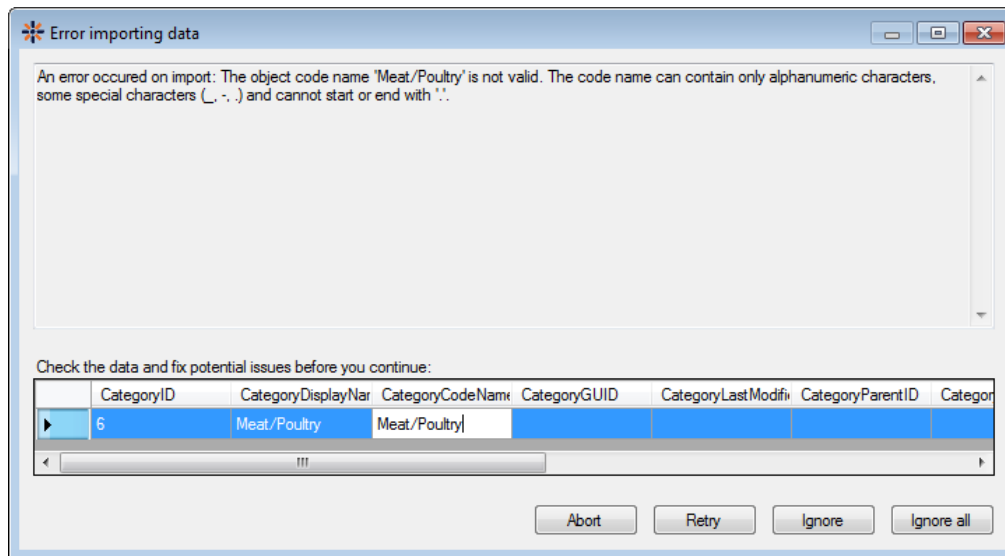

After making your choice, click the **Import data** button to perform the import.

10. A log will be displayed, showing you the progress of the import.

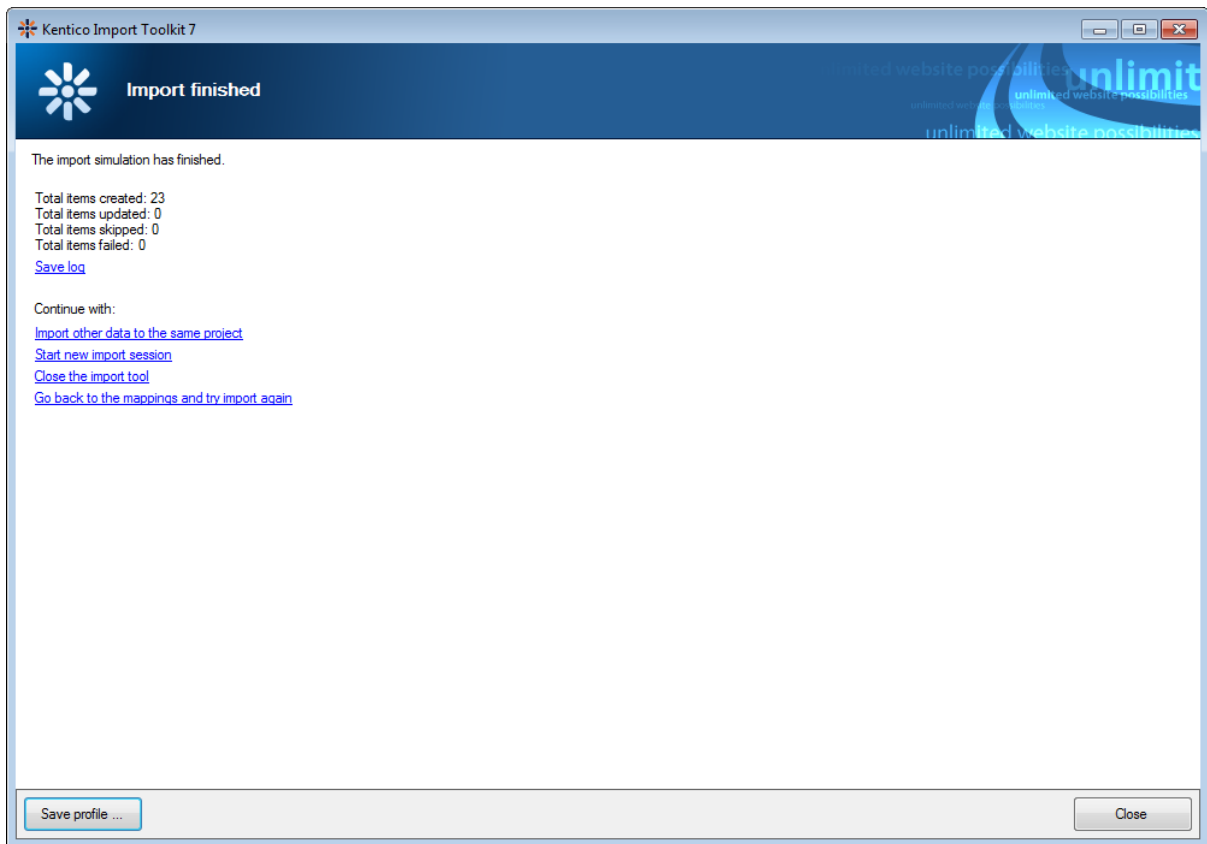

11. If an error occurs during the import, e.g., when there are restricted characters in imported data, the dialog that follows is displayed. The dialog displays an error message explaining the issue and provides you with the following options:

- **Abort** - aborts the whole import process.
- **Retry** - you can correct the data in the displayed row and click this button to import the corrected data — without the need of going through the import process again.
- **Ignore** - the current record will be skipped and not imported.
- **Ignore all** - all records containing errors will be skipped during the rest of the import.

12. The final step informs you of the results of the import. Imported data should already be visible in Kentico CMS at this point. You can perform the following actions:

- **Save log** - saves the import log created while the import was being performed.
- **Import other data to the same project** - redirects you to Step 2 of the wizard where you can select object type to import for the same target project.
- **Start new import session** - redirects you to Step 1 of the wizard where you can start a new import session.
- **Close the import tool** - closes the utility.
- **Go back to the mappings and try import again** - this options becomes available if you selected the *Only simulate import* option in Step 7 or if you chose to *Abort* the import process.

9.2.7 Import Toolkit from command line

Apart from using the wizard described in the [initial steps](#) chapter, you can also run the Import Toolkit utility from the command line.

To perform the actual import, you need to have an import profile file. You can run the utility by executing the **ImportToolkit.exe** file located in **<Kentico CMS installation folder>\Bin** (typically *C:\Program Files (x86)\KenticoCMS\<version number>\Bin*) using a special syntax.

Important!

The profile file used in the command line needs to be created in the last step of the wizard—once the import has finished. This way the file will contain all the required data for a successful import.

You can launch the utility with an optional **-i** parameter, which ignores errors during the import:

```
ImportToolkit <path to your i.profile file> -i
```

You can specify either a relative or an absolute path to the *.iprofile* file. Make sure you use proper quotation when entering an absolute path containing special characters ,e.g., blank spaces:

```
ImportToolkit my_profile.xml
ImportToolkit "C:\Temp\AD Import\my_profile.xml"
```

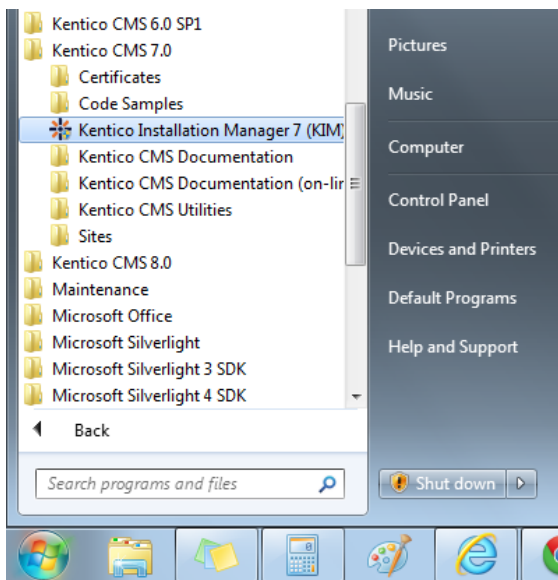

After executing the command, data will be imported to your Kentico CMS instance based on settings contained in the specified import profile.

9.3 Kentico Installation Manager

9.3.1 Overview

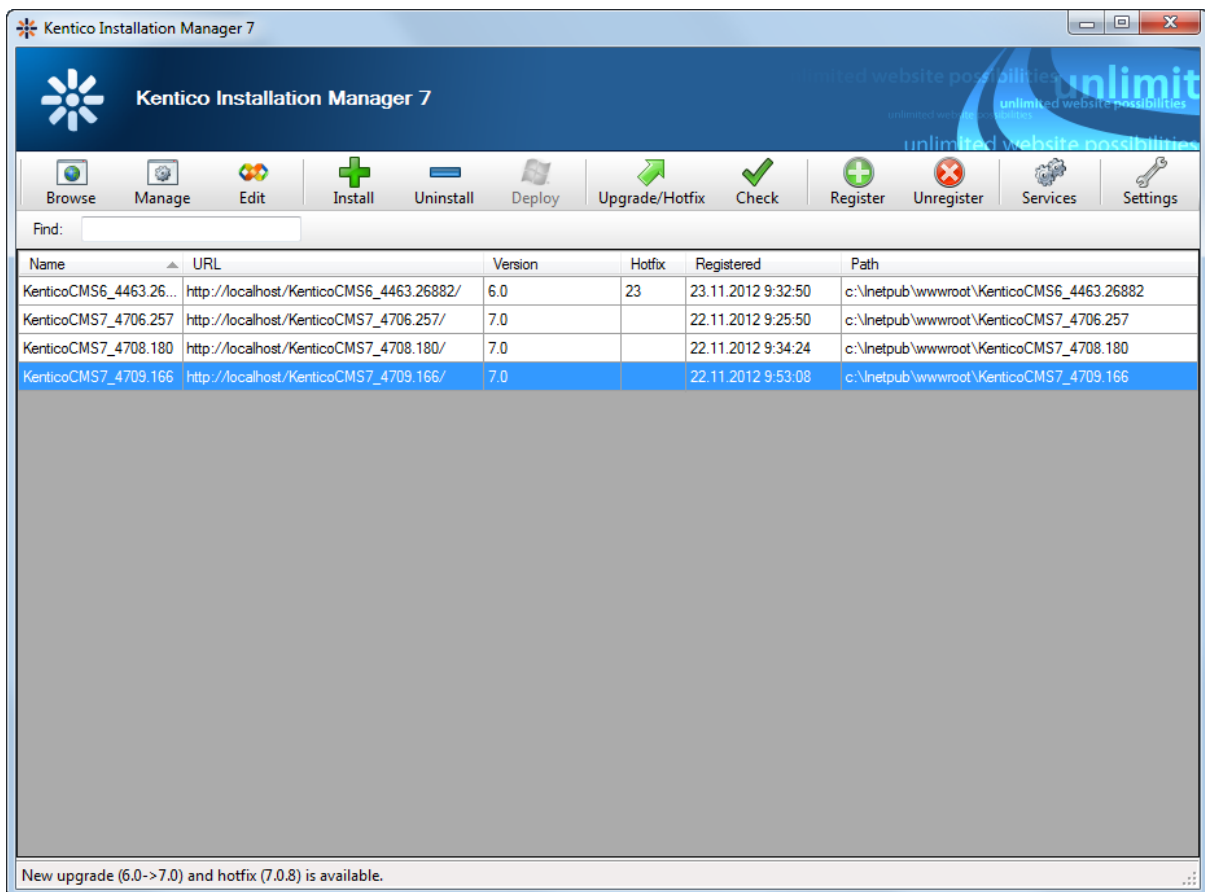

Kentico Installation Manager (also referred to as **KIM**) is an external utility which enables installation and management of Kentico CMS instances. You can manage all instances installed on a single machine using this tool, which is especially useful on machines with a large number of instances.

You can launch this utility by selecting **Kentico Installation Manager** from the Kentico CMS folder in Windows Start menu.

Running KIM 7.0 in Windows

KIM 7.0 interface

Kentico Installation Manager 7.0

- Browse** - opens the URL in the URL column of the selected instance in a new browser window.
- Manage** - opens the Site Manager of the selected instance in a new browser window.
- Edit** - opens the selected instance's web project in Visual Studio.
- Install** - opens [Kentico Web Installer](#), which you can use to install a new Kentico CMS instance.
- Uninstall** - uninstalls the selected instance, optionally including a removal from the file system, IIS, database and from the instances list in KIM.
- Deploy** - deploys the selected instance to Windows Azure. See [Deployment to Azure](#).
- Upgrade/Hotfix** - opens a dialog box where you can upgrade or hotfix the currently selected instances. See [Upgrading and hotfixing](#) for more details.
- Check** - checks if there are any new upgrades or hotfixes available for any of the managed instances. See [Upgrading and hotfixing](#) for more details.
- Register** - opens a dialog where you can register a new instance for management by KIM (add it to the list). See [Instance registration](#) for more details.
- Unregister** - unregisters the selected instance from KIM (removes it from the list). See [Instance registration](#) for more details.
- Services** - opens [Kentico Service Manager](#), where you can install and manage Kentico CMS Windows services.
- Settings** - opens a dialog where you can adjust settings related to upgrading and hotfixing. See [Upgrading and hotfixing](#) for more details.

In cases where large numbers of instances are registered in the utility, you can use the **Find** text box below the toolbar to search for particular instances by the value stored in their **Name** column.

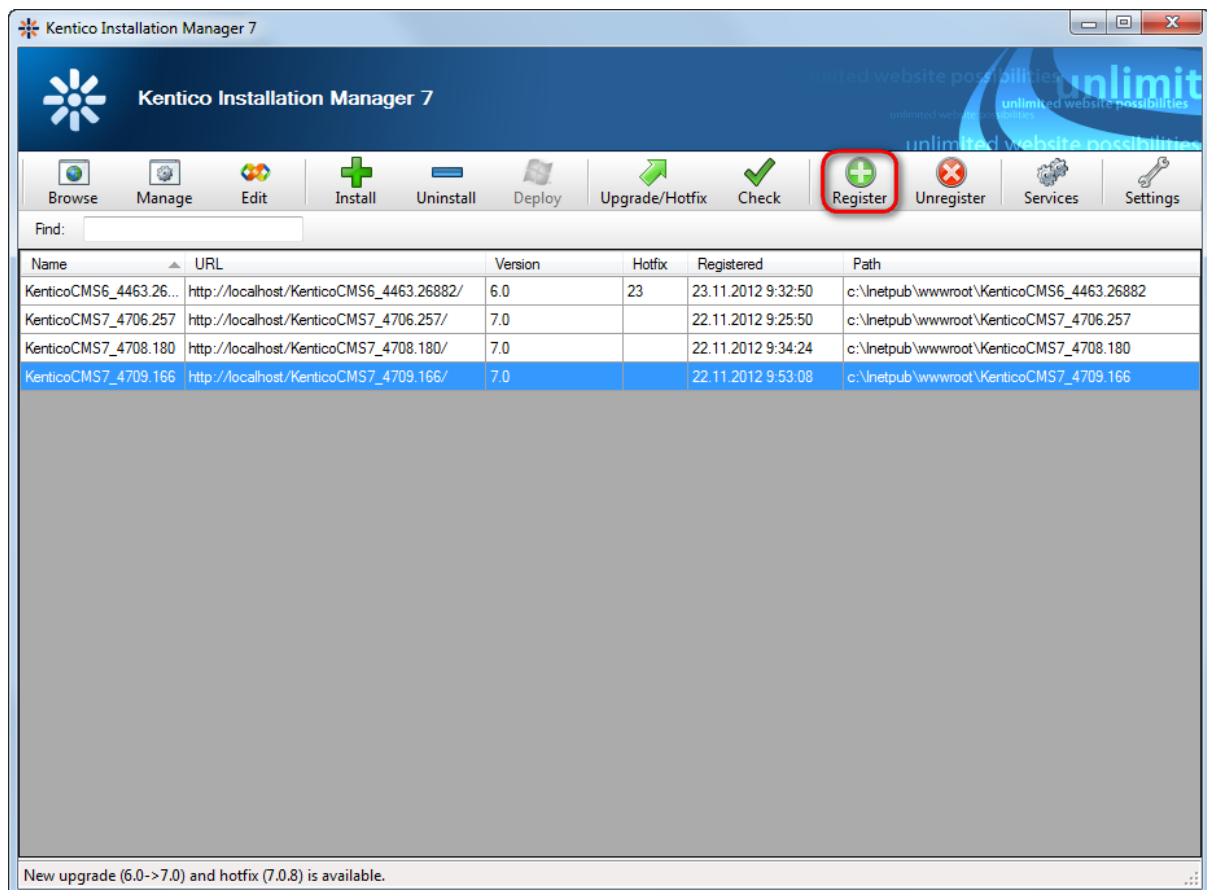

9.3.2 Instance registration

Kentico Installation Manager is able to register installed Kentico CMS instances automatically. In some cases though, the registration process may not complete successfully and you will have to register the instances manually. Such cases can include:

- You have Kentico CMS instances of versions prior to 6.0 already installed on your machine.
- You installed a Windows Azure project.

To register an instance in KIM:

1. Click  **Register** on the main toolbar.

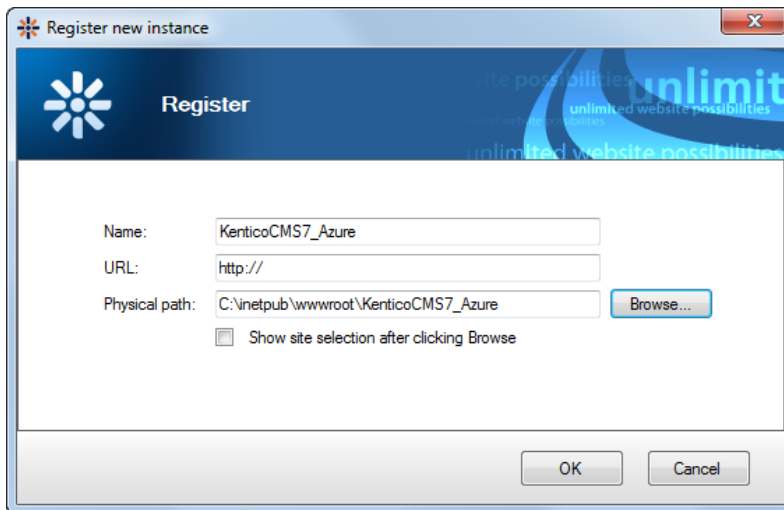

Registering a new KenticoCMS instance

A new dialog box appears.

2. Enter the following details:

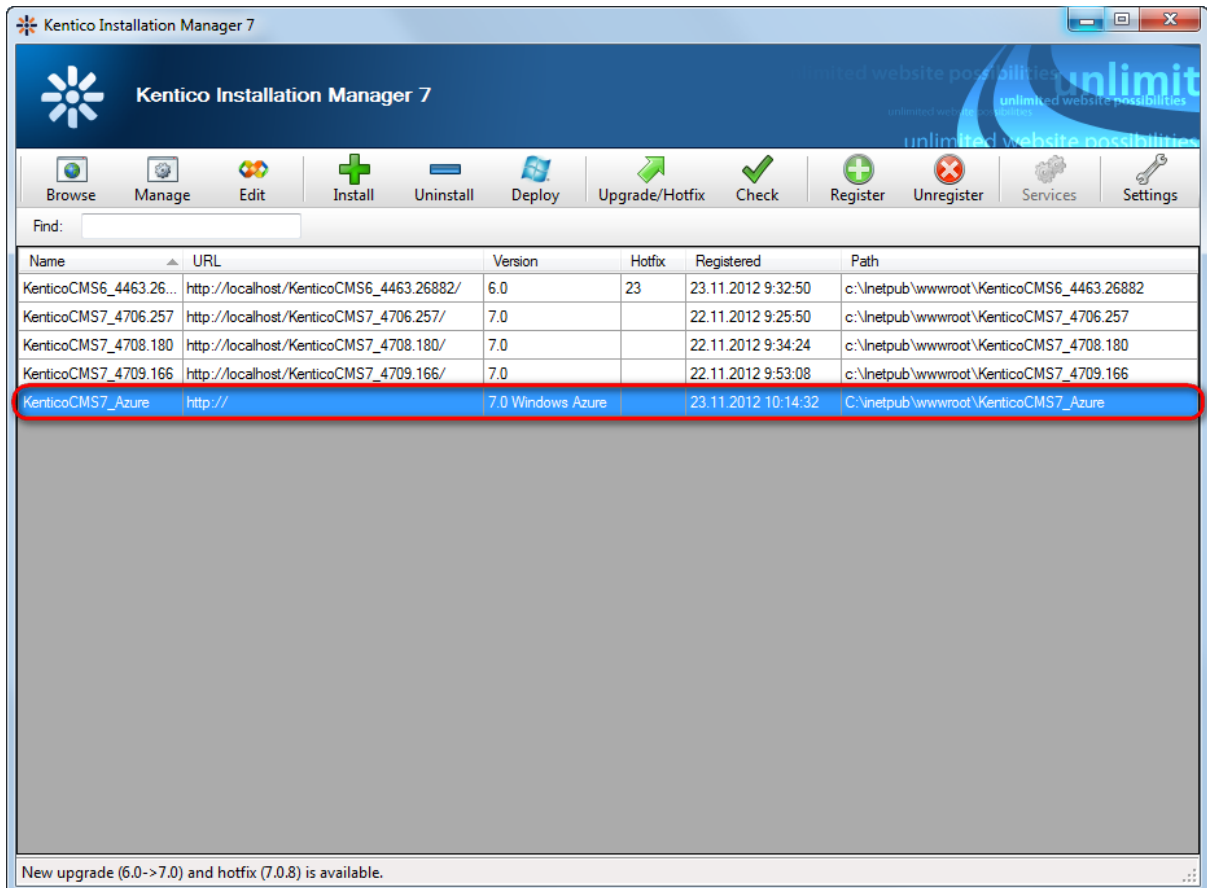

- **Name:** identifying name of the instance displayed in the **Name** column in the list of instances.
- **URL:** URL under which the instance is accessible.
- **Physical path:** path to the instance's web project root folder in the file system.
- **Show site selection after clicking Browse:** if enabled, the tool displays a dialog box with available web sites of the particular instance after clicking the  **Browse** button (useful for multi-site instances).

The details of the instance to be registered

3. Click **OK**.

The KIM registers your instance and displays it in the list of managed instances.

The tool adds the newly registered instance to the list

Where is the information stored

Information about registered instances is stored in `c:\ProgramData\KIM\kim.xml`. Within the root `<sites>` element, it contains a number of `<item>` elements which represent particular registered instances. The `<item>` elements have the following sub-elements representing properties of the registered instances:

- **<guid>** - unique identifier of the instance. Its value is taken from the **CMSApplicationGuid** key in the *appSettings* section of the instance's *web.config* file.
- **<url>** - URL under which the instance is accessible.
- **<name>** - identifying name of the instance displayed in the **Name** column in the list of instances.
- **<version>** - version of Kentico CMS.
- **<path>** - path to the instance's web project root folder in the file system.
- **<created>** - date and time when the instance was registered in Kentico Installation Manager.
- **<hotfix>** - number of the latest hotfix applied to the instance.
- **<netversion>** - version of .NET Framework used by the instance. The number of .NET version does not correspond to the number stored here, they are encoded in the following way:

| .NET version | Encoding number |
|--------------|-----------------|
| 2 | 2 |
| 3.5 | 4 |
| 4 | 8 |
| 4.5 | 16 |

- **<showlist>** - indicates if a dialog box with available web sites of the particular instance is displayed after clicking the  **Browse** button.

Here is a sample extract from the xml file:

```
<?xml version="1.0"?>
<sites>
  <item>
    <guid>7d6b7a6e-5f3a-4403-97d0-970dcabba91d</guid>
    <url>http://localhost/KenticoCMS7</url>
    <name>Kentico CMS 7</name>
    <version>7.0</version>
    <path>c:\inetpub\wwwroot\KenticoCMS7</path>
    <created>2012-10-30T11:52:59</created>
    <hotfix>0</hotfix>
    <netversion>8</netversion>
    <showlist>1</showlist>
  </item>
  ...
</sites>
```

9.3.3 Upgrading and hotfixing

You can upgrade and hotfix Kentico CMS instances using Kentico Installation Manager. There are two actions related to these tasks on the main panel:

-  **Upgrade/Hotfix** - opens a dialog box, where you can upgrade or hotfix the currently selected instance.
-  **Check** - checks if there are any new upgrades or hotfixes available for any of the managed instances.

Upgrading and hotfixing

1. Select an instance (or multiple instances) you want to upgrade or hotfix.
2. Click  **Upgrade/Hotfix**.

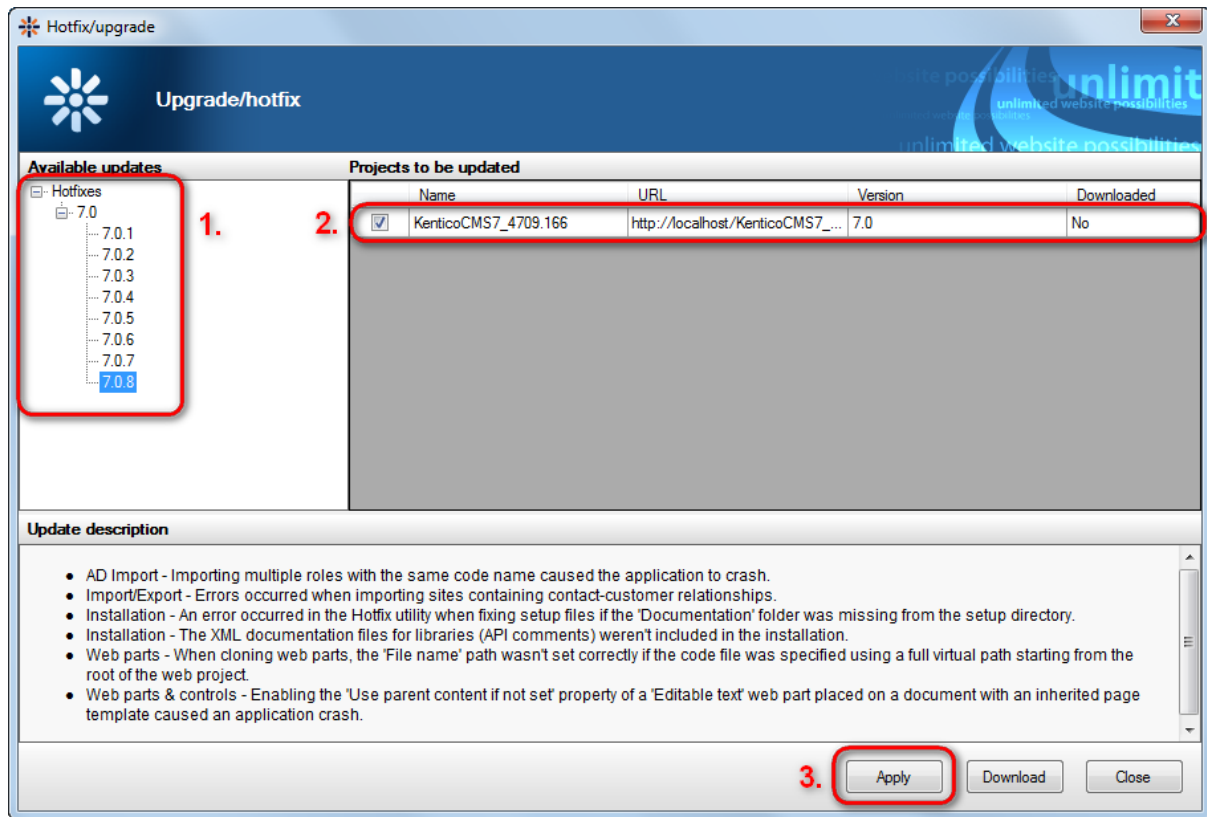

Upgrading/hotfixing an instance

KIM displays a dialog box with upgrades and hotfixes available for the selected instance.

3. Select an upgrade/hotfix from the tree on the left.
4. Select the instances you want to apply this upgrade/hotfix to.
5. Click on one of the following buttons:

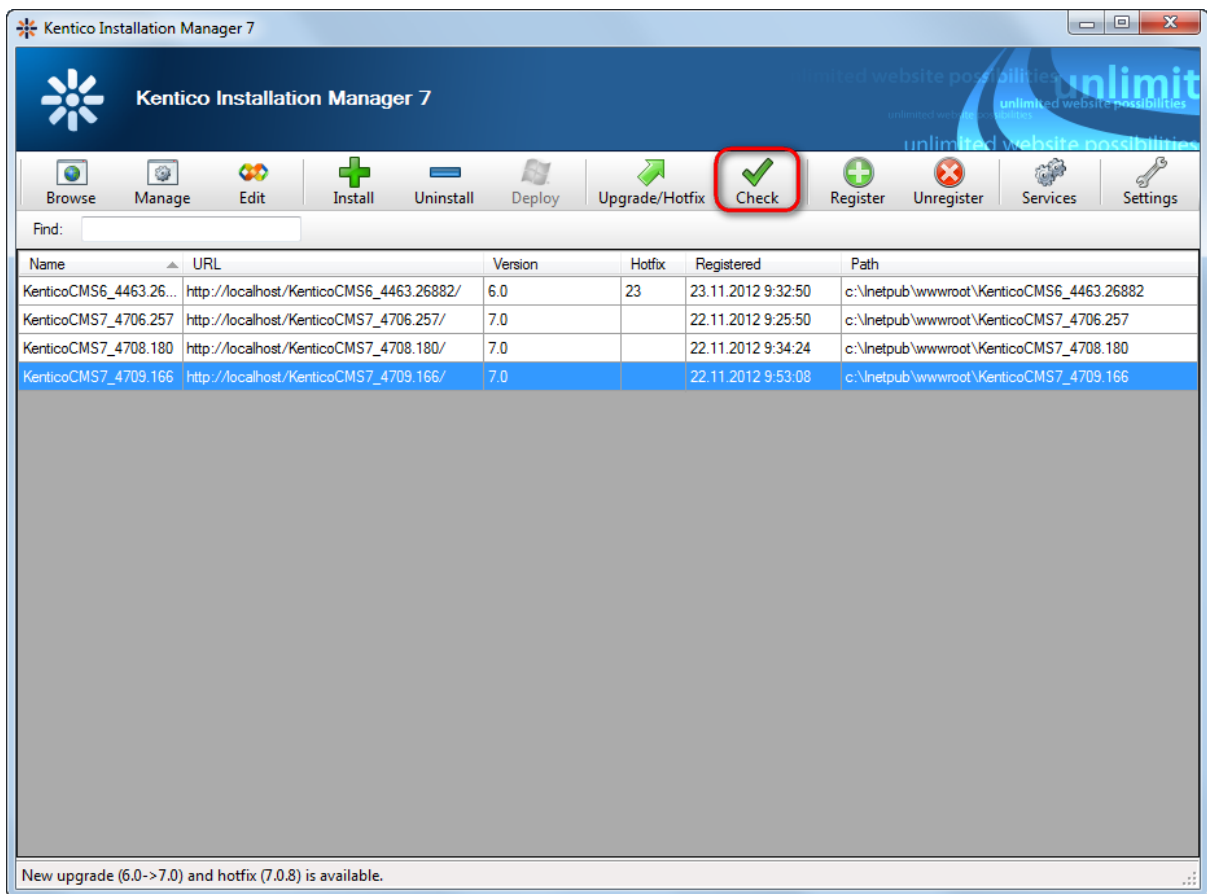

- **Apply** - the tool downloads the upgrade or hotfix and launches the [Kentico Upgrade or Hotfix Utility](#).
- **Download** - the tool only downloads the upgrade or hotfix and stores it in `C:\ProgramData\KIM`. You can apply the upgrade/hotfix later.

Applying a hotfix on an instance

Checking for available upgrades and hotfixes

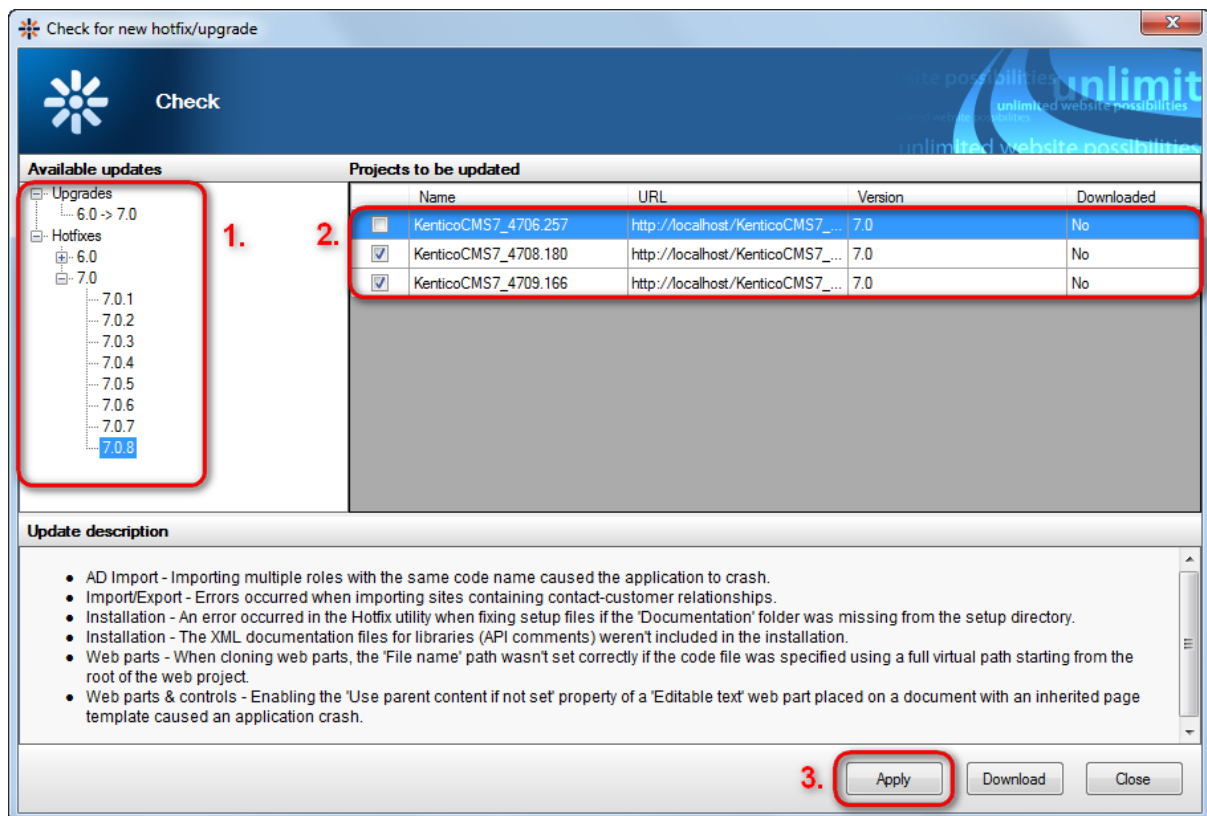

1. Click  **Check**.

Checking for updates/hotfixes

KIM displays a dialog box with upgrades and hotfixes available for all instances included in the list.

2. Select an upgrade/hotfix from the tree on the left.
3. Select all the instances you want to apply this upgrade/hotfix to.
4. Click on one of the following buttons:
 - **Apply** - the tool downloads the upgrade or hotfix and launches the [Kentico Upgrade or Hotfix Utility](#).
 - **Download** - the tool only downloads the upgrade or hotfix and stores it in *C:\ProgramData\KIM*. You can apply the upgrade/hotfix later.

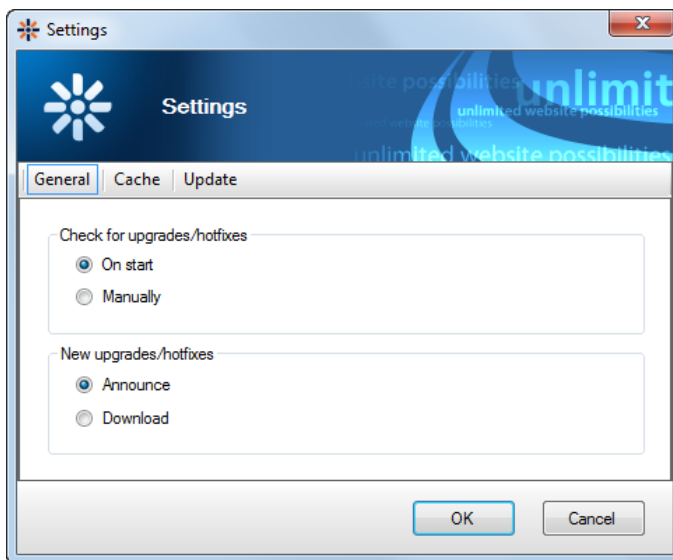

Applying a hotfix on multiple instances

Settings

You can adjust the settings related to upgrading and hotfixing by clicking the **Settings** button on the main toolbar.

On the **General** tab, you can adjust the following settings:

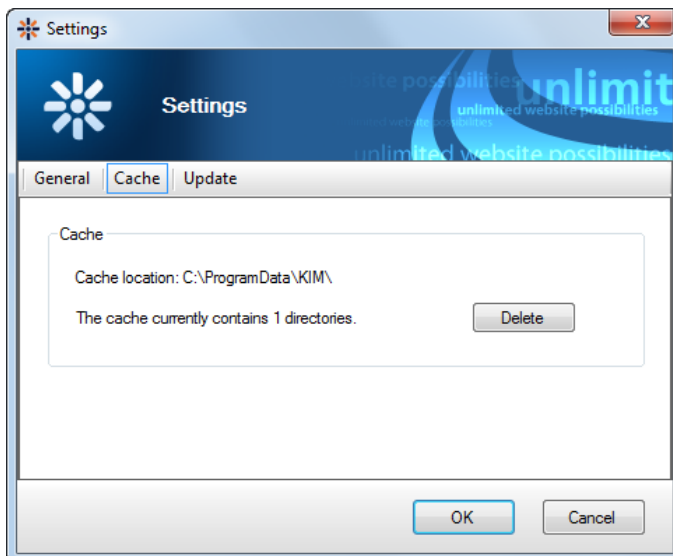

- **Check for upgrades/hotfixes** - determines when KIM checks if new hotfixes or upgrades are available for registered instances.
 - **On start** - KIM checks for updates/hotfixes automatically upon launching.
 - **Manually** - KIM checks only after selecting the **Upgrade/Hotfix** or **Check** action from the toolbar.
- **New upgrades/hotfixes** - determines what to do when new upgrades or hotfixes are found. Only applicable if **On start** is selected above.
 - **Announce** - KIM displays a notification message.
 - **Download** - KIM downloads all new upgrades and hotfixes automatically.

Configuring how should KIM check for updates

On the **Cache** tab, you can see the number of temporary upgrade and hotfix folders. These folders contain upgrade/hotfix data unpacked from downloaded upgrade/hotfix packages and are stored in *C:\ProgramData\KIM*.

You can delete these temporary folders by clicking the **Delete** button.

Deleting the cache files

On the **Update** tab, you can check for available updates of Kentico CMS **program files**.

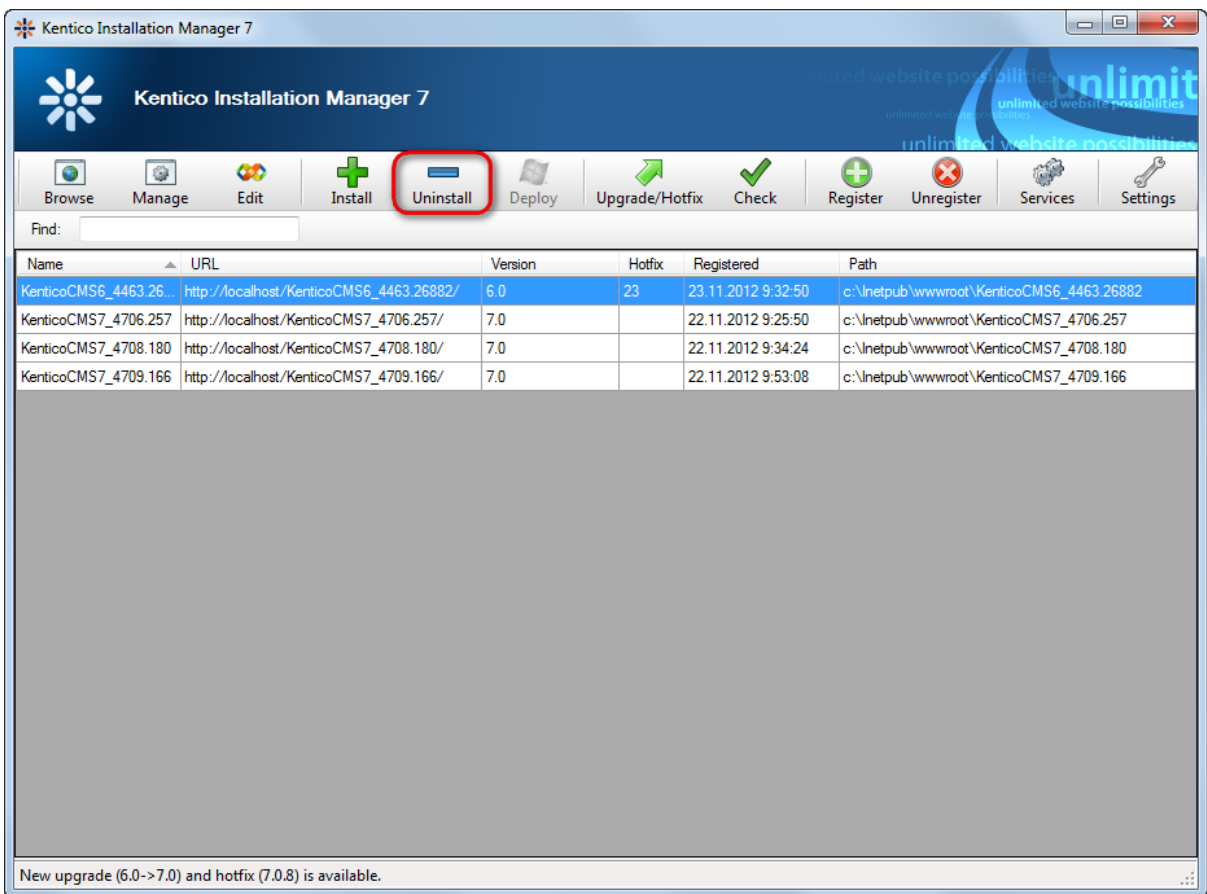

Updating the Kentico CMS program files

9.3.4 Uninstallation

You can also use Kentico Installation Manager to uninstall Kentico CMS instances, including their project folders in the file system, websites in IIS and databases on a database server.

1. Select the instance (or multiple instances) that you want to uninstall and click **Uninstall** on the main toolbar.

Uninstalling an instance

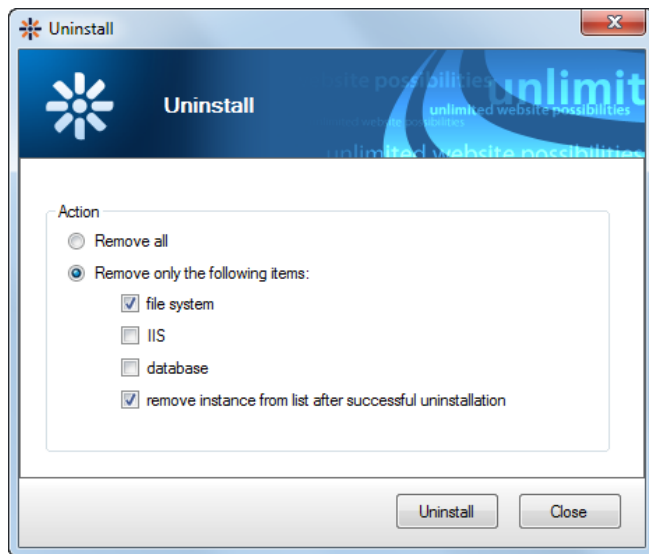

KIM displays a dialog box showing the name and path of the website to be uninstalled.

Confirming an instance to be uninstalled

2. Click **Next**.

3. Choose which parts of the installation you want to uninstall:
- **Remove all** - removes the instance completely, including its file system folder, IIS website, database and registration in KIM.
 - **Remove only the following items** - removes only the parts of the installation selected by the check-boxes below.
 - **file system** - deletes the instance's project folder and all its content.
 - **IIS** - removes the instance's website from IIS. If the website is installed in a custom application pool not shared with another website, the pool is deleted as well.
 - **database** - removes the instance's database from the database server.
 - **remove instance from list after successful uninstallation** - unregisters the instance from KIM so that it is no longer visible in the managed instances list.

Choosing the items to uninstall

4. Click **Uninstall**.

KIM displays a log, showing the progress of the uninstallation.

Successful completion of the uninstallation process

9.3.5 Deployment to Azure

Using the  **Deploy** button, you can easily deploy your Windows Azure instance of Kentico CMS on a Windows Azure server.

Before you can use this feature, you have to **create a certificate**, which will provide you with the access to the Windows Azure Service Management API functionality.

The page <http://msdn.microsoft.com/en-us/library/windowsazure/gg432987.aspx> will help you create a X.509 v3 certificate on your machine and create a personal information exchange certificate, which you have to upload to the Windows Azure via Windows Azure portal.

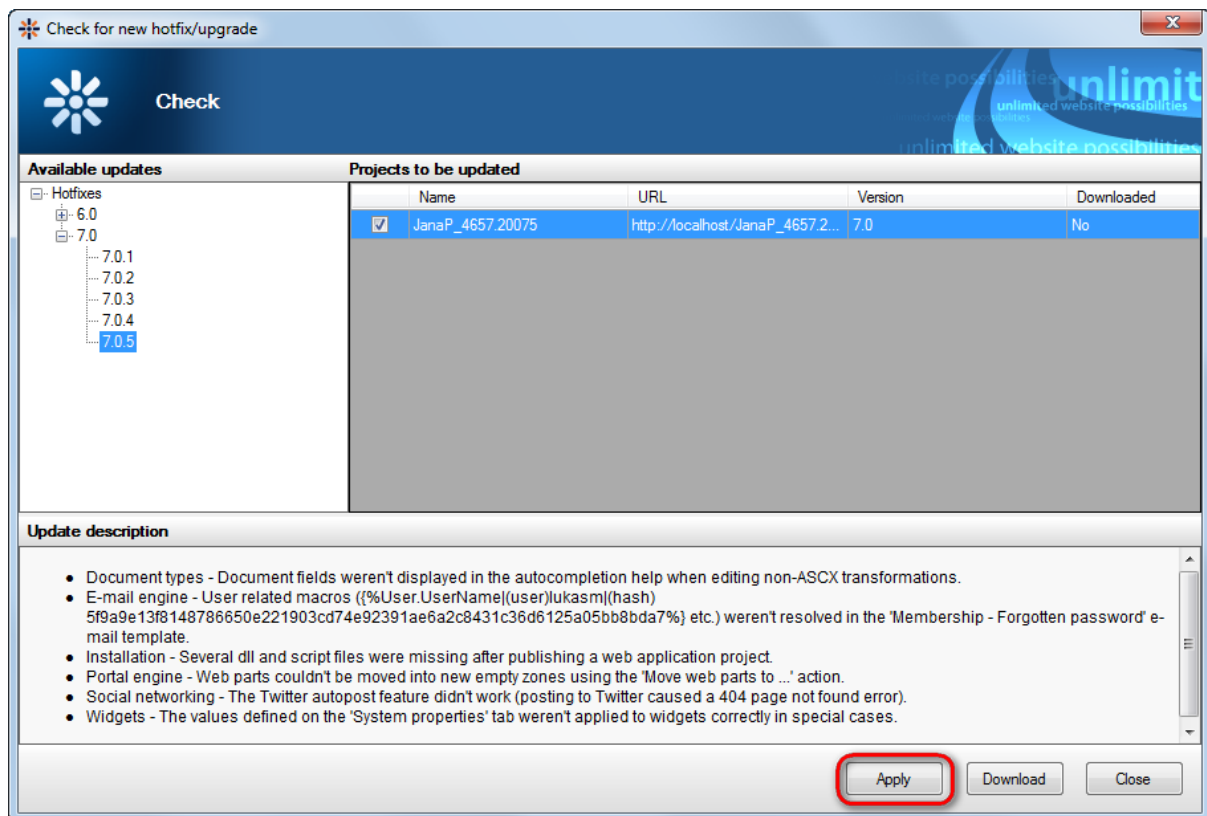

For general instructions on how to configure your Azure project, refer to the [Windows Azure Deployment Guide](#).

9.4 Kentico Hotfix and Upgrade Utility

9.4.1 Overview

Kentico Hotfix Utility and Kentico Upgrade Utility are two identical external utilities that can be used to hotfix or upgrade Kentico CMS instances. They are included in Kentico CMS hotfix and upgrade packages as the *Hotfix.exe* and *Upgrade.exe* executables. The utilities can be launched in two ways:

- By clicking the **Apply** button in the [Upgrade/Hotfix and Check dialogs](#) of [Kentico Installation Manager](#).

Applying a hotfix

- By executing the file unpacked from the hotfix package.

Running a hotfixing utility

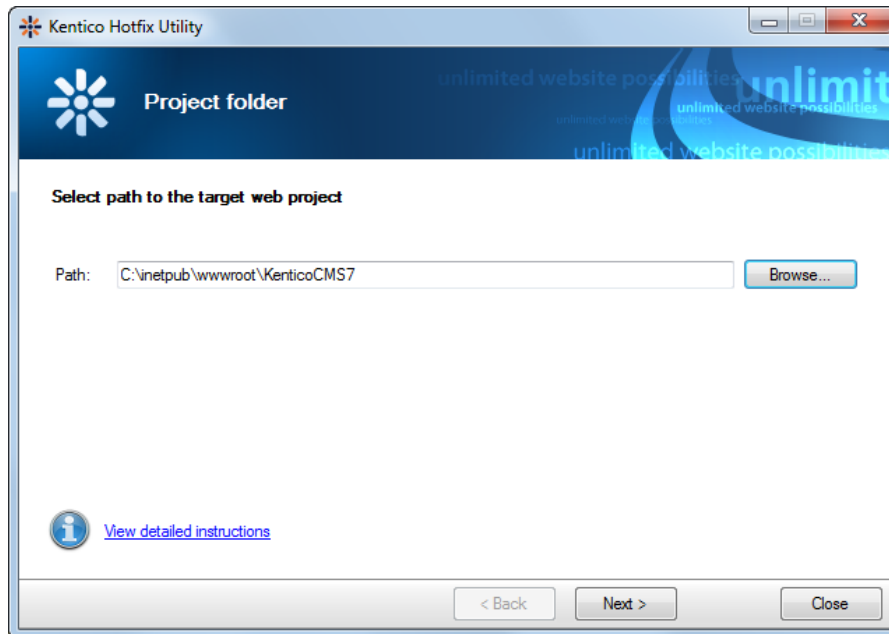

Please refer to the [Using the wizard](#) topic for a step-by-step guide through individual steps of the utility's

wizard.

9.4.2 Using the wizard

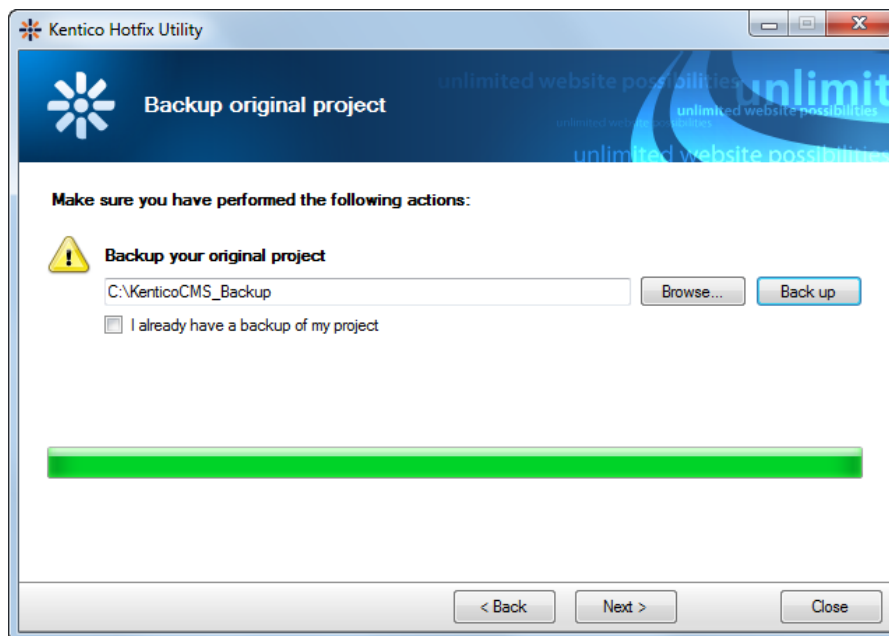

The hotfix or upgrade process consists of the following steps:

1. Specify the root folder of the Kentico CMS instance you want to upgrade or hotfix.
 - o This is only necessary if you ran the utility manually (not from [Kentico Installation Manager](#)).

Setting the folder of a project to upgrade/hotfix

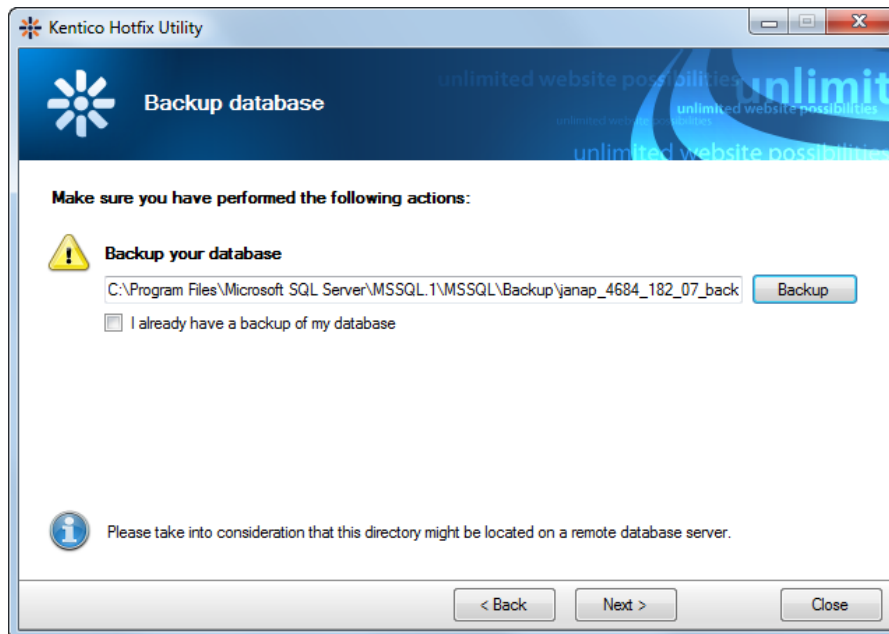

2. Click **Next**.
3. Specify a project backup folder and click **Backup** OR check the **I already have a backup of my project** check-box.

Creating a backup of a project

4. Click **Next**.

5. Specify a database backup folder and click **Backup** OR check the **I already have a backup of my database** check-box.

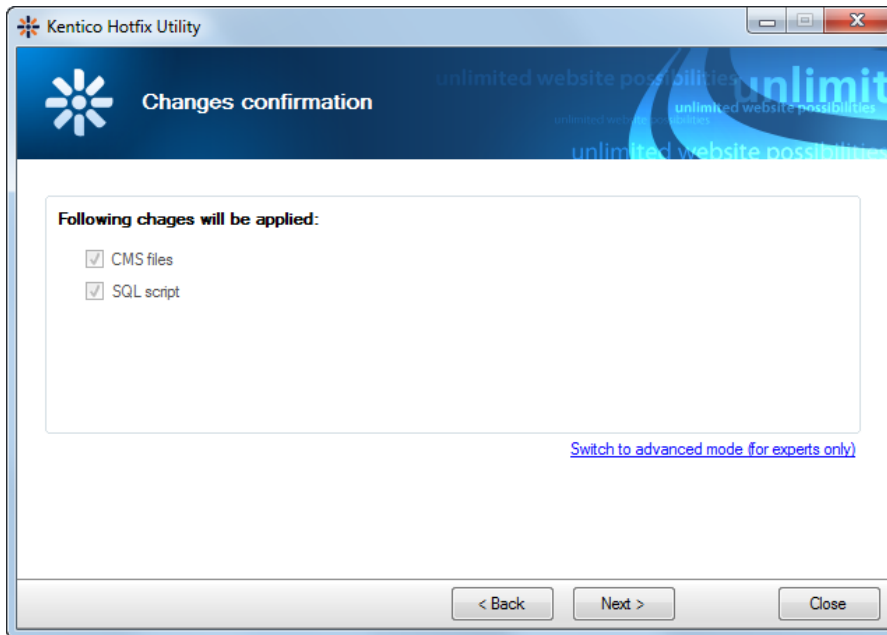

Creating a database backup

6. Click **Next**.

7. Keep the default settings (i.e., all options enabled) OR click the **Switch to advanced mode (for experts only)** link and specify, if the upgrade or hotfix should replace project files, setup files (i.e.,

external utilities) and execute SQL scripts..

Configuring the upgrade/hotfix settings

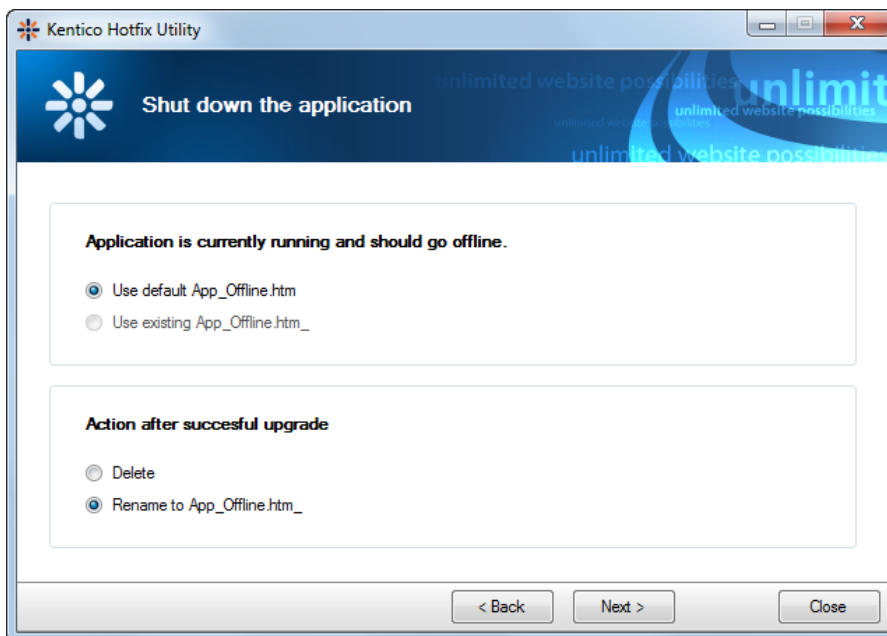

8. Click **Next**.

9. Select one of the first set of options:

- **Use default App_Offline.htm** - the utility creates a new *App_Offline.htm* file in the root of the web project to put the instance into an offline mode (see <http://msdn.microsoft.com/en-us/library/ff925031.aspx> for more details on the use of the file).
- **Use existing App_Offline.htm_** - uses an existing *App_Offline.htm_* file and renames it to *App_Offline.htm*. The file must be present in the project's root folder for this option to be available. See the second option below for more details.

10. Select one of the second set of options, which lets you choose what to do with the *App_Offline.htm* file:

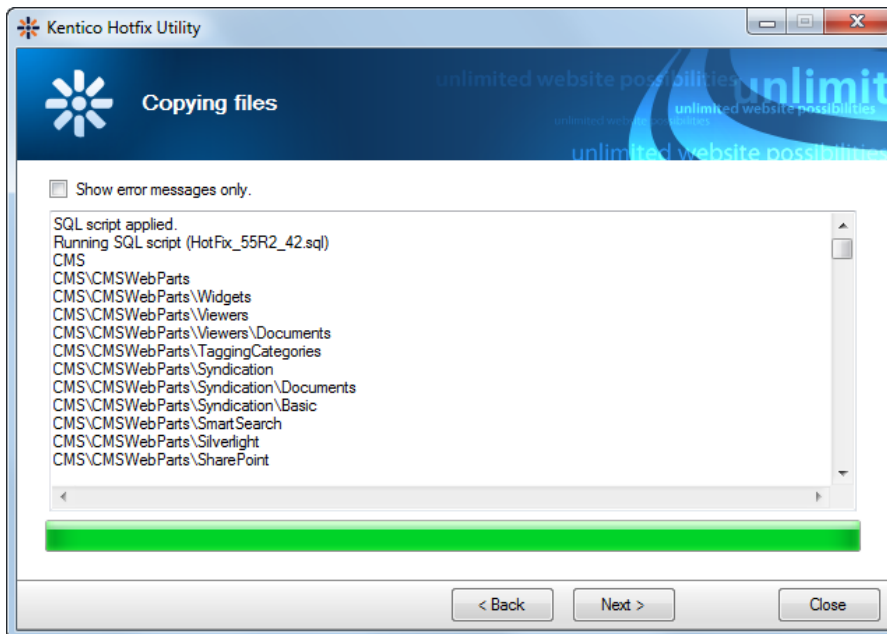

- **Delete** - the file will be deleted.
- **Rename to App_Offline.htm_** - the file will be renamed to *App_Offline.htm_* and usable on next upgrade or hotfix.

Shutting down the application

11. Click **Next**.

A log showing progress of the hotfix or upgrade is displayed. You can enable the **Show error messages only** check-box to display only error messages in the log.

Upgrading/hotfixing process

12. Click **Next**, once the process finishes.

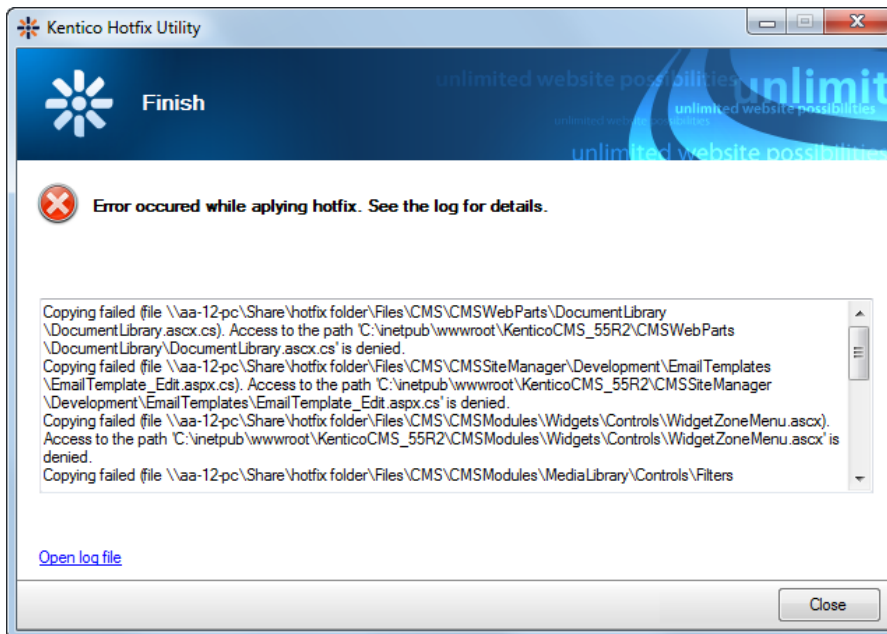

The utility lets you know if the hotfix or upgrade finished successfully. By clicking the **Open log file** link, you can open the upgrade process log that was displayed in the previous step.

Physically, the log is saved in `~\App_Data\log.txt`, so you can inspect it even after closing the utility.

Successful hotfix application

If an error occurred while applying the hotfix or upgrade, the utility will notify you with a message and an error log.

Failed hotfix application

13. Click **Close** to finish and close the utility.

9.5 Kentico Service Manager

9.5.1 Overview

Kentico CMS Service Manager is an external Windows utility which allows management of external Windows services used by Kentico CMS. Using the utility, you can install, uninstall, start, stop and restart Windows services for individual instances of Kentico CMS. While installation and uninstallation can be performed from Windows command line and the services can be started, stopped and restarted from Windows Services manager (*services.msc*), this utility integrates these tasks into a single tool where Kentico CMS services can be managed separately from other services running in Windows.

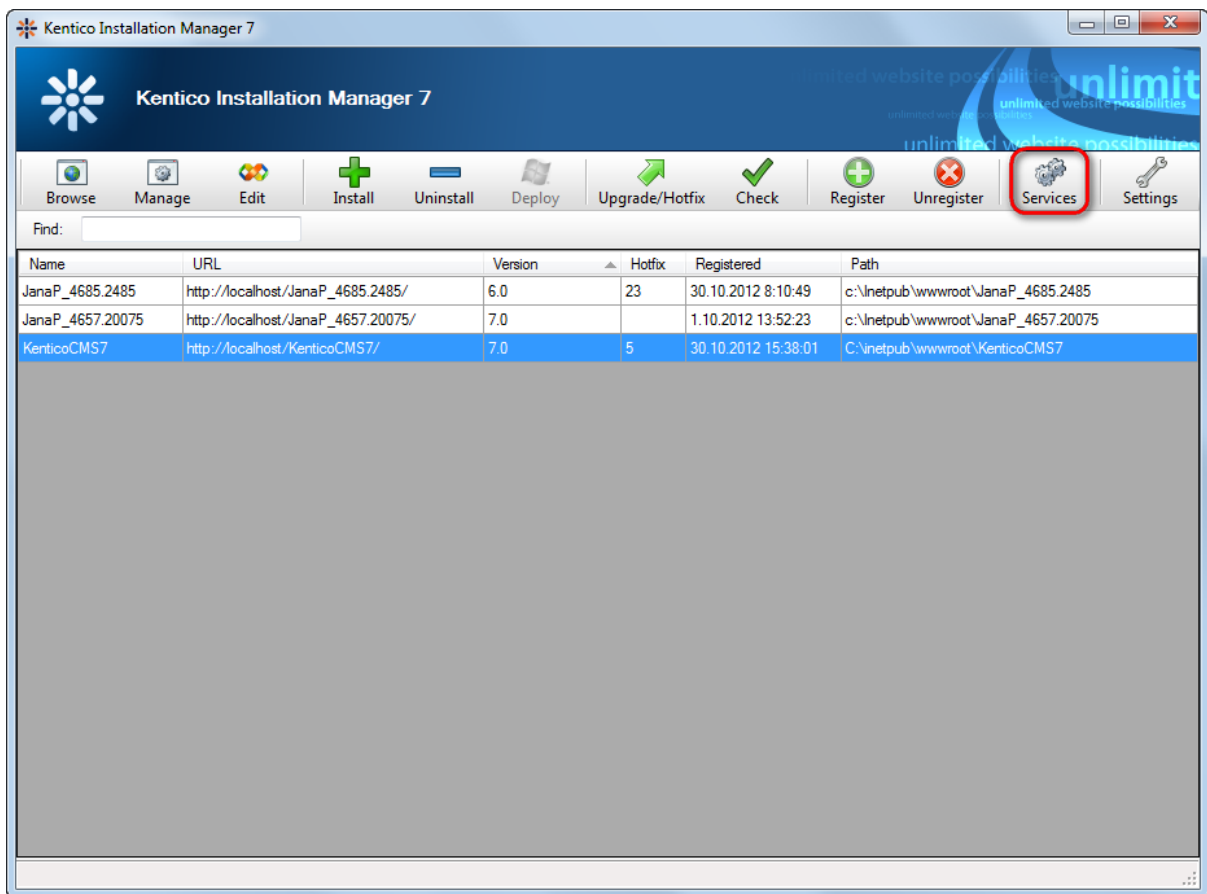

In the [Using the utility](#) topic, you can learn how services can be managed using the utility. Windows services for each particular Kentico CMS instance are defined in a dedicated XML file. Only services that are defined in the file can be managed by the Service Manager. To learn more about this file and its required format, please refer to the [Services definition XML](#) topic.

Launching the utility

Kentico Service Manager can be launched two ways.

A) First way:

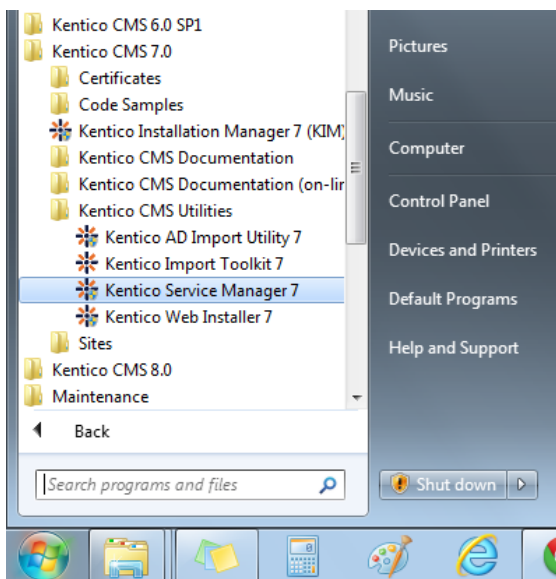

1. Run [Kentico Installation Manager](#).
2. Select an instance of Kentico CMS.
3. Click the  **Services** button on the toolbar.

Running a Kentico Service Manager from KIM

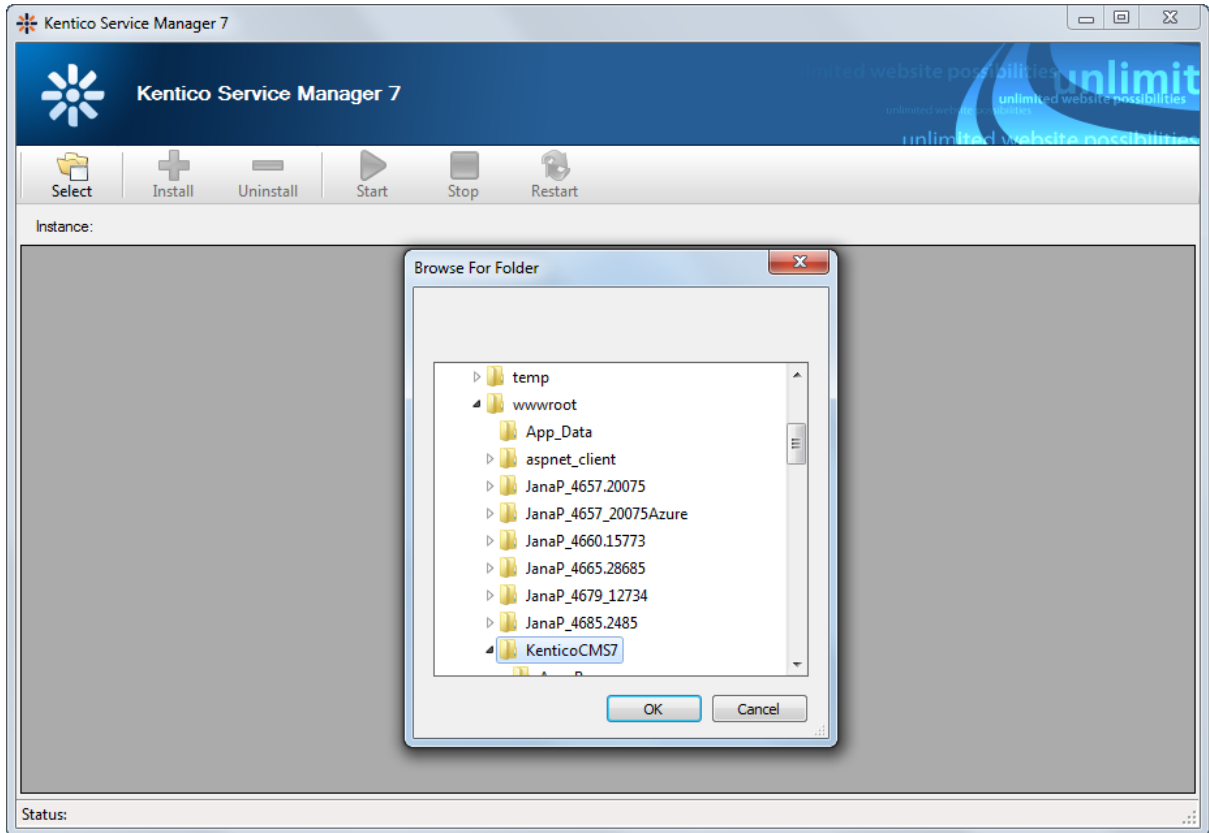

B) Second way:

1. Launch the **Kentico Service Manager** from Windows Start menu.

Running KSM 7.0 in Windows

2. Select the root of the Kentico CMS instance, whose services you want to manage, in the **Browse For Folder** dialog box.

Selecting a root folder of an instance

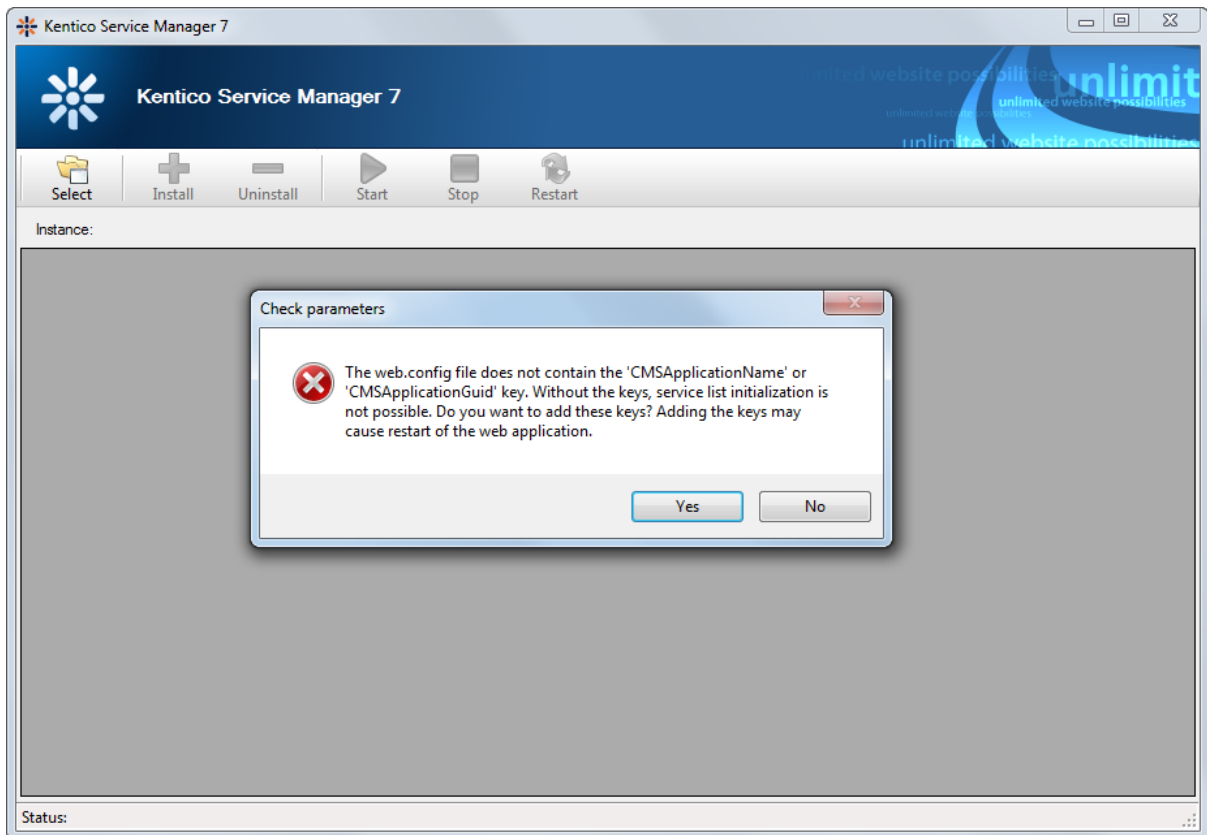

3. Click **OK**.

The Kentico Service Manager launches. For the description of its functions, continue to the [Using the utility](#) topic.

Problems with required web.config keys

Kentico CMS Windows services require the **CMSApplicationName** or **CMSApplicationGuid** keys to be added in the *appSettings* section of the *web.config* file. Values of these keys are used in names of the Windows services and for identification of the Kentico CMS instance by the services. These keys are included in the *web.config* by default. However, when neither of the two keys is in the *web.config* of the selected instance (e.g., after being removed manually), you will encounter the dialog depicted in the screenshot below.

By clicking **Yes**, you tell the Service Manager to add these keys to the *web.config* so that services can work with the selected Kentico CMS instance. By clicking **No**, the keys will not be added, resulting in no services to be manageable for the selected instance. In the second case, another instance can be selected after clicking the **Select** (📁) button in the top toolbar.

Missing parameters

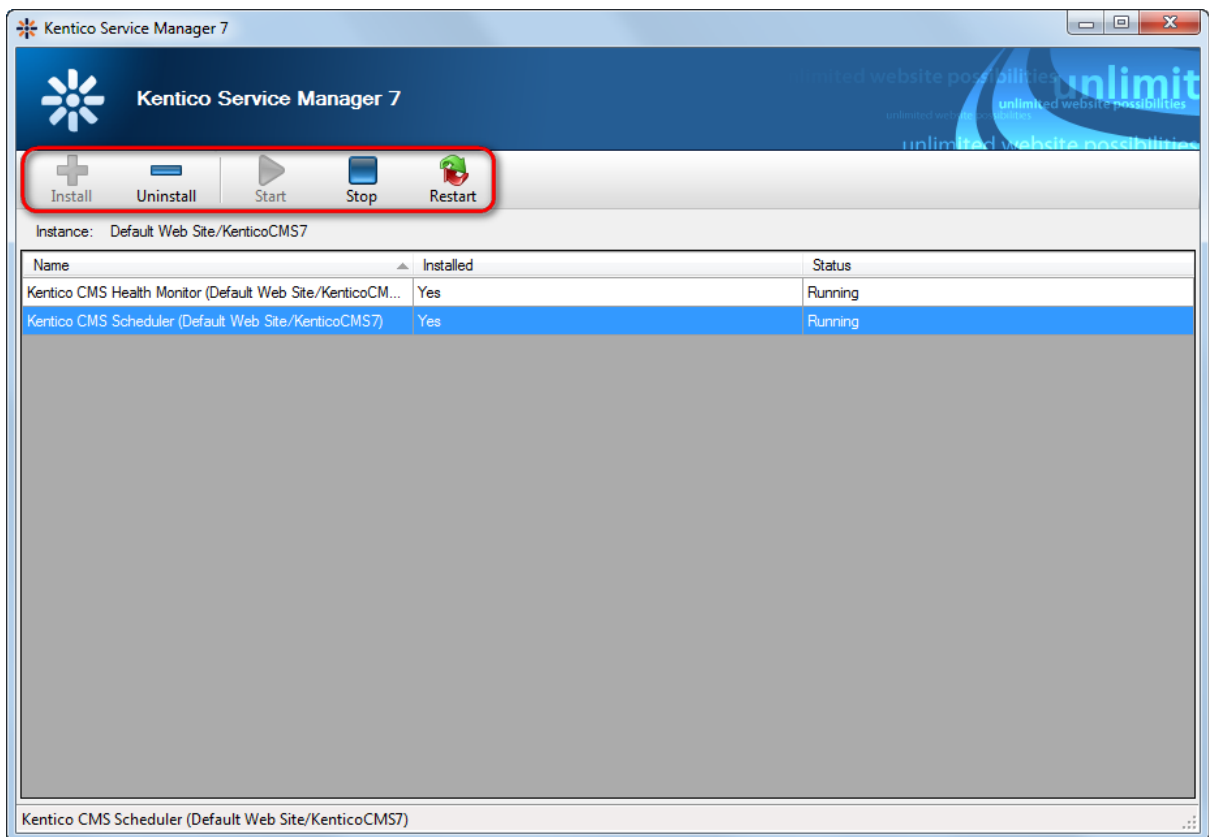

9.5.2 Using the utility

After launching the utility (and successful selection of the managed Kentico CMS instance when launched from Start menu), available services are listed in the main area. The following information is listed for each services:

- **Name** - name of the Windows service in format **<service name> (<CMSApplicationName web.config key value>)**.
- **Installed** - shows if the service is installed or not.
- **Status** - shows if the service is running or stopped, or intermediate statuses when the service is being started, stopped or restarted.

If you select a service in the listing, the following management actions are available in the top toolbar. The same actions are also available in a context menu accessible by right-clicking a service.

- **+ Install** - installs the selected service. Only available if the service is not installed.
- **- Uninstall** - uninstalls the selected service. Only available if the service is installed.
- **▶ Start** - starts the selected service. Only available if the service is installed and not running.
- **■ Stop** - stops the selected service. Only available if the service is installed and running.
- **🔄 Restart** - restarts the selected service. Only available if the service is installed and running.

Kentico Service Manager toolbar

9.5.3 Services definition XML

Windows services that can be managed by Kentico Service Manager are defined in `~/App_Data/CMSModules/WinServices/services.xml`. All health monitoring services that should be manageable by Kentico Service Manager and generally all Windows services that should work with the respective Kentico CMS instance (e.g. your custom ones) need to be defined in this file.

Below, you can see the default content of the `services.xml` file with the [Health monitoring](#) and [Scheduler](#) services defined. As you can see, the XML has a root `<Services>` element containing any number of `<Service>` elements, each of which represents a single Windows service. Each `<Service>` element contains the following sub-elements:

- **<basename>** - identifying name of the service, the same for all instances of Kentico CMS.
- **<name>** - the same as `<basename>`, with the `{0}` part appended. The `{0}` part gets replaced with the value of the `CMSApplicationName` or alternatively `CMSApplicationGuid` `web.config` keys to differentiate services of particular Kentico CMS instances.
- **<displayname>** - name of the Windows service in friendly format, displayed in user interfaces of Windows Services manager (`services.msc`) and Kentico CMS Service Manager.
- **<description>** - text describing the functionality provided by the service.
- **<assemblyname>** - name of the service's executable file stored inside the `bin` folder in the application root.

```
<?xml version="1.0"?>
```

```
<Services>
  <Service>
    <basename>KenticoCMSHealthMonitor</basename>
    <name>KenticoCMSHealthMonitor{0}</name>
    <displayname>Kentico CMS Health Monitor ({0})</displayname>
    <description>Registers categories with counters where information will be
subsequently stored. Then it gets data from the database (e.g. the number of e-
mails in the e-mail queue, the number of tasks in the queue, etc.) and stores it
in the respective counters.</description>
    <assemblyname>HealthMonitoringService.exe</assemblyname>
  </Service>
  <Service>
    <basename>KenticoCMSScheduler</basename>
    <name>KenticoCMSScheduler{0}</name>
    <displayname>Kentico CMS Scheduler ({0})</displayname>
    <description>Processes Kentico CMS scheduled tasks that have the 'Allow run in
external service' option enabled. Processing is performed in regular intervals and
only tasks with the mentioned option enabled are processed by the service.</
description>
    <assemblyname>SchedulerService.exe</assemblyname>
  </Service>
</Services>
```

Part

API programming and Kentico CMS internals

10 API programming and Kentico CMS internals

10.1 Overview

Kentico CMS allows you to script any action that you would normally make through the user interface, such as:

- content management (select/create/update/delete documents)
- workflow management
- security (create users, roles, set permissions, etc.)
- and many others

This allows you to create customized features and add them to the user interface or write procedures for integration with external systems.

10.2 CMSContext class

`CMS.CMSHelper.CMSContext` class provides useful methods that allow you to access information about the current page, user, etc. All methods are static, which means you can access them directly like `CMS.CMSHelper.CMSContext.CurrentAliasPath`, without instantiating the `CMSContext` class.

| | |
|------------------|--|
| CurrentAliasPath | Alias path of the currently required document. |
| CurrentDocument | Currently processed document. This object contains all document data including the product data. Please note that retrieving this property is time consuming because it may need to access the database to get the data. You can use the property <code>CurrentPageInfo</code> to get basic document data without additional operations required. It is cached when Content caching is enabled. |
| CurrentPageInfo | Currently processed page info. This property provides only basic document fields, such as <i>NodeID</i> , <i>NodeName</i> , <i>AliasPath</i> , <i>ClassName</i> , etc. It is cached if Page info caching is enabled. |
| CurrentSite | Provides information on the current site. |
| CurrentSiteName | Provides code name of the current site. |
| CurrentUser | Provides information on the current user and their preferences. Beside the standard <code>UserInfo</code> properties, it also provides the following ones:

PreferredCultureCode – gets/sets user's preferred content culture. You can use this property to change the culture of the displayed content.

PreferredUICultureCode – gets/sets user's preferred UI culture. It's used mainly by Kentico CMS webparts, controls and in the administration interface.

IsAuthorizedPerResource – returns true if the current user is authorized with given permission for given module (resource).

IsAuthorizedPerClassName – returns true if the current user is authorized with given permission for the given document type (class name). It checks the global document permissions. |

| | |
|--------------------|--|
| | <p>IsAuthorizedPerTreeNode – returns true if the current user is authorized with given permission for given document (node).</p> <p>IsPublic – returns true if the current user is the Public user account used for anonymous visitors.</p> |
| ViewMode | The view mode in which the documents are displayed (edit, design, form, live site, preview). |
| ResolveCurrentPath | <p>Returns current path or its part according to the provided formatting string. You can use it to get only the first N levels of the path – e.g.:</p> <p><code>/{0}/{1}</code>
 applied on
 <code>"/products/computers/ibm"</code>
 results in:
 <code>"/products/computers"</code></p> |

10.3 TreeHelper class

CMS.CMSHelper.TreeHelper class provides useful methods that allow you to access documents. All methods are static, which means you can access them directly like `CMS.CMSHelper.TreeHelper.SelectNodes`.

| | |
|----------------------|--|
| SelectSingleNode | Returns single node (document) specified by given NodeID or path. |
| SelectSingleDocument | Return single node (document) specified by given DocumentID (culture-specific document version). |
| SelectNodes | Returns a DataSet object containing nodes (documents) of given path. |

10.4 Registering custom classes in App_Code

By preparing custom classes that inherit from an appropriate base class, you can extend the functionality of Kentico CMS. This approach allows you to implement the following types of objects:

- [integration connectors](#)
- [marketing automation actions](#)
- [notification gateways](#)
- [scheduled tasks](#)
- [smart search custom indexes and analyzers](#)
- [translation services](#)
- [workflow actions](#)

If you create the custom classes in your project's **App_Code** folder (or **Old_App_Code** on *web application* installations), you do not need to integrate a new assembly into the web project. Code in the App_Code folder is compiled dynamically and automatically referenced in all other parts of the application.

Registering custom classes in the App_Code folder

To ensure that the system can load custom classes placed in App_Code, you need to write code that

registers each class.

1. Extend the **CMSModuleLoader** [partial class](#). You can either extend an existing definition of the class, or create a new source file with the following code.

[C#]

```
using System;

using CMS.SettingsProvider;

public partial class CMSModuleLoader
{
}

```

2. Create a new class inside the **CMSModuleLoader** that inherits from *CMSLoaderAttribute*.

[C#]

```
private class ClassLoader : CMSLoaderAttribute
{
}

```

3. Add the attribute defined by the internal class before the definition of the **CMSModuleLoader** partial class.

[C#]

```
[ClassLoader]
public partial class CMSModuleLoader
{
...
}

```

4. Override the **Init** method inside the attribute class, and assign a handler to the *ClassHelper.OnGetCustomClass* event.

[C#]

```
public override void Init()
{
    ClassHelper.OnGetCustomClass += GetCustomClassEventHandler;
}

```

5. Define the handler method for the *OnGetCustomClass* event as follows:

[C#]

```
private static void GetCustomClassEventHandler(object sender, ClassEventArgs e)
{
    if (e.Object == null)
    {
        switch (e.ClassName)
        {
            case "CustomAction":
                e.Object = new CustomAction();
                break;
        }
    }
}
```

To load your App_Code class into the system, create a new instance and assign it to the **Object** property of the event handler's *ClassEventArgs* parameter (**e**). The *switch* structure allows you to use the handler to load any number of custom classes based on the specified class name.

Overall code example:**[C#]**

```
using System;

using CMS.SettingsProvider;

[ClassLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Attribute class that ensures the loading of custom classes.
    /// </summary>
    private class ClassLoader : CMSLoaderAttribute
    {
        /// <summary>
        /// Called automatically when the application starts.
        /// </summary>
        public override void Init()
        {
            // Assigns a handler for the OnGetCustomClass event
            // This event is triggered when the system requests a class with
            App_Code as the assembly name
            ClassHelper.OnGetCustomClass += GetCustomClassEventHandler;
        }

        /// <summary>
        /// Gets the custom class object based on the specified class name.
        /// </summary>
        private static void GetCustomClassEventHandler(object sender,
            ClassEventArgs e)
        {
```

```

// Checks whether an object is already assigned to the requested class
if (e.Object == null)
{
    // Checks the name of the requested class
    switch (e.ClassName)
    {
        // Loads an instance of the 'CustomTask' class for the
        'CustomTaskName' name
        case "CustomTaskName":
            e.Object = new CustomTask();
            break;

        // Loads an instance of the 'CustomIndex' class for the
        'CustomIndexName' name
        case "CustomIndexName":
            e.Object = new CustomIndex();
            break;
    }
}
}
}
}
}

```

Once you have registered your custom classes, you can use them as the source for objects in the system. When assigning App_Code classes to objects in the editing interface, fill in the following values:

- **Assembly name:** App_Code
- **Class name:** must match the name that identifies the corresponding custom class in the switch statement of your *OnGetCustomClass* handler method. When the *OnGetCustomClass* event is triggered, the value of the *Class name* field is passed on through the *ClassName* property of the *ClassEventArgs* parameter.

Scheduled tasks

Site: Corporate Site

Tasks System tasks

> Scheduled tasks > New task

Save

Task display name: Custom scheduled task

Task name: (automatic)

Task assembly name: App_Code

Task class name: CustomTaskName

Assigning a custom App_Code class to a new scheduled task

10.5 Site management, import and export

10.5.1 Creating a new website

The following example shows how you can create a new site based on the Blank website template:

[C#]

```
using CMS.SettingsProvider;
using CMS.CMSHelper;
using CMS.GlobalHelper;
using CMS.SiteProvider;
using CMS.CMSImportExport;

...

// Site name
string siteName = "testAPIsite";

try
{
    // Create site import settings
    SiteImportSettings settings = new SiteImportSettings();

    //Initialize the settings
    settings.SiteName = siteName;
    settings.SiteDisplayName = "Test API site";
    settings.SiteDescription = "Site for testing the API examples";
    settings.SiteDomain = "127.0.0.254";

    // Get 'Blank site' web template
    WebTemplateInfo template = WebTemplateInfoProvider.GetWebTemplateInfo
("BlankSite");

    // Template exists
    if (template != null)
    {
        // Set source file path
        string templatePath = template.WebTemplateFileName;
        settings.SourceFilePath = Server.MapPath(templatePath.TrimEnd('\\') +
"\\");

        // Load default selection to preselect the objects
        settings.LoadDefaultSelection();

        // Create new site using 'Blank' template
        ImportProvider.ImportObjectsData(settings);

        // Run site
        SiteInfoProvider.RunSite(siteName);

        this.lblInfo.Text = string.Format("New site with code name '{0}' has
been created.", siteName);
        return;
    }
    else
    {
        this.lblInfo.Text = string.Format("Failed to create new site '{0}'.<br
/>Web template 'Blank site' doesn't exist.", siteName);
        this.lblInfo.CssClass = "ErrorLabel";
    }
}
catch (RunningSiteException)
{

```

```
        this.lblInfo.Text = string.Format("Failed to run site '{0}'.", siteName);
        this.lblInfo.CssClass = "ErrorLabel";
    }
    catch (Exception ex)
    {
        this.lblInfo.Text = string.Format("Failed to create new site '{0}'.<br /
>Original exception: " + ex.Message, siteName);
        this.lblInfo.CssClass = "ErrorLabel";
    }
}
```

10.5.2 Import and export of a website

You can export and import a website using Kentico CMS API, using the **CMS.CMSImportExport.ImportProvider/ExportProvider** classes. You can use the following methods:

- `public static void ImportSite(string siteName, string siteDisplayName, string siteDomain, string fullSourcePath, string websitePath, UserInfo currentUser)`
 - **siteName** - code name of the newly created website.
 - **siteDisplayName** - display name of the newly created website.
 - **siteDomain** - domain name of the newly created website.
 - **fullSourcePath** - physical disk path of the package containing the site that should be imported.
 - **websitePath** - physical disk path of the website root.
 - **currentUser** - the `UserInfo` object of the user under which the import should be performed.
- `public static void ExportSite(string siteName, string fullExportFilePath, string websitePath, bool template, UserInfo userInfo)`
 - **siteName** - code name of the site to be exported.
 - **fullExportFilePath** - physical disk path of the export package.
 - **websitePath** - physical disk path of the website root.
 - **template** - if false, a .zip file containing the site will be created under *fullExportFilePath* (should be the full path including the .zip file name). Otherwise, the whole site will be exported as a website template to the same location (in this case, the full path should be used without any file name specified).
 - **userInfo** - the `UserInfo` object of the user under which the export should be performed.

10.5.3 Updating website properties

The following example shows you how to modify website properties using the API:

[C#]

```
using CMS.CMSHelper;
using CMS.SiteProvider;
using CMS.WorkflowEngine;

...

// Get current site name (you can use code name of the required site instead)
string siteName = CMSContext.CurrentSiteName;

// Check if the site name is available
```

```
if (siteName != null)
{
    try
    {
        // Stop the site because we will change the domain of the site
        SiteInfoProvider.StopSite(siteName);

        // Get site info
        SiteInfo si = SiteInfoProvider.GetSiteInfo(siteName);

        if (si != null)
        {
            si.DisplayName = "New display name";
            si.Description = "New description";

            // Change domain of the site
            si.DomainName = "mynewdomain.com";

            // Save the changes
            SiteInfoProvider.SetSiteInfo(si);
        }

        // Run the site
        SiteInfoProvider.RunSite(siteName);

        lblInfo.Text = string.Format("Site '{0}' has been edited.", siteName);
    }
    catch (RunningSiteException ex)
    {
        lblError.Text = "Site cannot be started.<br />Original exception: " +
ex.Message;
    }
    catch (Exception ex)
    {
        lblError.Text = "Error when modifying site properties.<br />Original
exception: " + ex.Message;
    }
}
```

The following sample code shows how you can add a new content culture to an existing website:

[C#]

```
using CMS.SiteProvider;

...

// Get site and culture objects
SiteInfo si = SiteInfoProvider.GetSiteInfo("CorporateSite");
CultureInfo ci = CultureInfoProvider.GetCultureInfo("AR-Sa");

// If both exists
if ((si != null) && (ci != null))
{
    // Add culture to site
    CultureSiteInfoProvider.AddCultureToSite(ci.CultureID, si.SiteID);
}
```

```
}
```

10.6 Custom providers

10.6.1 Writing custom providers

Providers in Kentico CMS are classes that allow the system to manipulate objects and perform various actions. The following list presents the providers that the system uses and their purpose:

- **Info providers** contain methods for working with specific types of objects stored in the database, such as users, contacts, custom table records, etc.
- **Data provider** handles low-level database operations. The Info providers are built on top of the Data provider and use it to store and fetch data.
- **E-mail provider** manages the e-mail queue and sends e-mails.
- **Search provider** ensures the functionality of the SQL search.
- **Storage providers** allow you to access various file systems. They extend the CMS.IO namespace. See [File system access API](#) for information how to write a custom file system provider.

By developing custom providers and using them instead of the standard ones, you can modify the behavior of the application (or a specific module) according to your exact requirements.

Adding your custom code files

When developing custom functionality, you can place your code files in:

- The **App_Code** folder (named **Old_App_Code** if you use a web application project)
- A separate project (assembly) integrated into the main web project

Placing your customizations into the App_Code folder ensures that the code is compiled dynamically when required and automatically referenced in all other parts of the application.

Writing the custom code

Every class used to customize the application must **inherit from the original class**. This allows you to implement your modifications or additions by overriding the members of the given class. When creating overrides for existing methods, it is recommended to call the original base method within your custom code.

You can find information about the available provider, helper and manager classes in the Kentico CMS [API reference](#), including their inheritance hierarchy and lists of methods.

Registering custom providers

After you write the code, you must register your custom classes to ensure that the system uses them instead of the default providers. You can choose between two options of registering custom provider classes:

- [In App_Code using the CMSModuleLoader partial class](#) - the most straightforward way to register providers.

- [Using the web.config file](#) - allows you to switch between different providers (custom or default) without having to edit the application code.

Other customization options

In addition to providers, you can also customize the following helper classes:

| Helper Class Name | Namespace | Description |
|-----------------------|---|--|
| AutomationHelper | CMS.DataCom.Automation
CMS.SalesForce.Automation | These two helper classes provide marketing automation support for common actions related to Data.com and SalesForce integration. |
| CacheHelper | CMS.GlobalHelper | Handles operations with cache items. |
| ClassHelper | CMS.SettingsProvider | Takes care of dynamically loaded classes and assemblies. |
| CookieHelper | CMS.GlobalHelper | Contains methods for managing cookies. |
| DirectoryHelper | CMS.IO | Manages directories in the file system. |
| LeadReplicationHelper | CMS.SalesForce | Replicates contacts into SalesForce leads. |
| MediaHelper | CMS.GlobalHelper | Provides methods for rendering media content. |
| OutputHelper | CMS.OutputFilter | Manages the HTML output and the output cache. |
| SyncHelper | CMS.Synchronization | Synchronizes document and object data to other instances of the application when using Content staging . |
| TransformatonHelper | CMS.Controls | Provides methods that can be used in ASCX transformations . |

You can also use [global event handlers](#) to customize the behavior of the system. Handlers allow you to execute custom code whenever a specific event occurs in the system, such as document or object changes, various parts of the user authentication process, etc.

Examples

- [Custom Info provider](#) - demonstrates how to customize standard Info providers.
- [Custom E-mail provider](#) - shows a sample customization of the e-mail provider. Uses the web.config extensibility section to register the custom provider.
- [Custom Data provider](#) - describes the specific steps that you need to take to customize the Data provider.
- [Custom SQL search provider](#) - demonstrates how you can modify the SQL search provider.

10.6.2 Registering providers in App_Code

The most direct way to register [custom providers or helpers](#) is using the **CMSModuleLoader** [partial class](#), which is included in the App_Code folder of your web project by default (*Old_App_Code* folder on

web application installations).

1. Extend the **CMSModuleLoader** partial class inside the App_Code folder. You can either create a new code file for this purpose, or extend an existing definition of the class.

[C#]

```
using CMS.SettingsProvider;  
  
public partial class CMSModuleLoader  
{  
  
}
```

2. If you have defined your custom providers in external assemblies, add using statements referring to these assemblies.

3. Create a new class inside the **CMSModuleLoader** that inherits from *CMSLoaderAttribute*.

[C#]

```
private class CustomProviderLoader : CMSLoaderAttribute  
{  
  
}
```

4. Add the attribute defined by the internal class before the definition of the **CMSModuleLoader** partial class.

[C#]

```
[CustomProviderLoader]  
public partial class CMSModuleLoader  
{  
    ...  
}
```

5. Override the **Init** method inside the attribute class.

[C#]

```
public override void Init()  
{  
  
}
```

6. In the *Init* method, assign a new instance of your custom provider class to the **ProviderObject** property of the original provider (*UserInfoProvider* in this example).

[C#]

```
public override void Init()
{
    UserInfoProvider.ProviderObject = new CustomUserInfoProvider();
}
```

You can assign classes from both App_Code and other assemblies.

Note: When customizing helpers, assign a new instance of your custom class into the **HelperObject** property instead.

Overall code example:

[C#]

```
using CMS.SettingsProvider;
using CMS.SiteProvider;
using CMS.GlobalHelper;

[CustomProviderLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Attribute class that ensures the loading of custom providers.
    /// </summary>
    private class CustomProviderLoader : CMSLoaderAttribute
    {
        /// <summary>
        /// Called automatically when the application starts.
        /// </summary>
        public override void Init()
        {
            // Registers the 'CustomUserInfoProvider' class as the
            UserInfoProvider.ProviderObject = new CustomUserInfoProvider();

            // Registers the 'CustomCacheHelper' class as the CacheHelper
            CacheHelper.HelperObject = new CustomCacheHelper();
        }
    }
}
```

The application now uses your customized provider(s) instead of the default functionality.

10.6.3 Registering providers via the web.config

You can register [custom providers and helpers](#) through your application's **web.config** file. This is done by mapping provider objects to the appropriate custom classes. Registering providers in the web.config allows you to switch between different providers (custom or default) without having to edit the application

code

Note: If you do not need your provider customizations to be adjustable through the web.config file, it is more efficient to register custom providers directly through the API in the App_Code folder (as described in [Registering providers in App_Code](#)).

1. Edit your **web.config** file and add the following section into the `<configSections>` element:

```
<?xml version="1.0"?>
<configuration xmlns="http://schemas.microsoft.com/.NetConfiguration/v2.0">
  <configSections>
    ...

    <!-- Extensibility BEGIN -->
    <section name="cms.extensibility"
      type="CMS.SettingsProvider.CMSExtensibilitySection" />
    <!-- Extensibility END -->

  </configSections>
  ...
```

This defines the `cms.extensibility` web.config section where you can register custom providers and helpers.

2. Create the actual **<cms.extensibility>** section directly under the root level of the web.config.

3. Assign your custom classes to providers or helpers via `<add>` elements with the following attributes:

- **name** - must match the name of the provider/helper class that you wish to customize (without the extension).
- **assembly** - specifies the assembly where your custom class is located. Set the value to `App_Code` for classes placed in the App_Code folder (even on web application installations, where the actual name of the folder is `Old_App_Code`).
- **type** - specifies the name of your custom provider class (including namespaces).
 - If the class is in the App_Code folder, the system triggers the `OnGetCustomClass` event when requesting the provider class. The `type` value is passed on through the `ClassName` property of the event's `ClassEventArgs` parameter. When writing the event's handler, use the value to identify and load an instance of the appropriate custom provider class.

You need to categorize the `<add>` elements under `<providers>` or `<helpers>` sub-sections based on the type of the customized class.

```
<configuration>
  ...

  <!-- Extensibility BEGIN -->
  <cms.extensibility>
    <providers>
      <add name="EmailProvider" assembly="App_Code" type="CustomEmailProvider" />
    </providers>
  </cms.extensibility>
  </!-- Extensibility END -->
</configuration>
```

```
<add name="SiteInfoProvider" assembly="App_Code"
type="CustomSiteInfoProvider" />
<add name="ForumPostInfoProvider" assembly="CMS.CustomProviders"
type="CMS.CustomProviders.CustomForumPostInfoProvider" />
...
</providers>
<helpers>
  <add name="CacheHelper" assembly="App_Code" type="CustomCacheHelper" />
  ...
</helpers>
</cms.extensibility>
<!-- Extensibility END -->

...

</configuration>
```

In the case of custom providers placed in a separate assembly, the registration is now complete.

Loading App_Code classes

When using the web.config to register custom providers defined in the App_Code folder, you also need to ensure that the system can [load the classes](#).

Example:

[C#]

```
using System;

using CMS.SettingsProvider;

[ClassLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Attribute class that ensures the loading of custom classes.
    /// </summary>
    private class ClassLoader : CMSLoaderAttribute
    {
        /// <summary>
        /// Called automatically when the application starts.
        /// </summary>
        public override void Init()
        {
            // Assigns a handler for the OnGetCustomClass event
            // This event is triggered when the system requests a class with
            App_Code as the assembly name
            ClassHelper.OnGetCustomClass += GetCustomClassEventHandler;
        }

        /// <summary>
```

```
    /// Gets the custom class object based on the specified class name (i.e.
type value).
    /// </summary>
    private static void GetCustomClassEventHandler(object sender,
ClassEventArgs e)
    {
        // Checks whether an object is already assigned to the requested
class.
        if (e.Object == null)
        {
            switch (e.ClassName)
            {
                // Loads an instance of the 'CustomEmailProvider' class
                case "CustomEmailProvider":
                    e.Object = new CustomEmailProvider();
                    break;

                // Loads an instance of the 'CustomSiteInfoProvider' class
                case "CustomSiteInfoProvider":
                    e.Object = new CustomSiteInfoProvider();
                    break;

                // Loads an instance of the 'CustomCacheHelper' class
                case "CustomCacheHelper":
                    e.Object = new CustomCacheHelper();
                    break;
            }
        }
    }
}
```

When the system requests an App_Code provider class registered through the *cms.extensibility* section of the web.config, the *OnGetCustomClass* event is triggered and the handler method returns an instance of the appropriate class.

10.6.4 Custom Info provider

The system uses *Info providers* to work with individual types of objects. A provider class contains methods for creating, updating, getting, and deleting the data of the corresponding objects. By customizing the appropriate Info provider, you can change or extend the functionality of nearly any object in the system.

Example

The following example customizes the *ShippingOptionInfoProvider*, which the [E-commerce](#) module uses to manage shipping options for product orders. The sample customization modifies how the provider calculates shipping costs.

You can use the same general approach to customize any standard provider or helper class in Kentico CMS (i.e. those that inherit from the *AbstractProvider* or *AbstractHelper* class respectively).

Writing the custom provider

1. Open your web project in Visual Studio and create a new class in the **App_Code** folder (or **Old_App_Code** if the project is installed as a web application). For example, name the class **CustomShippingOptionInfoProvider.cs**.

2. Edit the class and add the following references:

[C#]

```
using CMS.Ecommerce;
using CMS.SettingsProvider;
using CMS.SiteProvider;
```

3. Modify the class's declaration so that it inherits from the **CMS.Ecommerce.ShippingOptionInfoProvider** class:

[C#]

```
/// <summary>
/// Customized ShippingOptionInfo provider.
/// </summary>
public class CustomShippingOptionInfoProvider : ShippingOptionInfoProvider
{
}
}
```

Custom providers must always inherit from the original provider class. This ensures that the custom provider supports all of the default functionality and allows you to add your own customizations by overriding the existing members of the class.

4. Add the following override of the **CalculateShippingInternal** method into the class:

[C#]

```
/// <summary>
/// Calculates the shipping price for the specified shopping cart (shipping taxes
/// are not included).
/// Returns the shipping price in the site's main currency.
/// </summary>
/// <param name="cart">
/// Object representing the related shopping cart. Provides the data used to
/// calculate the shipping price.
/// </param>
protected override double CalculateShippingInternal(ShoppingCartInfo cart)
{
    // Checks that the shopping cart specified in the parameter exists
    if (cart != null)
    {
        // Ensures free shipping for customers who belong to the 'Gold partner'
        role
    }
}
```

```

        if ((cart.User != null) && cart.User.IsInRole("GoldPartners",
cart.SiteName))
        {
            return 0;
        }
        else
        {
            // Gets the customer's shipping address details from the shopping cart
            AddressInfo address = AddressInfoProvider.GetAddressInfo
(cart.ShoppingCartShippingAddressID);

            if (address != null)
            {
                // Gets the country from the shipping address
                CountryInfo country = CountryInfoProvider.GetCountryInfo
(address.AddressCountryID);

                // Sets an extra shipping charge for addresses outside of the USA
                if ((country != null) && (country.CountryName.ToLowerCSafe() !=
"usa"))
                {
                    // Replace this flat charge with your own shipping
calculations
                    // You can also create a custom setting and use it to
dynamically load the value
                    double extraCharge = 10;

                    // Returns the standard shipping price with the extra charge
added
                    return base.CalculateShippingInternal(cart) + extraCharge;
                }
            }
        }

        // Calculates the shipping price using the default method for regular
customers from the USA
        return base.CalculateShippingInternal(cart);
    }

```

This override of the *CalculateShippingInternal* method ensures that:

- Users who belong to the *Gold partner* role always have free shipping
- An extra flat charge is added for customers with shipping addresses outside of the USA

Note: The override gets the standard shipping price by calling the base method from the parent class. This allows you to calculate the default price based on the shipping option settings, and then modify it as needed.

Registering the provider class

Use the following steps to register your custom provider [directly in App Code](#):

1. Extend the **CMSModuleLoader** partial class. You can either create a new App_Code class file for this purpose or add the partial class declaration directly into the file containing your custom provider (*CustomShippingOptionInfoProvider.cs* in this case).

[C#]

```
public partial class CMSModuleLoader
{
}
```

2. Create a new attribute class inside the **CMSModuleLoader** that inherits from *CMSLoaderAttribute*. Add the attribute to the **CMSModuleLoader** partial class:

[C#]

```
using CMS.SettingsProvider;

[CustomProviderLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Attribute class that ensures the loading of custom providers.
    /// </summary>
    private class CustomProviderLoader : CMSLoaderAttribute
    {
    }
}
```

3. Override the **Init** method inside the attribute class and assign a new instance of the *CustomShippingOptionInfoProvider* class into the **ProviderObject** property of the original *ShippingOptionInfoProvider*.

[C#]

```
using CMS.Ecommerce;
using CMS.SettingsProvider;

[CustomProviderLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Attribute class that ensures the loading of custom providers.
    /// </summary>
    private class CustomProviderLoader : CMSLoaderAttribute
    {
        /// <summary>
        /// Called automatically when the application starts.
        /// </summary>
        public override void Init()
        {
            // Registers the 'CustomShippingOptionInfoProvider' class as the
            ShippingOptionInfoProvider.ProviderObject = new
            CustomShippingOptionInfoProvider();
        }
    }
}
```

```
}
```

Result

You can try out how the customization affects the e-commerce module on the sample Corporate site.

1. Open the live website and log on as the Sample Gold Partner user (user name *gold*).
2. Navigate to the **Products** section and add any product to the shopping cart.
3. Go through the checkout process for the order.

In the **Order preview** (step 5 of the checkout process), you can see that the shipping is always free, no matter what shipping address you entered.

If you repeat the same process as a regular user (e.g. *Andy*), the system calculates the shipping costs normally and adds the extra charge if the shipping address is in a different country than the USA.

10.6.5 Custom E-mail provider

Customizing the e-mail provider allows you to:

- Execute custom actions when sending e-mails (for example logging the sent e-mails for auditing purposes)
- Use third-party components for sending e-mails

Once you create and register your custom e-mail provider, it is used to process all e-mails sent out by Kentico CMS and its modules.

Example

The following example demonstrates how to define a custom e-mail provider. This sample provider supports all of the default e-mail functionality, but additionally creates an entry in the [Event log](#) whenever the system sends an e-mail.

Writing the custom e-mail provider

1. Open your web project in Visual Studio and create a new class in the **App_Code** folder (or **Old_App_Code** if the project is installed as a web application). For example, name the class **CustomEmailProvider.cs**.
2. Edit the class and add the following references:

[C#]

```
using System.ComponentModel;
using System.Net.Mail;

using CMS.EmailEngine;
using CMS.EventLog;
using CMS.SettingsProvider;
```

3. Modify the class's declaration to make it inherit from the **CMS.EmailEngine.EmailProvider** class:

[C#]

```
/// <summary>
/// Customized e-mail provider.
/// </summary>
public class CustomEmailProvider : EmailProvider
{
}
```

Custom e-mail providers must always inherit from the default **EmailProvider** class. This allows you to call the base methods before adding your own custom functionality.

4. Add the following method overrides into the class:

[C#]

```
/// <summary>
/// Customized e-mail provider.
/// </summary>
public class CustomEmailProvider : EmailProvider
{
    /// <summary>
    /// Synchronously sends an e-mail through the SMTP server.
    /// </summary>
    /// <param name="siteName">Site name</param>
    /// <param name="message">E-mail message</param>
    /// <param name="smtpServer">SMTP server</param>
    protected override void SendEmailInternal(string siteName, MailMessage
message, SMTPServerInfo smtpServer)
    {
        base.SendEmailInternal(siteName, message, smtpServer);

        string detail = string.Format("E-mail from {0} was sent via {1}
(synchronously)", message.From.Address, smtpServer.ServerName);

        EventLogProvider.LogInformation("CMSCustom", "EMAIL SENDOUT", detail);
    }

    /// <summary>
    /// Asynchronously sends an e-mail through the SMTP server.
    /// </summary>
    /// <param name="siteName">Site name</param>
    /// <param name="message">E-mail message</param>
    /// <param name="smtpServer">SMTP server</param>
    /// <param name="emailToken">E-mail token that represents the message being
sent</param>
    protected override void SendEmailAsyncInternal(string siteName, MailMessage
message, SMTPServerInfo smtpServer, EmailToken emailToken)
    {
        base.SendEmailAsyncInternal(siteName, message, smtpServer, emailToken);
    }
}
```

```

        string detail = string.Format("E-mail from {0} was dispatched via {1}
(asynchronously)", message.From.Address, smtpServer.ServerName);

        EventLogProvider.LogInformation("CMSCustom", "EMAIL SENDOUT", detail);
    }

    /// <summary>
    /// Raises the SendCompleted event after the send is completed.
    /// </summary>
    /// <param name="e">Provides data for the async SendCompleted event</param>
    protected override void OnSendCompleted(AsyncCompletedEventArgs e)
    {
        base.OnSendCompleted(e);

        string detail = "Received callback from asynchronous dispatch";

        EventLogProvider.LogInformation("CMSCustom", "SEND COMPLETE", detail);
    }
}

```

The provider uses these methods to send out e-mails. Each method calls the base from the parent provider class and then logs an information event into the system's event log. You can use the same approach to add any type of custom functionality.

Registering the provider class (via the web.config)

This example uses the [web.config approach](#) for registering the custom e-mail provider:

1. Open your application's **web.config** file and add the following section into the *configSections* element (if it is not already present):

```

<?xml version="1.0"?>
<configuration xmlns="http://schemas.microsoft.com/.NetConfiguration/v2.0">
  <configSections>

    ...

    <!-- Extensibility BEGIN -->
    <section name="cms.extensibility"
    type="CMS.SettingsProvider.CMSExtensibilitySection" />
    <!-- Extensibility END -->

  </configSections>

  ...

```

This defines the *cms.extensibility* web.config section where you can register custom providers, helpers and managers.

2. Create the actual **cms.extensibility** section directly under the root level of the web.config and add the e-mail provider:

```
...  
  
<!-- Extensibility BEGIN -->  
<cms.extensibility>  
  <providers>  
    <add name="EmailProvider" assembly="App_Code"  
type="EmailProviderWithEventLog" />  
  </providers>  
</cms.extensibility>  
<!-- Extensibility END -->  
  
...  
  
</configuration>
```

Because the custom provider is defined in `App_Code`, you also need to ensure that the system can [load the class](#).

3. Extend the **CMSModuleLoader** partial class. You can either create a new class file for this purpose or add the partial class declaration directly into the file containing your custom provider (*CustomEmailProvider.cs* in this case).

[C#]

```
public partial class CMSModuleLoader  
{  
}
```

4. Create a new attribute class inside the **CMSModuleLoader** that inherits from *CMSLoaderAttribute*. Add the attribute to the **CMSModuleLoader** partial class:

[C#]

```
using CMS.SettingsProvider;  
  
[ClassLoader]  
public partial class CMSModuleLoader  
{  
    /// <summary>  
    /// Attribute class that ensures the loading of custom classes.  
    /// </summary>  
    private class ClassLoader : CMSLoaderAttribute  
    {  
    }  
}
```

5. Add the following code into the attribute class:

[C#]

```
/// <summary>
/// Called automatically when the application starts.
/// </summary>
public override void Init()
{
    // Assigns a handler for the OnGetCustomClass event
    ClassHelper.OnGetCustomClass += GetCustomClassEventHandler;
}

/// <summary>
/// Gets the custom class object based on the specified class name.
/// </summary>
private static void GetCustomClassEventHandler(object sender, ClassEventArgs e)
{
    if (e.Object == null)
    {
        // Checks the name of the requested class
        switch (e.ClassName)
        {
            // Gets an instance of the 'CustomEmailProvider' class
            case "EmailProviderWithEventLog":
                e.Object = new CustomEmailProvider();
                break;
        }
    }
}
```

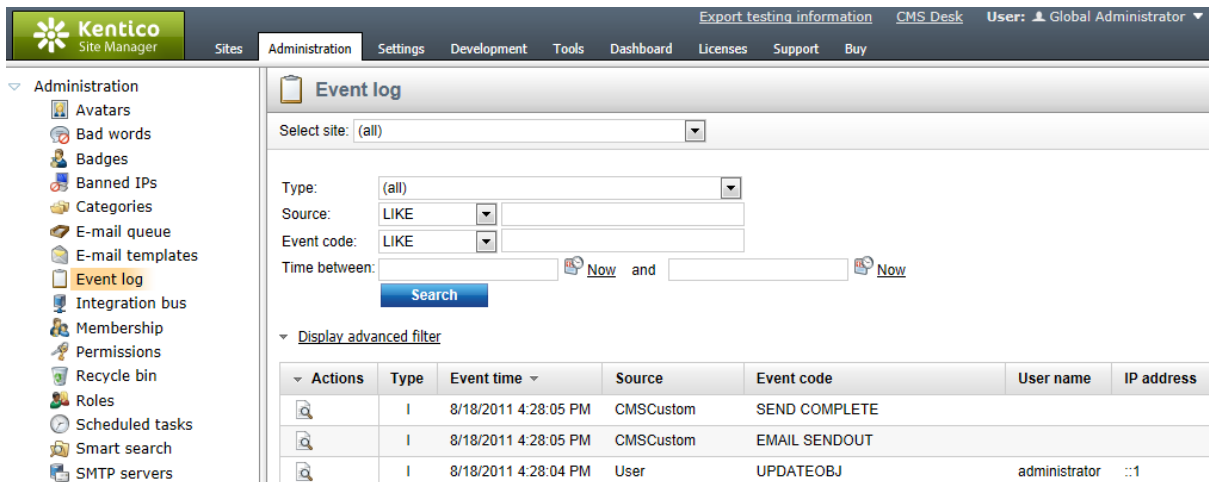

Note: The string used to identify the custom e-mail provider class must match the value of the **type** attribute set for the corresponding *add* element in the web.config extensibility section (*EmailProviderWithEventLog* in this example).

Result

The system now uses the custom e-mail provider (defined in the *CustomEmailProvider* class) when sending e-mails.

To try out the functionality:

1. Send some e-mails using Kentico CMS.
 - o For example, you can use the **Site Manager -> Administration -> System -> E-mail** interface to send a test e-mail (synchronously).
2. Check the log in **Site Manager -> Administration -> Event log**.

The screenshot shows the Kentico CMS Administration interface. The left sidebar contains a navigation menu with various administrative options. The main content area is titled "Event log" and includes search filters for "Select site", "Type", "Source", "Event code", and "Time between". A "Search" button is present. Below the filters, there is a checkbox for "Display advanced filter". A table displays the event log entries:

| Actions | Type | Event time | Source | Event code | User name | IP address |
|---------|------|----------------------|-----------|---------------|---------------|------------|
| | I | 8/18/2011 4:28:05 PM | CMSCustom | SEND COMPLETE | | |
| | I | 8/18/2011 4:28:05 PM | CMSCustom | EMAIL SENDOUT | | |
| | I | 8/18/2011 4:28:04 PM | User | UPDATEOBJ | administrator | :::1 |

Every successfully sent e-mail should have its own entry identified by the *CMSCustom* **Source** value (two entries for e-mails sent asynchronously).

10.6.6 Custom Data provider

Customization of the data provider allows you to implement your own database connector.

You cannot modify the data provider in the **App_Code** folder. The customizations must be added as part of a new assembly, which you then need to register via the **CMSDataProviderAssembly** web.config key.

Note

Custom data providers are NOT intended for accessing non-Microsoft SQL Server database engines. They only allow you to modify how queries are executed against the Microsoft SQL Server.

Adding the custom data provider assembly

1. Copy the **CustomDataProvider** project from your Kentico CMS installation directory (typically *C:\Program Files\KenticoCMS\<version>\CodeSamples\CustomDataProvider*) to a development folder.
2. Open your CMS web project in Visual Studio through the **WebProject.sln** file (or **WebApp.sln** if you are using a web application installation).
3. Click **File -> Add -> Existing Project** and select **CustomDataProvider.csproj** in the folder where you copied the CustomDataProvider project.
4. Unfold the **References** section of the **CustomDataProvider** project and delete all invalid references.
5. Right-click the **CustomDataProvider** project and select **Add Reference**.
6. Open the **Browse** tab of the **Add Reference** dialog and navigate to the **bin** folder of your CMS web

project on the disk.

7. Add references to the following libraries:

- CMS.DataEngine.dll
- CMS.SettingsProvider.dll

8. Right-click the CMS website object (or the **CMSApp** project if your installation is a web application) and select **Add Reference**.

9. Open the **Projects** tab and add a reference to the **CustomDataProvider** project.

The *CustomDataProvider* project is now integrated into your application. By default, the classes in the custom data provider are identical to the ones used by default, but you can modify them according to your own requirements. Remember to **Build** the *CustomDataProvider* project after making changes.

Registering the custom data provider

1. Edit your application's **web.config** file.
2. Add the following key to the **configuration/appSettings** section:

```
<add key="CMSDataProviderAssembly" value="CMS.CustomDataProvider" />
```

The system loads the *DataProvider* class from the namespace specified as the value of the *CMSDataProviderAssembly* key.

Your application now uses the custom data provider for handling database operations.

10.6.7 Custom SQL search provider

Kentico CMS allows you to write your own SQL search provider, which you can use to integrate a third-party search engine. You can also create a custom search provider if you need to modify or filter search results returned by the standard search engine.

You cannot customize the search provider in the **App_Code** folder. The modifications must be added as part of a new assembly, which you then need to register via the **CMSSearchProviderAssembly** web.config key.

Note

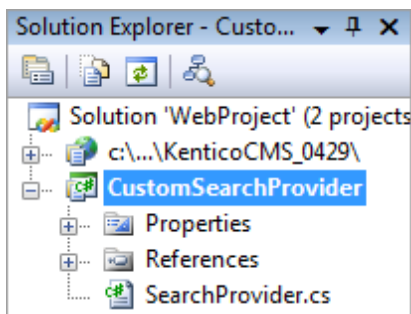

This provider only affects the SQL Search engine. The Smart Search engine remains unchanged.

To modify the smart search, create and use a custom search index as described in [Modules -> Smart Search -> Managing indexes -> Defining custom index content](#).

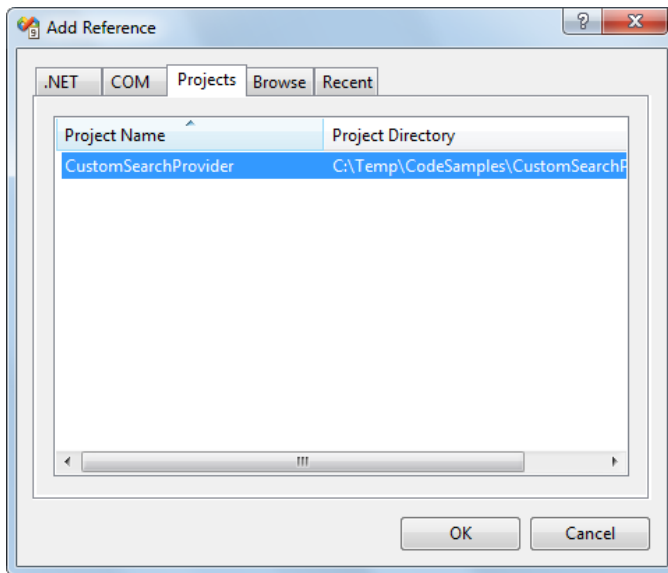

The following example demonstrates how to customize the SQL search provider so that it only searches a limited section of the website.

Adding the custom search provider assembly

1. Copy the **CustomSearchProvider** project from your Kentico CMS installation directory (typically `C:\Program Files\KenticoCMS\<version>\CodeSamples\CustomSearchProvider`) to a development folder.
2. Open your CMS web project in Visual Studio through the **WebProject.sln** file (or **WebApp.sln** if you are using a web application installation).
3. Click **File -> Add -> Existing Project** and select **CustomSearchProvider.csproj** in the folder where you copied the CustomSearchProvider project.

4. Unfold the **References** section of the **CustomSearchProvider** project and delete all invalid references.
5. Right-click the **CustomSearchProvider** project and select **Add Reference**.
6. Open the **Browse** tab of the **Add Reference** dialog and navigate to the **bin** folder of your CMS web project on the disk.
7. Add references to the following libraries:
 - CMS.ISearchEngine.dll
 - CMS.SearchProviderSQL.dll
8. Right-click the CMS website object (or the **CMSApp** project if your installation is a web application) and select **Add Reference**.
9. Open the **Projects** tab and add a reference to the **CustomSearchProvider** project.

The *CustomSearchProvider* project is now integrated into your application.

Modifying the search provider class

1. Edit the **SearchProvider.cs** class in the *CustomSearchProvider* project.
2. Modify the code of the **Search** method according to the following:

[C#]

```
public DataSet Search(string siteName, string searchNodePath, string cultureCode,
string searchExpression, SearchModeEnum searchMode, bool searchChildNodes, string
classNames, bool filterResultsByReadPermission, bool searchOnlyPublished, string
whereCondition, string orderBy, bool combineWithDefaultCulture)
{
    // Limits the search path to only the /Products section of the website
    searchNodePath = "/Products/%";

    // Gets a new instance of the SQL SearchProvider
    CMS.SearchProviderSQL.SearchProvider limitedSearchProvider = new
    CMS.SearchProviderSQL.SearchProvider();

    // Gets the search result dataset based on the parameters of the Search method
    and the limited search path
    DataSet searchResults = limitedSearchProvider.Search(siteName, searchNodePath,
cultureCode, searchExpression, searchMode, searchChildNodes, classNames,
filterResultsByReadPermission, searchOnlyPublished, whereCondition, orderBy,
combineWithDefaultCulture);

    return searchResults;
}
```

In real customization scenarios, you can modify the **Search** method to behave according to any requirements. The method must always return a **DataSet** containing the search results.

3. Save the file and **Build** the *CustomSearchProvider* project.

Registering the custom search provider

1. Edit your application's **web.config** file.
2. Add the following key to the **configuration/appSettings** section:

```
<add key="CMSSearchProviderAssembly" value="CMS.CustomSearchProvider" />
```

The system loads the *SearchProvider* class from the namespace specified as the value of the *CMSSearchProviderAssembly* key.

Result

To try out the customized search engine, open the live website and search for text using the SQL Search engine. For example, you can use the **Examples -> Web Parts -> Full-Text Search -> SQL Search -> SQL Search dialog with results** page on the sample *Corporate site* website.

The search now only returns results from the **/Products** section of the website.

Tip

This customization example is purely demonstrational. If you need to change the search path, directly set the **Path** property of individual SQL search web parts or controls.

10.7 Data layer

10.7.1 Overview

Kentico CMS has its own data layer components that ensure unified access to the database. Each entity, such as "user", "site", "document", has its own "data class". The data class represents the data structure of the entity (using the XML schema) and SQL queries for INSERT, UPDATE, SELECT and DELETE operations. The data layer currently only works with Microsoft SQL Server, but it's designed for use with other data engines in the future.

How it Works

When you need to create a new user record, you create a new instance of **SimpleDataClass** type and specify its class name as "cms.user", which is a code name of this entity. The system automatically creates a new DataRow based on the user entity XML Schema. Then you set the values of its attributes, such as Username or FullName and call the Insert method. The system uses a pre-defined INSERT query to insert the values into the appropriate table that is also stored in the definition of the cms.user entity.

Related Namespaces

CMS.DataEngine
CMS.DataProviderSQL
CMS.IDataConnectionLibrary
CMS.SettingsProvider

Related Tables

CMS_Class
CMS_Query

10.7.2 Code examples

The following examples show how you can use the CMS.DataEngine and CMS.SettingsProvider libraries for low-level data manipulation.

Only for illustration

The code is used only for illustration. It's recommended that you use the **CMS.SiteProvider.UserInfoProvider** class for manipulation of the user data.

Creating a new user

[C#]

```
using CMS.DataEngine;
...

// create a new object based on the cms.user data class
IDataClass userObj = DataClassFactory.NewDataClass("cms.user");
// Set some values. The first parameter of the SetValue method accepts database
// column names that belong to the particular object.
userObj.SetValue("UserName", "johns");
userObj.SetValue("FullName", "John Smith");
// insert the new user into the database, in this case, the CMS_User table
userObj.Insert();
```

Selecting and updating an existing user

[C#]

```
using CMS.DataEngine;
...

// prepare the user's ID
```

```
int userId = 10;

// get the object from database according to the data class name and ID
IDataClass userObj = DataClassFactory.NewDataClass("cms.user", userId);
// acquire the user's name
string userName = userObj.GetValue("UserName").ToString();
// change the user's full name
userObj.SetValue("FullName", "John Smith");
// update the database record
userObj.Update();
```

Deleting a user

[C#]

```
using CMS.DataEngine;
...
// prepare the user's ID
int userId = 10;

// get the object from the database
IDataClass userObj = DataClassFactory.NewDataClass("cms.user", userId);
// if the object exists, delete it
if (userObj != null)
{
    userObj.Delete();
}
```

Running a custom query

You can run a custom query if you first create it either manually in the **CMS_Query** table or through the administration interface (if this is supported for the given entity).

[C#]

```
using CMS.SettingsProvider;
...
QueryDataParameters parameters = new QueryDataParameters();
parameters.Add("@UserName", "administrator");

DataSet ds = SqlHelperClass.ExecuteQuery("cms.user.selectbyusername", parameters,
null, null);
```

10.7.3 Pre- and post-processing queries

You can pre-process database queries and post-process query results using the **OnBeforeExecuteQuery** and **OnAfterExecuteQuery** events in the **SqlHelperClass**.

Pre-processing queries

The **OnBeforeExecuteQuery** event is executed before any query is executed. Using it, you can influence the behavior of the query and its code on the fly.

The code below is the delegate definition for the event:

```
/// <summary>
/// Query execution event handler
/// </summary>
/// <param name="query">Executed query</param>
/// <param name="conn">Connection</param>
public delegate void BeforeExecuteQueryEventHandler(QueryParameters query,
IDataConnection conn);
```

And this code example shows how you can use the event. You need to create a new module class in *App_Code* (or *Old_App_Code* if you installed the project as a web application), e.g. *~App_Code\Custom\PreProcessingQueriesModule.cs*, which will extend the *CMSModuleLoader* partial class. The class should contain the method to be executed on the event and its registration into the event in the *Init()* method, which is executed on each application start.

The method in this particular example replaces *CMS_User* with *View_CMS_User* in case that the processed query is *cms.user.selectall*.

```
using CMS.SettingsProvider;

[PreProcessingQueriesLoaderModule]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Module registration
    /// </summary>
    private class PreProcessingQueriesLoaderModuleAttribute : CMSLoaderAttribute
    {
        /// <summary>
        /// Initializes the module
        /// </summary>
        public override void Init()
        {
            SqlHelperClass.OnBeforeExecuteQuery += new
            SqlHelperClass.BeforeExecuteQueryEventHandler(BeforeExecuteQuery);
        }

        static void BeforeExecuteQuery(CMS.SettingsProvider.QueryParameters query,
        CMS.SettingsProvider.IDataConnection conn)
        {
            if (query.Name != null)
            {
                switch (query.Name.ToLower())
                {
                    case "cms.user.selectall":
                        query.Text = query.Text.Replace("CMS_User",
"View_CMS_User");
                        break;
                }
            }
        }
    }
}
```

```
}  
}  
}
```

Post-processing queries

The **OnAfterExecuteQuery** event is raised after any query is executed and you can use it to modify the result of the query. It can handle only a *DataSet*, thereby only calls using the *ExecuteQuery* method can be post-processed this way.

The code below is the delegate definition for this event:

```
/// <summary>  
/// Query execution event handler  
/// </summary>  
/// <param name="query">Executed query</param>  
/// <param name="conn">Connection</param>  
public delegate void BeforeExecuteQueryEventHandler(QueryParameters query,  
IDataConnection conn);
```

And this code example shows how you can use the event. You need to create a new module class in **App_Code** (or **Old_App_Code** if you installed the project as a web application), e.g. `~\App_Code\Custom\PreProcessingQueriesModule.cs`, which will extend the **CMSModuleLoader** partial class. The class should contain the method to be executed on the event and its registration into the event in the *Init()* method, which is executed on each application start.

The method in this particular example basically gives dynamically generated full name instead of the one that is set in the user settings. This will not be reflected in the UI as you are only processing the result of the query, so please take this just as an example of how you can use the event.

```
using System.Data;  
  
using CMS.SettingsProvider;  
  
[PostProcessingQueriesModuleLoader]  
public partial class CMSModuleLoader  
{  
    /// <summary>  
    /// Module registration  
    /// </summary>  
    private class PostProcessingQueriesModuleLoaderAttribute : CMSLoaderAttribute  
    {  
        /// <summary>  
        /// Initializes the module  
        /// </summary>  
        public override void Init()  
        {  
            SqlHelperClass.OnAfterExecuteQuery += new  
            SqlHelperClass.AfterExecuteQueryEventHandler(AfterExecuteQuery);  
        }  
    }  
}
```

```
static void AfterExecuteQuery(QueryParameters query, IDataConnection conn,
ref DataSet result)
{
    if (query.Name != null)
    {
        switch (query.Name.ToLower())
        {
            case "cms.user.selectall":
                if (result != null)
                {
                    DataTable dt = result.Tables[0];
                    foreach (DataRow dr in dt.Rows)
                    {
                        dr["FullName"] = dr["FirstName"] + " " + dr
["MiddleName"] + " " + dr["LastName"];
                    }
                }
                break;
        }
    }
}
```

10.8 File system access API

10.8.1 Overview

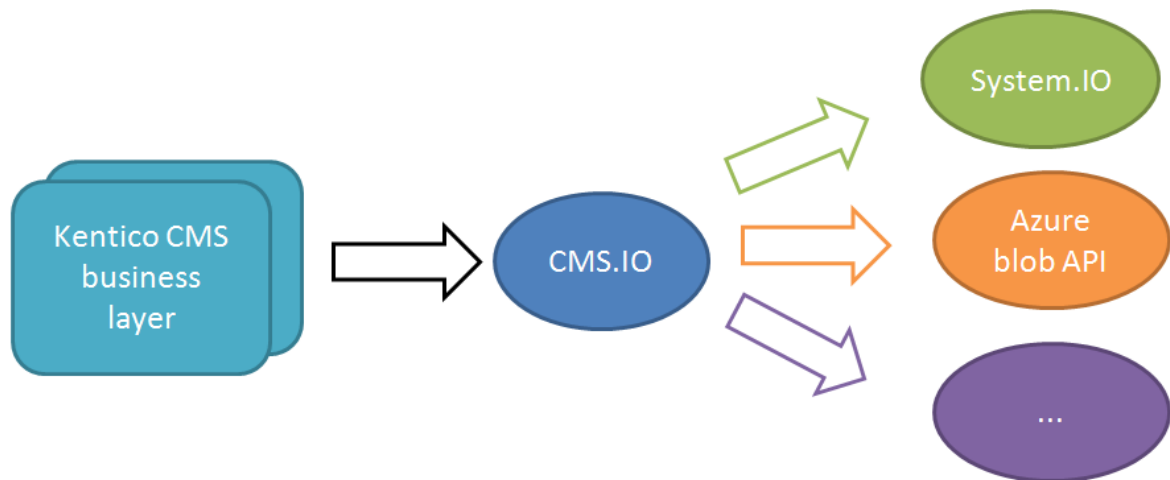

CMS.IO is a namespace that serves as an interlayer between the business layer of Kentico CMS and storages the application uses for physical files. It is used throughout the system instead of the default System.IO library provided by .NET Framework in order to be compatible with various types of file storages.

CMS.IO is an abstract layer, which accesses a file storage by means of a provider built on top of it. CMS.IO defines the classes and their methods and properties, which the provider overrides in order to manipulate files in a storage.

Depending on the storage type that you use for your files, the application utilizes one of the following providers:

- **CMS.CMSStorage** is used in the default installation which saves its files to the Windows file system. The provider only wraps around the System.IO library.
- **CMS.AzureStorage** is a custom-written provider that is employed when storing files in the Windows Azure blob storage (see the [Windows Azure Deployment Guide](#) for more information).
- **CMS.AmazonStorage** is used when you want to store files in the Amazon S3 storage service.

The following figure demonstrates how CMS.IO enables you to easily add the support of different file storages by building providers using the storages' APIs:

To learn how to use the CMS.IO namespace to access files in your custom code, refer to the [Using CMS.IO](#) topic.

To learn how to write a custom storage provider, see the [Writing a custom storage provider](#) topic.

Please note

This chapter assumes that you are familiar with the System.IO library and know how to use it to manipulate files and directories in the Windows file system. If you're new to System.IO, we recommend reading its [documentation](#) first.

10.8.2 Using CMS.IO

Working with CMS.IO is in most aspects the same as working with System.IO. We recommend using CMS.IO instead of System.IO in your code so that your custom functionality is not dependent on a single file system.

This topic describes the similarities and differences between the two libraries and presents examples of CMS.IO usage.

Classes

The following classes defined by CMS.IO are identical in function to their respective counterparts in the System.IO library:

- Directory
- DirectoryInfo
- File
- FileInfo
- FileStream
- MemoryStream
- Path
- StreamReader

- StreamWriter
- StringReader
- StringWriter

Enumerations

The following enumerations are also identical:

- FileAccess
- FileAttributes
- FileMode
- FileShare
- SearchOption
- SeekOrigin

Differences between CMS.IO and System.IO

The most significant difference is how new instances of objects are created. Instead of a constructor, each class contains a **New()** method, which accepts the same parameters as the class' constructor.

The following example shows how to write text into a file. On the highlighted line you can see that the instance of the *FileInfo* class is created using the *New()* method. Please note that the *StreamWriter* class used in the example is also a member of CMS.IO, not System.IO.

```
using CMS.IO;
...
FileInfo fi = FileInfo.New( "MyFile.txt" );
using (StreamWriter sw = fi.CreateText())
{
    sw.WriteLine( "Hello world!" );
}
```

There are a number of types which can be found in System.IO but are not implemented in CMS.IO. These include classes, class members and methods that are used rather seldom. Additionally, CMS.IO doesn't contain any definitions of **exceptions**. You will need to use System.IO exceptions or implement your own.

Working with streams

CMS.IO comes with its own set of streams and the associated readers and writers. These streams are not interchangeable with streams provided by System.IO. This can pose problems e.g. when a method accepts an object of type *CMS.IO.Stream* as a parameter, while you only have a *System.IO.Stream* available, and vice versa. However, CMS.IO provides classes that help work around the incompatibilities.

The following example shows how to store a System.IO.Stream object in a property that expects a CMS.IO.Stream.

```
using CMS.IO;
using CMS.SiteProvider;
...
MetaFileInfo mfi = new MetaFileInfo();
mfi.InputStream = StreamWrapper.New
(FileUploadControl.PostedFile.InputStream);
```

First, it creates a *MetaFileInfo* object, which represents a generic system file used throughout the CMS. The object has the *InputStream* property, which is of the *CMS.IO.Stream* type. To store the *InputStream* of a file uploaded via the standard ASP.NET upload control in that property, the **StreamWrapper.New()** method has to be called to encapsulate the *System.IO.Stream* in the *CMS.IO.Stream*.

The next example demonstrates the opposite approach - passing a *CMS.IO.Stream* to a method that accepts only objects of the *System.IO.Stream* type.

```
using System.Xml;
using CMS.IO;
...
Stream myStream = null;
XmlWriter xml = null;

myStream = FileStream.New("MyFile.xml", FileMode.Append);
xml = XmlWriter.Create(GeneralStream.New(myStream));
```

The example creates a *XmlWriter* object from a *CMS.IO.Stream*. Since *XmlWriter* is a system object, it expects that its *Create* method will be supplied with a *System.IO.Stream*. An instance of the *GeneralStream* class, which inherits from *System.IO.Stream*, has to be passed to the method, as shown on the highlighted line.

Helper methods

CMS.IO contains a number of additional methods and properties, which simplify operations with files and directories. The following list describes the most useful methods:

DirectoryHelper

- **void DeleteDirectoryStructure(string path)** - deletes the directory specified by the **path** parameter and all underlying directories.
- **void EnsureDiskPath(string path, string startingPath)** - checks whether all directories between **startingPath** and **path** exist and creates them if necessary.
- **void EnsurePathBackslash(string path)** - adds a backslash to the end of the **path** specified if the backslash is missing.

Directory

- **void PrepareFilesForImport(string path)** - converts all physical media files' names to lower case to ensure compatibility with case-sensitive file systems.

StorageHelper

- **IsExternalStorage** - this property indicates if the application is using a storage other than the default Windows file system. Returns **true** if the **CMSExternalStorageName** web.config key is set.
- **ExternalStorageName** - this property returns the name of the storage provider set by **CMSExternalStorageName** web.config key. See the [Configuration](#) section of the next chapter for more information.

The complete list of CMS.IO members can be found in the [Kentico CMS API Reference](#).

10.8.3 Writing a custom storage provider

The purpose of the CMS.IO library is to provide an easy way of customizing Kentico CMS to support a file system of your choice. As described in the [Overview topic](#), you can achieve this by developing a custom provider based on the classes contained within CMS.IO.

Preparation

A generic storage provider project is available in the CodeSamples directory in your Kentico CMS installation (e.g. C:\Program Files (x86)\Kentico CMS\7.0). The project contains definitions of all required classes and their members for easy implementation.

1. Copy the generic project folder (**CustomFileSystemProvider**) into your web project folder.
2. Choose to **add an existing project** to your web project solution and select the custom storage provider.
3. Add **CMS.IO** reference to the new project.
4. Add the project reference to your web project.

Implementation

If you choose to take advantage of the prepared provider, go through all files contained in the project and replace the *NotImplementedExceptions* inside methods with your implementation and implement property and method overrides. You can consult the following steps for reference or if you wish to create a provider from scratch.

1. Create classes that will inherit from the following abstract classes:
 - CMS.IO.AbstractDirectory
 - CMS.IO.AbstractFile
2. Implement all methods defined in those abstract classes.
3. Create classes that will inherit from the following classes:
 - CMS.IO.DirectoryInfo
 - CMS.IO.FileInfo
 - CMS.IO.FileStream

4. Override all methods and properties from those classes.
5. Create constructors for the classes listed previously according to the following table:

| Inherits from | Constructors |
|----------------------|--|
| CMS.IO.DirectoryInfo | <ul style="list-style-type: none"> • public DirectoryInfo(string path) |
| CMS.IO.FileInfo | <ul style="list-style-type: none"> • public FileInfo(string filename) |
| CMS.IO.FileStream | <ul style="list-style-type: none"> • public FileStream(string path, CMS.IO.FileMode mode) • public FileStream(string path, CMS.IO.FileMode mode, CMS.IO.FileAccess access) • public FileStream(string path, CMS.IO.FileMode mode, CMS.IO.FileAccess access, CMS.IO.FileShare share) • public FileStream(string path, CMS.IO.FileMode mode, CMS.IO.FileAccess access, CMS.IO.FileShare share, int bufferSize) |

Configuration

To start using your custom provider, you need to make configuration changes in your web.config file.

1. Add the **CMSStorageProviderAssembly** key to the *appSettings* section and set its value to the assembly name of your custom provider.
2. Add the **CMSExternalStorageName** key to the *appSettings* section. You can choose any string of characters as a value. The value will be used in code to determine whether the application uses an external storage. See [Using CMS.IO](#) for more information about the code that processes the storage name.

For example, if you named the project "**CustomFileSystemProvider**" and the provider name is "**custom**", the code inserted into the *web.config* file will look like the following:

```
<appSettings>
...
  <add key="CMSStorageProviderAssembly" value="CustomFileSystemProvider" />
  <add key="CMSExternalStorageName" value="custom" />
...
</appSettings>
```

After you save the web.config, the system starts using your custom provider.

10.8.4 Configuring storage providers

Using different storage providers for specific parts of the application's file repository

CMS.IO allows you to access different sections of the application's file repository using different [storage providers](#). For example, you can store media files in the Azure blob storage, while all other files stay in the default Windows file system.

1. Open the **CMSHttpApplication.cs** file from the *App_Code\Application* folder.
2. Add a *using* statement for **CMS.IO**.
3. In the **Application_Start** method, create a new instance of the **StorageProvider** class.

```
AbstractStorageProvider mediaProvider = new StorageProvider("Azure",  
"CMS.AzureStorage");
```

The value in the **first parameter** must match the value of the **CMSExternalStorageName** settings key value of the provider that you want to use. The value in the **second parameter** must match the **assembly name** of the provider. Use the constructor without parameters to create an instance of **CMSStorage** - the provider for Windows file system. See the table in [Storage provider names and assemblies](#) for values belonging to built-in storage providers.

4. Use the following code to map a directory to the provider you've instantiated in step 3.

```
StorageHelper.MapStoragePath("~/MySite/Media/", mediaProvider);
```

5. Save the file.
6. If you're using web application, rebuild the solution.

The application now uses the storage provider specified in step 3 to access the project folder specified in step 4.

Changing paths to content files

CMS.IO allows you to change default file paths. For example, when using the Windows file system, you can store media files on a different disk drive.

You utilize a similar procedure to [store files in a different container in Azure storage](#) or to [store files in a different bucket on Amazon S3](#).

1. Open the **CMSHttpApplication.cs** file from the *App_Code\Application* folder.
2. Add a *using* statement for **CMS.IO**.
3. In the **Application_Start** method, create a new instance of the **StorageProvider** class.

```
AbstractStorageProvider mediaProvider = new StorageProvider();
```

Use the constructor without parameters to create an instance of **CMSStorageProvider** - the provider for Windows file system. Otherwise, the method expects two string parameters. The value in the **first parameter** must match the value of the **CMSExternalStorageName** settings key value of the provider that you want to use. The value in the **second parameter** must match the **assembly name** of the provider. See the table in [Storage provider names and assemblies](#) for values belonging to built-in storage

providers.

4. Specify the target directory using the **CustomRootPath** property of the provider. This is the directory that you want to use instead of the default one.

```
mediaProvider.CustomRootPath = "D:\MySiteMedia";
```

5. (Optional) If the custom path is accessible via a URL (i.e. it is located on a file server), you can make the system access files via that URL. Insert the following code.

```
mediaProvider.CustomRootUrl = "http://www.example.com/MySiteMedia";
```

6. Use the following code to map a directory to the provider you've instantiated in step 3. This is the directory that you want to change.

```
StorageHelper.MapStoragePath("~/MySite/Media/", mediaProvider);
```

7. Save the file.

8. If you're using web application, rebuild the solution.

This code ensures that every time the application requests a file from the `~/MySite/Media` directory, the file will be served from the location specified in the `CustomRootPath` property. If you specified the `CustomRootUrl` property, links to the file will point to that URL.

Storage provider names and assemblies

The following table lists storage providers built into Kentico CMS, the [CMSExternalStorageName](#) setting values associated with the providers, and the assemblies where the providers reside.

| Storage provider | CMSExternalStorageName value | Assembly |
|--|------------------------------|-------------------|
| Amazon S3 | Amazon | CMS.AmazonStorage |
| Azure blob storage | Azure | CMS.AzureStorage |
| Windows file system (default provider) | - | CMS.CMSStorage |

10.8.4.1 Azure storage

Configuring Kentico CMS to use Azure storage

1. Add the following key into the **appSettings** section of your web.config. The key indicates that CMS.IO should use the Azure storage provider to access files.

```
<add key="CMSExternalStorageName" value="azure" />
```

2. Specify the storage account name by inserting the following key into the web.config.

```
<add key="CMSAzureAccountName" value="AccountName" />
```

3. Specify the primary access key by adding the following key into the web.config.

```
<add key="CMSAzureSharedKey" value="PrimaryAccessKey" />
```

Optionally, you can adjust the following properties:

| Key | Description | Sample Value |
|-------------------------|--|---|
| CMSAzureTempPath | The folder specified by this key will be used to store temporary files on a local disk, e.g. when transferring large files to or from the storage account. | <pre><add key="CMSAzureTempPath" value="C:\AzureTemp" /></pre> |
| CMSAzureCachePath | Specifies a folder on a local disk where files requested from the storage account will be cached. This helps minimize the amount of blob storage operations, which saves time and resources. | <pre><add key="CMSAzureCachePath" value="C:\AzureCache" /></pre> |
| CMSAzureBlobEndPoint | Sets the endpoint used for the connection to the blob service of the specified storage account. If you wish to use the default endpoint, remove the setting completely from the appropriate files. | <pre><add key="CMSAzureBlobEndPoint" value="http://127.0.0.1:10000/devstoreaccount1" /></pre> |
| CMSAzurePublicContainer | Indicates if the blob container used to store the application's file system should be public. If set to <i>true</i> , it will be possible to access files directly through the URL of the appropriate blob service, for example:

<i>http://<StorageAccountName>.blob.core.windows.net/cmsroot/corporatesite/media/imagelibrary/logo.png</i> | <pre><add key="CMSAzurePublicContainer" value="true" /></pre> |

| | | |
|---------------------|---|--|
| CMSAzureCDNEndpoint | URL of the HTTP endpoint of a Azure Blob storage CDN. | <code><add key="CMSAzureCDNEndpoint" value="kenticoc123.vo.msecnd.net" /></code> |
|---------------------|---|--|

Storing files in different containers

By default, the system stores files in a single container. However, the built-in Azure storage provider allows you to specify sections of the file system, which will be stored in a different container.

1. Open the **CMSHttpApplication.cs** file from the *App_Code\Application* folder.
2. Add a *using* statement for **CMS.IO**.
3. In the **Application_Start** method, create a new instance of the Azure storage provider.

```
AbstractStorageProvider mediaProvider = new StorageProvider("Azure",  
"CMS.AzureStorage");
```

4. Specify the target container using the **CustomRootPath** property of the provider.

```
mediaProvider.CustomRootPath = "mymediacontainer";
```

Optionally, you can specify whether you want the container to be publicly accessible using the **PublicExternalFolderObject** property of the provider. *True* means the container is publicly accessible.

```
mediaProvider.PublicExternalFolderObject = true;
```

5. Use the following code to map a directory to the provider you've instantiated in step 3. This is the directory that you want to store in the container.

```
StorageHelper.MapStoragePath("~/MySite/Media/", mediaProvider);
```

6. Save the file.
7. If you're using web application, rebuild the solution.

10.8.4.2 Amazon S3

Configuring Kentico CMS to use Amazon S3

1. Make sure you that have your Amazon S3 account set up and and that you have created at least one bucket.
2. Add the following key into the **appSettings** section of your web.config. This key specifies that CMS.IO will use the Amazon S3 provider..

```
<add key="CMSExternalStorageName" value="amazon" />
```

3. Add the following key into the **appSettings** section of your web.config. This key specifies the bucket which you want to use to store files. Replace the value with the name of the bucket.

```
<add key="CMSAmazonBucketName" value="YourBucketName" />
```

4. Specify the ID of your Amazon access key by inserting the following key into the **appSettings** section of your web.config.

```
<add key="CMSAmazonAccessKeyID" value="YourKey" />
```

5. Specify the Amazon access key by adding the following key into the **appSettings** section of your web.config.

```
<add key="CMSAmazonAccessKey" value="YourSecret" />
```

After you save your web.config, Kentico CMS starts storing its files in the specified Amazon S3 bucket.

You can configure the following optional settings:

| Key | Description | Sample Value |
|-----------------------|--|---|
| CMSAmazonTempPath | Path to a local directory that will be used for storing temporary files. If you don't specify a value, the provider will use the default operating system temporary directory. | <pre><add key="CMSAmazonTempPath" value="C:\Windows\Temp" /></pre> |
| CMSAmazonCachePath | Path to a local directory where the provider will store cached files. If you don't use this setting, the system will create a directory in the default operating system temporary directory. | <pre><add key="CMSAmazonCachePath" value="C:\Cache" /></pre> |
| CMSAmazonEndPoint | Allows to change the default endpoint, for example when you want to use CloudFront CDN.

The default endpoint address is <i>http://<yourbucketname>.s3.amazonaws.com</i> | <pre><add key="CMSAmazonEndPoint" value="http://someendpoint.s3.amazonaws.com" /></pre> |
| CMSAmazonPublicAccess | Specifies whether files uploaded to Amazon S3 through Kentico CMS will be accessible for public users.

The default value is true if you specify an endpoint. If no endpoint is specified, the | <pre><add key="CMSAmazonPublicAccess" value="true" /></pre> |

| | | |
|--|-------------------------|--|
| | default value is false. | |
|--|-------------------------|--|

Storing files in different buckets

By default, the system stores files in a single bucket. However, the built-in Amazon S3 storage provider allows you to specify sections of the file system, which will be stored in a different bucket.

1. Open the **CMSHttpApplication.cs** file from the *App_Code\Application* folder.
2. Add a *using* statement for **CMS.IO**.
3. In the **Application_Start** method, create a new instance of the Amazon S3 storage provider.

```
AbstractStorageProvider mediaProvider = new StorageProvider("Amazon",  
"CMS.AmazonStorage");
```

4. Specify the target bucket using the **CustomRootPath** property of the provider.

```
mediaProvider.CustomRootPath = "mymediabucket";
```

Optionally, you can specify whether you want the bucket to be publicly accessible using the **PublicExternalFolderObject** property of the provider. *True* means the bucket is publicly accessible.

```
mediaProvider.PublicExternalFolderObject = true;
```

5. Use the following code to map a directory to the provider you've instantiated in step 3. This is the directory that you want to store in the bucket.

```
StorageHelper.MapStoragePath("~/MySite/Media/", mediaProvider);
```

7. Save the file.
8. If you're using web application, rebuild the solution.

10.9 Global events and their handling

10.9.1 Global events

Global events allow you to execute custom actions when some CMS event occurs. For example, if a document is created in the CMS system, you can handle the corresponding event, get information about the new document and send its content by e-mail or use a third-party component to generate a PDF version of the document.

**Please note**

If you are accustomed to using custom handler libraries, please note that these global events provide the same functionality in a much simpler way. You can refer to the [Global events \(obsolete\)](#) topic to see the difference between the two approaches.

Handler classes

Modules with handlers contain classes with "Events" in their name, which provide the available handlers. They may also contain classes that store the handler arguments or handler results. The following are samples of classes that are available:

- **<name>EventArgs** - e.g., *DocumentEventArgs*, is an object that contains only properties and is used to store event data. It inherits from the *System.EventArgs* class.
- **<name>Events** - e.g., *DocumentEvents*, is a static class containing definitions of handlers for various events as static properties.

Registering event handlers

Registration of handlers for events can be performed by creating a custom class in the *App_Code* folder, which eliminates the need to add a dedicated handler library and update it when performing upgrades to new versions. The class needs to extend the *CMSModuleLoader* partial class and a new attribute must be added to it. In the *Init()* method of a private class representing the attribute, handlers can be assigned to the required events in the following format:

<event class>.<action>.<before or after> += <handler name>

The definitions of the handlers can then be added directly into the attribute class as shown in the example below:

[C#]

```
using CMS.DocumentEngine;
using CMS.SettingsProvider;

[CustomDocumentEvents]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Attribute class that ensures the loading of custom handlers
    /// </summary>
    private class CustomDocumentEventsAttribute : CMSLoaderAttribute
    {
        /// <summary>
        /// Called automatically when the application starts
        /// </summary>
        public override void Init()
        {
            // Assigns custom handlers to the appropriate events
        }
    }
}
```

```
        DocumentEvents.Insert.After += Document_Insert_After;
        DocumentEvents.InsertLink.Before += Document_InsertLink_Before;
    }

    private void Document_Insert_After(object sender, DocumentEventArgs e)
    {
        // Add custom actions here
    }

    private void Document_InsertLink_Before(object sender, DocumentEventArgs
e)
    {
        // Add custom actions here
    }
}
```

Events that you can handle

You can use the following event classes and their respective events. These events cover data management for both objects and documents.

- **ObjectEvents** - contains events fired upon any object change. Replaces the old *CustomDataHandler*. These events are fired for any object type in the system.
 - Insert - fired upon the insertion of a new object.
 - Update - fired upon the update of the existing object.
 - Delete - fired upon the object deletion.
 - GetContent - provides the additional object content to the search indexer.
 - [LogChange](#) - allows you to alter how the system logs object changes for the purposes of staging and integration.
- **<name>Info.TYPEINFO.Events** - provides the same set of events as *ObjectEvents*, but specific for a particular object type, for example *UserInfo.TYPEINFO.Events*.
- **ColumnTranslationEvents** - contains handlers that you can use to store objects' IDs to ensure the IDs' translation during import/export and [staging](#).
 - RegisterRecords - using this handler you can provide additional information for your custom field translation.
 - TranslateColumns - using this handler you can translate the field value using the provided info.
- **DocumentEvents** - contains events fired when changes are made to documents. These events relate to the published versions of documents, refer to *WorkflowEvents* for actions within editing of the documents under workflow. Replaces the old *CustomTreeNodeHandler*.
 - Insert - fired upon insertion of a new document.
 - InsertNewCulture - fired upon insertion of a new document culture version.
 - InsertLink - fired upon insertion of a new document link.
 - Update - fired upon update of any document.
 - Delete - fired upon deletion of any document.
 - Move - fired upon moving of any document.
 - Copy - fired upon copying of any document.
 - GetContent - provides additional document content to the search indexer.
 - [LogChange](#) - allows you to alter the way document changes are being logged.

- **NewsletterEvents** [*Only available after applying [hotfix 7.0.52](#) or newer*]
 - ResolveMacro - fired when all newsletter text macros are being resolved.
- **SystemEvents** - contains general system events, replaces the old *CustomExceptionHandler*.
 - Exception - fired when unhandled exception occurs.
- **SecurityEvents** - contains security and authentication events, replaces the old *CustomSecurityHandler*.
 - Authenticate - fired upon user authentication.
 - AuthorizeResource - fired upon security check for particular module permission.
 - AuthorizeClass - fired upon security check for particular object type or document type permission.
 - AuthorizeUIElement – fired upon permission check for particular UI element.
- **ActivityEvents** [*Only available after applying [hotfix 7.0.46](#) or newer*]
 - ActivityLogged - fired immediately when [on-line marketing activities](#) of any type occur in the system. The event does not trigger for custom activities logged using the *ActivityInfoProvider.SetActivityInfo* method.
- **WorkflowEvents** – contains events related to specific [workflow and versioning](#) actions, replaces the old *CustomWorkflowHandler*.
 - Approve – fired when a document is approved to the next step.
 - Reject – fired when a document is rejected to a previous step
 - Publish – fired when a document is being published.
 - Archive – fired when a document is being archived.
 - Action – fired when a workflow action step is being executed.

The following events are specific to [content locking](#) within versioning.

- CheckOut – fired when the document is checked-out.
- CheckIn – fired when the document is checked-in.
- UndoCheckOut – fired when undoing the check-out is performed on the document.

The following events are specific to updating a document version.

- SaveVersion – fired when the edited version of the document is updated.
- SaveAttachmentVersion – fired when the attachment of the edited version of the document is updated or inserted.
- RemoveAttachmentVersion – fired when the attachment of the edited version of the document is removed.

The following events are related to [document attachments](#):

- SaveAttachment – fired upon insertion or update of document attachment.
- DeleteAttachment – fired upon deletion of document attachment.

The following events are related to customizing document [security](#):

- AuthorizeDocument – fired when security check for particular document is requested.
- FilterDataSetByPermissions – fired when the DataSet of documents is filtered according the document permissions.

Application events

There are several sets of application events that you can leverage to customize the global behavior of the application, these are following:

- **CMSSessionEvents** – contains events related to session management of the application.
 - Start – fired when the session starts
 - End – fired when the sessions ends.
- **CMSApplicationEvents** – contains events related to the whole application run.
 - Start – fired when the application starts. It is recommended to bind only *After* handlers to make sure your handler has all necessary data initialized.
 - End – fired when the application ends.
 - Error – fired when application error occurs. Similar to SystemEvents.Exception, except for that this one covers wider range of handling code.
- **CMSRequestEvents** – contains events related to each request done to the application.
 - Begin – fired when the begin request method executes.
 - End - fired when the end request method executes.
 - Authenticate - fired when the authenticate request method executes.
 - Authorize - fired when the authorize request method executes.
 - MapRequestHandler- fired when the map request handler method executes.
 - AcquireRequestState - fired when the acquire request state method executes.

Control and page events

The last set of events is related to the life cycle of pages and controls. These events have their respective handlers directly in the base classes of pages and controls. You can leverage them to programatically customize the UI without the need to modify the original code of the solution. Please note that these events are direct delegates and do not provide *Before / After* sub-items.

- **AbstractUserControl** - contains events that are fired during processing of user controls.
 - OnBeforeUserControlInit
 - OnAfterUserControlInit
 - OnBeforeUserControlLoad
 - OnAfterUserControlLoad
 - OnBeforeUserControlPreRender
 - OnAfterUserControlPreRender
 - OnBeforeUserControlRender
 - OnAfterUserControlRender
- **CMSPage** - contains events that are fired within processing of the system pages.
 - OnBeforePagePreInit
 - OnAfterPagePreInit
 - OnBeforePageInit
 - OnAfterPageInit
 - OnBeforePageLoad
 - OnAfterPageLoad
 - OnBeforePagePreRender
 - OnAfterPagePreRender
 - OnBeforePageRender
 - OnAfterPageRender

10.9.2 LogChange handler

By default, Kentico logs changes that you make to objects and documents. You can use the *LogChange* handler to affect logging of these changes for tasks such as [staging](#) or [integration](#).

Excluding documents

In the following example, you can see the use of the *LogChange* handler to exclude documents contained under the "/Home" path from [staging](#).

For more information on registering handlers, visit the [Global events topic](#).

[C#]

```
using System;

using CMS.DocumentEngine;
using CMS.SettingsProvider;

/// <summary>
/// Exclude documents under '/Home' path from staging.
/// </summary>
[CustomDocumentEvents]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Ensure the loading of custom handlers
    /// </summary>
    private class CustomDocumentEventsAttribute : CMSLoaderAttribute
    {
        /// <summary>
        /// Called automatically when the application starts
        /// </summary>
        public override void Init()
        {
            // Assign custom handlers to the appropriate events
            DocumentEvents.LogChange.Before += new
            EventHandler<LogDocumentChangeEventArgs>(LogDocumentChange_Before);
        }

        void LogDocumentChange_Before(object sender, LogDocumentChangeEventArgs e)
        {
            var document = e.Settings.Node;
            if (document.NodeAliasPath.StartsWith("/Home"))
            {
                e.Settings.LogStaging = false;
            }
        }
    }
}
```

Excluding objects

In the following example, you can see the use of the *LogChange* handler to exclude objects of the object type "role" whose code name starts with "CMS" from [staging](#).

For more information on registering handlers, visit the [Global events topic](#).

[C#]

```
using System;

using CMS.SettingsProvider;

/// <summary>
/// Exclude objects of the object type 'role' whose code name starts with 'CMS'
/// from staging.
/// </summary>
[CustomObjectEvents]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Ensure the loading of custom handlers
    /// </summary>
    private class CustomObjectEventsAttribute : CMSLoaderAttribute
    {
        /// <summary>
        /// Called automatically when the application starts
        /// </summary>
        public override void Init()
        {
            // Assign custom handlers to the appropriate events
            ObjectEvents.LogChange.Before += new
            EventHandler<LogObjectChangeEventArgs>(LogObjectChange_Before);
        }

        void LogObjectChange_Before(object sender, LogObjectChangeEventArgs e)
        {
            var obj = e.Settings.InfoObj;
            if ((obj.ObjectType == PredefinedObjectType.ROLE) &&
                (obj.ObjectCodeName.StartsWith("CMS")))
            {
                e.Settings.LogStaging = false;
            }
        }
    }
}
```

10.9.3 Translation handlers

When transferring data to a different instance of Kentico — via import/export or [staging](#) — IDs of the same objects can differ after the transfer. Kentico handles the situation for system objects, but not for custom objects. For example, when you stage a document type or a custom table that has a field containing object IDs, then the IDs are not guaranteed to stay the same once staged to the target server.

You can use the following two handlers to make sure the IDs are translated correctly:

RegisterRecords - use this handler to provide additional information for your custom field translation.

TranslateColumns - use this handler to translate the field value using the provided information.

Example

You have a custom table that contains a UserID field. The field contains the ID of a user to whom the item belongs. Because the UserID field is a custom field, you want to ensure its correct translation during import/export and [staging](#).

1. [See how you can register the handlers](#).
2. Use the following code to ensure the correct translation of the UserID field.

[C#]

```
using System;

using CMS.SettingsProvider;
using CMS.GlobalHelper;
using CMS.SiteProvider;

/// <summary>
/// Ensure translation of UserID column in a custom table item
/// </summary>
[CMSModuleLoaderAttribute]
public partial class CMSModuleLoader
{
    private class CMSModuleLoaderAttribute : CMSLoaderAttribute
    {
        public override void Init()
        {
            // Register the events
            ColumnsTranslationEvents.RegisterRecords.Execute += new
            EventHandler<ColumnsTranslationEventArgs>(RegisterRecords_Execute);
            ColumnsTranslationEvents.TranslateColumns.Execute += new
            EventHandler<ColumnsTranslationEventArgs>(TranslateColumns_Execute);
        }

        void RegisterRecords_Execute(object sender, ColumnsTranslationEventArgs e)
        {
            if (e.ObjectType == CustomTableItemProvider.GetObjectType(
                "customtable.sampletable"))
            {
                // Register the object type, user ID, and username for custom
                field translation
                int userId = ValidationHelper.GetInteger(e.Data.GetValue(
                    "UserID"), 0);
                e.TranslationHelper.RegisterRecord(PredefinedObjectType.USER,
                    userId, UserInfoProvider.GetUserNameById(userId), 0);
            }
        }

        void TranslateColumns_Execute(object sender, ColumnsTranslationEventArgs
            e)
        {
            if (e.ObjectType == CustomTableItemProvider.GetObjectType(
                "customtable.sampletable"))
            {
```

```
        // Translate the field using the column name, User ID, and object
type of user
        e.TranslationHelper.TranslateColumn(e.Data, "UserID",
PredefinedObjectType.USER, 0, true, true);
    }
}
}
```

10.9.4 Event handler libraries (obsolete)

10.9.4.1 Overview

Obsolete!

This way of event handling is now obsolete. It is still functional due to backward compatibility reasons, but the recommended way is to use the [global event handlers](#).

Events that can be handled

- [Data updates](#) - insert/update/delete actions for all data items.
- [Exceptions](#)
- [Security events](#) - authentication and authorization.
- [Document events](#) - insert/update/delete/logchange operations.
- Object events - insert/update/logchange operations.
- [Workflow events](#) - document approval/rejection/publishing/archiving operations.

Enabling custom event handling

If you want to use custom event handlers, make sure the `<appSettings>` node of your web project's `web.config` file contains the following key:

```
<add key="CMSUseCustomHandlers" value="true" />
```

Default event handler library

The default custom event handler library is **CMS.CustomEventHandler**. Its name can be changed by means of a parameter in the `<appSettings>` node of your project's `web.config` file.

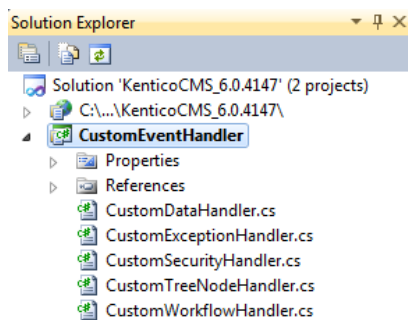

If the following line is inserted in the `<appSettings>` node, the library name will be changed to `CMS.CustomEventHandlerVB`:

```
<add key="CMSCustomHandlersAssembly" value="CMS.CustomEventHandlerVB" />
```

If you wanted to use this library in the following series of examples, it would require you to write the code in Visual Basic instead of C#.

Writing an event handler

1. Copy the **CustomEventHandler** project from the Kentico CMS installation directory (typically *C:\ProgramFiles\KenticoCMS\<version_number>\CodeSamples\CustomEventHandler*) to any custom folder that is not under the root of your web project (e.g. *C:\customhandler*).
2. Open the **CMS** web project using the **WebProject.sln** file. Click **File -> Add -> Existing Project** and select the **CustomEventHandler.csproj** file located in the folder where you copied the **CustomEventHandler** project. Your Solution Explorer window should look like this:

3. Unfold the **References** section under the **CustomEventHandler** project and remove all invalid references (marked with the yellow exclamation icon).
4. Now you need to update the references. Right-click the **bin** folder and choose **Add Reference**. Choose the **Projects** tab and click **OK** to add a reference to the **CustomEventHandler** project:

5. Now right-click the **CustomEventHandler** project and choose **Add Reference**. Choose the **Browse** tab and locate the **bin** folder of your CMS web project on the disk. Choose to add a reference to the following libraries:

- CMS.GlobalEventHelper.dll
- CMS.DocumentEngine.dll
- CMS.GlobalHelper.dll
- CMS.SiteProvider.dll
- CMS.CMSHelper.dll
- CMS.SettingsProvider.dll
- CMS.Synchronization.dll
- CMS.DataEngine.dll
- CMS.EmailEngine.dll
- CMS.WorkflowEngine.dll

You can also navigate to the **bin** folder on the **Browse** tab and copy&paste the following string into the **Add Reference** dialog to add all the libraries.

```
"CMS.GlobalEventHelper.dll" "CMS.DocumentEngine.dll" "CMS.GlobalHelper.dll"  
"CMS.SiteProvider.dll" "CMS.CMSHelper.dll" "CMS.SettingsProvider.dll"  
"CMS.Synchronization.dll" "CMS.DataEngine.dll" "CMS.EmailEngine.dll"  
"CMS.WorkflowEngine.dll"
```

If you need to use another library in your custom handlers, please add a reference to it the same way as described in this step.

6. Click **Build -> Rebuild solution**.

Now you can modify the libraries under the **CustomEventHandler** project and add your own code to handle the appropriate events. The places where you should place the code are marked with upper-case comments.

You can find more details on particular events in the following chapters.

10.9.4.2 Data handler (CustomDataHandler class)

This handler allows you to add custom actions to the following events:

- OnBeforeUpdate
- OnAfterUpdate
- OnBeforeInsert
- OnAfterInsert
- OnBeforeDelete
- OnAfterDelete
- OnGetContent

The events are applied to all data items that are stored to the database. It includes documents, user information or any other settings. They receive the data object of type **DataClass** that can be modified. In case of delete handlers, the class name and ID is provided.

Handling document events

For handling document events, please use the CustomTreeNodeHandler class instead

of the CustomDataHandler class. Every document uses up to 3 tables, which leads to three separate events in the CustomDataHandler class.

Example

The following example shows how to handle the OnAfterUpdate event and send the password to the user whenever their profile is updated:

1. Open the **CustomDataHandler** class and put the following code at the beginning of the file. It adds the reference to the namespaces we will use to handle the event:

[C#]

```
using CMS.DataEngine;  
using CMS.GlobalHelper;  
using CMS.EmailEngine;
```

2. Put the following code inside the **OnAfterUpdate** method.

[C#]

```
// type the data object as DataClass  
IDataClass dataItem = (IDataClass)dataObj;  
  
// we want to handle only updates of user objects  
if (dataItem.ClassName.ToLower() == "cms.user")  
{  
    // we will use the CMS.EmailProvider to send e-mails  
    EmailMessage email = new EmailMessage();  
    email.From = "admin@domain.com";  
    // get the user's e-mail address  
    email.Recipients = ValidationHelper.GetString(dataItem.GetValue("Email"),  
    "admin@domain.com");  
    email.Subject = "Your password";  
    // get the user's password  
    email.Body = "Your password is:" + ValidationHelper.GetString(dataItem.GetValue  
    ("UserPassword"), "");  
    EmailSender.SendEmail(email);  
}
```

Please note: getting user's password in the example above is only possible when passwords are stored in Plain text format; the setting is located in **Site Manager -> Settings -> Security & Membership**.

3. Set the From and Recipients e-mail addresses to your e-mail address.
4. If you don't have reference to CMS.EmailEngine in your CustomEventHandler, add it there.
5. Compile and run the project. Edit some user profile that uses your e-mail address. You should receive the e-mail message with your password.

10.9.4.3 Exception handler (CustomExceptionHandler class)

This class processes all **exceptions** that occur in the web application. You can use it to handle all exceptions and run custom actions, such as sending e-mail to administrator or logging the exception to your helpdesk or monitoring system.

The class has only one method: **OnException(Exception e)**

Example

The following example shows how to handle the OnException event and send the password to the administrator whenever an error occurs:

1. Open the **CustomExceptionHandler** class and put the following code at the beginning of the file. It adds the reference to the namespaces we will use to handle the event:

[C#]

```
using CMS.EmailEngine;
```

2. Put the following code inside the **OnException** method.

[C#]

```
// we will use the CMS.EmailProvider to send e-mails
EmailMessage email = new EmailMessage();
email.From = "admin@domain.com";
email.Recipients = "admin@domain.com";
email.Subject = "Exception";
email.Body = e.Message + "<br />" + e.StackTrace + "<br />" + e.Source;
EmailSender.SendEmail(email);
```

3. Set the From and Recipients e-mail addresses to your e-mail address.

4. Compile and run the project. Now, when some exception occurs or is raised by your code, the e-mail with exception details will be sent.

10.9.4.4 Security handler (CustomSecurityHandler class)

The security handler allows you to integrate external user databases and modify the authentication and authorization process.

Any code added to the handlers is executed after the standard authentication or authorization checks performed by the system.

The class contains handlers for the following events:

- **OnAuthentication** - triggered when a user attempts to sign in with a name and password.
- **OnResourceAuthorization** - triggered when the system checks if a user is authorized to access a module.
- **OnUIElementAuthorization** - triggered when the system checks if a [UI element](#) should be

displayed to a user.

- **OnClassNameAuthorization** - triggered when the system checks if a user is authorized to access a particular [document type](#).
- **OnTreeNodeAuthorization** - triggered when the system checks if a user is authorized to access a document in the content tree.
- **OnFilterDataSetByPermissions** - triggered when a DataSet is filtered according to the permissions or custom personalization rules of the current user.

Example

In the following example, you will learn how to integrate external user authentication using the custom security handler.

The handler of the **OnAuthentication** event will be used for this purpose. It has the following parameters:

- **object userInfo** - an object representing the user attempting to log in. This object is returned as the result of the standard authentication check performed by the system. It is *null* if the default authentication failed.
- **string username** - a string containing the username entered during the login attempt.
- **string password** - a string containing the password entered during the login attempt.

The handler must return an object representing the user if external authentication using the entered credentials is successful, or *null* to indicate that authentication failed.

Now modify the code of the **OnAuthentication** handler according to the following:

[C#]

```
public override object OnAuthentication(object userInfo, string username, string
password)
{
    // Check if the user was authenticated by the system
    if (userInfo != null)
    {
        return userInfo;
    }

    // Sample external user credentials
    UserInfo usr = null;

    // Authenticate against the external source
    if ((username.ToLower() == "externaluser") && (password == "pass"))
    {
        // Create base user record if external authentication is successful
        usr = new UserInfo();
        usr.IsExternal = true;
        usr.UserName = username;
        usr.FullName = "externaluser fullname";
        usr.Enabled = true;
    }

    // Return the user info object
    return usr;
}
```

```
}
```

For simplicity, the example does not use any particular database. Instead, it only checks if the current user name and password are equal to some constants. In a real-world scenario, you would need to replace this condition with code that checks if the user name with the given password is authenticated against your external database. Also, instead of simply assigning the user to a role named *external role*, you would have to implement code that checks the external database for any roles that the authenticated user is a member of and assigns them dynamically.

Once this is done, save the changes and **Build** the **CustomEventHandler** project. The system will now be able to perform authentication according to user data from an external source.

The roles created during this external authentication will not have any permissions assigned by default, so they will not authorize the user to perform any actions. You can programmatically check if a user belongs to a role using the **CMS.CMSHelper.CurrentUserInfo.IsInRole(string roleName, string siteName)** method and implement your own security logic in the other event handlers under the **CustomSecurityHandler** class.

However, we recommend importing all external roles into the **CMS_Role** table of the website's Kentico database. Then you can configure the appropriate permissions for these roles. This way, you will be able to fully use the built-in security model of Kentico CMS together with external users.

10.9.4.5 **TreeNode handler (CustomTreeNodeHandler class)**

The CustomTreeNodeHandler class allows you to execute custom actions when a document (TreeNode) is created, updated or deleted. It's useful if you need to synchronize changes to external systems, generate off-line version of the document in PDF, etc.

It handles the following events:

- OnBeforeInsert
- OnAfterInsert
- OnBeforeUpdate
- OnAfterUpdate
- OnBeforeDelete
- OnAfterDelete
- OnBeforeMove
- OnAfterMove
- OnBeforeCopy
- OnAfterCopy
- OnBeforeInsertNewCultureVersion
- OnAfterInsertNewCultureVersion

Example

The following example shows how to handle the OnAfterInsert event and send the newly added news item by e-mail:

1. Open the **CustomTreeNodeHandler** class and put the following code at the beginning of the file. It adds the reference to the namespaces we will use to handle the event:

[C#]

```
using CMS.DocumentEngine;  
using CMS.GlobalHelper;  
using CMS.EmailEngine;
```

2. Put the following code inside the **OnAfterInsert** method.

[C#]

```
// type the document as TreeNode  
TreeNode newsDoc = (TreeNode)treeNodeObj;  
  
// handle the event only for news items  
if (newsDoc.NodeClassName.ToLower() == "cms.news")  
{  
    // get content of the inserted news item and send it by e-mail  
    EmailMessage email = new EmailMessage();  
    email.From = "admin@domain.com";  
    email.Recipients = "admin@domain.com";  
    email.Subject = ValidationHelper.GetString(newsDoc.GetValue("NewsTitle"), "");  
    email.Body = ValidationHelper.GetString(newsDoc.GetValue("NewsSummary"), "");  
    EmailSender.SendEmail(email);  
}
```

3. Set the From and Recipients e-mail addresses to you e-mail address.

4. Compile and run the project. Create a new document of type News. You should receive the e-mail message with it text.

How to avoid neverending loops

If you need to call `TreeNode.Update` in the event handler (e.g. in the `OnAfterUpdate` event), you need to set **TreeProvider.UseCustomHandlers** property to false before calling the Update method.

10.9.4.6 Workflow handler

The workflow handler allows you to handle the following events:

- `OnBeforeCheckOut` - before document is checked out
- `OnAfterCheckOut` - after document is checked out
- `OnBeforeCheckIn` - before document is checked in
- `OnAfterCheckIn` - after document is checked in
- `OnBeforeApprove` - before document is approved
- `OnAfterApprove` - after document is approved
- `OnBeforeReject` - before document is rejected
- `OnAfterReject` - after document is rejected
- `OnBeforePublish` - before document is published
- `OnAfterPublish` - after document is published

When the document is published, the order of the events is following:

1. OnBeforeApprove
2. OnBeforePublish
3. OnAfterPublish
4. OnAfterApprove

Example

The following example shows how to send an e-mail with news document content when it's published:

1. Open the **CustomWorkflowHandler** class and put the following code at the beginning of the file. It adds the reference to the namespaces we will use to handle the event:

[C#]

```
using CMS.DocumentEngine;  
using CMS.GlobalHelper;  
using CMS.EmailEngine;  
using CMS.WorkflowEngine;
```

2. Put the following code inside the **OnAfterPublish** method:

[C#]

```
// type the document as TreeNode  
TreeNode newsDoc = (TreeNode)treeNodeObj;  
  
// handle the event only for news items  
if (newsDoc.NodeClassName.ToLower() == "cms.news")  
{  
    // get content of the inserted news item and send it by e-mail  
    EmailMessage email = new EmailMessage();  
    email.From = "admin@domain.com";  
    email.Recipients = "admin@domain.com";  
    email.Subject = ValidationHelper.GetString(newsDoc.GetValue("NewsTitle"), "");  
    email.Body = ValidationHelper.GetString(newsDoc.GetValue("NewsSummary"), "");  
    EmailSender.SendEmail(email);  
}
```

3. Set the From and Recipients e-mail addresses to you e-mail address.
4. Compile and run the project.
5. Configure your project so that it uses workflow for news items and create and publish a news item. You should receive the content of the news item by e-mail.

Getting the workflow step name

If you need to get the name of the workflow step (for example in the OnAfterApprove event), you need to

use code like this:

[C#]

```
CMS.WorkflowEngine.WorkflowStepInfo previousStep =  
(CMS.WorkflowEngine.WorkflowStepInfo) previousStepObj;  
string stepCodeName = previousStep.StepName;
```

10.10 API examples

10.10.1 Overview

The **Kentico CMS API Examples** feature provides API examples for creating, getting, updating and deleting objects and for other useful actions that relate to most of Kentico CMS modules. If you have the feature [installed](#) and have become familiar with its [user interface](#), [security](#) and [the data it uses](#), you can choose a particular module and [run its API examples](#).

As this chapter deals with API examples on the general level, documentation concerning actual API examples of the installed modules, together with description of these modules' database structure and closely related classes, can be found in the respective Internals and API sections; e.g. for the [Media libraries module in the Developer's Guide -> Modules -> Media libraries -> Media libraries internals](#) and API section.

Advanced API examples can be found in the [API programming and Kentico CMS internals](#) section of this guide. For detailed API documentation, such as a list of all methods from the module classes, please refer to the [Kentico CMS API Reference](#).

10.10.2 Installation

1. To install API examples, please choose **Full installation** in **Step 4** of [Kentico Web Installer](#). However, if you choose **Custom installation** in this step, API examples will not be installed.
2. If you perform web project installation with the settings described above, all available API examples will be installed. API examples source code will be located in `<web project folder>/CMSAPIExamples` and the interface enabling users to view and run these examples will be located in **Site Manager -> Support -> API examples**.

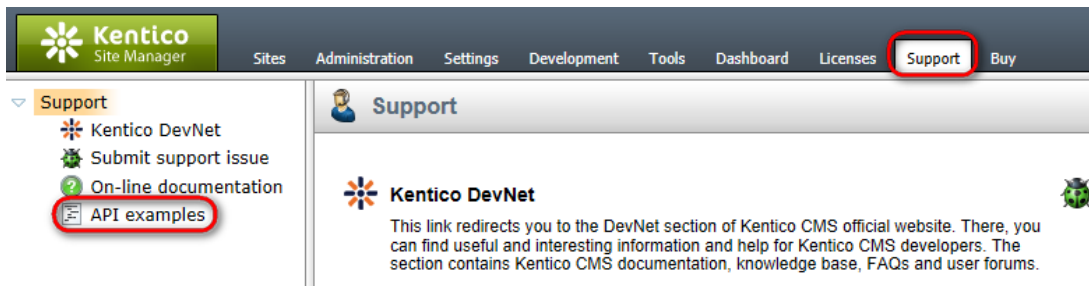

Please note

You will need to have at least one site installed in order to be able to run API examples.

10.10.3 API examples user interface

If you have Kentico CMS API examples [installed](#), you can access them by:

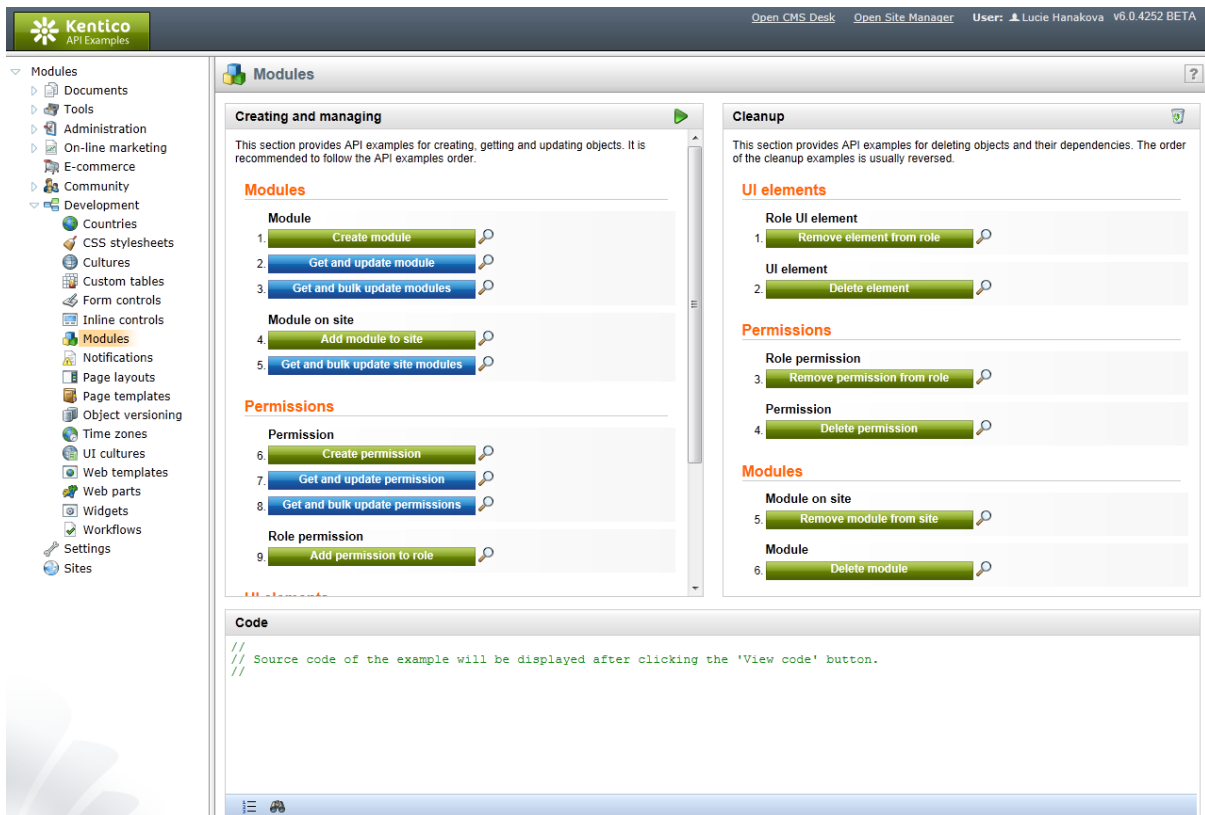

- Going to **Site Manager -> Support** and choosing **API examples** from the **Support** tree.

- Switching to the API examples directly by adding *CMSAPIExamples* to the application URL.

In either case, you will be redirected to the **Kentico CMS API Examples** user interface. Now choose from the **Modules** tree the module whose API examples you would like to see. This will display the interface of API examples of the particular module.

The API examples user interface consists of:

- **Creating and managing section** for creating, getting and updating objects,
- **Cleanup section** for deleting objects and their dependencies,
- **Code area** for displaying the examples code.

In this interface, you can [run API examples](#) and you can also display the code. This can be done by clicking the **View code** (🔑) icon next to the corresponding example. The code of the example will be displayed in the **Code** area. Using the following icons, you can show/hide line numbers (≡), toggle to the fit-to-window mode (🖼️) and search through the code (🔍). Besides, the interface enables you to copy the code to clipboard. However, editing the code directly in the **Code** area is not allowed.

Source codes of API examples can be found in **<web project folder>/CMSAPIExamples/Code**.

Please note

The Kentico CMS API Examples user interface does not have multilingual support.

10.10.4 Data used by the API examples

All API examples work with their own objects in the *MyNew<object>* format. It means your module data in Kentico CMS should not be influenced by running API examples. However, all API examples actions directly affect the database.

Typically, the **Create** action creates an object in the *MyNew<object>* format, e.g. *MyNewUser*. The **Get and Update** action gets and updates the *MyNew<object>* object. And the **Get and bulk update** action gets and bulk updates objects which start with *MyNew<object>*. Please ensure that your own objects starting *MyNew* will not be overwritten. This can be done best by running API examples on a dedicated testing Kentico CMS installation.

If an API example needs to use one of the general objects (site, role, user, document etc.), the following ones are used:

- **For site** - current site.
- **For role** - role CMS Desk Administrator.
- **For user** - current user.
- **For document** - root document from the current site.
- **For country** - USA.
- **For state** - Alabama.
- **For currency** - USD.

If other general objects are used in API examples, their list can be found in the **Internals and API** section of the respective module.

10.10.5 Running API examples

All API examples can be run by clicking the respective buttons in the module API examples user interface. In this interface you can display also [the examples code](#). To prevent any failures, it is recommended to follow the API examples order in the **Creating and managing** section and the reversed order in the **Cleanup** section. Please note that API examples marked blue in the user interface can be skipped.

Running an API example may result in:

- **Success** - the operation ran as expected.

- **Failure** - due to **non-existence of the object**. The given object was not found in the database.

- **Failure** - due to **other reasons**. You can refer to the event log for more details.

API examples in the **Creating and managing** section and those in the **Cleanup** section can also be run all at once by clicking the **Run all** (▶) and **Cleanup all** (🗑️) icons, respectively.

Please note that the result of running an API example can be verified in the UI listing or directly in the corresponding table in the database.

10.10.6 Security

Only a global administrator can access and run API examples. No additional permission check for reading API examples and for creating, modifying and deleting the objects is needed.

10.11 Using transactions and connections

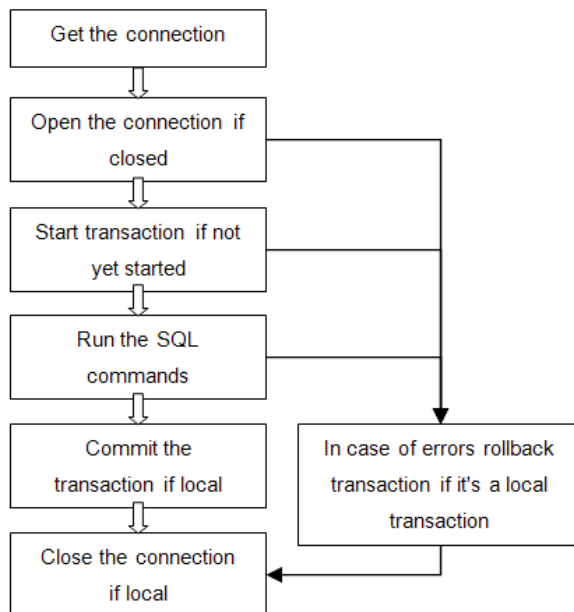

This chapter explains how to work with transactions in Kentico CMS API. Transactions are usually used to ensure database consistency.

Transactions

Kentico CMS uses SQL transactions to ensure the system database consistency when performing complex operations consisting of multiple steps. In such cases the whole operation forms a single block of SQL commands that can be rolled back when an error occurs or committed if the complete operation was successful. Transaction handling is provided by **CMS.DataEngine** library, in the **GeneralConnection** class.

Please note that you should always use a single connection for every operation within the open transaction to avoid deadlocks.

The transactions flow in Kentico CMS looks like this:

Please note: Always pass the existing connection as a parameter if you call a method that accesses the database within the transaction.

Example

Please use the following example as a template in all the methods that work with transactions:

[C#]

```

using System.Data;

using CMS.DataEngine;
using CMS.DocumentEngine;
using CMS.FileManager;
using CMS.WorkflowEngine;

/// <summary>
/// Sample method
/// </summary>
/// <param name="conn">Data connection to use</param>

public void DoSomethingInTransaction(GeneralConnection conn)
{

    // Process within transaction
    using (CMSTransactionScope tr = new CMSTransactionScope())
    {
        // --- HERE YOU CAN USE YOUR DATABASE ACCESS CODE LIKE: ---
        DataSet ds = conn.ExecuteNonQuery("cms.user.selectall", null, null, null);
    }
}

```

```
        // --- IF YOU NEED TO USE TREEPROVIDER, ALWAYS INSTANTIATE IT WITH
EXISTING CONNECTION
        TreeProvider tree = new TreeProvider(null, conn);

        // --- ALWAYS USE METHOD OVERRIDES THAT USE CONNECTION (TREEPROVIDER)
PARAMETER ---
        AttachmentInfo ai = DocumentHelper.GetAttachment(Guid.NewGuid(), 1, tree);

        // Commit transaction, you can also use the Complete() method to do the
same
        tr.Commit();
    }
}
```

You may also work with the **TreeProvider** class instead of connection objects. In that case, use its **Connection** property the same way like the **GeneralConnection** in this example and use the same connection object in all operations inside the transaction.

Connections

You can also ensure that all operations performed by a piece of code use the same connection. This can be done similarly as with the transactions above. Please use the code extract below as a template for such code:

```
using CMS.DataEngine;

private void DoSomethingWithinTheSameConnection()
{
    using (CMSConnectionScope cs = new CMSConnectionScope())
    {
        // perform your actions
    }
}
```

The connection of the scope is put to the context, making all nested connections use the same backend connection. If you do not specify a connection using the constructor parameter, one will be created automatically. The overridden constructor gets the existing connection and also a parameter which says if the connection should be open within this scope. In case it is, it is also closed automatically:

```
new CMSConnectionScope(IDataConnection conn, bool openConnection)
```

Connections within threads

When a new thread is created, the connection is not passed to the thread to maintain thread safety. So you should create a dedicated within the thread *CMSConnectionScope* for its operations.

Nesting connection and transaction scopes

It is possible to nest connection and transaction scopes, because basically there is always a *CMSConnectionScope* around *CMSTransactionScope* so the outermost code handles the connection. So you may do following:

- Use *CMSConnectionScope* inside another *CMSConnectionScope* - this does exactly the same as not having the inner one. The outer one says "use this connection for everything within", so the inner one doesn't make sense in this context and is skipped. There is no need to do this at all (but this happens if you use some of our methods within your scope, yours (the outer one) will always take priority).
- Use *CMSTransactionScope* inside *CMSConnectionScope* - the transaction just uses the existing connection from the scope. This can be used if you do some reading and then use the same connection for writing within the transaction. A single connection will always be used.
- Use *CMSTransactionScope* inside another *CMSTransactionScope* - it acts the same way as for the connections. The outer one still needs to commit the change, so the inner one is not used (as if it didn't exist).
- Use *CMSConnectionScope* inside *CMSTransactionScope* - this is a situation where you use our reading code in your transaction code. A *CMSTransactionScope* does always have a *CMSConnectionScope* around it (either an existing one or a new one), so it is basically the same scenario as the first one, the inner connection is not used.

10.12 Customizing system objects with custom data or objects

You can extend system objects in Kentico CMS by adding your own fields (i.e. properties).

To do this, create a custom data class containing the required fields and connect it to the appropriate system object. All standard system objects implement the **IRelatedData** interface, which allows you to connect any type of object:

- Through the **RelatedData** property
- Dynamically by handling the **OnLoadRelatedData** event

If the connected object implements the **IDataContainer** interface, the data stored in the custom fields can then be accessed as part of the system object via the API (**GetValue** and **SetValue** methods) or [macro expressions](#).

Example

The following sections demonstrate how to extend the **SiteInfo** object, which represents sites in Kentico CMS. The example adds two custom properties for sites:

- **SiteOwner** (string)
- **SiteValidUntil** (DateTime)

Defining the custom data class

1. Open your web project in Visual Studio.

2. Create a new class named **SiteRegistrationData.cs**.
 - o Place the class file into the **App_Code** folder if your Kentico CMS installation is a *Web site* project.
3. Write the code of the class.
 - o The class must implement the **IDataContainer** interface.
 - o Define your custom properties and all required *IDataContainer* members (as shown in the code below).

[C#]

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Web;

using CMS.SettingsProvider;

public class SiteRegistrationData : IDataContainer
{
    #region "Variables"

    private string mSiteOwner = null;
    private DateTime mSiteValidUntil = DateTime.MinValue;

    #endregion

    #region "Properties"

    /// <summary>
    /// Gets or sets the name of the site owner.
    /// </summary>
    public string SiteOwner
    {
        get
        {
            return mSiteOwner;
        }
        set
        {
            mSiteOwner = value;
        }
    }

    /// <summary>
    /// Gets or sets the date until which the site is valid.
    /// </summary>
    public DateTime SiteValidUntil
    {
        get
        {
            return mSiteValidUntil;
        }
        set
    }
    }
}
```

```
        {
            mSiteValidUntil = value;
        }
    }

#endregion

#region "IDataContainer members"

/// <summary>
/// Gets a list of column names.
/// </summary>
public List<string> ColumnNames
{
    get
    {
        return new List<string>() { "SiteOwner", "SiteValidUntil" };
    }
}

/// <summary>
/// Returns true if the class contains the specified column.
/// </summary>
/// <param name="columnName"></param>
public bool ContainsColumn(string columnName)
{
    switch (columnName.ToLower())
    {
        case "siteowner":
        case "sitevaliduntil":
            return true;

        default:
            return false;
    }
}

/// <summary>
/// Gets the value of the specified column.
/// </summary>
/// <param name="columnName">Column name</param>
public object GetValue(string columnName)
{
    switch (columnName.ToLower())
    {
        case "siteowner":
            return mSiteOwner;

        case "sitevaliduntil":
            return mSiteValidUntil;

        default:
            return null;
    }
}

/// <summary>
```

```
/// Sets the value of the specified column.
/// </summary>
/// <param name="columnName">Column name</param>
/// <param name="value">New value</param>
public bool SetValue(string columnName, object value)
{
    switch (columnName.ToLower())
    {
        case "siteowner":
            mSiteOwner = (string)value;
            return true;

        case "sitevaliduntil":
            mSiteValidUntil = (DateTime)value;
            return true;

        default:
            return false;
    }
}

/// <summary>
/// Returns a boolean value indicating whether the class contains the
specified column.
/// Passes on the specified column's value through the second parameter.
/// </summary>
/// <param name="columnName">Column name</param>
/// <param name="value">Return value</param>
public bool TryGetValue(string columnName, out object value)
{
    switch (columnName.ToLower())
    {
        case "siteowner":
            value = mSiteOwner;
            return true;

        case "sitevaliduntil":
            value = mSiteValidUntil;
            return true;

        default:
            value = null;
            return false;
    }
}

/// <summary>
/// Gets or sets the value of the column.
/// </summary>
/// <param name="columnName">Column name</param>
public object this[string columnName]
{
    get
    {
        return GetValue(columnName);
    }
    set
    {

```

```
        SetValue(columnName, value);
    }
}

#endregion
}
```

Connecting the custom data class to the system object

You need to bind the custom *SiteRegistrationData* class to the *SiteInfo* object. The example uses the **OnLoadRelatedData** event, which you can handle for specific object types, including *SiteInfo* objects. This type of binding is dynamic, which means that the system loads the data only when it is requested.

1. Create a new class file in the **App_Code** folder (or **Old_App_Code** if your project was installed as a web application).
2. Delete the default class declaration and instead extend the **CMSModuleLoader** partial class.
3. Create a new class inside the CMSModuleLoader that inherits from **CMSLoaderAttribute**.
4. Add the attribute defined by the internal class before the declaration of the **CMSModuleLoader** partial class.
5. Override the **Init** method inside the attribute class, and assign a handler to the **SiteInfo.TYPEINFO.OnLoadRelatedData** event.
6. Define the handler method for the **OnLoadRelatedData** event:
 - o The handler must return an instance of your custom data class (with appropriate values assigned to the class's fields).

[C#]

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Web;

using CMS.SettingsProvider;
using CMS.SiteProvider;

[SystemObjectCustomizationLoader]
public partial class CMSModuleLoader
{
    /// <summary>
    /// Custom attribute class for the CMSModuleLoader.
    /// </summary>
    private class SystemObjectCustomizationLoaderAttribute : CMSLoaderAttribute
    {
        /// <summary>
        /// Called automatically when the application starts.
        /// </summary>
    }
}
```

```
public override void Init()
{
    // Assigns a handler to the OnLoadRelatedData event of the SiteInfo
    object type
    SiteInfo.TYPEINFO.OnLoadRelatedData += new
    TypeInfo.ObjectLoadRelatedDataEventHandler(SiteInfo_OnLoadRelatedData);
}

/// <summary>
/// Handler method for the OnLoadRelatedData event of the SiteInfo class.
/// Gets the related data from the custom storage class (must implement
the IDataContainer interface).
/// </summary>
static object SiteInfo_OnLoadRelatedData(BaseInfo infoObj)
{
    SiteRegistrationData siteData = new SiteRegistrationData();

    siteData.SiteOwner = "John Smith";
    siteData.SiteValidUntil = DateTime.Now.AddDays(1);

    return siteData;
}
}
```

Result

You can now work with the custom fields of site objects using the API.

For example, open your website in CMS Desk and add the following code into the ASCX [layout](#) of one of your website's pages:

```
<asp:Label runat="server" id="lblSiteInfo" />
<script runat="server">
    protected void Page_PreRender(object sender, EventArgs e)
    {
        CMS.SiteProvider.SiteInfo currentSite = CMSContext.CurrentSite;

        this.lblSiteInfo.Text = String.Format("Site '{0}' is valid until {1} and owned
        by {2}.", currentSite.DisplayName, currentSite.GetValue("SiteValidUntil"),
        currentSite.GetValue("SiteOwner"));
    }
</script>
```

The **GetValue** method allows you to retrieve the data stored in the custom properties, just like with native fields of the *SiteInfo* object.

The label control displays information on the page in the following format:

Site 'Corporate Site' is valid until 1/15/2013 1:00:00 PM and owned by John Smith.

Accessing properties through macros:

You can also load the values of custom properties using [macro expressions](#). For example:

1. Add the **Static text** web part to the page (via the **Design** tab).
2. Copy the following text into the web part's **Text** property.

```
<ul>
  <li>Site: {% CurrentSite.SiteDisplayName %}</li>
  <li>Valid until: {% CurrentSite.SiteValidUntil %}</li>
  <li>Owned by: {% CurrentSite.SiteOwner %}</li>
</ul>
```

The web part displays a list of information about the current website, including the values of the custom fields.

10.13 Using API and CMS Controls outside the CMS project

This topic describes how to configure external ASP.NET applications so that they support the Kentico CMS API and Controls. Using Kentico CMS functionality outside of the CMS web project allows you to create scenarios such as:

- Separate applications integrated with your main Kentico CMS website
- Custom websites or applications that use Kentico CMS as a content repository

Start Visual Studio and open your external application's project.

Connecting to the Kentico CMS database

To be able to access the Kentico CMS database, you need to specify the appropriate connection string in your application's **web config** file.

Add the connection string into the *configuration/connectionStrings* section using an `<add>` element named **CMSConnectionString**.

```
<configuration>
  <connectionStrings>
    ...
    <add name="CMSConnectionString" connectionString="Persist Security Info=False;
database=KenticoCMS;server=myserver;user id=username;password=mypassword;Current
Language=English;Connection Timeout=120;" />
  </connectionStrings>
```

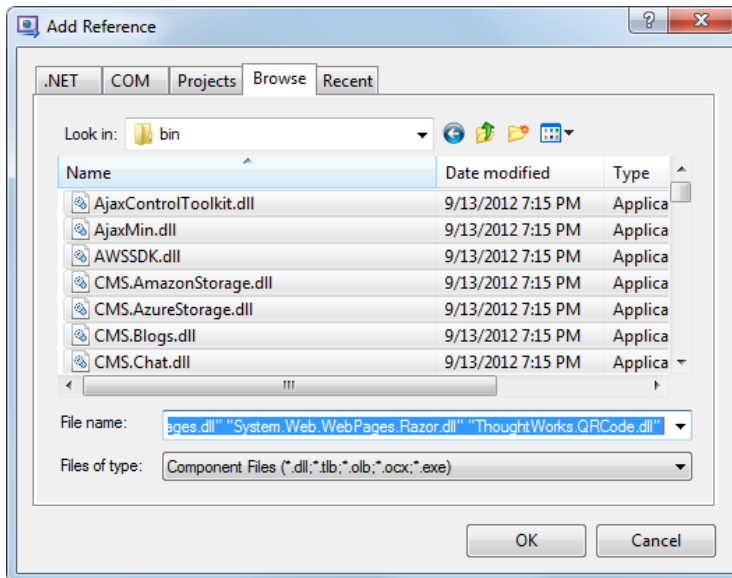

Note: It is recommended to copy the exact connection string from the web.config file of the Kentico CMS web project.

Adding references to Kentico CMS API libraries

Before you can use Kentico CMS functionality in your application, you need to add references to the

libraries containing the required code:

1. Right-click your application's web project root in the **Solution Explorer** and select **Add Reference**.
2. Open the **Browse** tab and navigate to the **bin** folder of the Kentico CMS web project.
3. Select all dll files in the folder and click **OK**.

Initializing Kentico CMS

You need to initialize Kentico CMS before making calls to its API from an external project.

Execute the **CMSContext.Init** method in the code of your application:

[C#]

```
CMS.CMSHelper.CMSContext.Init();
```

You can call this method at any point in your application's life cycle, but it must occur before you use any other Kentico CMS API.

Enabling ASCX transformations in external applications

Registering the Virtual path provider:

Kentico CMS uses a virtual path provider to retrieve the code of ASCX [transformations](#). If you wish to use ASCX transformations in your external project, you need to register the virtual path provider when the application starts.

1. If necessary, create the [Global.asax](#) file for your application.
2. Execute the following line from the **Application_Start** method in the *Global.asax* file.

[C#]

```
void Application_Start(object sender, EventArgs e)
{
    CMS.VirtualPathHelper.VirtualPathHelper.RegisterVirtualPathProvider();
}
```

**Running without the virtual path provider**

If you cannot use the virtual path provider in your environment (e.g. when using medium trust and .NET 3.5), you need to:

1. Save your virtual objects to the local disk using the **Site Manager -> Administration -> System -> Virtual objects** interface.
2. Copy the **~/CMSVirtualFiles** folder from the Kentico CMS project to the root of your own project.

See also: [Deployment and source control](#)

Adding the CMSTransformation class:

The *CMSTransformation* partial class allows you to write your own methods for use in ASCX transformations. The system checks the *CMSTransformation* class for method definitions whenever listing controls load transformations and an error occurs if the class is not present in the given project.

If you plan to use ASCX transformations, you must add the class to your project:

1. Create a new class file in your project named **CMSTransformation.cs**.
 - o In *web site* projects, you need to add the file into the **App_Code** folder.
 - o In *web application* projects, you can create the class in any location.
2. Add the following code into the class:

[C#]

```
namespace CMS.Controls
{
    /// <summary>
    /// Base class for transformation methods
    /// </summary>
    public partial class CMSTransformation : CMSAbstractTransformation
    {
    }
}
```

You can leave the class empty if you do not need to register any custom methods.

Example: Displaying content from the Kentico CMS database

Once you have completed the configuration described in the sections above, you can use the Kentico CMS API and [Controls](#) in your application. A typical example is loading and displaying data from Kentico CMS.

Using the Kentico CMS API

The Kentico CMS API allows you to perform any action available in the standard administration interface. You can also use the API to load or modify records in the database.

The following example shows how to retrieve document content from the Kentico CMS database and display it using a standard ASP.NET Repeater control.

1. Create a new page (web form) in your external web project using Visual Studio.
2. Add the standard ASP.NET **Repeater** control onto the page.
3. Insert the following item template markup into the `<asp:Repeater>` control element:

```
<asp:Repeater ID="Repeater1" runat="server">

    <ItemTemplate>
        <strong>
            <%# Eval("NewsTitle") %>
        </strong>
        (<%# ((DateTime) Eval("NewsReleaseDate")).ToString("d") %>)
        <br />
        <i><%# Eval("NewsSummary") %></i>
        <br />
    </ItemTemplate>

</asp:Repeater>
```

4. Switch to the page's code behind and add the following references to the beginning of the code:

[C#]

```
using CMS.DocumentEngine;
using System.Data;
```

5. Add the following code into the page's **Page_Load** method:

[C#]

```
protected void Page_Load(object sender, EventArgs e)
{
```

```
// Creates a data set containing all released news documents from the
Corporate Site
TreeProvider tp = new TreeProvider();
DataSet ds = tp.SelectNodes("CorporateSite", "/news/%", "en-us", true,
"cms.news", " NewsReleaseDate <= GetDate() ", " NewsReleaseDate DESC ", -1, true);

// Binds the news data to the Repeater control
Repeater1.DataSource = ds;
Repeater1.DataBind();
}
```

Note

When performing other types of document operations (editing, deleting etc.), you need to initialize the tree provider within the context of a specific user:

[C#]

```
using CMS.SiteProvider;

...

// Gets an Info object representing the administrator user
UserInfo user = UserInfoProvider.GetUserInfo("administrator");

// Creates a tree provider instance using administrator context
TreeProvider tp = new TreeProvider(user);
```

If you run the website and open the new page, the Repeater control displays a list of news article summaries.

Community Website Section (6/28/2011)

As a result of our continuous effort to improve our services, we have recently introduced the [Community](#) section of our website. It is a place where you can both receive interesting information about the company from various communication channels and express your opinions and thoughts yourselves.

Company Growth Exceeds Expectations (6/17/2011)

Our company growth has reached astonishing 256% in the last financial year. It is not only thanks to the excellent and devoted work of our employees, but mainly thanks to you, our faithful customers. Therefore, we would like to thank you for your loyalty and state a promise that we will keep to the high standard of products and services we currently provide.

Apple iPad 2 In Stock (6/9/2011)

Today, we have good news for all fans of the awesome Apple iPad. We are glad to announce that its new version, Apple iPad 2, is available in our web shop. Furthermore, we keep our reasonable pricing policy, providing the lowest price currently available on the Web.

New Consulting Services (6/5/2011)

We are proud to announce that the range of services we provide was extended by web development consulting. The most experienced and skilled employees from our web development department have been promoted to consultants and are here to help you with your web development projects.

ASP.NET Repeater control displaying news data loaded by the Kentico CMS API

Using Kentico CMS controls

This example demonstrates how to display Kentico CMS documents via the built-in [CMSRepeater](#) control.

Note: For quick access to Kentico CMS controls, [add the controls to your Visual Studio Toolbox](#).

1. Create a new page (web form) in your application's project using Visual Studio.
2. Add the **CMSRepeater** control onto the page.
 - You can either drag the control from the toolbox or manually register the *CMS.Controls* assembly on the page and then use the Visual Studio IntelliSense.
3. Set the following properties for the *CMSRepeater* control:
 - **ClassNames:** cms.news
 - **SiteName:** CorporateSite (or any other site code name)
 - **TransformationName:** cms.news.preview
 - **SelectedItemTransformationName:** cms.news.default

```
<%@ Register Assembly="CMS.Controls" Namespace="CMS.Controls" TagPrefix="cms" %>
...
<cms:CMSRepeater ID="CMSRepeater1" runat="server" ClassNames="cms.news"
SiteName="CorporateSite" TransformationName="cms.news.preview"
SelectedItemTransformationName="cms.news.default" />
```

If you run your project and navigate to the new page, you can see the list of news documents.

[New Consulting Services](#)

We are proud to announce that the range of services we provide was extended by web development consulting. The most experienced and skilled employees from our web development department have been promoted to consultants and are here to help you with your web development projects.

[Apple iPad 2 In Stock](#)

Today, we have good news for all fans of the awesome Apple iPad. We are glad to announce that its new version, Apple iPad 2, is available in our web shop. Furthermore, we keep our reasonable pricing policy, providing the lowest price currently available on the Web.

[Company Growth Exceeds Expectations](#)

Our company growth has reached astonishing 256% in the last financial year. It is not only thanks to the excellent and devoted work of our employees, but mainly thanks to you, our faithful customers. Therefore, we would like to thank you for your loyalty and state a promise that we will keep to the high standard of products and services we currently provide.

[Community Website Section](#)

As a result of our continuous effort to improve our services, we have recently introduced the Community section of our website. It is a place where you can both receive interesting information about the company from various communication channels and express your opinions and thoughts yourselves.

News documents displayed by the CMSRepeater

Handling document links in external applications:

The [default URLs](#) of Kentico CMS documents are based on the structure of the content tree and the settings of individual documents. These URLs will not work correctly outside of the Kentico CMS application. For example, the links in the news item headings in the example above lead to pages that most likely do not exist in your custom web project.

The following steps extend the previous example so that the news detail links work in external applications. The CMSRepeater control renders the links using the *cms.news.preview* [transformation](#), which you can modify.

1. Open Kentico CMS and go to **Site Manager -> Development -> Document types**.
2. Edit (✎) the **News** document type.
3. Select the **Transformations** tab and edit the **preview** transformation.
4. Change the transformation code that defines the link URL from:

```
<a href="<%# GetDocumentUrl() %>">
```

to:

```
<a href="?aliasPath=<%# Eval("NodeAliasPath") %>">
```

5. Click  **Save**.

The original *GetDocumentUrl()* transformation method generates document URLs in the default Kentico CMS format. The modified link URL leads to the same page containing the listing control, but with an **aliasPath** parameter in the query string of the URL. The parameter contains the alias path of the corresponding news document.

Kentico CMS listing controls automatically process the *aliasPath* URL parameter and insert its value into the **Path** property. In this case, the link URLs ensure that the CMSRepeater control only loads one specific news document. When the source data only contains one document, the control uses the transformation specified by the **SelectedItemTransformationName** property (*cms.news.default* in this case) to display the details of the given document.

Note: Controls cache transformations, so you need to restart your application to apply the changes.

Implementing custom document selection for listing controls:

You can alternatively use your own custom logic to dynamically set the path of listing controls according to the URL or other variables.

For example, the following steps demonstrate how to ensure document selection based on a custom URL parameter:

1. Edit the **cms.news.preview** transformation again and change the name of the URL parameter in the link code to *customParameter*.

```
<a href="?customParameter=<%# Eval("NodeAliasPath") %>">
```

2. Open the markup of the page in Visual Studio and set the **DataBindByDefault** property of the CMSRepeater control to *false*.
3. In the page's code behind, add the following code into the **Page_Load** method:

[C#]

```
protected void Page_Load(object sender, EventArgs e)
{
    // Checks whether the URL contains the 'customParameter' query string
    parameter
    if (Request.QueryString["customParameter"] != null)
    {
        // Limits the path of the CMSRepeater to the document specified by the URL
        parameter
        CMSRepeater1.Path = Request.QueryString["customParameter"];
    }
    else
    {
        // Loads documents from the entire website if the URL doesn't contain the
        'customParameter' parameter
        CMSRepeater1.Path = "%";
    }

    // Loads and binds the data of the CMSRepeater control (with regard to the
    dynamically set Path)
    CMSRepeater1.ReloadData(true);
}
```

Setting CMS control properties dynamically

By default, Kentico CMS listing controls load content during the *Init* stage of the [control life cycle](#). If you need to programmatically assign control properties that affect the content, use one of the following approaches:

1. Set the **DelayedLoading** property to *true* in the control's markup.
 - o This moves the automatic data binding to the control's *Load* event.
2. Assign the required properties during the page's *Load* event (in the **Page_Load** handler) or sooner.

OR

1. Set the **DataBindByDefault** property to *false* in the control's markup.
 - o This completely disables automatic data binding for the control.
2. Assign the required properties at any appropriate point in the page life cycle.
3. Explicitly call the control's **ReloadData(true)** method.

The control then loads the content based on the dynamically assigned properties.

The page now uses the *customParameter* query string parameter to select specific news documents. The custom parameter works the same way as the default *aliasPath* parameter.

10.14 Database table API

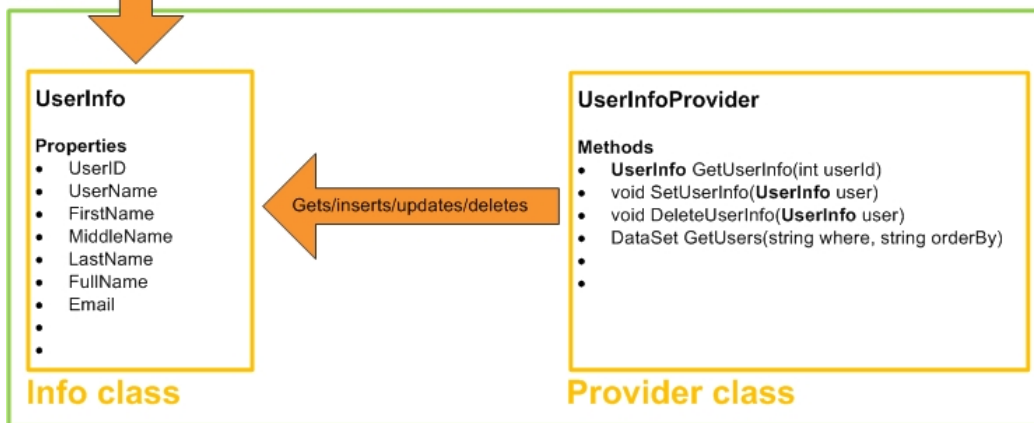

Kentico CMS uses database tables to store data. There are two API classes for each database table to manage its data - Info class and Provider class. See the example for the *CMS_User* table below.

Database table

| CMS_User | | | | | | | |
|----------|----------|-----------|------------|-----------|----------------|--------------------------------|--------|
| UserID | UserName | FirstName | MiddleName | LastName | FullName | Email | UserEr |
| 341 | Mia | Mia | | Lee | Mia Lee | mia.lee@localhost.local | 1 |
| 342 | Steevie | Jack | | Stevenson | Jack Stevenson | jack.stevenson@localhost.local | 1 |
| 343 | Jimbo | James | | Culligan | James Culligan | james.culligan@localhost.local | 1 |
| 344 | Tessie | Iman | | Teshome | Iman Teshome | iman.teshome@localhost.local | 1 |
| 345 | Turbo | Noel | | Turpin | Noel Turpin | noel.turpin@localhost.local | 1 |
| 346 | Nikky | Nicole | Claire | Dubois | Nicole Dubois | nicole.dubois@localhost.local | 1 |
| 347 | Pogo | Wayne | | Pronger | Wayne Pronger | wayne.pronger@localhost.local | 1 |
| 348 | Suru | Ratan | | Gupta | Ratan Gupta | ratana.gupta@localhost.local | 1 |
| 349 | | Joshua | | O'Neil | Joshua O'Neil | joshua.oneil@localhost.local | 1 |
| 350 | | Jane | | Oakley | Jane Oakley | jane.oakley@localhost.local | 1 |
| 352 | | David | | Silver | David Silver | david.silver@localhost.local | 1 |
| 353 | | Kelly | | Taylor | Kelly Taylor | kelly.taylor@localhost.local | 1 |

Data row

API

Info class

Each info class is related to a database table. An info class reflects one particular entry (line) in the table. This means an info class is a data container holding data of one table entry. The properties of an info class correspond to the columns of the related table.

Provider class

A provider class is used to manage data from the related table. It usually uses the related info object when manipulating with the data. A typical provider class contains methods used for getting, inserting, updating and deleting table data, together with various other methods used for further table data manipulation.

Part

XI

Appendix A - Path expressions

11 Appendix A - Path expressions

Path expressions allow you to select a set of documents from the content tree of Kentico CMS websites. The expressions are based on the [alias path](#) values of documents. You can use either the exact paths of individual documents or expressions containing special characters, which specify multiple documents or relative paths.

For example, path expressions are commonly used in the **Path** property of web parts and controls that provide navigation elements or display document data.

Using wildcard characters % and _

You can use **% as a wildcard character for any number of characters**, which allows you to select all documents under the specified site section.

Examples:

/ - only the root document
/% - all documents

/Products - only the *Products* document
/Products/% - all child documents under the *Products* document

You can also use **_ as a wildcard representing single character**.

Examples:

/Product_ - selects documents */ProductA*, */Product1*, etc.

Leaving the Path value empty

In many cases, you can leave the Path value empty.

For **navigation** controls/web parts (such as *CMSMenu/Drop-down menu*), an empty value sets the path to all documents: */%*

Listing controls/web parts with document data sources (such as *CMSRepeater/Repeater*) evaluate empty path values dynamically based on the [document type](#) of the current document:

- If the type matches the value of the web part or control's **ClassNames (Document types)** property, the empty path automatically selects the current document.
- If the document type does not match, the path is set to all child documents: *<current alias path>/%*

Getting parts of the path

You can use special expressions to **extract parts of the current document's path**.

- *{0}* - the alias of the document on the first level of the current path
- *{1}* - the document alias of the current path's second level
- ...

For example, if the document path is: ***/Company/Careers/USA-Branch/Development/QA-Engineer***

- **{0}** = Company
- **{1}** = Careers
- **{3}** = Development

Path examples:

/{0}/{1}/% - all documents under the second level of the current path

/{0}/{1}/Details - document *Details* under the second level of the current path

Note

If you attempt to extract a level that does not exist in the current document's path:

- The expression returns an empty value.
- If there is a slash (/) after the expression, the system removes it when resolving the overall path.

Using relative paths

You can use relative paths expressions to specify **sub-documents or parent documents**:

Examples:

. - current path

.. - parent document of the current path

./Product - document *Product* under the current path

../Product - document *Product* under the parent document of the current path

./% - all documents under the current path

../% - all documents under the parent document of the current path

Part

XII

Appendix B - Web.config parameters

12 Appendix B - Web.config parameters

The system settings include appSettings keys and other settings, such as a connection string placed in appropriate sections of the web.config file. AppSettings keys are stored in the **/configuration/appSettings** section.

The following setting categories are available:

- [General settings](#)
- [Assembly settings](#)
- [Forbidden character settings in user and role names](#)
- [Forbidden character replacement in URLs](#)
- [Staging settings](#)
- [WYSIWYG editor settings](#)
- [Code editor settings](#)
- [E-commerce settings](#)
- [Event log settings](#)
- [File export settings](#)
- [Item listing settings](#)
- [URL settings for cultures](#)
- [Query string parameter name settings](#)
- [Transaction isolation settings](#)
- [Scheduler settings](#)
- [Contact management settings](#)
- [Security settings](#)
- [Smart search settings](#)
- [Translation services](#)
- [UI culture settings](#)
- [Web farm synchronization settings](#)
- [Windows Azure deployment settings](#)
- [Debugging settings](#)

General settings

| Key | Description | Sample Value |
|------------------------|---|---|
| CMSProgrammingLanguage | Indicates the programming language used in transformations and in custom code added to web parts.

The default value is C#. | <pre><add key = "CMSProgrammingLanguage" value="C#" /></pre> <p>or</p> <pre><add key = "CMSProgrammingLanguage" value="VB" /></pre> |
| CMSTrialKey | Contains a temporary trial license key. You can remove this value after | |

| | | |
|---------------------------|--|---|
| | <p>installation.</p> <p>The default value is "" (empty string).</p> | |
| CMSHashStringSalt | <p>Sets the salt value that the system uses in hash functions, for example when creating macro signatures. The installer automatically adds the key for new instances of Kentico, with a random GUID as the value.</p> <p>Note: Changing the hash salt on a website that already has defined content may prevent macros from resolving correctly, or break dialog links and images on your website. If you encounter such problems, you need to re-save the given content or globally re-sign macros (the system then creates the hashes using the new salt).</p> | <pre><add key="CMSHashStringSalt" value="eb2d6fac-8b9e- 427c-b98b- 3c562dffbb35" /></pre> |
| CMSUseCustomHandlers | <p>Indicates if custom handlers should be executed to process system events. See the Global events and their handling chapter for more details.</p> <p>The default value is <i>false</i>.</p> | <pre><add key ="CMSUseCustomHandlers" value="true" /></pre> |
| CMSUseVirtualPathProvider | <p>Indicates if the virtual path provider should be used (true by default). Before you switch off the virtual path provider, please read the Pre-compilation (Publish function) chapter.</p> <p>The default value is <i>true</i>.</p> | <pre><add key = "CMSUseVirtualPathProvid er" value="false" /></pre> |
| CMSShowWebPartCodeTab | <p>Indicates if the Code tab should be displayed in the web part properties dialog in CMS Desk. This parameter can be used for the purposes of backwards compatibility. Otherwise, using the Code tab is now obsolete.</p> <p>The default value is <i>false</i>.</p> | <pre><add key ="CMSShowWebPartCodeTab" value="true" /></pre> |
| CMSShowWebPartBindingTab | <p>Indicates if the Binding tab should be displayed in the web part properties dialog in CMS Desk. This parameter can be used for the purposes of backwards compatibility. Otherwise, using the Binding tab is now obsolete.</p> <p>The default value is <i>false</i>.</p> | <pre><add key = "CMSShowWebPartBindingTa b" value="true"/></pre> |
| CMSRenderGeneratorName | <p>Indicates if the 'generator' meta tag stating that the page was generated by Kentico CMS is generated in the header</p> | <pre><add key =</pre> |

| | | |
|--------------------------------|--|--|
| | <p>of each page.</p> <p>The default value is <i>false</i>.</p> | <pre>"CMSRenderGeneratorName" value="true" /></pre> |
| CMSClearFieldEditor | <p>Determines field editor behavior when creating new fields. If true, new fields will have empty values of attributes. If false, new fields will have pre-defined values, the same as the previously selected field.</p> <p>The default value is <i>true</i>.</p> | <pre><add key ="CMSClearFieldEditor" value="true" /></pre> |
| CMSShowTemplateASPXTab | <p>Indicates if ASPX code tab is displayed when editing a page template. Using this tab, ASPX code of a page template created using the portal engine can be exported.</p> <p>The default value is <i>false</i>.</p> | <pre><add key = "CMSShowTemplateASPXTab" value="true" /></pre> |
| CMSTatabaseCulture | <p>Specifies the default culture of the system's database.</p> <p>The default value is <i>en-us</i>.</p> | <pre><add key="CMSTatabaseCulture" value="en-us" /></pre> |
| CMSTisposeConnectionAfterClose | <p>If true, database connection is automatically disposed (allocated resources released) when a database connection is closed.</p> <p>The default value is <i>false</i>.</p> | <pre><add key = "CMSTisposeConnectionAfterClose" value="true" /></pre> |
| CMSTiseSessionCookies | <p>Indicates if session cookies are used or not.</p> <p>The default value is <i>true</i>.</p> | <pre><add key ="CMSTiseSessionCookies" value="true" /></pre> |
| CMSTimportWindowsRoles | <p>When Windows authentication is used and this key set to true, roles available in the Active Directory will be imported into the system.</p> <p>The default value is <i>true</i>.</p> | <pre><add key ="CMSTimportWindowsRoles" value="true" /></pre> |
| CMSTileScriptTimeout | <p>The maximum number of seconds a script can run before the server terminates it.</p> <p>The default value is <i>7200</i>.</p> | <pre><add key ="CMSTileScriptTimeout" value="7200" /></pre> |
| CMSTiseExtensionOnPostback | <p>When using friendly URL extensions, postback doesn't work in some cases. If you enable this setting, .aspx extension is attached to the URL in the form tag, which prevents the postback problems.</p> <p>The default value is <i>true</i>.</p> | <pre><add key = "CMSTiseExtensionOnPostback" value="true" /></pre> |

| | | |
|--|--|---|
| CMSUseSQLResourceManager | <p>If true, SQL Resource manager is used to retrieve strings used in the user interface.</p> <p>The default value is <i>true</i>.</p> | <pre><add key = "CMSUseSQLResourceManager" value="true"/></pre> |
| CMSAllowCheckIOPermissions | <p>If true, write permissions on the site folder are checked when necessary and produce an error message when they are insufficient.</p> <p>The default value is <i>true</i>.</p> | <pre><add key = "CMSAllowCheckIOPermissions" value="true"/></pre> |
| CMSWorkflowSendEmailToModerator | <p>If true, workflow notification e-mails will be sent to the user who is performing the current workflow step along with other users involved in the workflow.</p> <p>The default value is <i>false</i>.</p> | <pre><add key = "CMSWorkflowSendEmailToModerator" value="true"/></pre> |
| CMSControlElement | <p>If present in the web.config, the tag entered in the value will be used instead of the SPAN tag when generating pages.</p> <p>The default value is <i>span</i>.</p> | <pre><add key="CMSControlElement" value="div"/></pre> |
| CMSUseParsedSelfClose | <p>Indicates if parsed self closing tags operations (faster) are used instead of standard self close filter.</p> <p>The default value is <i>true</i>.</p> | <pre><add key ="CMSUseParsedSelfClose" value="true"/></pre> |
| CMSGetFileEndRequest | <p>If true, <i>ApplicationInstance.CompleteRequest()</i> is used instead of <i>Response.End()</i> in the <i>CompleteRequest</i> method.</p> <p>The default value is <i>true</i>.</p> | <pre><add key ="CMSGetFileEndRequest" value="true"/></pre> |
| CMSDefaultUserID | <p>Specifies default user ID.</p> <p>The default value is <i>0</i>.</p> | <pre><add key="CMSDefaultUserID" value="53"/></pre> |
| ImportFilesDiskPath | <p>Specifies path to attachments that should be attached to documents imported via the SQL Import windows application.</p> <p>The default value is "" (empty string).</p> | <pre><add key ="ImportFilesDiskPath" value="C:\Temp"/></pre> |
| CMSDeleteTemporaryAttachmentsOlderThan | <p>Specifies how old should be attachments deleted by the 'Delete old temporary attachments' scheduled task. The value is entered in hours. Attachments older than the entered value will be deleted when the scheduled task is executed.</p> <p>The default value is <i>24</i>.</p> | <pre><add key = "CMSDeleteTemporaryAttachmentsOlderThan" value="12"/></pre> |

| | | |
|-----------------------------------|---|---|
| CMSAllowGZip | <p>Enables Gzip compression of output HTML code.</p> <p>The default value is <i>false</i>.</p> | <pre><add key="CMSAllowGZip" value="true" /></pre> |
| CMSDisableAdministrationInterface | <p>Disables the administration interface. The 'Access denied' screen is displayed on each attempt to access CMS Desk or Site Manager.</p> <p>The default value is <i>false</i>.</p> | <pre><add key="CMSDisableAdministrationInterface" value="true" /></pre> |
| CMSMaxNodeAliasLength | <p>Determines the maximum allowed length of document aliases. The default value is 50 characters and larger names are trimmed. You can increase the allowed length if you need to enter very long aliases (URLs).</p> <p>If you increase the key's value, you also need to:</p> <ol style="list-style-type: none"> 1. Edit the <code>~\CMSModules\Content\CMSDesk\Properties\Alias_List.aspx</code> file and increase the MaxLength property of the txtAlias control. 2. Delete the following views from your database: <ul style="list-style-type: none"> • View_CMS_Tree_Joined_Linked • View_CMS_Tree_Joined_Regular 3. Increase the nvarchar size for the NodeAlias column in the CMS_Tree database table. 4. Increase the nvarchar size for the NodeAlias column in the code of the following stored procedures: <ul style="list-style-type: none"> • Proc_CMS_Tree_InitNodeOrders • Proc_CMS_Tree_MoveNodeAlphabetical • Proc_CMS_Tree_OrderAlphaAsc • Proc_CMS_Tree_OrderAlphaDesc 5. Recreate the deleted views. Run the following scripts found in the <code>~\App_Data\Install\SQL\Objects</code> folder: <ul style="list-style-type: none"> • View_CMS_Tree_Joined_Linked.sql • View_CMS_Tree_Joined_Regular.sql <p>Note: The maximum allowed length for the Node alias path is 450 characters, so the system may trim the alias path for</p> | <pre><add key="CMSMaxNodeAliasLength" value="120" /></pre> |

| | | |
|------------------------------------|--|---|
| | documents deep in the content tree regardless of the allowed length. | |
| CMSMaxNodeNameLength | <p>Sets the maximum possible length for the names of documents in the content tree. The default value is <i>100</i> characters and larger names are trimmed. This key can be used to increase the allowed length, which can be useful if you wish to enter very long document names.</p> <p>If you use the key, you also need to set the same size for the following columns in the database:</p> <ul style="list-style-type: none"> • NodeName (<i>CMS_Tree</i> table) • DocumentName (<i>CMS_Document</i> table) • PageTemplateDisplayName (<i>CMS_PageTemplate</i> table) • VersionDocumentName (<i>CMS_VersionHistory</i> table) | <pre><add key ="CMSMaxNodeNameLength" value="150" /></pre> |
| CMSWebAnalyticsSlidingIPExpiration | <p>This key is used when the <i>Site Manager -> Settings -> On-line marketing -> Web Analytics -> Remember visitors by IP (minutes)</i> key has a value higher than 0. If <i>enabled</i> (by default), users who are active on the site but have disabled cookies are not logged as new visitors after the set time. If <i>disabled</i>, even an active user with disabled cookies is logged as a new site visitor after the set time.</p> | <pre><add key ="CMSWebAnalyticsSlidingI PEXpiration" value="false" /></pre> |
| CMSAuthenticationType | <p>This key overrides the values returned by the <i>IsFormsAuthentication</i> and <i>IsWindowsAuthentication</i> methods in <i>CMS.GlobalHelper.RequestHelper</i>.</p> <p>You will typically use this if you are using a custom authentication provider whose authentication type is a non-standard one (e.g. Federated authentication) to make Kentico CMS handle it as if it was windows or forms authentication.</p> <p>The following values are available:</p> <ul style="list-style-type: none"> • default: standard behavior • forms: <i>IsFormsAuthentication</i> always returns <i>true</i>, <i>IsWindowsAuthentication</i> always returns <i>false</i> • windows: <i>IsFormsAuthentication</i> always returns <i>false</i>, | <pre><add key ="CMSAuthenticationType" value="windows" /></pre> |

| | | |
|-----------------------------|---|---|
| | <p><i>IsWindowsAuthentication</i> always returns <i>true</i></p> <ul style="list-style-type: none"> • both: <i>IsFormsAuthentication</i> always returns <i>true</i>, <i>IsWindowsAuthentication</i> always returns <i>true</i> <p>The default value is <i>default</i>.</p> | |
| CMSTemporaryFilesFolderPath | <p>Overrides the default <code>~/AppData/CMSTemp</code> location where various temporary files are stored by the system. As a value, you can use:</p> <ul style="list-style-type: none"> • physical disk path - e.g. <code>c:\myfiles\mysite</code> • virtual path - e.g. <code>~/UploadedFiles</code> • UNC path - e.g. <code>\\server\folder</code> | <pre><add key = "CMSTemporaryFilesFolder Path" value="\ \server\MyCustomFolder " /></pre> |
| CMSEnableInlineControls | <p>Indicates if inline control insertion should be possible using the Insert inline control button in the WYSIWYG editor toolbar.</p> <p>This key does not affect the resolving of inline control macro expressions.</p> <p>The default value is <i>false</i>.</p> | <pre><add key = "CMSEnableInlineControls " value="true" /></pre> |
| CMSDefaultTheme | <p>Sets name of the folder within <code>~/App_Themes\</code> containing the theme to be used as the default theme by the CMS.</p> <p>The default value is <i>Default</i>.</p> | <pre><add key="CMSDefaultTheme" value="MyTheme" /></pre> |
| CMSImagesDirectory | <p>Sets a custom path to the <i>Images</i> folder of the theme to be used by the CMS. It can be located in a different location than within the default theme folder.</p> <p>The default value is <code>~/App_Themes/<default theme folder>/Images</code>.</p> | <pre><add key="CMSImagesDirectory" value="~/App_Themes/ MyTheme/Images" /></pre> |
| CMSApplicationName | <p>Used by Kentico CMS Windows services to identify the Kentico CMS instance. In case of IIS installation, path to the instance in IIS is used as its value. In case of Visual Studio web server installation, name of the target web project root folder is used. The value must be less than 60 characters long.</p> <p>It is also used to register Health monitoring performance counters and to identify respective counter categories when writing monitored values to them.</p> | <pre><add key="CMSApplicationName" value="Default Web Site/CMS" /></pre> |
| CMSApplicationGuid | <p>Unique identifier of the Kentico CMS</p> | <pre><add</pre> |

| | | |
|-----------------------------------|--|--|
| | instance. Used by Kentico CMS Windows services to identify the Kentico CMS instance. | <code>key="CMSApplicationGuid" value="fe5493b6-4ea9-42e6-92fa-0db1156b9163" /></code> |
| CMSEnableAutomaticCampaignCreate | <p>If set to <i>true</i>, a campaign object will automatically be added to the current website if it is viewed by a user coming from an undefined campaign (typically specified through the campaign tracking URL parameter).</p> <p>If the key is set to <i>false</i> (this is the default state), then undefined campaigns will be ignored.</p> <p>Please see Modules -> Web analytics -> Campaigns for further information.</p> | <code><add key = "CMSEnableAutomaticCampaignCreate" value="true" /></code> |
| CMSMediaFileMaxVersioningSize | <p>Sets the maximal file size of versioned media files in kiloBytes. Files in media libraries that are larger than the entered value will not have versions created on their update.</p> <p>The default value is <i>2147483647 (int.MaxValue)</i>.</p> | <code><add key = "CMSMediaFileMaxVersioningSize" value="1024" /></code> |
| CMSShowForgottenPassLink | <p>Indicates if a link that allows users to recover a forgotten password should be displayed on the logon page for the administration interface (CMS Desk and Site Manager).</p> <p>The default value is <i>true</i>.</p> | <code><add key = "CMSShowForgottenPassLink" value="false" /></code> |
| CMSDisableMacroParameters | <p>Disables resolving of macro parameters. If set to <i>true</i>, macro parameters will be ignored and the macro expressions will return results as if they contained no parameters.</p> <p>The default value is <i>false</i>.</p> | <code><add key = "CMSDisableMacroParameters" value="true" /></code> |
| CMSSelectorMaxDisplayedTotalItems | <p>Determines the maximum number of items that can be displayed in drop-down list selectors in the administration interface. If there are more selectable objects, the list will be shortened and the (<i>more..</i>) option will be added.</p> <p>The value of this key can be overridden for individual UniSelector controls.</p> | <code><add key = "CMSSelectorMaxDisplayedTotalItems" value="30" /></code> |
| CMSAlwaysCacheResources | Enables/disables client caching of (minifiable) resources. | <code><add key="CMSAlwaysCacheResources" value="false"/></code> |

| | | |
|---|--|---|
| | <p>The default value is <i>true</i>.</p> <p>Please note that caching on the client side is not done at all if the Client cache (minutes) setting is disabled (set to 0) in Site Manager -> Settings -> System -> Performance.</p> | |
| CMSStorageProviderAssembly | <p>Indicates the assembly name of storage provider.</p> <p>The default value is <i>CMS.CMSStorage</i>.</p> | <pre><add key="CMSStorageProviderA ssembly" value="CMS.CMSStorage" /></pre> |
| CMSProcessTrailingSlashForFile | <p>Allows to disable processing of the trailing slash for attachment URLs.</p> <p>The default value is <i>true</i>.</p> | <pre><add key="CMSProcessTrailingS lashForFile" value="false" /></pre> |
| CMSWebAnalyticsShowFullData | <p>Indicates whether the amount of data displayed in the analytics reports should be reduced before being rendered.</p> <p>The default value is <i>false</i> (for performance reasons).</p> | <pre><add key="CMSWebAnalyticsShow FullData" value="true" /></pre> |
| CMSPhysicalFilesCacheMinutes | <p>Determines expiration time in minutes that should be set for the physical files in the client cache.</p> <p>The default value is <i>10080</i>.</p> | <pre><add key="CMSPhysicalFilesCac heMinutes" value="10080" /></pre> |
| CMSHTMLEncodeEval | <p>If true, the EvalXXX() methods in the CMSAbstractTransformation class encode string values.</p> <p>The default value is <i>false</i>.</p> | <pre><add key="CMSHTMLEncodeEval" value="true" /></pre> |
| CMSInstancePath | <p>Contains the instance path.</p> | <pre><add key="CMSInstancePath" value="c: \inetpub\wwwroot\Kentico CMS\" /></pre> |
| CMSEmailValidationRegex | <p>Allows to customize a regular expression string for email validation.</p> | <pre><add key="CMSEmailValidationR egex" value="^[A-Z0-9._% +-]+@[A-Z0-9.-]+\.[A-Z] {2,4}\$" /></pre> |
| CMSEmailTransferEncoding
<i>[Only available after applying hotfix 7.0.44 or newer]</i> | <p>Specifies the type of transfer encoding used for e-mails sent from the CMS.</p> <p>Supported values are: <i>base64</i>, <i>quotedprintable</i>, <i>sevenbit</i>.
The default value is <i>base64</i>.</p> | <pre><add key = "CMSEmailTransferEncodin g" value ="QuotedPrintable" /></pre> |
| CMS55Compatibility | <p>Ensures compatibility with CMS version</p> | <pre><add</pre> |

| | | |
|--|---|--|
| | <p>5.5 (includes the CMS.Compatibility namespace in transformations).</p> <p>The default value is <i>false</i>.</p> | <pre>key="CMS55Compatibility" value="true" /></pre> |
| CMSMacrosCaseSensitiveComparison | <p>If true, string comparisons are case sensitive (if not overridden by /<i>(casesensitive)</i> macor parameter).</p> <p>The default value is <i>false</i>.</p> | <pre><add key="CMSMacrosCaseSensitiveComparison" value="true" /></pre> |
| CategoryIDLength | <p>Category IDs in the CategoryIDPath column/field (the CMS_Category table) will be padded with leading zeros to the width specified in the key, e.g. 00001232.</p> <p>The default value is 8.</p> | <pre><add key="CategoryIDLength" value="9" /></pre> |
| UIelementIDLength | <p>UI element IDs in the ElementIDPath column/field (the CMS_UIElement table) will be padded with leading zeros to the width specified in the key, e.g. 00001232.</p> <p>The default value is 8.</p> | <pre><add key="UIelementIDLength" value="9" /></pre> |
| SettingsCategoryIDLength | <p>Settings category IDs in the CategoryIDPath column/field (the CMS_SettingsCategory table) will be padded with leading zeros to the width specified in the key, e.g. 00001232.</p> <p>The default value is 8.</p> | <pre><add key="SettingsCategoryIDLength" value="9" /></pre> |
| CMSDeleteTemporaryUploadFilesOlderThan | <p>Specifies how old (in hours) unfinished upload files should be deleted by the 'Delete old temporary upload files' scheduled task.</p> <p>The default value is 24.</p> | <pre><add key="CMSDeleteTemporaryUploadFilesOlderThan" value="12" /></pre> |
| CMSImageEditorMaxVersionsCount | <p>Indicates how many versions of edited image should be saved in the image editor temporary folder.</p> <p>The default value is 999.</p> | <pre><add key="CMSImageEditorMaxVersionsCount" value="500" /></pre> |
| CMSImageExtensions | <p>Specifies a list of file extensions which should be allowed as image files.</p> <p>The default value is "".</p> | <pre><add key="CMSImageExtensions" value="" /></pre> |
| CMSAudioExtensions | <p>Specifies a list of file extensions which should be allowed as audio files.</p> <p>The default value is "".</p> | <pre><add key="CMSAudioExtensions" value="" /></pre> |
| CMSVideoExtensions | <p>Specifies a list of file extensions which should be allowed as video files.</p> | <pre><add key="CMSVideoExtensions"</pre> |

| | | |
|--------------------------------------|--|---|
| | The default value is "". | <code>value="" /></code> |
| CMSUrlPort | <p>Specifies the port number that will be used in certain types of URLs in the administration interface (e.g. those of stylesheet images or modal dialogs). Standard navigation URLs are not affected.</p> <p>If not set, the URL port is automatically taken from the current request (80 in most cases).</p> <p>Add this key if you wish to generate URLs with a custom port number, regardless of the request port.</p> <p>It may also be useful in scenarios where requests are redirected to a non-standard port number, but you wish to use the usual HTTP port in URLs.</p> | <code><add key="CMSURLPort" value="80" /></code> |
| CMSUseServerSideLiveIDAuthentication | <p>Determines which authentication mode should be used during Windows Live ID authentication. Each mode generates a different authentication token for the same Live ID user.</p> <p>Setting the value to <i>false</i> is necessary to ensure backward compatibility for users created via Live ID authentication by versions of Kentico CMS older than 6.0 (or those users created while this key is set to <i>false</i>).</p> <p>The default value is <i>true</i>.</p> | <code><add key="CMSUseServerSideLiveIDAuthentication" value="false" /></code> |
| CMSDefaultCookieLevel | <p>Can be used to set the default cookie level system-wide. Available cookie levels are: <i>None</i>, <i>System</i>, <i>Essential</i>, <i>Editor</i>, <i>Visitor</i>, <i>All</i>.</p> <p>The default value is <i>All</i>.</p> | <code><add name="CMSDefaultCookieLevel" value="System" /></code> |
| CMSUseSilverlightUploader | Indicates whether the system should use the multi-file uploader written in Microsoft Silverlight. | <code><add key="CMSUseSilverlightUploader" value="false" /></code> |
| CMSDefaultPageClassName | <p>Use the key to change the default value of the page menu item classname.</p> <p>The default value is <i>CMS.MenuItem</i>.</p> | <code><add key="CMSDefaultPageClassName" value="CMS.MenuItem" /></code> |

| | | |
|-----------------------|--|---|
| CMSXUACompatibleValue | <p>Defines a value of X-UA-Compatible header meta tag. This meta tag allows you to choose the version of Internet Explorer, in which the page should be rendered.</p> <p>Available options are:</p> <ul style="list-style-type: none"> • IE=5 • IE=EmulateIE7 • IE=7 • IE=EmulateIE8 • IE=8 • IE=EmulateIE9 • IE=9 • IE=edge <p>Default value is <i>IE=9</i>. The meta tag is added if IE browser is used.</p> | <pre><add key ="CMSXUACompatibleValue" value="IE=edge" /></pre> |
| CMSUseXUACompatible | <p>Defines if X-UA-Compatible header meta tag can be added.</p> <p>The default value is <i>true</i>.</p> | <pre><add key ="CMSUseXUACompatible" value="false" /></pre> |

Special settings for assemblies

You can use the following keys to specify which assemblies are used:

| Key | Description | Sample Value |
|------------------------------|---|--|
| CMSDirectoryProviderAssembly | <p>Name of the assembly that should be used for operations in the file system. You can choose from the following options:</p> <ul style="list-style-type: none"> • CMS.DirectoryProviderDotNet - this is a managed code library that uses System.IO methods for disk operations. It is useful for environment that allows only managed code. • CMS.DirectoryProviderWin32 - this is an unmanaged code library that uses Win32 API for disk operations. It is useful for environment that requires Win32 API calls. <p>The default assembly is <i>CMS.DirectoryProviderDotNet</i>.</p> | <pre><add key = "CMSDirectoryProviderAssembly" value = "CMS.DirectoryProviderDotNet" /> or <add key = "CMSDirectoryProviderAssembly" value = "CMS.DirectoryProviderWin32" /></pre> |

| | | |
|------------------------------------|--|---|
| CMSSearchProviderAssembly | Name of the assembly that is used for full-text search based on the SQL engine.

The default assembly is <i>CMS.SearchProviderSQL</i> . | <pre><add key = "CMSSearchProviderAssembly" value = "CMS.SearchProviderSQL" /></pre> |
| CMSSDataProviderAssembly | Specifies custom data provider assembly used as the database connector for the CMS. See this topic for more details.

The default assembly is <i>CMS.DataProviderSQL</i> . | <pre><add key = "CMSSDataProviderAssembly" value = "CMS.CustomDataProvider" /></pre> |
| CMSCustomHandlersAssembly | Specifies custom event handler assembly. Read this topic for more information.

The default assembly is <i>CMS.CustomEventHandler</i> . | <pre><add key = "CMSCustomHandlersAssembly" value = "CMS.CustomEventHandler" /></pre> |
| CMSSVirtualPathProviderAssembly | Specifies the Custom virtual path provider assembly.

The default assembly is <i>CMS.VirtualPathProvider</i> . | <pre><add key = "CMSSVirtualPathProviderAssembly" value = "CMS.CustomVirtualPathProvider" /></pre> |
| CMSCustomEcommerceProviderAssembly | Specifies the custom e-commerce provider assembly.

The default assembly is <i>CMS.EcommerceProvider</i> . | <pre><add key = "CMSCustomEcommerceProviderAssembly" value = "CMS.CustomECommerceProvider" /></pre> |

Special settings for forbidden characters in user and role names

You can use the following keys to configure forbidden characters in user and role names:

| Key | Description | Sample Value |
|------------------------|---|--------------------|
| CMSEnsureSafeUserNames | Indicates if forbidden characters in user | <pre><add</pre> |

| | | |
|---|--|--|
| | names imported from AD should be replaced. If turned off by setting the value to <i>false</i> , you may experience problems when editing users imported with forbidden characters. Therefore, it is NOT RECOMMENDED to turn it off.

The default value is <i>true</i> . | <pre>key = "CMSEnsureSafeUserNames" value="false" /></pre> |
| CMSEnsureSafeRoleNames | Indicates if forbidden characters in role names imported from AD should be replaced. If turned off by setting the value to <i>false</i> , you may experience problems when editing roles imported with forbidden characters. Therefore, it is NOT RECOMMENDED to turn it off.

The default value is <i>true</i> . | <pre><add key = "CMSEnsureSafeRoleNames" value="false" /></pre> |
| CMSForbiddenUserNameCharactersReplacement | Sets the character by which forbidden characters in user names imported from AD should be replaced.

If not set, value from <i>Site Manager -> Settings -> URLs and SEO -> Forbidden characters replacement</i> is used. | <pre><add key = "CMSForbiddenUserNameCharactersReplacement" value="-" /></pre> |
| CMSForbiddenRoleNameCharactersReplacement | Sets the character by which forbidden characters in role names imported from AD should be replaced.

If not set, value from <i>Site Manager -> Settings -> URLs and SEO -> Forbidden characters replacement</i> is used. | <pre><add key = "CMSForbiddenRoleNameCharactersReplacement" value="-" /></pre> |
| CMSUserValidationRegEx | Sets custom regular expression used for user name validation (used when new accounts are created or when existing usernames are modified).

The default value is <code>"^[a-zA-Z0-9_\\-\\.@]+"</code> .

If the <i>CMSEnsureSafeUserNames</i> key is set to <i>false</i> , the following regular expression is used by default: <code>"^[a-zA-Z0-9_\\-\\.\\ \\ @]+"</code> . | <pre><add key = "CMSUserValidationRegEx" value="([A-Za-z0-9- +])" /></pre> |

Special settings for forbidden character replacement in URLs

You can use the following keys to configure how [forbidden URL characters](#) should be replaced:

| Key | Description | Sample Value |
|-----------------------|---|------------------------|
| CMSForbiddenURLValues | The characters entered as the value of this key are forbidden in URLs (document | <pre><add key</pre> |

| | | |
|-----------------------------------|---|---|
| | <p>aliases and URL paths) and will be replaced automatically by the character specified in the Forbidden characters replacement setting in Site Manager -> Settings -> URLs and SEO.</p> <p>By default, the following characters are forbidden:</p> <p><code>\/:*?"<> &%.'#[]+=, " ' and the space character.</code></p> <p>If you add this key to the web.config, its value will override the default forbidden character set. This way, you can either allow some of the forbidden characters or add new ones.</p> <p>Please note that it is recommended to keep the default characters forbidden, since they may prevent certain types of URLs from working correctly if entered into URL paths.</p> <p>Also keep in mind that some characters need to be escaped in the web.config according to standard XML rules, e.g. enter <code>&lt;</code> instead of the <code><</code> character.</p> | <pre>= "CMSForbiddenURLValues" value="\/:\$?&quot;&lt; &gt; &amp;%.'&apos;#[] =" /></pre> |
| CMSLimitUrlReplacements | <p>While enabled, consecutive forbidden characters in URLs will be replaced by only a single replacement character and forbidden URL characters located at the beginning or end of the path will be removed completely instead of being replaced. If set to <i>false</i>, each forbidden character is replaced individually.</p> <p>The default value is <i>true</i>.</p> | <pre><add key = "CMSLimitUrlReplacements " value="false" /></pre> |
| CMSUseLimitReplacementsForUrlPath | <p>Indicates if the functionality enabled by the CMSLimitUrlReplacements key should be applied to the Document URL Path property.</p> <p>The default value is <i>true</i>.</p> | <pre><add key = "CMSUseLimitReplacements ForUrlPath" value="false" /></pre> |

Special settings for content staging

You can use the following keys to achieve specific behavior of the [Staging](#) module:

| Key | Description | Sample Value |
|---------------------------------|--|------------------------|
| CMSStagingAcceptAllCertificates | Causes all certificates to be accepted when performing content staging tasks | <pre><add key</pre> |

| | | |
|---------------------------------------|--|---|
| | <p>through SSL (X.509). If false, only certificates generated by a certification authority will be accepted.</p> <p>The default value is <i>false</i>.</p> | <pre>= "CMSStagingAcceptAllCertificates" value="true" / ></pre> |
| CMSStagingUseTreeCustomHandlers | <p>Ensures that events will be raised in <i>CustomTreeNodeHandler</i> when performing content staging synchronization.</p> <p>The <i>CMSUseCustomHandlers</i> key needs to be enabled too for this to work.</p> <p>The default value is <i>false</i>.</p> | <pre><add key = "CMSStagingUseTreeCustomHandlers" value="true" / ></pre> |
| CMSMediaFileMaxStagingSize | <p>Sets the maximal file size of synchronized media files in kiloBytes. Files in media libraries that are larger than the entered value will not be synchronized using the Staging module.</p> <p>The default value is 2147483647 (<i>int.MaxValue</i>).</p> | <pre><add key = "CMSMediaFileMaxStagingSize" value="1024" /></pre> |
| CMSStagingTreatServerNamesAsInstances | <p>Global metadata changes such as changes to document types, custom tables and system tables produce staging tasks for all staging servers of all sites. In such case, it is recommended to synchronize such changes to all servers of all sites at the same time to prevent overwriting of such metadata and losing the data by synchronizing the older tasks later.</p> <p>You can use this key to make sure that once the global task is synchronized, it is deleted from all other servers with the same name to prevent such possibility.</p> <p>The default value is <i>false</i> since staging can use multiple target instances targeted with the same names.</p> | <pre><add key = "CMSStagingTreatServerNamesAsInstances" value="true" /></pre> |
| CMSStagingServerName | <p>Name of the staging server used for advanced bi-directional content staging. The value needs to be used as Server code name when defining this server as a target server on the remaining servers.</p> <p>The default value is "" (empty string).</p> | <pre><add key ="CMSStagingServerName" value="server2" /></pre> |
| CMSStagingServiceTimeout | <p>Sets timeout interval for the staging service. The value should be entered in seconds.</p> <p>The default value is 180.</p> | <pre><add key = "CMSStagingServiceTimeout" value="240" /></pre> |

| | | |
|--|---|---|
| CMSStagingLogSynchronization | Indicates if performed staging synchronization tasks should be logged as new staging tasks (that can be subsequently transferred to other staging servers). The primary use of this key is to disable logging of these tasks globally for all sites in the system.

The default value is <i>true</i> . | <pre><add key = "CMSStagingLogSynchroniz ation" value="false" /></pre> |
| CMSynchronizeSharedTemplatesWithDocuments | Indicates if changes made to page templates used by multiple documents should be synchronized together with document update synchronization tasks of all documents using the template. If disabled, document update tasks will not include page template synchronization tasks.

The default value is <i>true</i> . | <pre><add key = "CMSynchronizeSharedTem platesWithDocuments" value="false" /></pre> |
| CMSStagingLogGlobalObjectsOnlyForAssignedSites | If true, tasks for global objects are logged only for the sites to which the respective objects are assigned.

The default value is <i>false</i> . | <pre><add key = "CMSStagingLogGlobalObje ctsOnlyForAssignedSites" value="true" /></pre> |

Special settings for the WYSIWYG editor

You can use the following keys to configure the [WYSIWYG editor](#):

| Key | Description | Sample Value |
|---------------------------------------|---|---|
| CMSWYSIWYGFixXHTML | Indicates if the WYSIWYG editor should automatically try to fix XHTML incompatibilities in the code it generates.

Supported values are <i>true</i> and <i>false</i> . The default value is <i>true</i> . | <pre><add key="CMSWYSIWYGFixXHTML" value="true" /></pre> |
| CKEditor:BasePath | Specifies the location of the WYSIWYG editor (CKEditor).

By default, it is located in ~/CMSAdminControls/CKEditor. | <pre><add key="CKEditor: BasePath" value="/ CKEditor/" /></pre> |
| CKEditor:PersonalizeToolbarOnLiveSite | Indicates if the CK toolbar can be personalized on the live site. See this topic for more details.

Supported values are <i>true</i> and <i>false</i> . The default value is <i>false</i> . | <pre><add key="CKEditor: PersonalizeToolbarOnLive Site" value="true" /></pre> |

Special settings for the code editor

You can use the following keys to configure the [Code editor](#), which is used in the interface to ensure syntax highlighting and work with code fields:

| Key | Description | Sample Value |
|--|---|--|
| CMSEnableSyntaxHighlighting | Globally enables or disables the advanced editor and syntax highlighting support for all code fields. This can be used to turn off the editor if it is causing performance issues or other problems.

The default value is <i>true</i> . | <pre><add key = "CMSEnableSyntaxHighlighting" value="false" /></pre> |
| CMSEnableSyntaxHighlighting.<Language> | Can be used to disable the advanced editor and syntax highlighting support for fields that display code in a specific language.

Replace the <Language> string with the name of the language that you wish to disable. The following language options are available: Text, HTML, CSS, JavaScript, XML, CSharp, SQL, HTMLMixed, ASPNET, CMSSharp .

All languages are enabled by default. | <pre><add key = "CMSEnableSyntaxHighlighting.CSS" value="false" /></pre> |
| CMSShowLineNumbers | If set to true, the panel that displays the number of every line in the editor will be displayed by default when the page is loaded. Please note that some fields in the user interface are not affected by this setting.

The default value is <i>false</i> . | <pre><add key="CMSShowLineNumbers" value="true" /></pre> |

Special settings for E-commerce

You can use the following keys when you need to achieve specific behavior of the [E-commerce](#) module:

| Key | Description | Sample Value |
|---------------------------------|---|---|
| CMSShoppingCartExpirationPeriod | Number of days after which E-commerce shopping cart content is deleted from the database. It's used for deleting unused shopping carts of anonymous users that are stored in the database with ID stored in the browser cookie.

The default value is 30. | <pre><add key = "CMSShoppingCartExpirationPeriod" value="60" /></pre> |
| CMSUseCurrentSKUData | Indicates if the E-commerce module should use the price from the existing order items or from the current SKU data when re-calculating the order. | <pre><add key ="CMSUseCurrentSKUData" value="true" /></pre> |

| | | |
|--------------------------------|---|---|
| | The default value is <i>false</i> . | |
| CMSEnableOrderItemEditing | If true, order item parameters, such as order item name and order item unit price, can be modified when editing an existing order.

The default value is <i>false</i> . | <pre><add key = "CMSEnableOrderItemEditing" value="true"/></pre> |
| CMSUseMetaFileForProductImage | Indicates if meta files should be used for product images in E-commerce.

The default value is <i>true</i> . | <pre><add key = "CMSUseMetaFileForProductImage" value="true"/></pre> |
| CMSUseCustomEcommerceProviders | Specifies whether to use custom E-commerce provider handlers. See this topic for more details.

The default value is <i>false</i> . | <pre><add key = "CMSUseCustomEcommerceProviders" value="true"/></pre> |

Special settings for Event log

You can use the following keys when you need to achieve specific behavior of the [Event log](#):

| Key | Description | Sample Value |
|----------------------------|---|---|
| CMSLogEvents | Indicates if logging of events in the Event log is enabled.

The default value is <i>true</i> . | <pre><add key="CMSLogEvents" value="true"/></pre> |
| CMSLogKeepPercent | Coefficient for Event log deletion. Keeps the specified percentage of extra log items in the log with regards to the Site Manager -> Settings -> System -> Event log size setting. The specified percentage of the oldest events is deleted by batch when the percentage is exceeded. If 0, the exact number of records is kept in the log.

The default value is <i>10</i> . | <pre><add key="CMSLogKeepPercent" value="10"/></pre> |
| CMSLogEventsToFile | If true, events are also logged into the <code>~App_Data\logs\events.log</code> file.

The default value is <i>false</i> . | <pre><add key="CMSLogEventsToFile" value="true"/></pre> |
| CMSLogFieldChanges | If true and the Site Manager -> Settings -> System -> Log metadata changes option is enabled, details about particular object changes are included in the respective log records.

The default value is <i>false</i> . | <pre><add key="CMSLogFieldChanges" value="true"/></pre> |
| CMSLogDocumentFieldChanges | If true and the Site Manager -> Settings -> System -> Log metadata changes | <pre><add key</pre> |

| | | |
|---|--|---|
| | <p>option is enabled, details about changes of values in document fields are included in the respective log records.</p> <p>The default value is <i>false</i>.</p> | <pre>= "CMSLogDocumentFieldChanges" value="true" /></pre> |
| <p>CMSLogNewsletterIssueEvents</p> <p>[Only available after applying hotfix 7.0.18 or newer]</p> | <p>Indicates if the system logs newsletter issue changes into the event log (including logging of all sent issues).</p> <p>You can disable logging of these events if you encounter problems with performance or a cluttered event log when mailing issues to a very large number of subscribers.</p> <p>The default value is <i>true</i>.</p> | <pre><add key = "CMSLogNewsletterIssueEvents" value="false" /></pre> |
| <p>CMSLogMATransitions</p> <p>[Only available after applying hotfix 7.0.18 or newer]</p> | <p>Indicates if the system logs all step transitions in Marketing automation processes into the event log.</p> <p>You can disable logging of these events if you encounter performance issues or a cluttered event log when running automation processes for a very large number of contacts.</p> <p>The default value is <i>true</i>.</p> | <pre><add key ="CMSLogMATransitions" value="false" /></pre> |
| <p>CMSDataExportTemplateFolder</p> | <p>Indicates the starting path for template lookup.</p> <p>The default value is <code>~/App_Data/CMSModules/DataExport</code>.</p> | <pre><add key="CMSDataExportTemplateFolder" value="~/App_Data/CMSModules/DataExport" /></pre> |

Special settings for export/import

You can use the following keys when you want to configure [file exporting](#):

| Key | Description | Sample Value |
|--------------------------|---|--|
| CMSExportExcludedFolders | <p>Specifies which folders will be filtered from being included in Files folder of the export package.</p> <p>.svn folders are excluded by default, even without this key added. More info here.</p> | <pre><add key = "CMSExportExcludedFolders" value="test*;cms*" /></pre> |
| CMSExportExcludedFiles | <p>Specifies which files will be filtered from being included in the Files folder of the export package.</p> <p>.scc files are excluded by default, even without this key added. More info here.</p> | <pre><add key = "CMSExportExcludedFiles" value="test*;cms*" /></pre> |

| | | |
|------------------------|---|---|
| CMSSiteUtilsFolderPath | <p>Enables to override the default ~/CMSSiteUtils/location where export and import packages are stored. As a value, you can use:</p> <ul style="list-style-type: none"> • physical disk path - e.g. c:\myfiles\mysite • virtual path - e.g. ~/UploadedFiles • UNC path - e.g. \\server\folder | <pre><add key = "CMSSiteUtilsFolderPath" value="\ \server\MyCustomFolder" /></pre> |
|------------------------|---|---|

Special settings for item listing

You can use the following keys when you want to configure item listing:

| Key | Description | Sample Value |
|-------------------------------------|--|---|
| CMSSiteDefaultListingFilterLimit | <p>Determines the minimum number of items that must be included in a listing in order for a filter to be shown. If the number of listed items is lower than this value, the filter is not displayed. If it is larger, the filter is displayed. This applies to all listings (UniGrid controls) across the entire UI</p> <p>The default value is 25.</p> <p>The value of this key can be overridden for individual UniGrid controls.</p> | <pre><add key = "CMSSiteDefaultListingFilterLimit" value="40" /></pre> |
| CMSSiteDefaultListingPageSize | <p>Initial page size (the <i>Items per page</i> setting) of listings across the whole UI.</p> <p>The default value is 25.</p> | <pre><add key = "CMSSiteDefaultListingPageSize" value="50" /></pre> |
| CMSSiteListingShowFirstLastButtons | <p>If enabled, the first and last page link buttons will be included in the pagers of listings in the UI with a large enough number of items. If disabled, the buttons will always be hidden.</p> <p>If both this and the <i>ShowDirectPageControl</i> keys are disabled, only <i>TopN</i> items are loaded, while $TopN = PageSize * (currentPageIndex + CurrentPagesGroupSize)$.</p> <p>The default value is <i>true</i>.</p> | <pre><add key = "CMSSiteListingShowFirstLastButtons" value="false" /></pre> |
| CMSSiteListingShowDirectPageControl | <p>If enabled, a textbox that allows the current page to be changed by directly entering a number will be included in pagers of listings in the UI with a large enough number of items. If disabled, the</p> | <pre><add key = "CMSSiteListingShowDirectPageControl"</pre> |

| | | |
|--|---|--------------------------------|
| | <p>control will always be hidden.</p> <p>If both this and the <i>ShowFirstLastButtons</i> keys are disabled, only <i>TopN</i> items are loaded, while $TopN = PageSize * (currentPageIndex + CurrentPagesGroupSize)$.</p> <p>The default value is <i>true</i>.</p> | <pre>value="false" /></pre> |
|--|---|--------------------------------|

Special settings for culture URLs

You can use the following keys to set up URL behavior for the culture (language) versions of documents:

| Key | Description | Sample Value |
|------------------------------------|---|--|
| CMSUseCultureForBestPageInfoResult | <p>Indicates whether the currently selected culture should have the highest priority when deciding which language version of a document should be displayed.</p> <p>The default value is <i>false</i>, which means that accessing a document through the custom URL set for one of its specific culture versions will override and change the preferred culture accordingly.</p> <p>If set to <i>true</i>, the currently selected culture will be reflected even when a culture-specific document URL path is used.</p> | <pre><add key = "CMSUseCultureForBestPageInfoResult" value="true" /></pre> |
| CMSRedirectLangToPrefix | <p>This key indicates whether URLs with a language defined through a query string parameter should automatically be redirected to a corresponding URL with a language prefix.</p> <p>Supported values are <i>true</i> and <i>false</i>. The default value is <i>true</i>.</p> | <pre><add key = "CMSRedirectLangToPrefix" value="false" /></pre> |

Special settings for query string parameter names

You can use the following keys to change certain query string parameter names:

| Key | Description | Sample Value |
|--------------------------|---|---|
| CMSLanguageParameterName | <p>Changes the name of the query string parameter used to set the culture. For example, this allows you to get <i>Home?sprache=de-de</i> instead of the default <i>Home?lang=de-de</i>.</p> | <pre><add key = "CMSLanguageParameterName" value="sprache" /></pre> |

| | | |
|---------------------------|--|---|
| | The default value is <i>lang</i> . | |
| CMSAliasPathParameterName | Changes the name of the <i>aliaspath</i> query string parameter so that you get <i>products.aspx?ap=/products/myproduct</i> instead of the default <i>products.aspx?aliaspath=/products/myproduct</i> .

The default value is <i>aliaspath</i> . | <add
key
=
"CMSAliasPathParameterName" value="ap" /> |

Special settings for transaction isolation

You will use the following settings only in special cases when you encounter problems with deadlocks when updating a document:

| Key | Description | Sample Value |
|---|---|---|
| CMSTransactionIsolationLevel | Isolation level for explicit transactions.

The default value is <i>ReadUncommitted</i> . | <add
key
=
"CMSTransactionIsolationLevel"
value="ReadCommitted" /> |
| CMSDefaultIsolationLevel | Isolation level for all queries, even without transactions.

The default value is <i>ReadUncommitted</i> . | <add
key
=
"CMSDefaultIsolationLevel"
value
="ReadUncommitted" /> |
| CMSUseDefaultIsolationLevelOnlyWithOpenTransactions | If true, the default isolation level is used only when some transaction is already running.

The default value is <i>true</i> . | <add
key
=
"CMSUseDefaultIsolationLevelOnlyWithOpenTransactions" value="true" /> |
| CMSAllowSimultaneousTransactions | If false, there can be only one transaction running at the same time.

The default value is <i>true</i> . | <add
key
=
"CMSAllowSimultaneousTransactions"
value="true" /> |
| CMSMaxTransactionWaitTimeout | Indicates how many seconds a transaction should wait for completion of another running transaction if simultaneous transactions are not allowed.

The default value is <i>1</i> . | <add
key
=
"CMSMaxTransactionWaitTimeout" value="1" /> |

Special settings for the scheduler

By adding the following keys to your web.config, you can configure the [Scheduler](#):

| Key | Description | Sample Value |
|-----------------------------------|--|---|
| CMSUseAutomaticScheduler | Indicates if automatic scheduling should be used. When enabled, the scheduler periodically requests the cmspages/scheduler.aspx page which ensures that scheduled tasks are processed regularly, even if there is no website activity.

If turned off (<i>false</i> - by default), tasks are processed at the end of standard page requests. | <pre><add key = "CMSUseAutomaticScheduler" value="true" /></pre> |
| CMSRunSchedulerWithinRequest | If <i>true</i> (the default value), the scheduler is executed within the standard EndRequest event of a page. If <i>false</i> , the scheduler is executed via the <code>~/cmspages/scheduler.aspx</code> page. | <pre><add key = "CMSRunSchedulerWithinRequest" value="false" /></pre> |
| CMSSchedulerURL | URL of the physical location of the scheduler.aspx page.

The default value is <code>~/cmspages/scheduler.aspx</code> | <pre><add key="CMSSchedulerURL" value="https://domain/cmspages/scheduler.aspx" /></pre> |
| CMSSchedulerAcceptAllCertificates | If true, all security certificates (including not valid ones) will be accepted when accessing the <code>scheduler.aspx</code> page via a secured protocol.

The default value is <i>false</i> . | <pre><add key = "CMSSchedulerAcceptAllCertificates" value="true" /></pre> |
| CMSSchedulerUserName | Sets the user name under which the <code>scheduler.aspx</code> page should be accessed (e.g. when using windows authentication).

The default value is "" (blank username). | <pre><add key ="CMSSchedulerUserName" value="office\myname" /></pre> |
| CMSSchedulerPassword | Sets the password for the user name under which the <code>scheduler.aspx</code> page should be accessed.

The default value is "" (blank password). | <pre><add key ="CMSSchedulerPassword" value="mypassword123" /></pre> |

Special Contact management settings

By adding the following keys to your web.config, you can configure the behavior of the [Contact management](#) module.

| Key | Description | Sample Value |
|-------------------------------|---|---|
| CMSLogActivityImmediatelyToDB | If <i>false</i> , activities are logged to temporary files on the server disk, which are then | <pre><add key="CMSLogActivityImmed</pre> |

| | | |
|----------------------|--|---|
| | <p>regularly processed by a scheduled task. Otherwise, activities are logged immediately to the database.</p> <p>The default value is <i>false</i>.</p> <p>Please note that logging activities directly to the database may cause performance issues on high-traffic websites.</p> | <pre>imatelyToDB" value="true" /></pre> |
| CMSEnableContactBots | <p>Determines whether web bots (e.g. search engine crawlers) should be logged and tracked as contacts when they access the website.</p> <p>The default value is <i>false</i>.</p> | <pre><add key ="CMSEnableContactBots" value="true" /></pre> |

Special settings for security

By adding the following keys to your web.config, you can configure certain [Security](#) options:

| Key | Description | Sample Value |
|--------------------------|---|---|
| CMSCheckParameters | <p>Indicates if parameter checking is allowed. Read this topic for more details.</p> <p>The default value is <i>false</i>.</p> | <pre><add key="CMSCheckParameters" value="true" /></pre> |
| CMSReportCheckParameters | <p>If true, an exception reporting the parameters is thrown when the parameters do not match. Read this topic for more details.</p> <p>The default value is <i>false</i>.</p> | <pre><add key ="CMSReportCheckParameters" value="true" /></pre> |
| CMSAcceptAllCertificates | <p>Indicates whether application requests should accept all certificates (including invalid certificates). This key ensures the same as when both <i>CMSSchedulerAcceptAllCertificates</i> and <i>CMSStagingAcceptAllCertificates</i> were enabled at the same time.</p> <p>The default value is <i>false</i>.</p> | <pre><add key ="CMSAcceptAllCertificates" value="true" /></pre> |
| CMSPasswordSalt | <p>The password salt is a string that is appended to user passwords before they are hashed (to improve security). By default, it always contains the randomly generated GUID of the given user. The content of this key is added after the GUID, so it can be used to further increase the length of the salt.</p> <p>This is only applied if you store passwords using the <i>SHA2 with salt</i></p> | <pre><add key="CMSPasswordSalt" value="SaltText" /></pre> |

| | | |
|--------------------------|---|--|
| | format, which can be configured in Site Manager -> Settings -> Membership & Security -> Passwords -> Password format . | |
| CMSAllowOnlySimpleMacros | <p>If true, only simple macros (i.e. those which do not need a security check) are allowed. All others will not be resolved. If true, CMSTextBox does not add security.</p> <p>The default value is <i>false</i>.</p> | <pre><add key="CMSAllowOnlySimpleMacros" value="true" /></pre> |

Special settings for the Smart search module

The following keys can be used to configure the [Smart search](#) module:

| Key | Description | Sample Value |
|---------------------------------|---|--|
| CMSSearchIndexPath | Sets the path of a custom directory where smart search index files should be physically stored. | <pre><add key="CMSSearchIndexPath" value = "App_Data\MyCustomIndexes" /></pre> |
| CMSSearchOnlyWhenContentPresent | <p>Determines if smart searches should be performed only when there is at least one standard content keyword specified in the search expression. The default value is <i>true</i>.</p> <p>Setting this key to <i>false</i> allows search expressions containing only special Lucene query syntax, i.e. direct field searches such as:</p> <p><i>DocumentNodeID:(int)17</i></p> <p>This key is now obsolete. The same result can be ensured by leaving the Block field-only search property disabled for individual Smart search results or Smart search dialog with results web parts.</p> | <pre><add key = "CMSSearchOnlyWhenContentPresent" value="false" /></pre> |
| CMSCreateTemplateSearchTasks | <p>If enabled, any changes made to a page template will automatically trigger an update of all documents that are based on the given template in the appropriate smart search indexes.</p> <p>The default value is <i>true</i>.</p> <p>You can set this key to <i>false</i> if you wish to</p> | <pre><add key = "CMSCreateTemplateSearchTasks" value="false" /></pre> |

| | | |
|-----------------------------------|--|---|
| | <p>improve performance or save resources in scenarios where you have a very large number of documents on your website that share the same page template. This way, the system will no longer perform bulk updates of documents in the search index whenever their template is modified.</p> <p>Disabling this key will mean that your document index will not reflect changes to the template (e.g. if you add static text to the template through a web part) until the given documents are updated for some other reason, or the entire index is rebuilt.</p> <p>The key only affects changes to page templates. Editing the content of editable regions on a specific document will always cause it to be updated in the index.</p> | |
| CMSPProcessSearchTasksByScheduler | <p>By default, the smart search creates and runs indexing tasks immediately whenever content covered by a search index is created or modified.</p> <p>If you set this key to <i>true</i>, the system does NOT run indexing tasks upon creation — they need to be processed periodically, for example using the Execute search tasks scheduled task.</p> <p>The default value is <i>false</i>.</p> | <pre><add key = "CMSPProcessSearchTasksByScheduler" value="true" /></pre> |
| CMSSmartSearchLockPollInterval | <p>Specifies how often (time in milliseconds) the smart search indexer tries to acquire a lock on an index file.</p> <p>The default value of this key is 500 milliseconds.</p> <p>You should lower the value if the following exception gets logged into your Event log.</p> <p><i>Lock obtain timed out:
CMS.SiteProvider.SearchLock</i></p> | <pre><add key = "CMSSmartSearchLockPollInterval" value="500" /></pre> |
| CMSSmartSearchLockTimeout | <p>Defines the timeout period (in milliseconds) during which the smart search indexer should try to acquire a lock on the index file.</p> | <pre><add key = "CMSSmartSearchLockTimeout" value="1000" /></pre> |

| | | |
|--|--|--|
| | <p>The default value of this key is 1000 milliseconds.</p> <p>You should increase the value if the following exception gets logged into your Event log.</p> <p><i>Lock obtain timed out:
CMS.SiteProvider.SearchLock</i></p> | |
|--|--|--|

You can also use the keys below to configure how **Documents crawler** [search indexes](#) access sites:

| Key | Description | Sample Value |
|--------------------------|--|--|
| CMSCrawlerSearchDomain | Specifies the name of the domain that the crawler should use when indexing sites. This is most useful for web farm servers that do not have access to the main domain. | <pre><add key = "CMSCrawlerSearchDomain" value="domain_name" /></pre> |
| CMSCrawlerFormsUserName | Sets the user name under which the crawler indexes site documents. Documents for which the specified user does not have <i>Read</i> permissions will not be indexed.

If not defined, the default <i>administrator</i> user account is used. | <pre><add key = "CMSCrawlerFormsUserName" value="user_name" /></pre> |
| CMSCrawlerDomainUserName | Used instead of the CMSCrawlerFormsUserName key if Windows authentication is enabled. | <pre><add key = "CMSCrawlerDomainUserName" value ="windows_user_name" /></pre> |
| CMSCrawlerDomainPassword | Contains the password for the account used by the crawler if Windows authentication is enabled. | <pre><add key = "CMSCrawlerDomainPassword" value="password" /></pre> |

Special settings for the Translation services module

You can use the following key to configure the Translation services module:

| Key | Description | Sample Value |
|--|---|---|
| CMSTranslationServicesUseCDATAForTransUnit | Use if you want to export XLIFF files without the CDATA notation. | <pre><add key = "CMSTranslationServicesUseCDATAForTransUnit"</pre> |

```
value="false" />
```

Special settings for user interface cultures

By adding the following keys to your web.config, you can configure [UI cultures](#):

| Key | Description | Sample Value |
|-----------------------------------|---|---|
| CMSDefaultSpellCheckerCulture | Specifies the default culture of the built-in spell-checker. This culture is used when the dictionary for the currently selected content culture is not found.

The default value is <i>en-us</i> . | <pre><add key = "CMSDefaultSpellCheckerC ulture" value="en-US" /></pre> |
| CMSShowLogonCultureSelector | Indicates if the user interface logon page should display a drop-down list with available user interface languages.

The default value is <i>true</i> . | <pre><add key = "CMSShowLogonCultureSele ctor" value="false" /></pre> |
| CMSDefaultUICulture | Specifies the default UI culture. If you use this key, you also need to rename the <code>~\CMSResources\CMS.resx</code> file to <code>CMS.en-us.resx</code> and the <code>CMS.en-nz.resx</code> file to <code>CMS.resx</code> . This is needed because the <code>CMS.resx</code> file is used when the (<i>default</i>) option is selected in users' <i>Preferred user interface culture</i> .

The default value is <i>en-us</i> . | <pre><add key ="CMSDefaultUICulture" value="en-nz" /></pre> |
| CMSUseSQLResourceManagerAsPrimary | Changes the priority of used localization resource strings to:
1. custom.resx
2. cms.resx
3. database (Site Manager -> Development -> UI Cultures)

The default value is <i>true</i> . | <pre><add key = "CMSUseSQLResourceManage rAsPrimary" value="false" /></pre> |
| UICulture | Specifies the default user interface culture.

The default value is <i>en-us</i> . | <pre><add key="UICulture" value="en-us" /></pre> |

Special settings for synchronization on web farms

By adding the following keys to your web.config, you can enable or disable [web farm synchronization](#) of certain kind of files stored in the file system:

| Key | Description | Sample Value |
|-------------------|---|--|
| CMSWebFarmEnabled | Indicates if Web farms are enabled (true) or not (false). | <pre><add key="CMSWebFarmEnabled"</pre> |

| | | |
|---------------------------------------|---|---|
| | The default value is <i>false</i> . | <code>value="true" /></code> |
| CMSWebFarmServerName | Code name of the web farm server. This value is used for native web farm synchronization support.

The default value is "" (empty string). | <code><add
key
="CMSWebFarmServerName"
value="server1" /></code> |
| CMSWebFarmSynchronizeFiles | General key determining if files should be synchronized (true) or not (false). This key enables synchronization of: <ul style="list-style-type: none"> • Attachments • Meta files • Media files • Form files • Avatars • Forum attachments The default value is <i>true</i> . | <code><add
key
=
"CMSWebFarmSynchronizeFiles" value="true" /></code> |
| CMSWebFarmSynchronizeAttachments | Enables/disables synchronization of attachments.

The default value is <i>true</i> . | <code><add
key
=
"CMSWebFarmSynchronizeAttachments"
value="true" /></code> |
| CMSWebFarmSynchronizeMetaFiles | Enables/disables synchronization of meta files.

The default value is <i>true</i> . | <code><add
key
=
"CMSWebFarmSynchronizeMetaFiles" value="true" /></code> |
| CMSWebFarmSynchronizeMediaFiles | Enables/disables synchronization of media files.

The default value is <i>true</i> . | <code><add
key
=
"CMSWebFarmSynchronizeMediaFiles" value="true" /></code> |
| CMSWebFarmSynchronizeBizFormFiles | Enables/disables synchronization of form files.

The default value is <i>true</i> . | <code><add
key
=
"CMSWebFarmSynchronizeBizFormFiles"
value="true" /></code> |
| CMSWebFarmSynchronizeAvatars | Enables/disables synchronization of Avatars.

The default value is <i>true</i> . | <code><add
key
=
"CMSWebFarmSynchronizeAvatars" value="true" /></code> |
| CMSWebFarmSynchronizeForumAttachments | Enables/disables synchronization of forum attachments.

The default value is <i>true</i> . | <code><add
key
=
"CMSWebFarmSynchronizeFo</code> |

| | | |
|-----------------------------------|--|--|
| | | <code>rumAttachments"
value="true" /></code> |
| CMSWebFarmSynchronizeDeleteFiles | Enables/disables synchronization of deleted files.

The default value is <i>true</i> . | <code><add
key
=
"CMSWebFarmSynchronizeDeleteFiles"
value="true" /></code> |
| CMSWebFarmMaxFileSize | If the CMSWebFarmSynchronizeFiles key is enabled, you can limit the maximal size of synchronized files using this key. The value is entered in kiloBytes and files larger than this value will not be synchronized.

The default value is <i>2147483647</i> (<i>int.MaxValue</i>). | <code><add
key
="CMSWebFarmMaxFileSize"
value="1024" /></code> |
| CMSWebFarmUpdateWithinRequest | If true, web farm servers are updated with changes made on the other servers once per request. If false, web farm servers can be updated based on the interval settings of the Synchronize web farm changes scheduled task - recommended for high-traffic sites.

The default value is <i>true</i> . | <code><add
key
=
"CMSWebFarmUpdateWithinRequest" value="false" /></code> |
| CMSWebFarmUseDBUpdater | Indicates whether the database updater should be used. | <code><add
key
=
"CMSWebFarmUseDBUpdater"
value="true" /></code> |
| CMSWebFarmGenerateServers | If true, web farm servers will be generated automatically. You don't need to create them manually in the user interface. | <code><add
key
=
"CMSWebFarmGenerateServers" value="true" /></code> |
| CMSWebFarmApplicationPhysicalPath | Path to the application on the disk used for synchronizing physical files. | <code><add
key
=
"CMSWebFarmApplicationPhysicalPath" value="C:\inetpub\wwwroot\KenticoCMS" /></code> |
| CMSTeamDevelopmentEnabled | If true, turns on CMSWebFarmGenerateServers and CMSWebFarmUseDBUpdater settings | <code><add
key
=
"CMSTeamDevelopmentEnabled" value="true" /></code> |

Special settings for deployment to Windows Azure

By adding the following keys to your web.config, you can set up the deployment of your website to Windows Azure and configure its behaviour. For more information, please refer to the [Windows Azure Deployment Guide](#).

| Key | Description | Sample Value |
|-----------------------|---|---|
| CMSAzureProject | <p>Must be set to <i>true</i> if you wish to run the application on Windows Azure.</p> <p><i>True</i> by default if the application is installed as a Windows Azure project, <i>false</i> in standard installations.</p> | <pre><add key="CMSAzureProject" value="true" /></pre> |
| CMSAzureAccountName | <p>Specifies the name of the storage account that the application will use for its file system. The account must belong to a valid Windows Azure subscription.</p> <p>If you wish to run the application on the local emulator, enter <i>devstoreaccount1</i> as the value.</p> | <pre><add key ="CMSAzureAccountName" value ="devstoreaccount1" /></pre> |
| CMSAzureSharedKey | <p>Must contain the primary access key of the storage account specified in the CMSAzureAccountName setting.</p> <p>You can find the appropriate value for your storage account on the Windows Azure Management Portal.</p> | <pre><add key="CMSAzureSharedKey" value = "Eby8vdM02xNocqFlqUwJPLl mEt1CDXJ1OUzFT50uSRZ6IFs uFq2UVErCz4I6tq/ K1SZFPT0tr/ KBHBeksoGMGw==" /></pre> |
| CMSAzureBlobEndPoint | <p>Sets the endpoint used for the connection to the blob service of the specified storage account. If you wish to use the default endpoint, remove the setting completely from the appropriate files.</p> | <pre><add key ="CMSAzureBlobEndPoint" value = "http://127.0.0.1:10000/ devstoreaccount1" /></pre> |
| CMSAzureQueueEndPoint | <p>Sets the endpoint used for the connection to the queue service of the specified storage account. If you wish to use the default endpoint, remove the setting completely from the appropriate files.</p> | <pre><add key ="CMSAzureQueueEndPoint" value = "http://127.0.0.1:10001/ devstoreaccount1" /></pre> |
| CMSAzureTableEndPoint | <p>Sets the endpoint used for the connection to the table service of the specified storage account. If you wish to use the default endpoint, remove the setting completely from the appropriate files.</p> | <pre><add key ="CMSAzureTableEndPoint" value = "http://127.0.0.1:10002/ devstoreaccount1" /></pre> |

| | | |
|--------------------------------|--|--|
| <p>CMSAzureRootContainer</p> | <p>Specifies the name of the blob container that will serve as the root of the application's file system on the Windows Azure storage account.</p> <p>This can be useful in scenarios where multiple applications use the same storage account.</p> <p>The default value is <i>cmsroot</i>.</p> | <pre><add key ="CMSAzureRootContainer" value="CustomRoot" /></pre> |
| <p>CMSAzurePublicContainer</p> | <p>Indicates if the blob container used to store the applications file system should be public. If set to <i>true</i>, it will be possible to access files directly through the URL of the appropriate blob service, for example:</p> <p><i><StorageAccountName>.blob.core.windows.net/cmsroot/corporatesite/media/imagelibrary/logo.png</i></p> | <pre><add key = "CMSAzurePublicContainer" value="true" /></pre> |

If you wish to host the website itself on-premise, but use a file system based on the Blob service of a Windows Azure storage account, you can specify the following settings:

| Key | Description | Sample Value |
|-------------------------------|---|--|
| <p>CMSExternalStorageName</p> | <p>You can add this key to specify that the application should use a Windows Azure storage account for its file system. This can be done by setting the value to <i>Azure</i>.</p> <p>It is not necessary to add this key if CMSAzureProject is set to <i>true</i>. Only use this option if you are setting up a hybrid scenario with the application itself hosted on-premise outside of the Windows Azure cloud.</p> | <pre><add key = "CMSExternalStorageName" value="Azure" /></pre> |
| <p>CMSAzureTempPath</p> | <p>The folder specified by this key will be used to store temporary files on a local disk, e.g. when transferring large files to or from the storage account.</p> <p>Do not use this key if the entire application is deployed as a Windows Azure hosted service.</p> | <pre><add key="CMSAzureTempPath" value="C:\AzureTemp" /></pre> |
| <p>CMSAzureCachePath</p> | <p>Specifies a folder on a local disk where files requested from the storage account will be cached. This helps minimize the amount of blob storage operations, which saves time and resources.</p> <p>Do not use this key if the entire application is deployed as a Windows Azure hosted service.</p> | <pre><add key="CMSAzureCachePath" value="C:\AzureCache" /></pre> |

| | | |
|------------------------|--|--|
| CMSDownloadBlobTimeout | <p>Specifies the timeout interval in minutes for importing files from Windows Azure Blob storage into Kentico.</p> <p>The default value is <i>1.5</i> minutes. Increase the interval if you encounter problems when importing large (about 2GB) files.</p> | <pre><add key = "CMSDownloadBlobTimeout" value="50" /></pre> |
|------------------------|--|--|

Special settings for debugging

While debugging can be turned and configured on by means of settings in **Site Manager -> Settings -> System -> Debug**, it is also possible to perform this configuration by adding certain keys into your project's *web.config* file. These keys are listed and described together with the respective settings in the [Development -> Debugging and system information](#) chapter of this guide.

| | | |
|------------------------|--|--|
| CMSDebugScheduler | <p>If false, all the scheduler operations are excluded from debugs.</p> <p>The default value is <i>true</i>.</p> | <pre><add key="CMSDebugScheduler" value="false" /></pre> |
| CMSDebugFiles | <p>Enables IO operation debugging and the IO tab in Site Manager -> Administration -> System -> Debug.</p> <p>The default value is <i>false</i>.</p> | <pre><add key="CMSDebugFiles" value="true" /></pre> |
| CMSDebugFilesLive | <p>If enabled, IO operation debug information is also displayed at the bottom of each live site page. This option requires IO operation debugging to be enabled.</p> <p>The default value is <i>false</i>.</p> | <pre><add key="CMSDebugFilesLive" value="true" /></pre> |
| CMSDebugAllFiles | <p>If enabled, IO operations called by pages of the administration interface (CMS Desk and Site Manager) will also be included in the IO operation debug. This option requires IO operation debugging to be enabled.</p> <p>The default value is <i>false</i>.</p> | <pre><add key="CMSDebugAllFiles" value="true" /></pre> |
| CMSDebugFilesLogLength | <p>Sets the maximum length of the IO operation debug log on the Debug -> IO tab, i.e. the number of requests for which debug information is preserved and displayed on the tab. If empty, value of the Default log length setting (or the CMSDebugEverythingLogLength key) is used.</p> <p>The default value is <i>10</i>.</p> | <pre><add key="CMSDebugAllFiles" value="15" /></pre> |

| | | |
|-------------|---|---|
| CMSLogFiles | If enabled, the IO operation debug log is saved into the <i>logfiles.log</i> file in the <i>~App_Data</i> folder. This option does not require IO operation debugging to be enabled.

The default value is <i>false</i> . | <pre><add key="CMSLogFiles" value="true" /></pre> |
|-------------|---|---|

Connection string

The database used by Kentico CMS engine is specified by the connection string `CMSConnectionString` in the `/configuration/connectionStrings` section. Here's an example of such connection string:

```
<add name="CMSConnectionString" connectionString="Persist Security Info=False;
database=CMS;server=myserver;user id=sa;password=mypassword123;Current
Language=English;Connection Timeout=120;" />
```
